Mail Server Port	Enter the SMTP port that is used by the notifications mail server.
Secure Mail Server Connection	When enabled, the SMTP server connection is secured.
Mail Server Sender Address	Enter the sender's email address for email notifications.
Mail Server Username	Enter the user name for sending email notifications.

Table 723. Mail server settings (continued)

Field	Description
	Some email servers and firewalls treat emails with different sender and user names suspiciously. Therefore, consider specifying the same name for both fields.
Mail Server Password	Enter the user password for sending email notifications.
Max Recipients Per Email	Specify the maximum number of recipients to include in a single email. Mutliple emails will be sent when this is exceeded.

Table 724. External Approval settings

Field	Description
Resource Type to Run External Approvals	Choose any of the following options: • None: to use no agent or agent pool to run external approval processes. • Agent: to use an agent as the default resource type to run external approvals. Specify agent in the **Agent for External Approvals** field which will be used for external approval processes. • Agent Pool: to use an agent pool to specify a group of agents to run external approvals on instead of using a specific agent. Specify agent pool in the **Agent Pool for External Approvals** field which will be used for external approval processes. For more information, see Managing external approval processes on page 2392.

Table 725. Legacy Configuration Options

Field	Description
Enable "Prompt On Use"	When enabled, the option to set Prompt On Use for properties in workflow steps is displayed.
Fail Processes With Unresolved Properties	When enabled, any running process which comes across a property which it cannot resolve will automatically fail.
Component Environment Properties Override Environment Properties	When enabled, component environment properties overrides environment properties when using `${p:propName}` notation as opposed to `${p:environment/propName}`.
Enable Deleting Resources From Environments	When enabled, allows you to delete resources that are mapped with environment while deleting that environment.

Table 725. Legacy Configuration Options (continued)

Field	Description
	Note that the resources are deleted globally and affects the other environments that uses the same resource tree.
Show Compliancies Automatically	When enabled, environment compliancies are loaded automatically on the **Application Environment** and **Snapshot** pages rather than loading on demand.

High-availability agent communication

Agents communicate with the server over HTTP or HTTPS. These modes of communication are handled differently in a high availability scenario.

HTTP or HTTPS communication

A standard load balancer handles HTTP or HTTPS server-agent communications. Authentication is run on every request; any server can run validation for any request. You configure HTTP or HTTPS server-agent communication when you configure your cluster of servers. See Setting up clusters of servers on page 2063.

In case of server failure, user-server authentication must be redone unless the 'remember me' cookie is used.

High-availability server processes

While high-availability servers complete the same processes as standalone servers, they run slightly differently and access files in run slightly different locations than individual servers do.

In a high-availability topology, all servers use the same database and a common network storage. The server log and CodeStation repository are stored in the common network storage. Most configuration information and runtime data is stored in the shared database. Each server maintains some independent configuration information, such as the connection information for the database.

Because the servers share the database, all servers run on the same interval.

Many activities run the same on high-availability servers as on a standalone server. Some activities run slightly differently:

Importing component versions (CodeStation)

In a clustered high-availability configuration, any server can start the process that imports a component version. If components are configured for automatic imports, all servers poll for component version changes, but they are limited to the polling duration in the system settings. To prevent more than one server from importing a component version or checking for new versions, the database handles server synchronization and a server acquires a database lock before importing or polling.

Notifications

Notifications are handled by the server that runs the process or starts the related event. For more information, see Creating Notifications in a Notification Scheme on page 2081.

Running processes and handling failures

While processes are running, step failures are shown in the process log as usual. Error handling is the responsibility of the process author; for example, processes can include steps that run when other steps fail, including automatic rollback steps.

When a process is requested, a request is created in the database. Servers poll the database regularly for new process requests. The first server that finds the process request runs the requested process. Due to a limitation on the server, the process can not be transferred to another server in the cluster. Therefore, if the server fails in the middle of running a process, the process fails. The other servers in the high-availability cluster run future processes, but they can not take over processes that the failed server was running.

If an agent relay stops while a connected agent is running a process, the agent uses its failover settings to connect to other servers or agent relays. If the agent exhausts its failover options, it continues trying to reconnect. If an agent relay or server comes back online, the agent continues to run the process.

Step failures do not cause agents themselves to fail. If an agent stops while it is running a process, the server assumes that the agent is still running the process and does not mark the process as failed.

Storing reusable post-processing scripts

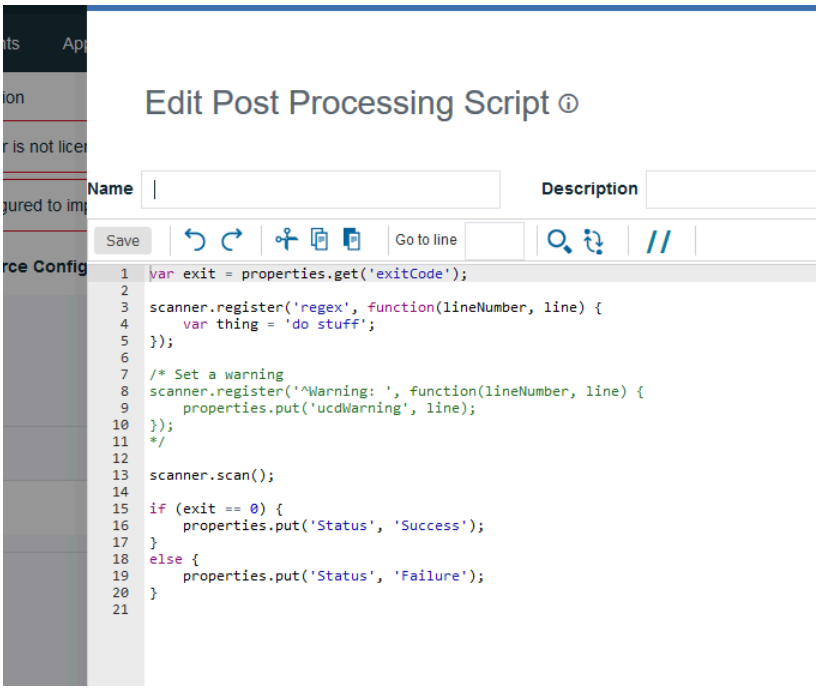
You can store post-processing scripts on the server so you can reuse them in component processes and in generic processes.

About this task

When a step finishes, the agent runs the post-processing script for that step. When the agent runs the script, it first loads the server log file. It finds the exit code property of the target step with regular expressions that are defined in the script. It then applies any actions that are defined in the script before it runs the next step.

The HCL DevOps Deploy (Deploy) server log file is normally found in the following location: *server_installation_directory*`/var/log/deployserver.out`.

1. Click **Settings > Post Processing Scripts** and then click **Create Script**.
   Result
   The **Edit Script** window opens, as shown in the following figure.



2. Specify a name for the process step.
3. Give a description for the process step.
4. Specify the teams that can access and edit the script.
5. Enter or paste the script into the **Script Body** field.
   See the roll-over help next to the field for information about the properties and variables that are available for user-defined scripts.

   Post-processing scripts must set the **Status** property to specify the status of the script. The script can specify any value for the **Status** property. For example, to specify that the script was a success, run the following command in the post-processing script:

   ```
   properties.put("Status","Success");
   ```

Creating statuses

Define component version, snapshot, and inventory statuses on the **Statuses** tab.

1. Click **Settings > Statuses**.
2. For the status type to create, click **Add Status**.
3. Configure the status in the **Add Status** window:

Parameter	Description
Name	Identifies the status and is included in many UI elements.
Description	Conveys more information about the process.
Color	Defines the status color that is displayed in the UI.

Parameter	Description
Unique	When checked, specifies that only a single instance of the status describes a component. For inventory or snapshot statuses, an application removes the status from existing versions in the environment or resource inventory. For version or snapshot statuses, the status can be used by only one version or snapshot at a time.
Required Role	Specifies the user role that is necessary for a user to assign the status.

4. Save your work when finished.
   Statuses are stored in the HCL DevOps Deploy (Deploy) database.

Tip: Default statuses are defined in an XML file, which you can edit to add your own values.

Adding version statuses

Manage component version statuses through the version options interface.

About this task

You add or remove statuses from individual component versions to provide information about the version. If you copy files to an agent without deploying them, you might apply a `Staged` status to them. When you install the version, you might set the status to `Active`.

1. To select the component, click **Components > *selected component***.
2. To select the version, click **Versions > *selected version***.
3. Click **Add a Status**.
4. Select the status from the list, and click **Save**.

What to do next

Add a status by using the Add Status to Version plug-in step, which is available from the Version plug-in.

Modeling Software Deployment

Modeling software deployment in HCL DevOps Deploy (Deploy) includes configuring components and component processes and adding those components to applications. Then, you use processes to deploy the components to environments.

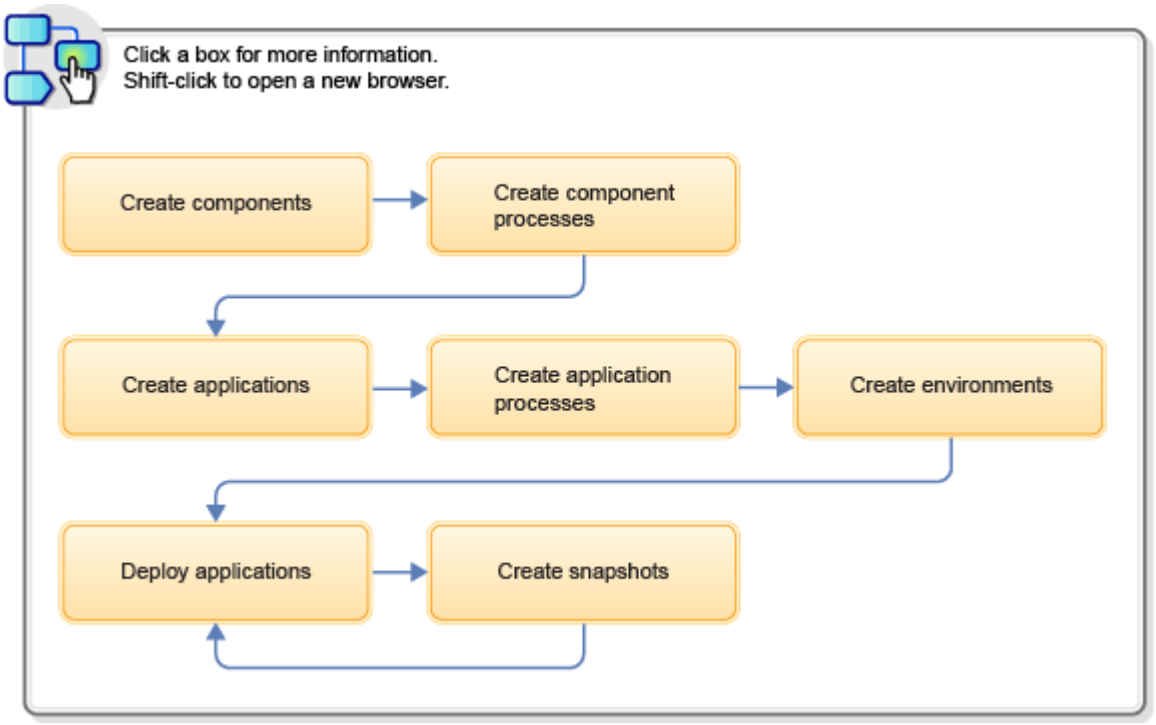
About this task

The general steps in this typical workflow include:

1. Import the parts of the application as components. See Creating components on page 2248.
2. Create processes that deploy components. See Component processes on page 2299.
3. Create an application to group the components together. See Applications on page 2344.
4. Create an application process that runs each component process. See Creating application processes on page 2429.
5. Create one or more environments on which to deploy the components. See Creating environments on page 2354.

6. Run the application process to deploy the components. See Deploying applications on page 2526.
7. Take snapshots of working deployments so you can save these arrangements and deploy them to other environments. See Creating snapshots on page 2383.

The following diagram illustrates this workflow:



1. Creating components on page 2248
2. Component processes on page 2299
3. Applications on page 2344
4. Creating application processes on page 2429
5. Creating environments on page 2354
6. Deploying applications on page 2526
7. Creating snapshots on page 2383

Dashboard

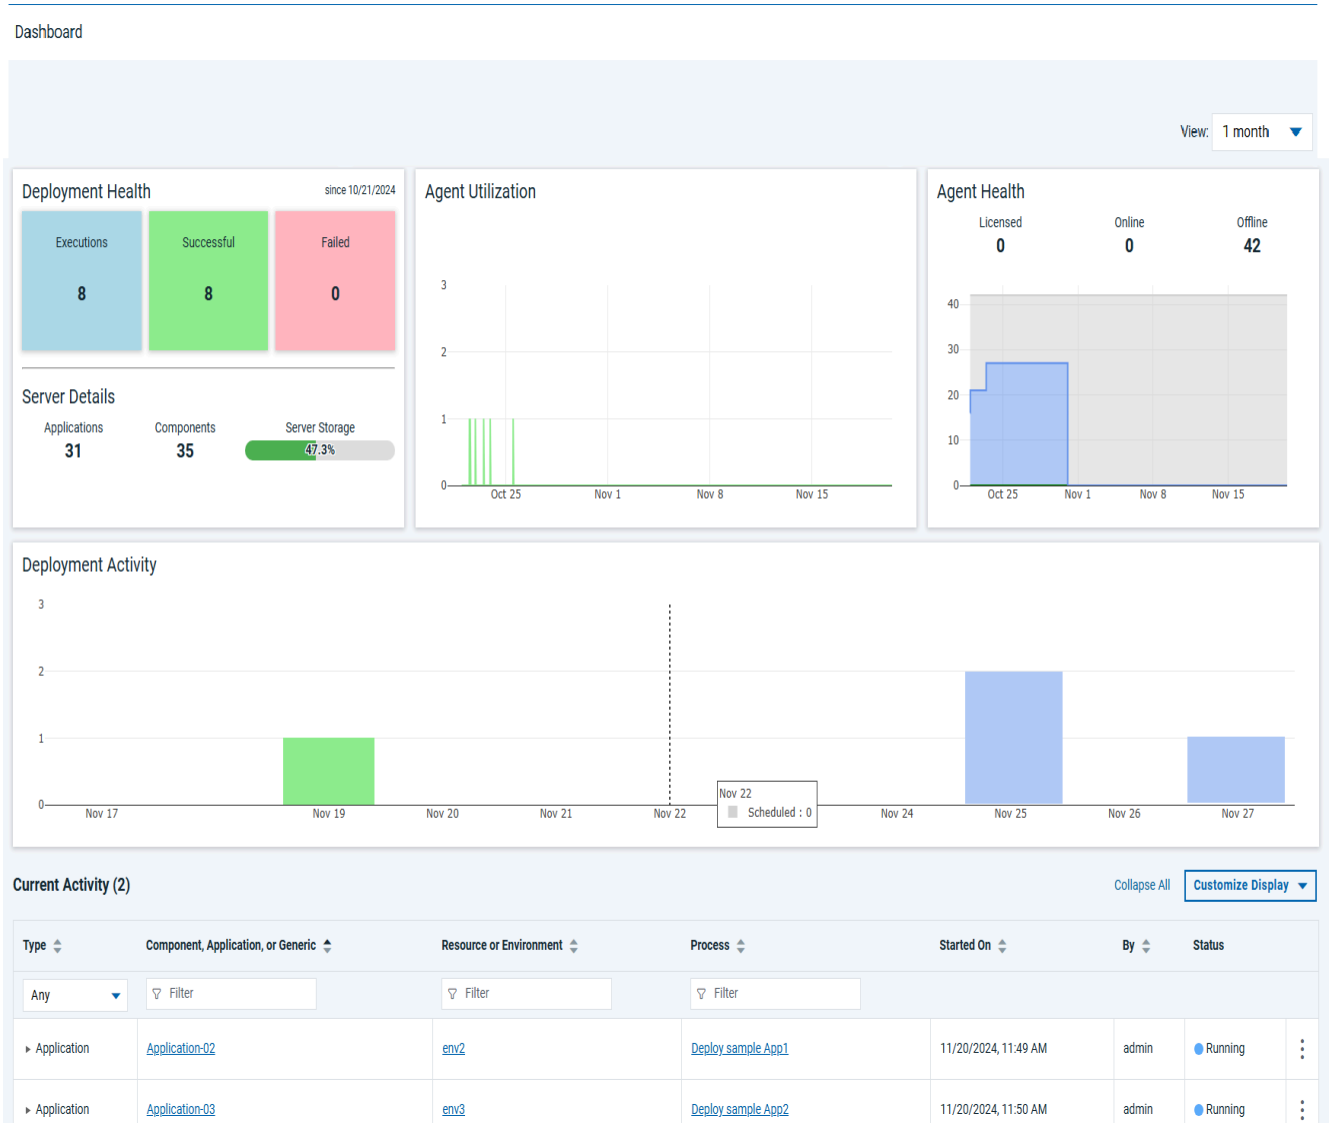
The Dashboard is a live page that gives you real-time insights into the status of your deployments and agents through graphs and charts.

The dashboard has multiple widgets that help you track, analyze, and monitor your deployments and agents. The following widgets are available in the Dashboard:

- Deployment Health on page 2246
- Agent Utilization on page 2247
- Agent Health on page 2247

- Deployment Activity on page 2247
- Current Activity on page 2247

The following screenshot is an example representation of the Dashboard page:



Note: By default, the **Deployment Health**, **Agent Utilization**, and **Agent Health** widgets display data covering the last one month. You can view a custom time frame such as the past week, three months, or one year by clicking the **View** drop-down menu in the upper-right corner of the dashboard and selecting your preferred range.

Deployment Health

The Deployment Health widget gives you an overall status of your deployments in the last month.

Widget part	Description
Executions	Displays the total number of deployments executed.
Successful	Displays the total number of successful deployment jobs.
Failed	Displays the total number of failed deployment jobs.
Server Details	• **Application**: Displays the total number of applications created in the system. • **Environment**: Displays the total number of environments created for these applications. • **Server Storage**: Displays the amount of CodeStation storage being used by artifacts in percentage. You can define the storage size to display in **Server Storage Display '100%' Size (MB)** field on the **System Settings** page.

Agent Utilization

The Agent Utilization widget is indicative of the agent usage data. It displays a time series chart along with counts to show the agents' usage data for the month.

Agent Health

The Agent Health widget gives you an insight into your agent's health. It displays a time series chart along with counts to show the agents' health data, including `Total Licensed`, `Total Online`, and `Total Offline` for the month.

Deployment Activity

The Deployment Activity widget shows you scheduled deployment counts. It displays a bar chart to show the scheduled deployment jobs count starting with the last 2 days till the next 7 days from the current date.

Current Activity

The Current Activity widget gives you an insight into your active deployments. It displays a table view to give you details on active deployments, that includes deployment information such as `Type`, `Component, Application, or Generic`, `Resource or Environment`, `Process`, and `Start Time`.

Components

Components represent deployable items along with user-defined processes that operate on them, usually by deploying them.

Understanding components is critical to understanding HCL DevOps Deploy (Deploy).

Deployable items or artifacts, can be files, images, databases, configuration materials, or anything else that is associated with a software project. Artifacts can come from a number of sources, such as: file systems, build servers, source version control systems, and repositories. When you create a component, you identify the source and define how the artifacts are imported into Deploy. For example, if the source is Subversion, you specify the Subversion repository that contains the artifacts. Each component represents artifacts from a single source. Sources are defined using source-type plug-ins.

Components have *component processes*. A component process is a series of user-defined steps that operate on the component or its artifacts. Each component has at least one process and can have several. A component process can be a single step or contain numerous relationships, branches, and process switches. Component processes are created with the process editor on page 2398. The process editor is a visual drag-and-drop editor that lets you drag process steps onto the design space and configure them as you go. As more steps are placed, you visually define their relationships with one another. Process steps are selected from a menu of standardized steps. Steps are provided for several utility processes, such as inventory management, and workflow control. More process steps are provided by automation-plug-ins. A component process can have steps from more than one plug-in. See Plug-ins on page 2556.

After you define the source and processes for a component, you import its artifacts into the artifact repository, CodeStation. Artifacts can be imported automatically or manually. By default, a complete copy of the content is imported into CodeStation. The original artifacts are untouched. Each time a component is imported it is assigned a *component version*, which is used to ensure that the appropriate component instances get deployed. Versions can be assigned automatically, applied manually, or from a build server. Every time the artifacts are modified and imported, a new version of the component is created.

You can create *Component templates* that contain processes and configuration properties, which you can use to create components. See Component templates on page 2308.

Creating components

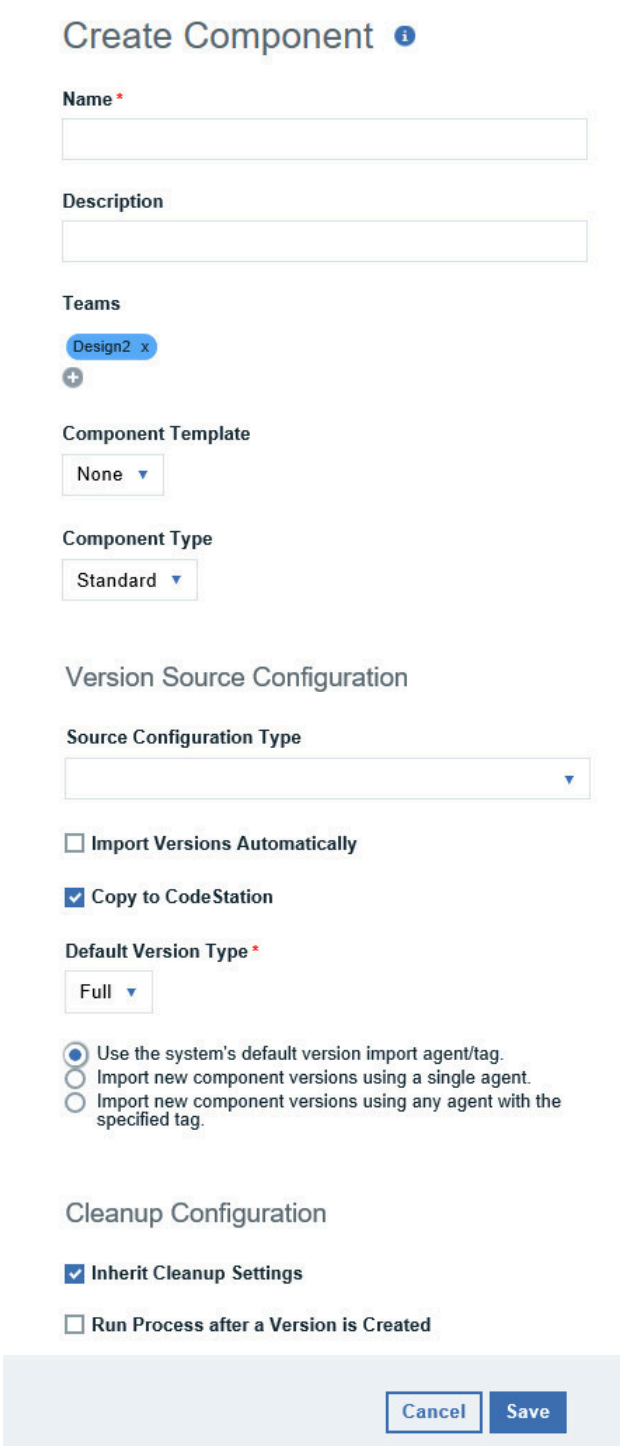
A component consists of artifacts of a single source type and one or more processes. Component creation is the same for all source types, however; the content can be different.

About this task

Components can be created manually, by using a template, or imported. This topic includes the steps for creating a component manually. See Component templates on page 2308 and Importing components on page 2296 for the other methods.

Several fields in the **Create Component** window are the same for every source type, while others depend on the source that is selected from the **Source Configuration Type** list. The graphic below show the **Create Component** window with the common fields for all configuration types.

Some of the configuration options might be restricted based on the role assigned to you. Check with your administrator, if you need a specific option enabled.



1. On the **Components** page, click **Create Component**.
2. To use a template for the new component, select a template from the **Component Template** list.

   When using a template, the component inherits source configuration, properties, and processes from the template. A component can have a single template associated with it. The default value is none.

If you select a template, the **Template Version** field is displayed which is used to select a template version. By controlling the version, you can roll out template changes as needed. The default value is `Latest Version`, which means that the component uses the newest version which is based on creation date.

Note: If you select a template that includes a source type, the dialog box changes to reflect values that are defined for the template. Several fields, including the **Source Configuration Type** field are populated and locked.

For information about templates, see Component templates on page 2308.

3. Type a name and description for the component.
   The name identifies the component throughout the product user interface. The description conveys more information about the component. If the component is used by more than one application, for example, entering `Used in applications A and B` can help identify how the component is used. The **Name** field is required and must contain a value.
4. Specify one or more teams that can manage the component.
   Click **Add Teams** and select from the list of previously defined teams. For information about teams, see Managing Security on page 2149.
5. Select the component type in the **Component Type** field.
   Select **z/OS** if the component is based on IBM® z/OS® artifacts, otherwise use the default value of `Standard`. If you select **z/OS**, the source configuration controls are not available. Artifacts that are stored in z/OS® do not use source configurations. To learn more about configuring and deploying z/OS® components, see Deploying components to the z/OS platform on page 2531.
6. In the **Source Configuration Type** list, select type of source for which the component is being defined. This field defines the source type for the component's artifacts.

   Sources are defined with source configuration plug-ins. If you do not see a desired source type, verify that the source-type plug-in is installed.

   All artifacts must have the same source type. Selecting a source type shows the fields that are associated with the plug-in. Source-dependent fields are used to identify and configure the component's artifacts.
7. Complete common properties that configure how and when artifact versions are imported.

   Import Versions Automatically

   If selected, the source location is periodically polled for new versions. Found versions are automatically imported. The default polling period is 300 seconds, which can be changed with the **Automatic Version Import Check Period** setting on the **System Settings** pane. If left cleared, you can manually create versions by using the **Versions** pane. By default, the box is cleared.

   Copy to CodeStation

   If selected, imported artifacts are copied to a CodeStation repository which is a tamper-proof embedded artifact repository. If cleared, only metadata about the artifacts is imported. For additional information, see System settings on page 2086.

Default Version Type

Defines how component versions are imported into CodeStation. The `Full` value means that the version is comprehensive and contains all artifacts. The `Incremental` value means that the version contains only the artifacts that were modified from the previous version. The default value is `Full`.

8. Select the type of versions to create by default on version imports.
   You can import full version or increment type during version import and specify the additional import configuration:

   Use the system's default version import agent/tag

   If selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. The agent or tagged agents must have access to the system where the artifacts are located. See System settings on page 2086

   Import new component versions using a single agent

   If selected, use the **Agent for Version Imports** field to designate the agent that imports artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from the server location, install an agent in the same location and specify that agent.

   Import new component versions using any agent with the specified tag

   If selected, use the **Agent Tag for Version Imports** field to designate the tag that is used to identify the agents that can import artifacts into the component. Tagged agents must have access to the system where the artifacts are located.

9. Configure common cleanup properties.

   Inherit Cleanup Settings

   Specify whether to use the values specified in the system settings for artifact cleanup or specified them for this component. If this check box is cleared, you must specify values for the following settings:

   Days to Retain Versions

   The number of days to retain component versions after they are created. For example, if you specify 30, component versions are archived when they are older than 30 days and have no other setting that keeps them. To retain component versions indefinitely, enter - 1. To use the system default retention value, enter 0.

   Number of Versions to Retain

   The number of versions to retain for each component. For example, if you specify 10, the server keeps the 10 most recently created component versions. To retain all component versions, enter -1. To use the system default retention value, enter 0.

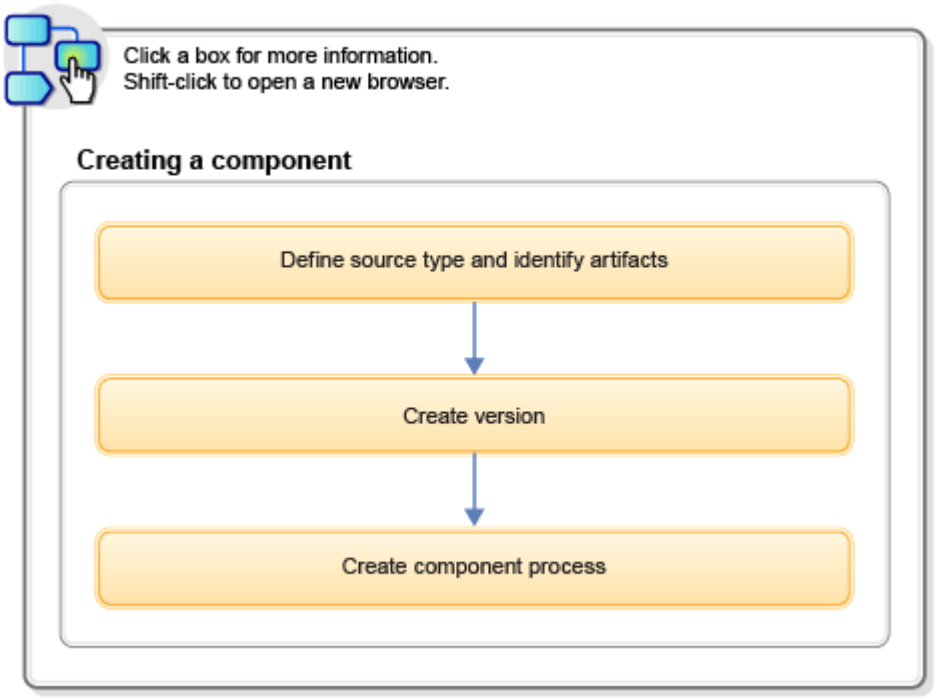
   For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

10. Complete properties based on the source configuration type selected.
    Each source configuration has a unique set of required and optional properties that are displayed after the configuration type is selected. For details on these properties, refer to the plug-in used to integrate the source type.
11. Click **Save**.
    Saved components are listed in the **Components** pane.

Getting started with creating components

Components are the centerpiece of the HCL DevOps Deploy (Deploy) deployment engine. Components associate deployable items (artifacts) with processes that deploy them.

The following diagram summarizes the basic steps for creating components:



1. Click this area for information about defining components. on page 2248
2. Click this area for information about importing component versions. on page 2301
3. Click this area for information about creating component processes. on page 2299

The source type identifies the artifacts that the component uses. The source type can be almost anything that is associated with a software project. Sources are defined with *source plug-ins*.

Component versions are created when artifacts are imported into the artifact repository, CodeStation. Version history is maintained and components can be rolled back to earlier versions.

Component processes consist of user-configured steps that operate on components, typically by deploying them. Process steps are provided by *automation plug-ins*. Processes can be created with the process design editor or by using the command-line interface.

Manual application tasks on page 2387

Installing plug-ins from the plug-in site on page 2559

Component templates on page 2308

Importing components on page 2296

Creating components from the file system

You can create components by importing artifacts from the file system on the HCL DevOps Deploy (Deploy) server. You can import a single version or automatically import versions as they are added to the file system.

About this task

Deploy imports local files by two methods:

File System

This method imports all files in the specified directory. You can manually update these files to create component versions, but the server does not create versions automatically. See Creating components from a nonversioned file system on page 2253.

File System (Versioned)

This method treats each subdirectory in the target directory as a different version of the artifacts. You can set the server to check for new subdirectories periodically and automatically create component versions when new subdirectories are detected. See Creating components from a versioned file system on page 2256.

In either case, the artifacts must be on the same file system as the Deploy server.

Creating components from a nonversioned file system

To import artifacts that are not stored in versioned folders, store the artifacts in a folder and create a component with the **File System** source configuration type.

About this task

When you use this type of component, you must manually create versions. To create versions of components automatically, see Creating components from a versioned file system on page 2256.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **File System**.
6. Specify the following parameters for the component:

   Base Path

   Specify the path to the directory that contains the artifacts.

Always Use Name Pattern

If you select this check box, new versions are automatically named according to the pattern in the **Version Name Pattern** field. If you clear this check box, you must specify a name each time you create a version.

Version Name Pattern

Specify a pattern for each version name. You can use the *${version}* variable to include an automatically incremented version number. For example, by using the `mycomp_${version}` pattern, the server produces versions such as `mycomp_1` and `mycomp_2`.

This parameter is meaningful only if you select the **Always Use Name Pattern** check box.

Next Version Number

Specify the version number for the next version.

This parameter is meaningful only if you select the **Always Use Name Pattern** check box.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

This parameter has no effect on this source configuration type. You must import new versions manually.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

   Result

   The new component is included in the list of components.
8. Import the first version of the component:
   a. Go to the **Versions** tab.
   b. Click **Import New Versions**.
   c. Specify a name for the new version and then click **Save**.

   Result

   The new version is included in the list of versions. You can confirm that the artifacts are included in the version by clicking the version and looking at the list of artifacts.
9. To import future versions of the component, click **Import New Versions** again and specify a name for the new version.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from a versioned file system

To import artifacts with versions, create a directory with subdirectories that represent the versions of the artifacts. Then, create the component with the **File System (Versioned)** source configuration type.

Before you begin

To create this type of component, first arrange the artifacts inside a parent folder for the component and then arrange the artifacts inside subfolders for each version of the component. For example, the following file structure shows a component with three versions and two files in each version:

```
myComponent/
  1.0/
    fileA.txt
    fileB.txt
  2.0/
    fileA.txt
    fileC.txt
  experimental/
    fileA.txt
    fileD.txt
```

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **File System (Versioned)**.
6. Specify the following parameters for the component:

   Base Path

   Specify the path to the directory that contains the artifacts. The content of each subdirectory within this base directory is considered a distinct component version. The subdirectory with the most recent time stamp is considered to be the latest version.

   Preserve Execute Permissions

   For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

   Text File Extensions

   If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

   ```
   txt,log,ini,sh
   ```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from source-code management systems

You can create components from the artifacts in various source-code management systems.

Creating components from Git

Git is a source-code management system.

Before you begin

Install Git on the HCL DevOps Deploy (Deploy) server. When you create the component, you must specify the path to the Git executable file.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **Git**.
6. Specify the following parameters for the component:

   Repository URL

   The location of the Git repository, such as `https://git.example.com/myproject.git`.

   Branch

   The name of the branch to use.

   User Name

   The user name to authenticate with the Git repository if using HTTPS protocol.

   Password

   The password to authenticate with the Git repository if using HTTPS protocol. You can also use the Git Personal Access Token (PAT) if the PAT is defined in the key-value store of the Vault.

   Watch for tags

   Select this check box to use tags as the basis for new component versions.

Includes

A list of file patterns to include in the component. Separate each pattern with a carriage return.

Excludes

A list of file patterns to exclude from the component. Separate each pattern with a carriage return.

GIT Path

The path to the Git executable file on the Deploy server. If you added the Git executable to the system PATH variable, you can specify the name of the executable, such as `git`. If you did not add the Git executable to the system PATH variable, specify the complete path to the Git executable, such as `/usr/bin/git`.

Preserve Execute Permissions

For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from Subversion

Subversion is a source-code management system.

Before you begin

Install the Subversion client on the HCL DevOps Deploy (Deploy) server. For example, on Linux™, you can use the package manager to install Subversion with a command that is similar to these examples:

```
yum install subversion
```

```
apt-get install subversion
```

```
zypper install subversion
```

All Subversion server configurations are supported.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **Subversion**.
6. Specify the following parameters for the component:

   Repository URL

   The location of the Subversion repository, such as

   ```
   http://svn.example.com/svn/myrepository
   ```

   Watch for tags

   Select this check box to use tags as the basis for new component versions.

   Includes

   A list of file patterns to include in the component. Separate each pattern with a carriage return.

   Excludes

   A list of file patterns to exclude from the component. Separate each pattern with a carriage return.

   User

   The user name for the repository.

   Password

   The password for the repository.

   SVN Path

   The path to the `svn` executable file on the Deploy server. If you added the executable file to the system PATH variable, you can specify the name of the executable file, such as `svn`. If you did not add the executable file to the system PATH variable, specify the complete path, such as `/usr/bin/svn`.

   Preserve Execute Permissions

   For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

   Extensions of files to Convert

   If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

   ```
   txt,log,ini,sh
   ```

Proxy Hostname

If you connect to the Subversion repository through a proxy server, specify the host name or IP address of the proxy server.

Proxy Port Number

Specify the port number that is used by the proxy server for client connections.

Proxy Username

If the proxy server requires authentication, specify the user name.

Proxy Password

If the proxy server requires authentication, specify the password.

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component* > Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from ClearCase

ClearCase is a source-code management system.

Before you begin

Install an agent that has access to the ClearCase version object base (VOB) repository.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **ClearCase**.
6. Specify the following parameters for the component:

   Path to location inside the View

   The location of the base directory on the IBM® Rational® ClearCase® server from which files are imported.

   Includes

   A list of file patterns to include in the component. Separate each pattern with a carriage return.

Excludes

A list of file patterns to exclude from the component. Separate each pattern with a carriage return.

Snapshot View

Check this box if the connection is a snapshot view.

Clear Tool Path

If the `cleartool` file is not on the **path** variable, type the location of the `cleartool` executable file.

Preserve Execute Permissions

For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from Microsoft™ Team Foundation Server SCM

Microsoft™ Team Foundation Server SCM is a source code management tool.

Before you begin

You must have performed the following tasks:

- Installed an agent on a computer that is running Microsoft™ Windows™. The agent computer must have access to the Microsoft™ Team Foundation Server. Ensure that Microsoft™ .NET Framework 3.5 is installed on the agent computer.

  Note: The agent must be installed on a computer that running is Windows™.

- Installed TFS Source Config plug-in from the HCL DevOps Deploy (Deploy)HCL DevOps Deploy plug-in site

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.

In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.

3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **TFS_SCM**.
6. Specify the following parameters for the component:

Repository URL

The URL of the TFS repository, such as `http://tfs2010:8080/tfs/mygroup`.

User

The user name of the TFS-credentialed user.

Password

The password of the TFS-credentialed user.

tf.exe Path

The location of the `tf.exe` file, for example, `C:\Program Files\Microsoft Visual Studio 10.0\Common7\IDE`.

Workspace

The name of the TFS workspace. A workspace maps local and version-controlled folders on the TFS server.

Server Folder

The location of the TFS server folder.

Local Folder

The location of the workspace local folder.

Preserve Execute Permissions

For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from build integration tools

You can create components from the artifacts in various build integration tools.

Creating components from DevOps Build

You can create components from IBM DevOps Build (Build), a build integration tool.

Before you begin

Install an agent that has access to the Build server.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **DevOps Build**.
6. Specify the following parameters for the component:

   DevOps Build Url

   The URL of the Build server, such as `https://devopsbuild.example.com`.

   User

   The user name of the Build-credentialed user.

   Password

   The password of the Build-credentialed user.

   Project

   The name of the project. Build projects roughly correspond to Deploy components.

   Build Process

   The name of the build process that contains the builds to import.

   Status

   The status that a build life must have before it can be imported. The server only imports build lives that contain this status.

   Artifact Sets

   If **Copy to CodeStation** is checked, type the list of artifact sets to resolve in CodeStation. Place each list item on a new line.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from Apache Maven

Apache Maven is a build integration tool for Java™ projects.

Before you begin

Install an agent that has access to the Apache Maven repository.

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **Maven**.
6. Specify the following parameters for the component:

   Repository URL

   The URL of the Maven repository, for example:

   ```
   https://MyMavenRepo.MyCompany.om/repository/
   ```

   HTTP Proxy Host

   The proxy host for the Maven repository.

   HTTP Proxy Port

   The proxy port for the Maven repository. You must supply the proxy port if you supply a proxy host.

HTTP Proxy Username

The user name for an account that can access the HTTP proxy.

HTTP Proxy Password

The password for an account that can access the HTTP proxy.

User

The user name for the Maven-credentialed user.

Password

The password for the Maven-credentialed user.

Group ID

The name of the `groupID` as defined in the Maven `pom.xml` file. The group ID identifies the project.

Artifact ID

Name of the `artifactID` as defined in the Maven `pom.xml` file. The artifact ID is the name of the unversioned JAR file.

Maven Qualifer

The optional qualifier is appended to the file name after the version number.

File Extension

The file extension for the file type to import.

Latest Build Count

The number of the builds to import. The default value is 1.

Version Name Pattern

The range of build versions to import. Versions are defined by regular expressions. For example, to import all 1.1.*, and 1.2.* versions, you might type `(1.[0-9]+).*`. A number of versions that is equal to the value in the **Latest Build Count** field is imported for each matching version.

Preserve Execute Permissions

For Linux™ and UNIX™ operating systems, select this check box to retain the execute permissions for each file.

Extensions of files to Convert

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component* > Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating components from Microsoft™ Team Foundation Server

Microsoft™ Team Foundation Server is a build integration tool.

Before you begin

You must have completed the following tasks:

- Installed an agent on a computer that is running Microsoft™ Windows™. The agent computer must have access to the Microsoft™ Team Foundation Server. Microsoft™ .NET Framework 3.5 must be installed on the agent computer.

  Note: The agent must be installed on a computer that running is Windows™.

- Installed Microsoft TFS plug-in from the HCL DevOps Deploy (Deploy)HCL DevOps Deploy plug-in site

1. In Deploy, click **Components**, and then click **Create Component**.
   The **Create Component** window displays.
2. To use a template for the new component, select a template from the **Template** list.
   In this case, the component inherits source configuration, properties, and processes from the template. For information about templates, see Component templates on page 2308.
3. Specify a name and description for the component.
4. In the **Teams** fields, specify the access information for the new component.
5. In the **Source Configuration Type** list, select **TFS**.
6. Specify the following parameters for the component:

   TFS URL

   The URL of the TFS server, such as `http://tfs2010:8080/tfs/mygroup`.

   TFS Version

   Select the installed version of the TFS server.

   TFS Username

   The user name of the TFS-credentialed user.

   TFS Password

   The password of the TFS-credentialed user.

TFS Team Project

The name of the project. Projects are collections of items that track related work.

Build Definition

The name of the build to import.

Build Status

Select the status that a build must have before it can be imported. The server only imports builds with this status.

Build Quality

To limit imports to builds with a specific build quality (or build rating), supply the rating. For example, type `Self Test with Work arounds`.

Directory Offset

The offset is relative to the base directory.

File Includes

A list of file patterns to include in the component. Separate each pattern with a carriage return. To include all files, type `**/*`.

File Excludes

A list of file patterns to exclude from the component. Separate each pattern with a carriage return.

Text File Extensions

If text-type files must be converted into another character set, type the list of file extensions to be converted. Matching file types are converted into the default or system character set of the system where the agent is located. Separate list items with commas, for example:

```
txt,log,ini,sh
```

Import Versions Automatically

Select this check box to check for new versions periodically and to import new versions automatically. If you do not import versions automatically, you can import versions manually by clicking **Components > *selected component*** **> Versions** and then clicking **Import New Versions**.

Copy to CodeStation

This option, which is selected by default, creates tamper-protected copies of the artifacts and stores them in the embedded artifact management system, CodeStation. If the check box is cleared, only metadata about the artifacts is imported. In most cases, keep this check box selected. The default for this setting is in the system setting **Components copy to CodeStation by default**. For more information, see System settings on page 2086.

Default Version Type

Specify how to import versions into CodeStation:

Full

Each version is comprehensive and contains all artifacts.

Incremental

Each version contains a subset of artifacts.

Use the system's default version import agent/tag

If this parameter is selected, the agent or tag that you specified on the **System Settings** page is used to import component artifacts. Agents must have access to the system where the artifacts are located. For more information, see System settings on page 2086.

Import new component versions using a single agent

If this parameter is selected, use the **Agent for Version Imports** field to identify the agent that is used to import artifacts into the component. The agent must have access to the system where the artifacts are located. To import artifacts from where the server is located, install an agent in the same location and specify that agent.

Import new component versions using any agent with the specified tag

If this parameter is selected, use the **Agent Tag for Version Imports** field to identify the tag that is used to select agents to import artifacts into the component. All tagged agents must have access to the system where the artifacts are located.

Inherit Cleanup Settings

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Inherit Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

7. Click **Save**.

Results

The new component is listed on the **Components** page. The **Versions** tab shows the available versions of the component. If you selected the **Import Versions Automatically** check box, versions are displayed automatically. Otherwise, click **Import New Versions** to show the available versions. Depending on the number and size of the artifacts, it might take time before the versions are displayed. To see the artifacts in the component, click a component version.

What to do next

Create processes for the component. See Creating component processes on page 2425.

Creating component versions with the command-line client

If HCL DevOps Deploy (Deploy) does not have a source configuration type for your external tool, you can use the udclient command-line client to manage components.

Before you begin

To install the client, see Installing the command-line client on page 2592.

About this task

When you use the udclient client in this way, you can push new versions of components to the server, start processes, add links to external sources, and run many other tasks on the Deploy server as part of your build or SCM publishing process. In this way, you can work with your components in Deploy without changing your current technology.

Follow these general steps to set up a component that uses the command-line client:

1. Create one or more components in Deploy to represent the components of your build. Use the following parameters in the **Create Component** window:
   - In the **Source Configuration Type** field, select **None**.
   - Clear the **Import Versions Automatically** check box.
   - Complete the rest of the fields in the window as usual.

   You can also use the udclient client to create components, but because component creation is a one-time process, components are typically created withe the Web UI.
2. In the scripts for your component, add code that calls udclient client commands to create a component version and upload the artifacts to the Deploy server.
   In most cases, you use several different commands to create the version. The following steps show examples of some of the commands you might use.

   Note: These examples use code in an Apache Ant build file. Specifically, they call the udclient client with the Ant <exec> command, which calls external programs. If you are using a different build or SCM technology, you can adapt the examples to your specific technology to call the udclient client.

   a. Use the createVersion on page 2680 command to create the new version.
      Result
      The following example code creates a version of a component that is named `mycomponent`. The version name is set to the timestamp of the build. The variables `${udclient.weburl}`, `${udclient.username}`, and `${udclient.password}` represent the URL of the server and the user name and password for the server.

```
<exec executable="/bin/bash"
  outputproperty="mycomponent.component.output">

  <arg value="/opt/udclient/udclient"/>

  <arg value="-weburl"/>
  <arg value="${udclient.weburl}"/>

  <arg value="-username"/>
  <arg value="${udclient.username}"/>

  <arg value="-password"/>
  <arg value="${udclient.password}"/>

  <arg value="createVersion"/>

  <arg value="-component"/>
  <arg value="mycomponent"/>
```

```
  <arg value="-name"/>
  <arg value="${buildTimestamp}"/>

</exec>
```

b. Use the addVersionFiles on page 2612 command to upload the artifacts to the component version.

Example

The following example code uploads the files in the `${destdir}` folder to the version:

```
<exec executable="/bin/bash">

  <arg value="/opt/udclient/udclient"/>

  <arg value="-weburl"/>
  <arg value="${udclient.weburl}"/>

  <arg value="-username"/>
  <arg value="${udclient.username}"/>

  <arg value="-password"/>
  <arg value="${udclient.password}"/>

  <arg value="addVersionFiles"/>

  <arg value="-component"/>
  <arg value="mycomponent"/>

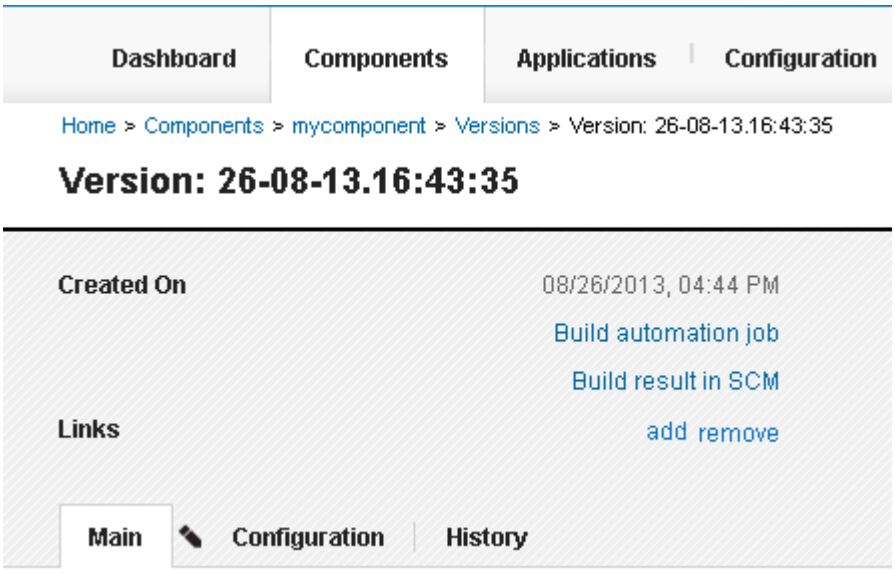
  <arg value="-version"/>
  <arg value="${buildTimestamp}"/>

  <arg value="-base"/>
  <arg value="${destdir}"/>

</exec>
```

c. **Optional:** Add links from the component version.

With the addVersionLink on page 2613 command, you can add links from the version to external build resources, such as the page that shows information about the build result. These links appear at the top of the information page for the component version. The following figure shows a component version with a link to the related build job and the related build result in the source-code management system:



Result

For example, the following code adds a link to the build result page at the URL `http://build.example.com/projects/mycomponent/${buildResultUUID}`:

```
<exec executable="/bin/bash">

  <arg value="/opt/udclient/udclient"/>

  <arg value="-weburl"/>
  <arg value="${udclient.weburl}"/>

  <arg value="-username"/>
  <arg value="${udclient.username}"/>

  <arg value="-password"/>
  <arg value="${udclient.password}"/>

  <arg value="addVersionLink"/>

  <arg value="-component"/>
  <arg value="mycomponent"/>

  <arg value="-version"/>
  <arg value="${buildTimestamp}"/>

  <arg value="-linkName"/>
  <arg value="External build result"/>

  <arg value="-link"/>
  <arg value="http://build.example.com/projects/mycomponent/${buildResultUUID}"/>

</exec>
```

Results

Now, when you run a build in your external build tool, the build process creates a component version and uploads the artifacts for the version to the Deploy server. From this point, you can work with the component and version on the server as usual, such as running processes with it.

You can also add other commands to your build script. For example, you can start application processes with the requestApplicationProcess on page 2866 command.

GitHub Action: Create new DevOps Deploy component version

Creating z/OS® component versions

You can create z/OS component version by running the buztool.sh command from job control language (JCL) or from the z/OS® UNIX™ System Services command line. You can also create z/OS component version by using the z/OS® File Source Config plug-in.

About this task

In an automated system, typically, you write a script that runs the buztool.sh command after a build is created by your build system. The buztool.sh command then creates a component version which can be deployed using a deploy process.

HCL DevOps Deploy (Deploy) server requires the time zone of the z/OS system to display the artifact modified date accurately. Identify the time zone of the z/OS system and set the TZ environment variable. To know more about the TZ environment variable, refer to the z/OS® documentation.

While packaging load modules, System Status Index (SSI) value is converted to epoch time and displayed as Last Modified Date in the component version page. For example, if a load module SSI value is 087ab85c. Converting to decimal format gives the Epoch time as 142260316 which is displayed as July 5, 1974 12:45:16 PM GMT in the component version page. For non-load modules, the buztool.sh command tries to read **ZLM4DATE**, **ZLMTIME** and **ZLMSEC** statistical values from ISPF.

When you create a z/OS component version with an external repository, you will store artifacts in the external repository and store only the metadata of artifacts in Codestation. Hence, when you download the version by using the **Download All** action on the web application, only the metadata XML file, which is stored in Codestation, is displayed in the `packageManifest.xml` file.

What to do next

You can work with the component that contains z/OS® files as you would work with any other component in Deploy. Use the z/OS® Utility plug-in to create processes that deploy components that contain z/OS® files.

See the Deploy website for information about the z/OS® Utility plug-in: Plugins.

Note: IMS.TFORMAT members (member name containing non-readable characters) are not supported. PDS members name can have ONLY [0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ@#$] characters.

Creating z/OS® component versions from JCL

To create IBM® z/OS® component versions from job control language (JCL), create and submit JCL to run the buztool.sh command.

About this task

Note: The JCL to run buztool.sh is changed in HCL DevOps Deploy (Deploy) 6.2.5 to use the BPXBATCH utility. The JCL created before version 6.2.5 needs to be updated to follow the format in the new example.

1. Create a JCL file in a partitioned data set and base the file on the sample in the *high_level_qualifier*.SBUZSAMP(BUZRJCL) file.
2. Use the buztool.sh createzosversion command to create the component version or buztool.sh createlinkedversion to create the linked version.

Table 726. Arguments for the buztool command

Parameter	Required	Description
-c, **-component**	true	The component name in Deploy. The component name can contain only letters, numbers, and spaces.
-v, **-version**	false	The name of the version to create. If a version is not specified, a version name is generated from the current time stamp. The version name can contain only letters, numbers, and spaces.
-desc, **-description**	false	Description for the version.
-s, **-shiplist**	true	The location of the ship list file.
-verb, **-verbose**	false	To display a trace log, set this parameter to true. If verbose is specified with no value, it is assumed true. This value should always be set to false in all environments, unless additional logging is needed for a specific need. Setting this to true, can cause out of memory errors, if the log generated is immense.
-o, **-output**	false	The full path name of the file where the output of the version creation is written.
-t, **-type**	false	The type of the version to create. Set to full to create a full version. Default is incremental.
-to, **-token**	false	The token used to authenticate the server. This token can be created by a user who has access to create versions in the corresponding component. If the token

Parameter	Required	Description
		is not provided, buztool takes the token from the `<agent_home>/conf/installed.properties` server.token value to authenticate.
-prop, **-propertiesFilePath**	false	The full path of the buztool properties file. The buztool property file contains `deployType` to `copyType` mappings. Use this parameter to pass details of external repository . See The buztool properties file on page 2286, for more information.
-url, **-serverUrl**	false	The URL of the server in which the version is to be created.
-runtime.deploy	false	When set to false, disables hash calculation of artifacts. Default is true.
-zpv	false	To use v2 package format, set this parameter to v2. If the parameter is not provided, it assumes it to be v1.
-extrepo.url	false	The URL of external repository.
-extrepo.repositoryType	false	The type of external repository. The value can be Nexus, or Artifactory.
-extrepo.repository	false	The name of the repository in Artifactory (or Nexus) to which the version is uploaded.
-extrepo.username	false	The user name of external repository.
-extrepo.password	false	The password of external repository.
-extrepo.apiKey	false	The API key of JFrog Artifactory to be used.
-extrepo.rawDirectory	false	The raw directory in the Nexus repository to be used.
-extrepo.httpProxyHost	false	The proxy host for external repository.
-extrepo.httpProxyPort	false	The proxy port for external repository.
createlinkedversion	true	The argument to create a linked version **Note:** This argument is applicable to z/OS linked versions.
-from.hash	true	Specifies the commit from which a build tool like IBM Dependency Based Build calculates the changed files and performs a build. The system assumes that a previous version already exists for this commit, and Deploy uses that version as the parent for the new version that you create.

Parameter	Required	Description
		Note: This argument is applies only to z/OS® linked versions.
-to.hash	true	Specifies the commit hash in the repository where the build runs, typically the HEAD of the branch. This commit will be mapped to the version that you are creating. **Note:** This argument applies only to z/OS® linked versions.
-parent.version	true	Specifies the parent version name for the version that you are creating. This field is required only when multiple versions exist for the commit ID specified in the `-from.hash` argument. **Note:** This argument applies only to z/OS® linked versions.

Example

For example, the following command creates a new version in the CICSModules component:

```
/opt/install-dir/agent/bin/buztool.sh "createzosversion" "-c" "CICSModules" "-v"
        "fixbug100" "-s" "/u/ucduser/build/shiplist.xml"
```

As shown, you must enclose all arguments in double quotation marks.

3. Modify the sample file to reflect your system configuration.
4. Submit the JCL.

Results

The content that the ship list file specifies is available in a component in Deploy.

Creating z/OS® component versions from z/OS® UNIX™ System Services

To create IBM® z/OS® component versions from z/OS® UNIX™ System Services, submit the buztool.sh command from a z/OS® UNIX™ shell.

1. Open a z/OS® UNIX™ shell.
2. Use the buztool.sh createzosversion command to create the component version or buztool.sh createlinkedversion to create the linked version.

Table 727. Arguments for the buztool command

Parameter	Required	Description
-c, **-component**	true	The component name in Deploy. The component name can contain only letters, numbers, and spaces.
-v, **-version**	false	The name of the version to create. If a version is not specified, a version name is generated from the current time stamp. The version name can contain only letters, numbers, and spaces.
-desc, **-description**	false	Description for the version.
-s, **-shiplist**	true	The location of the ship list file.
-verb, **-verbose**	false	To display a trace log, set this parameter to true. If verbose is specified with no value, it is assumed true. This value should always be set to false in all environments, unless additional logging is needed for a specific need. Setting this to true, can cause out of memory errors, if the log generated is immense.
-o, **-output**	false	The full path name of the file where the output of the version creation is written.
-t, **-type**	false	The type of the version to create. Set to full to create a full version. Default is incremental.
-to, **-token**	false	The token used to authenticate the server. This token can be created by a user who has access to create versions in the corresponding component. If the token is not provided, buztool takes the token from the `<agent_home>/conf/installed.properties>` server.token value to authenticate.
-prop, **-propertiesFilePath**	false	The full path of the buztool properties file. The buztool property file contains `deployType` to `copyType` mappings. Use this parameter to pass details of external repository . See The buztool properties file on page 2286, for more information.
-url, **-serverUrl**	false	The URL of the server in which the version is to be created.
-runtime.deploy	false	When set to false, disables hash calculation of artifacts. Default is true.
-zpv	false	To use v2 package format, set this parameter to v2. If the parameter is not provided, it assumes it to be v1.
-extrepo.url	false	The URL of external repository.
-extrepo.repositoryType	false	The type of external repository. The value can be Nexus, or Artifactory.

Parameter	Required	Description
-extrepo.repository	false	The name of the repository in Artifactory (or Nexus) to which the version is uploaded.
-extrepo.username	false	The user name of external repository.
-extrepo.password	false	The password of external repository.
-extrepo.apiKey	false	The API key of JFrog Artifactory to be used.
-extrepo.rawDirectory	false	The raw directory in the Nexus repository to be used.
-extrepo.httpProxyHost	false	The proxy host for external repository.
-extrepo.httpProxyPort	false	The proxy port for external repository.
createlinkedversion	true	The argument to create a linked version **Note:** This argument is applicable to z/OS linked versions.
-from.hash	true	Specifies the commit from which a build tool like IBM Dependency Based Build calculates the changed files and performs a build. The system assumes that a previous version already exists for this commit, and Deploy uses that version as the parent for the new version that you create. **Note:** This argument is applies only to z/OS® linked versions.
-to.hash	true	Specifies the commit hash in the repository where the build runs, typically the HEAD of the branch. This commit will be mapped to the version that you are creating. **Note:** This argument applies only to z/OS® linked versions.
-parent.version	true	Specifies the parent version name for the version that you are creating. This field is required only when multiple versions exist for the commit ID specified in the `-from.hash` argument.

Parameter	Required	Description
		Note: This argument applies only to z/OS® linked versions.

Example

For example, the following command creates a new version in the CICSModules component:

```
buztool.sh createzosversion -c CICSModules -v fixbug100 -s /u/ucduser/build/shiplist.xml
```

If an argument contains spaces, enclose the argument in double quotation marks, as shown in the following example:

```
buztool.sh createzosversion -c "CICS Modules" -v "fixbug 100" -s /u/ucduser/build/shiplist.xml
```

Results

The content that the ship list file specifies is available in a component in Deploy.

Note: If the agent is upgraded from V7.0.5, the postfix "/artifactory/" is not automatically added to the Artifactory URL from agent V7.1.0. This may result in HTTP response error code 404 while creating version using the buztool. Add postfix "/artifactory" manually to the *url* property in the artifactory properties file to avoid the 404 HTTP error.

Creating z/OS® component version using the v2 package format

You can create IBM® z/OS® component versions from a new package version called version 2 or v2. You can create v2 component versions using the buztool.sh command.

Currently, the artifacts are compressed at the partitioned data set (PDS) level and stored as binary files in Codestation, Nexus, or Artifactory. This condition makes HCL DevOps Deploy (Deploy) z/OS® versions unique because distributed systems packages are stored at the artifact level and not at the folder level.

The `cp` command is enhanced in USS to provide a way to copy artifacts to and from MVS without losing meta relations like ALIAS. The Deploy v2 package format utilizes the enhanced `cp` command to package versions as-is and store them in Codestation, Nexus, or Artifactory.

You can benefit from several advantages by using the v2 package format:

- Component version artifacts are downloaded from Codestation, Nexus, or Artifactory and viewed in an editor that supports viewing files in mainframe encoding. Artifacts are downloaded in native encoding that IBM® z/OS® uses rather than in ASCII.
- During deployments, the token replacements are done in USS because these files are extracted in USS. This way, you deploy the token replaced artifacts directly into the target environment.
- Merging component versions using the v2 package format has improved performances than merging in previous format

Note:

- The current packaging format is still supported. The v2 package format is optional.
- For better results, move components one at a time to the new package format. After Deploy component starts using v2 package format, stay in that format for best results.
- No change is required to the component process design to deploy component versions with the new package format.
- No change is required to the rollback process.
- Starting from version 7.1.0, you can merge component versions within the same package version. Note that merging is not supported between the v1 and v2 formats.
- Datasets with spanned records are not supported.

You can create component versions from the v2 package by using either of these methods:

- In the `buztool` command, use the `createzosversion2` option instead of `createzosversion`.
- Use the `-zpv v2` buztool parameter.

For example, use either of the following commands to create a new component version in the CICSModules component:

```
buztool.sh createzosversion2 -c CICSModules -v fixbug100 -s /u/deployuser/build/shiplist.xml
```

```
buztool.sh createzosversion -zpv v2 -c CICSModules -v fixbug100 -s /u/deployuser/build/shiplist.xml
```

Note:

- Enclose arguments, that have space, in double quotation marks.
- You can use additional parameters, if needed. The parameters are described in Creating z/OS component versions from z/OS UNIX System Services on page 2282

The buztool properties file

Copying files from MVS to USS and back requires that you know the content type of the artifact. Deploy must determine whether the artifact is an executable file (like a loadlib file) or a binary file (like a DBRM file), or a text file (like a COBOL program). To do this, a property file must be passed as input to the `buztool` command with the `-prop <property-file>` parameter. This file contains the `deployType` to `copyType` mapping. Any number of unique deploy types can be mapped to any of the copy types: load, binary, or text. Deploy types must be prefixed with the `deploytype` parameter. Uncomment the parameters you want to use.

By default, container level deployType attributes in shiplist XML are mapped to below copy types :

```
LOAD -> Executable
OBJ (or) DBRM -> Binary
TEXT -> Text
```

Note: The values of **EXTREPO.PASSWORD**, **EXTREPO.APIKEY**, and **SERVER.TOKEN** are encrypted in the buztool.sh script. Change the properties file permission to write during the first run of buztool.sh script. You can set the file permission back to read-only later on for security reasons.

Below is an example of the buztool properties file:

```
# This property file contains samples for following
#
#   1) Defining Deploy Type and Copy Type mappings
#    (which will be later used to create version in new package format)
#
#   2) Setting Runtime Delta Deployment Flag
#
#   3) Defining External Repository details
#
#   4) Declaring alternate Deploy Server details for creating version
#
# * All the lines in the properties file starting with "#" are comments
#   and can be kept as is for reference.
#
#   Please find detailed explaination for each section below
#
#
# Section - 1 :
# ~~~~~~~~~~~~
#
# Defining Deploy Type and Copy Type mappings to create version in
# new package format.
#
# * Deploytypes are mandatory for every Dataset Container in shiplist
#   to create version in new package format.
# * Deploytypes must be prefixed with "deploytype."
#
# Example:
# -------
#
# If deployType is "CICSDBRM", a BINARY dataset then add entry as below
# deploytype.CICSDBRM=BINARY
#
# If deployType is "CICSLOAD", a EXECUTABLE then add entry as below
# deploytype.CICSLOAD=EXEC
#
# If deployType is "CICSLIB", a TEXT dataset then add entry as below
# deploytype.CICSLIB=TEXT
#
# * Property file will have below entries.
#
# deploytype.CICSDBRM=BINARY
# deploytype.CICSLOAD=EXEC
# deploytype.CICSLIB=TEXT
#
#  Add deploytypes to the list as needed.
#
# NOTE:
# ----
# * DeployType is unique in the property file
```

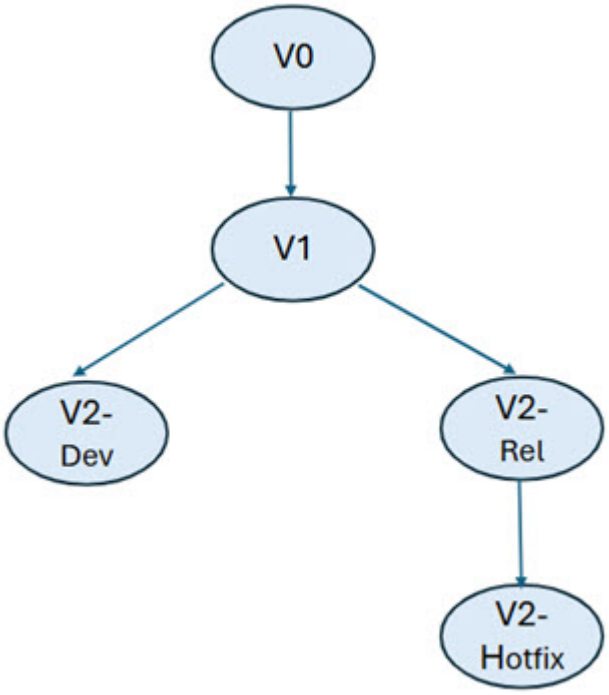
```
#   i.e., each deployType must be assigned to only one copyType.
#
deploytype.JCL=TEXT
# Above entry is used to define deploytype with JCL to copyType as TEXT
# to create a version in new package format from below script
# /var/devops-deploy/agents/deployuser/v7102/installTest/zossamples/test-create-version-new-format.sh
#
#
# Section - 2 :
# ~~~~~~~~~~~~
#
# Setting Runtime Delta Deployment Flag.
#
# Example:
#
# Defining property as below skips the Runtime Delta Deployment
# calculations Logic.
# RUNTIME.DELTADEPLOY=FALSE
#
# NOTE:
# ----
# * Default it is considered as TRUE for version creation.
#
# Section - 3 :
# ~~~~~~~~~~~~
# Defining details to store version artifacts to an external repository.
#
# Example:
#
# # Common external repository inputs
# EXTREPO.REPOSITORY_TYPE={Artifactory/Nexus}
# EXTREPO.USERNAME=
# EXTREPO.PASSWORD=
# EXTREPO.URL=
# EXTREPO.REPOSITORY=
#
# # Additional inputs, if external respository type is "Artifactory"
# EXTREPO.APIKEY=
# EXTREPO.httpProxyPort=
# EXTREPO.httpProxyHost=
#
# # Additional inputs, if external respository type is "Nexus"
# EXTREPO.RAWDIRECTORY=
#
#
# Section - 4 :
# ~~~~~~~~~~~~
#
# Declaring alternate Deploy Server details to create version
#
# Example:
#
# Buztool requires below two properties to create a version on a
# alternate Deploy Server
#
# SERVER.URL=
# SERVER.TOKEN=
#
```

```
# NOTE:
# ----
# * On default, buztool creates version on a Deploy Server defined during
#   installation
#
```

Linked versions in z/OS® components

A *linked version* is a new versioning model for HCL DevOps Deploy (Deploy) z/OS® component types. By using the *linked version*, you can create a sequence of interconnected versions that maintains the logical progression of changes similar to a Git commit history. When you deploy a *linked version* to an environment, it reflects the exact state of the application at that point in the version sequence of the application.

When you create a *linked version*, you must ensure that each version has a preceding version designated as its parent. The first version of the component does not require a parent. This tree-like structure forms a hierarchical sequence of versions, as shown in the following image:



***Linked versions* provides stronger traceability.**

Each *linked version* is created by using a specific GIT commit that you provide as input. This commit reference establishes a continuous chain of custody so that you trace the deployed binary artifacts back to the corresponding source code changes.

This granular traceability is essential for the following purposes:

- **Compliance and auditing**: You can quickly verify the specific code changes that were deployed to an environment.
- **Debugging and rollback**: You can identify the exact changes that introduced a defect, and you can to roll back to the version that corresponds to the preceding stable commit.

By modeling versions in this manner, Deploy ensures that deployed artifacts maintain the same degree of integrity, historical context, and detailed information as the source code. This method provides tight alignment between deployment tracking and established development workflows.

A linked version offers the efficiency of an incremental version while functioning like a *full version*. During deployment, only the delta artifacts are copied instead of copying the entire application, which reduces the processing time and resource usage.

Notes:

- Each component can have only one root-linked version.
- Every linked version that you create after the `root` must be a direct or indirect descendant of that `root` version

Restrictions and limitations: You cannot deploy an *incremental version* on top of a *linked version*; however, you can deploy a *linked version* over an *incremental version*. *Full versions* and *linked versions* are interoperable.

Creating z/OS® component linked versions

You can use the *linked version* type to create a sequence of interconnected versions that maintains the logical progression of changes.

Before you begin

You must have performed the following tasks:

- Installed the z/OS® agent and ensure that it is running.
- Ensured that a valid z/OS® component is available in the server.

Notes:

- The *linked version* type is currently supported for only external GIT repositories. Therefore, you must provide external repository inputs when you create a linked version.
- When you create the first *linked version* for a component, you must not provide the **-from.hash** parameter. The initial *linked version* is designated as the `root` version for the component. It typically serves as the baseline and includes all application binaries after the transition to *linked versions*.

About this task

You can create a linked version by running the buztool.sh command, which is included with the HCL DevOps Deploy (Deploy) z/OS® agent.

Run the buztool.sh command, which is included with the z/OS® Deploy agent package.
Example commands:

- Creating a root version

```
buztool.sh createlinkedversion -v feature-1.0 -c
 MYCOMP -s /u/build/shiplist.xml -prop /u/version.prop -to.hash 2b1820db6bd59dd5301038cb05b8411b81732b17
```

- Creating a child version

```
buztool.sh createlinkedversion -v feature-2.0 -c
 MYCOMP -s /u/build/shiplist.xml -prop /
u/version.prop -from.hash 6f755de14c77c9f688fb51f3801ac1cf4744dd6e
 -to.hash 2b1820db6bd59dd5301038cb05b8411b81732b17
```

Additionally, the buztool.sh arguments required for creating a linked version are as follows:

Buztool argument	Description
createlinkedversion	The argument to create a linked version
-from.hash	Specifies the commit from which a build tool like IBM Dependency Based Build calculates the changed files and performs a build. The system assumes that a previous version already exists for this commit, and Deploy uses that version as the parent for the new version that you create.
-to.hash	Specifies the commit hash in the repository where the build runs, typically the HEAD of the branch. This commit will be mapped to the version that you are creating.
-parent.version	Specifies the parent version name for the version that you are creating. This field is required only when multiple versions exist for the commit ID specified in the `-from.hash` argument.
-v, **-version**	The name of the version to create. If a version is not specified, a version name is generated from the current time stamp. The version name can contain only letters, numbers, and spaces.
-s, **-shiplist**	The location of the ship list file.
-c, **-component**	The component name in Deploy. The component name can contain only letters, numbers, and spaces.

Results

You have created a linked version.

Important:

- You can map a Git repository to one component only. Deploy enforces this rule by preventing you from creating a version in a component when a version for the same commit already exists in another component.
- For linked versions, the `shiplist` that you use to create the version must include a non-empty `deployType` attribute. This attribute classifies the artifacts and enables to process different artifact types separately

during deployment. For example, JCL artifacts might use a `deployType` value of `BATCH`, while `DBRM`artifacts might use `BINDS`.

- The `deployType` value must not contain spaces or special characters. Significantly, the `deployType` determines the directory name where all packaged artifacts for the version are stored. For more information on how this directory structure affects deployment behavior, see z/OS Utility.
- Before you begin using linked versions, you must select a consistent and meaningful naming convention for `deployType` to ensure proper grouping of artifacts.

Notes:

- The resource-level `deployType` takes precedence over the container-level `deployType` in plug-in steps such as **Generate Artifact Information** and **Multiple Generate Artifact Information**.
- You can delete only those versions that do not have child versions from the **Versions** tab of the component.

Example

A sample **shiplist** is as follows:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.JCL" type="PDS" deployType="JCL">
        <resource name="BLZCPBTK" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD1" type="PDS" deployType="CICSLOAD">
        <resource name="*" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD2" type="PDS">
        <resource name="ORDRSET" type="PDSMember" deployType="CICSLOAD"/>
        <resource name="RDBKC01" type="PDSMember" deployType="CICSLOAD"/>
    </container>
</manifest>
```

Creating z/OS component versions on page 2279

Creating z/OS component versions from z/OS UNIX System Services on page 2282

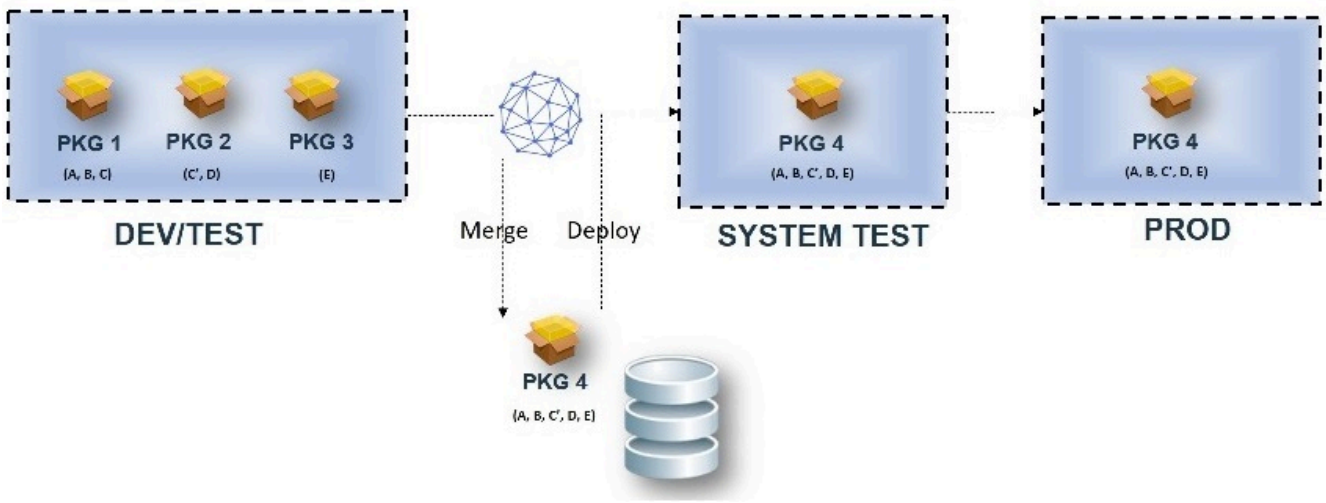
Merging z/OS component versions

Two or more z/OS component versions can be merged from a snapshot into one component version to simplify the deployment to the next environment. Merging component versions in this way avoids deploying intermediate programs into production.

Before you begin

Note the following items when you merge z/OS components.

- Only incremental versions of z/OS components can be merged.
- Only versions stored in the CodeStation can be merged. The merged version is also stored in the CodeStation.
- Merging of versions is not supported when any of the z/OS versions have HFS artifact (shiplist type as directory and file).
- Only data sets are merged into the new version.
- When two or more versions contain the same artifact, the artifact from the latest version in the snapshot is used.
- All customer properties on containers are added to the container in the merged version. This might lead to deployment failures if the deployment process relies on properties on containers.
- The merged version has version properties from the last version in the snapshot.



1. Create a snapshot from an new or existing environment.
2. Add or delete versions in the snapshot's Component Versions view. The **Component** column lists the merged artifacts from all the selected versions. The **Versions** column displays all the versions that contain the artifacts.
3. From the **Actions** menu, click **Merge** for the selected components and supply a name for the merged version. Click **Save**. A new version is created from the merged content of the selected versions.

4. In the **Artifacts** view, click **Show SYS properties**. The source version name and ID are displayed.

Create merged version for component DeltaDeploy
Version Name *
Save
Cancel

Results

The following outcomes apply to merged versions.

- Deployment, backup, and restore actions of merged versions proceed like any other version. No change is required in the deployment process.
- Deleting or archiving the original version has no impact on the merged version.
- A merged version can be merged with other versions again.
- Properties that you set on a Partitioned Data Set (PDS) are added from all versions to the PDS in the merged version for the same properties. The later value for the property overwrites the former value.

Note: Overwriting PDS properties might lead to deployment failures if your deployment process relies on the properties that you set in the PDS.

Importing components

Importing and exporting can be especially useful if you have multiple HCL DevOps Deploy (Deploy) servers, for example, and must quickly move or update components.

About this task

When you import components, you can create components or upgrade existing components. Additionally, if the imported components were created from a template, you can use the template or create one.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

Note: If the imported components have the **Import Versions Automatically** parameter set to `true`, the new components automatically import component versions if the artifacts are accessible to the importing server.

To import one or more components:

1. Open the **Import Component** window by clicking **Components > Import Components**.
2. Click **Choose File**, and then select the JSON file that contains the component definition.

   Note: You must create the JSON file that contains the component definition on a server that uses the same version of Deploy as the destination server.

3. To upgrade existing components, select the **Upgrade Component** check box. To create components, leave the check box cleared.
   If the component name in the JSON file (not the name of the file itself) matches an existing component name, then the component parameters are updated. If items such as processes or properties exist, new versions are created. New items, such as processes or properties, are also added. If the name of the component is not found, the import action has no effect.

Note: The component name is the first parameter in the defined file. This example shows the first parameter:

```
"name": "helloWorld",
```

4. If the imported components were created from a template, use the **Component Template Upgrade Type** list to specify how to use the template.
   For these options, the template must be on the importing server. If the imported components were not created from a template, these options are ignored.
   - To use the imported components' template, select **Use Existing Template**. The new components are an exact copy of the imported components. They contain a pointer to the imported components' template. This option is especially useful if you are importing many components that are based on the same template.

     If you are upgrading, the components also point to the imported template.
   - To create a template, select **Create Template**. The new components are an exact copy of the imported components. They contain a pointer to the newly created template, which is based on the imported components' template.

     If you are upgrading components, a template is also created.
   - To ensure that the server uses the newly imported template, select **Fail if Template Exists**. In this case, if the server already contains the template, the import action fails.
   - To create a fresh installation and ensure that a template is not on the importing server, select **Fail if Template Exists**. If you are creating components, the server creates both new components and a template unless the template exists, in which case the components are not imported.

     If you are upgrading components, the upgrade fails if the imported components' template exists.
   - To ensure that the template is on the importing server, select **Fail if Template Does Not Exist**. If you are creating components, it creates both components and a template unless the template does not exist, in which case the components are not imported.

     If you are upgrading components, the upgrade fails if the imported components' template does not exist on the importing server.
   - To upgrade the template, select **Upgrade if Exists**. This option creates components and upgrades the template on the importing server. If the template does not exist, a template is created.
5. If the processes of the imported components call generic processes, use the **Generic Process Upgrade Type** list to specify how the generic processes are upgraded or created. The import process has different results if the generic processes exist or do not exist.

Note: The server tracks generic processes by name. If a generic process on the server is assigned the same name as a generic process that is imported, then the generic process already exists on the server.

- To import a component without updating the generic processes that are on your server, select **Use Existing Generic Process**. If the generic process does not exist, a generic process is created. If a generic process with that name exists, another version is not created.
- To create new generic processes, select **Create Generic Process**. A copy of the generic process is always created. If a generic process with that name exists, a unique string is added to the new generic process's name. When run, the component process calls the new generic process.
- To create a fresh installation and ensure that generic processes are not on the importing server, select **Fail if Generic Process Exists**. If you are creating components, the server creates both new components and new generic processes unless generic processes exist, in which case the import action fails.

  If you are upgrading components, the upgrade fails if the imported components' generic processes exist.
- To ensure that generic processes are on the importing server, select **Fail if Generic Process Does Not Exist**. If you are creating components, it creates both new components and generic processes unless the generic processes do not exist, in which case the import action fails.
- To upgrade the generic processes, select **Upgrade if Generic Process Exists**. This option creates components and new versions of the generic processes on the importing server. If the generic processes do not exist, processes are created.

6. Click **Submit**.

Exporting components

Importing and exporting can be especially useful if you have multiple HCL DevOps Deploy (Deploy) servers, for example, and must quickly move or update components.

About this task

Exporting components creates a JSON file (file extension `json`) that contains the source configuration information, properties, and processes for the components. For more information about JSON, see http://www.json.org/.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

Note: Exporting components in this way includes only the most recent version of each component process.

To export components:

1. On the **Components** pane (**Components**), select the check box next to one or more components.
2. At the top of the table, click **Actions** and then click **Export**.

What to do next

You can load the file into a text editor or save it. Then, you can import the components to another server that uses the same version of Deploy. See Importing applications on page 2347. See Importing components on page 2296.

Component processes

A component process is a series of user-defined steps that operate on a component's artifacts.

Tip: For full coverage of component processes, see Component processes on page 2421 and its subtopics.

Each component has at least one process and can have several. Component processes are created with the process editor. The process editor is a visual drag-and-drop editor that enables you to drag process steps onto the design space and configure them as you go. Process steps are selected from a menu of standard steps. See Processes on page 2398.

HCL DevOps Deploy (Deploy) provides steps for several utility processes such as inventory management and workflow control. More process steps are provided by plug-ins. Deploy provides plug-ins for many common processes, such as downloading and uploading artifacts, and retrieving environment information.

The following process steps are provided by the server. For information about steps that are provided by plug-ins, see the documentation for the individual plug-in in the HCL plug-in site.

A frequently used process can be saved as a template and applied to other components. See Component templates on page 2308.

Importing specific component processes

Component processes define the steps required to deploy, configure, or update a specific component. You can import specific component processes to reuse a standardized deployment across multiple applications or environments without recreating a process each time.

Before you begin

You must have ensured that the component process source file to be imported is a JSON or YAML file.

About this task

By importing processes in HCL DevOps Deploy (Deploy), you can incorporate specific deployment logic for components, making them reusable across different applications and environments.

Note: When you export components, applications, processes, or templates, and then import them on a different computer, you must ensure that you install the same versions of the same plug-ins on both computers.

1. Log in to Deploy.
2. Click **Components**.
   Components page is displayed.
3. Select the component to which you want to import specific component processes.
4. Click **Processes > Import component process**.

The **Import Component process** dialog is displayed.

5. Select **Process Upgrade Type** from the dropdown list.
6. Click **Choose File** to upload the component process source file that you want to import.

Notes:

- You must create the JSON or YAML file that contains the component definition on a server that uses the same version of Deploy as the destination server.
- Only JSON and YAML file types are supported.

7. Click **Submit**.

Results

You have imported the specific component process. The imported component process is listed in **Processes** tab for the component.

What to do next

You can set environment-specific properties by editing the process in the process editor. See Editing processes on page 2453.

Related information

Components on page 2247

Processes on page 2398

Exporting specific component processes

You can export specific component processes to save and share deployment configurations for reuse across applications or environments.

Before you begin

You must have identified the component processes that are to be exported.

About this task

Exporting component processes creates JSON or YAML file (file extension), that contains processes for the components. For more information about JSON, see http://www.json.org/. You can export one or more specific component processes as YAML or JSON files.

Note: When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

1. Log in to Deploy.
2. Click **Components**.
   The **Components** page is displayed.

3. Click the component from which you want to export the specific process.
4. Click **Processes** tab.
   The list of associated process with the selected component is displayed.
5. Export the processes using any of the following methods:.
   - To export processes in bulk:
     a. Select the processes to be exported.
     b. Click **Bulk Actions**.
     c. Select **Export to JSON** or **Export to YAML**.
   - To export a latest promoted process:
     a. Click the menu option of the process to be exported.
     b. Select **Export to JSON** or **Export to YAML**.
   - To export a draft process:
     a. Open a process in the process designer.
     b. Select a draft version, if required.
     c. Click **Export > Export to JSON** or **Export > Export to YAML**.

Results

You have exported the specific component processes to your local system in the selected file format.

What to do next

After exporting the specified component processes, you can import them into other instances for future use.

Related information

Importing specific component processes on page 2299

Processes on page 2398

Component versions

Each time a component's artifacts are imported into the repository, including the first time, a separate version is stored in CodeStation. Versions can be assigned automatically by HCL DevOps Deploy (Deploy), applied manually, or come from a build server.

Every time a component's artifacts are modified and imported, a new version of the component is created and an entry is made in the Component Version Import log. So a component might have several versions in CodeStation, and each version is unique.

Note: By default, the component version import log is cleaned up every 24 hours. Only the most recent 100 entries are maintained in the log after cleanup.

Artifacts can be imported automatically or manually. By default, a complete copy of an artifact's content is imported into CodeStation. When you copy the artifact to CodeStation, the original artifact content is never modified.

A *version* can be full or incremental. A *full version* contains all component artifacts; an *incremental version* contains only artifacts that are different from the previous version. When performing an incremental import you only need to upload only the changed artifacts. Artifacts that are the same as the base version do not need to be uploaded.

Storing artifacts in CodeStation provides several benefits, such as tamper-proof storage, and the ability to review and validate artifacts with the Deploy user interface. But if you have storage concerns or use a tool like Maven, you can limit CodeStation to using references to the artifacts instead of copying them into CodeStation.

Note: Do not give component versions the name `latest`, `latestVersion`, or `newest`. These names are reserved to represent the most recently created version for certain CLI commands, including requestApplicationProcess on page and createSnapshot on page . You cannot use these keywords to represent component versions in the web interface.

Tracking environment inventory for components

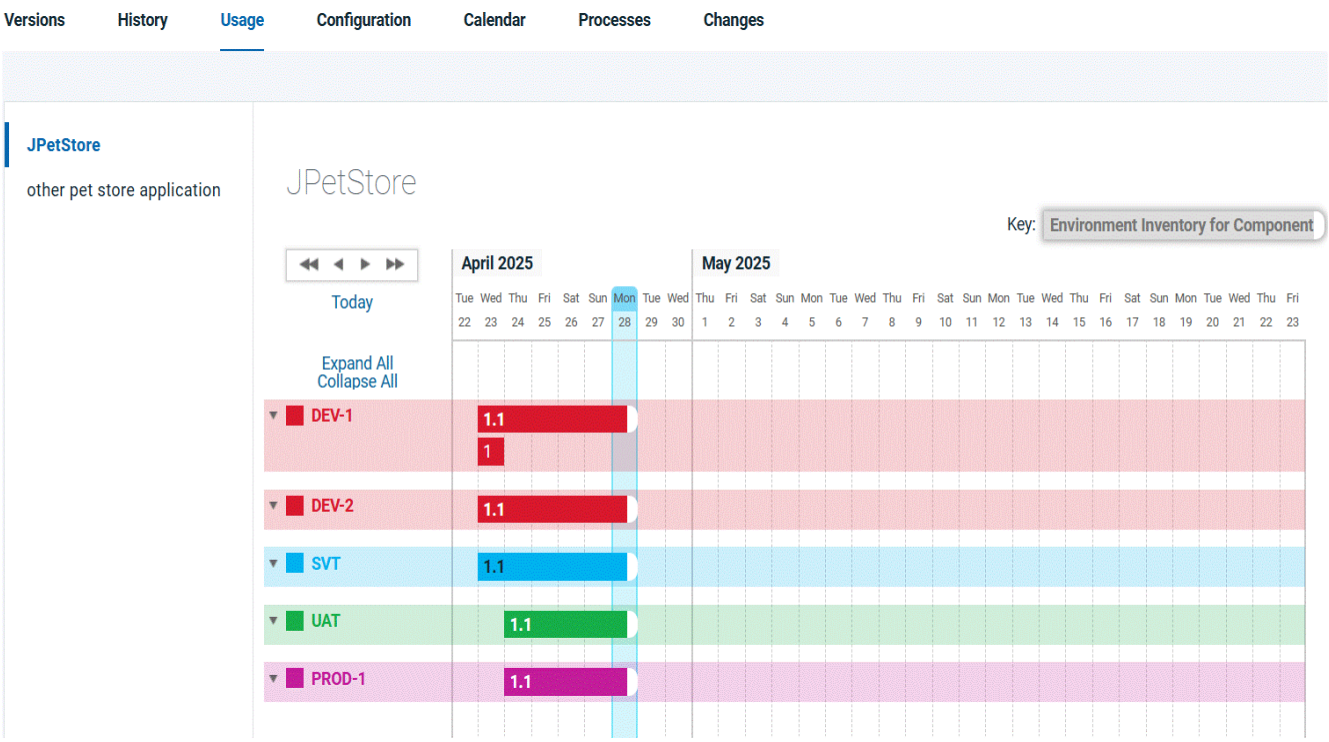
You can track the environment inventory for each component by clicking the component and then going to the **Usage** tab.

About this task

The calendar on this tab shows the deployment request history and state of the selected component. Select an application at the left side of the page, and the calendar shows the deployment history of that component. For each environment, the calendar shows bars that represent the different versions of the component. These bars show when the different versions of the component were installed to that environment or when there was an attempt to install the component to that environment.

Important: The **Usage** tab might not show the version of the component that is deployed. For example, if a deployment fails, the tab includes the component version that was part of the attempted deployment. It does not show the deployed version. Because a component version might not be deployed in an environment, this tab does not show compliancy.

For example, the following figure shows the deployment history for a component, including deployment requests that failed. Two different versions of the component were part of deployment requests to five different environments. The `DEV-1` environment requested the deployment of version 1 of the component on April 23. Then, it requested the deployment of version 1.1 of the component. Because these are incremental versions, the bars overlap when both versions are deployed at the same time.



Importing versions manually

If the component does not import new versions automatically, you can import versions manually.

About this task

To set up a component to import versions manually, see Creating components on page 2248.

Note: Do not give component versions the name `latest`, `latestVersion`, or `newest`. These names are reserved to represent the most recently created version for certain CLI commands, including requestApplicationProcess on page and createSnapshot on page. You cannot use these keywords to represent component versions in the web interface.

1. Display the **Version** pane for the component you want to use (**Components > *selected component* > Versions**).
2. Click **Import New Versions**.
   Depending on the source configuration type, you might see a window that prompts you for more information, such as the name of the version to import.

Results

The new version or versions appear in the table of versions.

Note: If the version import fails, check the logs in version import history.

What to do next

The imported component version can now be compared with an existing version (if any), copied, or deleted. You can also edit the component versions.

Deleting versions

If specific component versions meet the criteria for deletion, you can delete them.

Before you begin

If you want to archive deleted versions, click **Settings > System Settings** and in the **Archive Path** field, specify a folder location for archived versions. Then, click **Save**.

About this task

To delete a version, use the **Delete** action for the version: click **Components > *selected component* > Versions > *selected version* > Delete**. Deleting a version removes the artifacts from CodeStation and the component version from the list of versions.

Note: You cannot delete a component version that was deployed by an application or is used in an application, application snapshot, or resource. If configured, a archive zip will be created and the version will be marked as deleted.

To archive old component versions so that you can restore them later, see Cleaning up component versions on page 2136.

Results

If you specified a folder for archived versions, the deleted version artifacts are in that folder.

Downloading component version artifacts

Artifacts are generated when an application process of a component version runs successfully.

About this task

You can download all artifacts for a component version, or download a delta manifest for linked versions.

1. Display the component version artifacts you want to download (**Components > *selected component* > Versions > *selected version***).
2. Click **Download** and then choose one of the following options to download the artifacts:
   Choose from:
   - Click **Download All** to package all artifacts in one file.
   - For z/OS linked versions,
     - Click **Download Cumulative Manifest** to download an XML that contains the manifest of all artifacts in the application as they existed when the version was created.
     - Click **Download Delta Manifest**, and then select **From Version** from the drop-down to download the delta manifest that shows the differences in artifacts between the current version and the selected version.

Results

A copy of the artifacts is downloaded to your local system.

Adding links to component version

Component version links help you get information about what a particular version contains from various systems of record such as Anthill Pro, Jira, GitHub, and so on.

About this task

You can add links to a component version.

1. Display the component version you want to add links (**Components > *selected component* > Versions > *selected version***).
2. Click **Add**.
   The **Add Link window** is displayed.
3. Enter link name and the URL.
   Optionally, select **Make Priority** to mark the link as favorite.
4. Save your changes.

Results

The link is added to the component version. In case of multiple links, **View All** option is displayed. Using the **View All** option, you can manage the links in the Version Links page.

What to do next

You can make links as favorite by clicking on the star icon next to a link. Favorite links appear first in the list making it easier for you to navigate to the sites.

Component properties

Components can have several types of properties. The server keeps track of changes to component properties as property versions.

To define component properties, click the **Components** tab, click the component, and then go to the **Configuration** tab. The following table describes the types of properties that are available on components.

Table 728. Component properties

Type	Description
Component properties	Component properties are values that are assigned on individual components. Referenced: `${p:component/propertyName}`.
Component properties that	Components inherit custom properties from component templates. These properties cannot be changed on the component. Referenced: `${p:component/custom/propertyName}`.

Table 728. Component properties (continued)

Type	Description
are inherited from component templates	
Component environment properties	Component environment properties are defined on components. However, the property value is not set until the component is deployed to an environment. In this way, a component environment property can have a different value for each deployed instance of the component. However, a value that is set on a component environment property does not override an environment property that has the same name. The environment property has precedence over the component environment property. Referenced: `${p:environment/propertyName}`.
Component version properties	Component version properties are defined on components. However, the property value is not set until a component version is created. In this way, a component version property can have a different value for each component version. Referenced: `${p:version/propertyName}`.
Component resource properties	Component resource properties are defined on components. However, the property value is not set until you map a component to an environment and create a component resource. The property value is set on this component resource. In this way, if you need to deploy multiple copies of a component to the same environment, you can set a different property value for each copy. Note that the component resource property and the resource property definitions are not resolved during deployment when the component is mapped in the Resource Tree using a Component Tag Resource. Component resource properties also generate resource roles on the component resources. Referenced: `${p:resource/propertyName}`.
Component property definitions	Aside from component template properties that become component properties, component templates can also have component property definitions. These properties appear on the component **Basic Settings** tab. Referenced: `${p:component/template/propertyName}`. See Component template properties on page 2310 for more information.

Creating component manual tasks

A component manual task interrupts a component process until manual intervention is done. To create a component manual task, add a manual step to a component process, and select a notification template.

About this task

A process that is interrupted by a manual task remains suspended until the targeted user or users respond. During new process testing, use manual tasks to test the results of steps. After testing, use manual tasks for tasks that are too complicated to automate. Remove manual tasks after testing or when processes are automated.

Similar to approvals, triggered tasks notify targeted users. Affected users can accept or reject the task by using the **Work Items** pane (see Responding to approval requests on page 2394). Unlike approvals, component manual tasks are incorporated within a component process. Do not use a component manual task in place of an approval process. To obtain approval for an entire component, create an approval process instead of a component manual task (see Creating an approval process on page 2388).

1. Open a component process in the process editor.
2. From the **Utility Steps** folder, add a **Manual Task** step to the process.
3. In the **Edit Properties** window, specify the following properties for the step:

Table 729. Component manual task properties

Field	Description
Name	The name for the manual task.
Notification Template	Specify a notification template. The individual tasks map to the notification scheme used by the application (see Creating Notifications in a Notification Scheme on page 2081). If you do not want notifications created for the task, select **None**.
Approver requirements	**Any user** Any user can approve the task. **Only the deploying user** Restricts approval to the user who started the deployment. **Role members by environment** Specify an environment role that can approve the task. **Role members by application** Specify an application role that can approve the task. **Role members by component** Specify a component role that can approve the task.
Add Property	Add one or more properties to the task. You can use these properties later in the process just like output properties from other steps.

4. Click **Save** to save the properties for the step.
5. Add another step such as Shell and add the output properties of manual task to the step to print the approver and approval time information in the output log.

See Manual task output properties on page 2518.

6. Save the process.

Results

When you run the process, it pauses at this step, sends a notification, and waits for approval before the process continues. To approve the task and resume the process, click the **Respond** link for the step in the process log, click **Approve**, and then click **Submit**. You can also resume the process from the **Work Items** tab.

Component templates

With a *component template*, you can save and reuse component processes and properties and create components from them; template-based components inherit the template's properties and process.

Creating component templates

To create a component template, specify information about the template, such as which plug-in it is related to.

To create a template:

1. Display the **Create Component Template** dialog box (**Components > Templates > Create Template**).
2. Enter the template's name in the **Name** field.
3. Enter a description in the **Description** field.
   The description can be used to convey more information about the template.
4. In the **Teams** fields, specify the access information for the template.
5. In the **Component Type** list, select **z/OS** for System z® components and **Standard** for all other components.
6. In the **Source Configuration Type** list, select the source type of the component.
   Selecting a value other than the default `None`, displays more fields that are associated with your selection. Source-dependent fields are used to identify and configure the artifacts. If you select a source, components that are based on the template use the same source. You can also import versions automatically and import configurations. Under the **Import Configuration** field you can create a component template with any of the three options as well as not supplying an option.

   For information about creating components of specific types, see Creating components from the file system on page 2253, Creating components from build integration tools on page 2268, or Creating components from source-code management systems on page 2258.

   Note: If you select a source, any properties you configure are set for any components that are created with the template.

7. Click **Save** to save the template.
   Result
   Saved templates are listed in the **Component Templates** pane.
8. Add components, processes, and properties to the template.

Importing component templates

When you import a template, you can create an entirely new template or upgrade an existing one.

About this task

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

1. Display the **Import Template** dialog (**Components > Templates > Import Template**).
2. Click **Choose File**, and then select the JSON file that contains the template.

   Note: You must create the JSON file that contains the template on a server that uses the same version of HCL DevOps Deploy (Deploy) as the destination server.

3. If you want to upgrade an existing template, check the **Upgrade Template** check box. To create a template, leave the box cleared.
   If the template's name in the JSON file (not the name of the file itself) matches an existing template, the template is upgraded. If the name is not found, the command has no effect.

   Note: The template's name is the first parameter in the defined file. For example,

   ```
   "name": "helloWorldTemplate",
   ```

4. In the **Generic Process Update Type** list, specify how to handle generic processes that are being imported along with the component template and that have the same names as existing generic processes.

   Note: This field affects only generic processes, not component template processes.

   Use Existing Process

   Select this option to ignore generic processes in the imported component template when those processes have the same name as existing generic processes.

   Create Process

   Select this option to rename any generic processes that have the same name as existing processes.

   Fail If Process Exists

   Select this option to cancel the import if the imported component template references any generic processes that have the same name as existing generic processes.

   Fail If Process Does Not Exist

   Select this option to cancel the import if the imported component template references any generic processes that do not have the same name as existing generic processes.

Upgrade If Exists

Select this option to update generic processes to match the imported generic processes.

5. Click **Submit**.

Exporting component templates

Exporting a template creates a JSON file (file extension `json`) that contains the template's configuration information, properties, and processes.

About this task

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

To export a template, on the **Component Templates** pane (**Components > Templates**), click the **Export** link in the **Actions** field. You can load the file into a text editor, or save it. If you save it, a file is created with the same name as the selected component, for example, `helloWorldTemplate.json`.

Component template properties

Component template properties ensure that every component created from a template has the same properties. The types of available properties are described in the following table.

Type	Description
Properties	Custom property. Every component inherits the value that is defined in the template (it cannot be overridden by a component). If you change the value, the change is reflected in components that are created from the template, including components that were previously created.
Component Property Definitions	Every component has this property. It appears on the Create Component dialog box for every component that is created from this template (see Creating components on page 2248). A value that is defined here can be changed by created components.
Environment Property Definitions	Every environment that uses a component that is created by this template has this property. The property appears on the environment's **Component Mappings** pane (**Applications > *selected application* > Environments > *selected environment* > Component Mappings**), see Application environments on page 2354. A value that is defined here can be changed by environment.
Resource Property Definitions	This property appears on resources that the component is deployed to.

Related reference

Component properties on page 2305

Using component templates

When you create a component from a template, the component inherits the template's process and properties, if any.

1. Display the **Create Component** window (**Components > Templates > *selected template* > Create Component**).
   The **Create Component** dialog box (the same dialog box that is used to create non-template-based components) is used to configure components. Properties that are defined in the template are predefined. If a source was selected in the template, the source is set here and the **Source Configuration Type** field is locked. For information about using this dialog, see Creating components on page 2248
2. After you configure editable properties, save the component.

Results

Templates that are used to create components are listed in the **Templates** view.

Components that are created from templates are listed in the **Components** view.

Note: To delete a component template you will need to also delete the components that are using it. The template will be marked as deleted, after deletion, as well as all of it's processes.

Component change logs

Change logs provide information about modifications to components.

To see change details, display the log for a selected component-related activity (**Components > *selected component* > Changes**). Information for any change that triggered a Commit ID is displayed.

Deleting components

When a component is deleted, it cannot be activated later.

To delete a component, use the actions on the **Components** pane for the intended component.

When a component is deleted, it, along with all files for versions of that component, is removed. The component cannot be activated later. The original artifacts are not affected; only CodeStation copies are deleted. Components cannot be deleted if they are used by an application. To delete a component that is used by an application, first remove the component from the application. All deployment triggers from application that references the component will be removed. All inventory for the component will also be removed. All processes of component will be marked as deleted.

Note: Component will not be removed from the database; processes that reference deleted component can still be viewed.

To delete a specific component version, see Deleting versions on page 2304.

Resources

A *resource* is a logical deployment target that typically resolves to an agent and a user-defined construct that is based on the architectural model of HCL DevOps Deploy (Deploy).

Resources aid bookkeeping; inventory is tracked for resources. Resources are created and managed through the user interface.

A resource can represent an agent, agent pool, component, or an organizational entity that is used to group other resources. A component-type resource can point directly to the agent or agent pool that deploys it, or point to another resource in a hierarchical chain of resources. If a resource is part of a hierarchy, it delegates its automation, if any, up the chain until it finds an agent.

A resource represents a deployment target, such as a physical server, virtual machine, database, or Java™ Platform, Enterprise Edition container. Components are deployed to resources by agents (which are physical processes). Resources generally are hosted on the same host where its managing agent runs. A host can have more than one resource. If an agent is configured to handle multiple resources, a separate agent process runs for each one.

A resource can represent a physical server, which is the simplest configuration, or a specific target on a system, such as a database or server. So a host can have several resources represented on it. In addition, a resource can represent a process that is distributed over several physical or virtual machines. Finally, environments consist of resources.

To run a deployment, at least one resource must be defined and (usually) at least one agent. ("Usually" because trivial deployments can be done without an agent.) Typically, each host in a participating environment has an agent running on it to handle the resources that are located there.

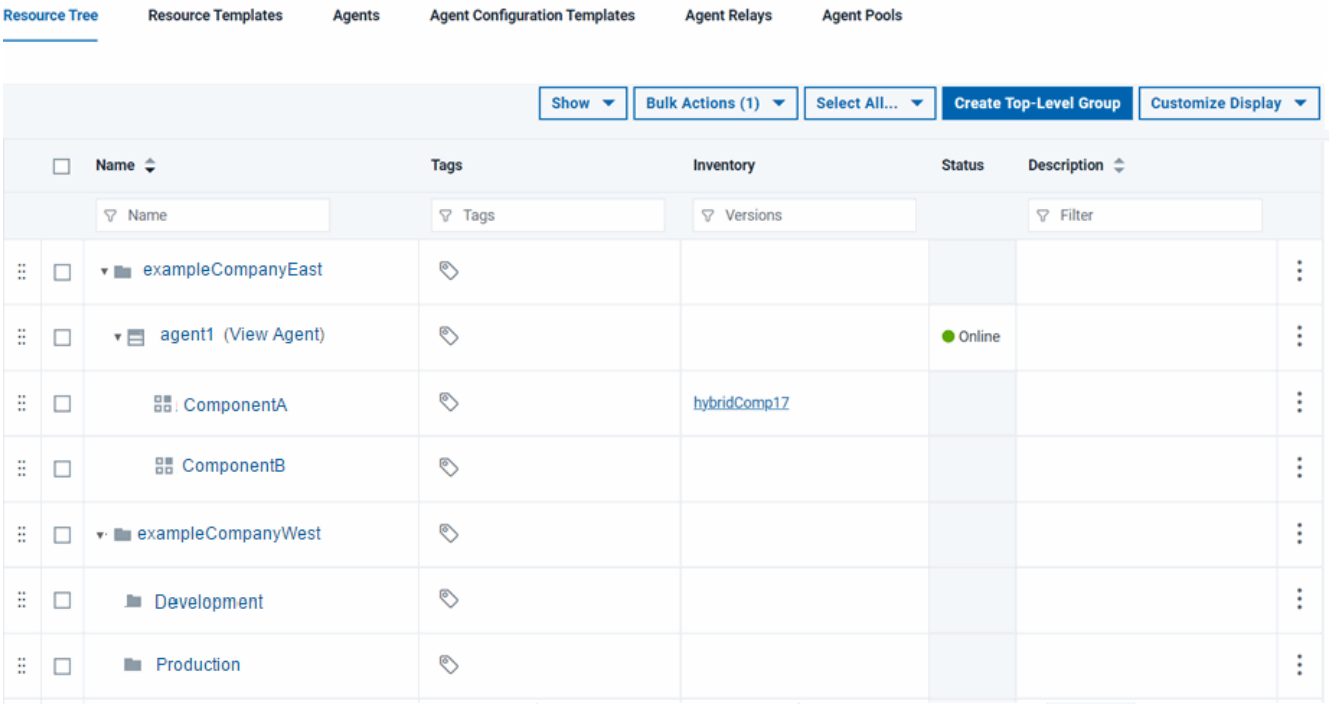
A *proxy resource* is a resource that is effected by an agent on a host other than the one where the resource is located. If an agent does not require direct interaction with the file system or with process management on the host, a proxy resource can be used. When a deployment must interact with a service that is exposed on the network (a database or Java™ Platform, Enterprise Edition server, for instance), the interaction can happen from any server that has access to the networked service.

A group-type resource can represent any logical collection of resources. In the following illustration, the top-level resource, `exampleCompanyEast`, represents a data center that contains the `Development` subresource (which represents an environment). In this instance, the `exampleCompanyEast` resource does not point to any higher level resource. The resource `ComponentA` represents a component, and delegates its automation up the chain until it reaches the `agent1` resource, which represents an agent. In order for an agent to be invoked, at least one resource must be defined for it.

Resources are created on the **Resources** page, which displays resources in a hierarchical tree structure. By displaying all resources across all environments, the **Resources** page provides a single place to see your entire infrastructure. Note: Resource names are limited to 255 characters.

The hierarchical structure is used wherever resources are used and not just on the **Resources** page, such as when assigning resources to environments. The hierarchical model is especially effective when several logical deployment targets reside on the same machine. In the accompanying illustration, the resources `ComponentA` and `ComponentB` could represent application servers on the same machine where the agent `agent1` is located. Both can be individually targeted for deployment.

Selecting a resource selects every resource below it, if any, in the hierarchy; for example, deleting or moving the `agent1` resource deletes or moves the `ComponentA` and `ComponentB` resources as well.



Whether you need one or multiple resources per environment is determined by your current infrastructure, deployment procedures, and other requirements. Many Deploy users have significant differences among environments. Whatever your structure, the **Resources** page displays the entire infrastructure across all environments.

If you are using IBM® WebSphere® Application Server, you can import information from cells as resources; see Importing resources from WebSphere Application Server on page 2325.

The resource tree

All of the resources on the Deploy server are organized into the *resource tree*. Top-level resource groups contain resources and other resource groups, and so on. Therefore, to refer to a resource, you must specify its path on the resource tree. For example, if an agent resource that is named `Agent1` is contained in the group `/Agents`, you can refer to the agent resource by the path `/Agents/Agent1`.

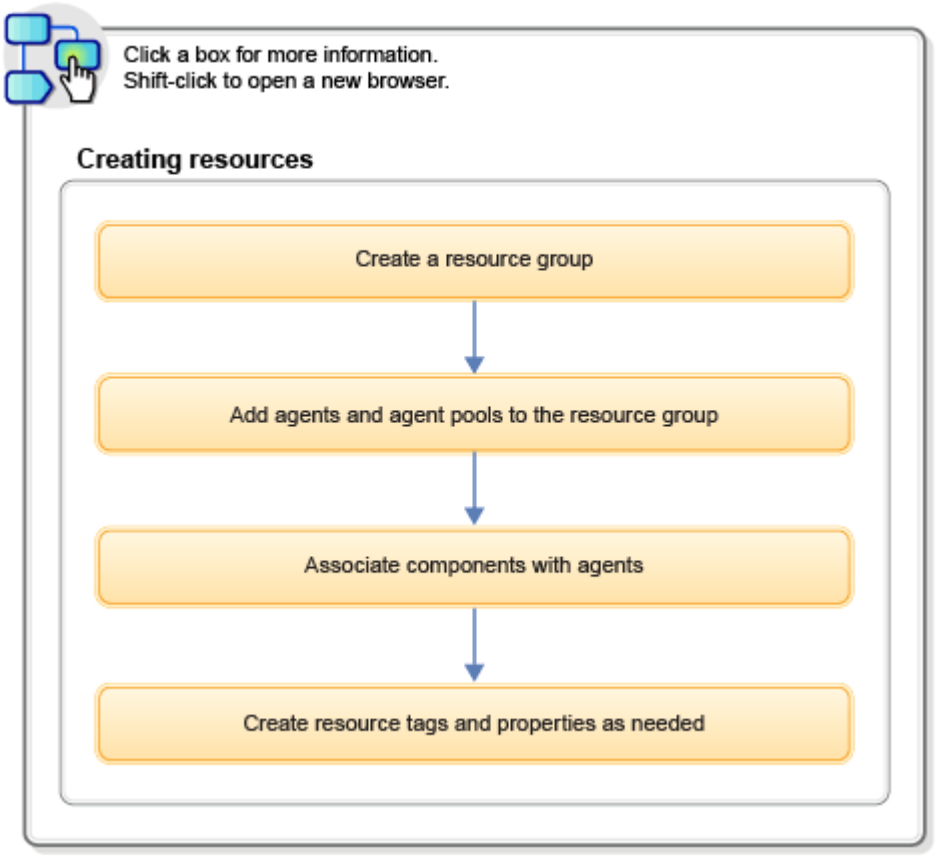
Resource groups

A *resource group* is a logical collection of resources. Resource groups enable collections of resources to be easily reused. Resource groups can manage multi-tenant scenarios, for example, in which several servers share resources.

Getting started with creating resources

Resources associate agents with components and, after they are mapped to an application environment, provide deployment targets.

The following diagram outlines the typical steps for creating and running a deployment:



1. Click this area for information about creating resource groups. on page 2315
2. Click this area for information about adding agents to resource groups. on page 2318
3. Click this area for information about creating component resources. on page 2317
4. Click this area for information about adding properties to resources. on page 2504

A resource group associates agents or agent pools with components. A resource group can itself belong to a parent group in a hierarchical collection. A component-type resource can point directly to the agent or agent pool that deploys it or point to another resource in a hierarchical chain of resources. If a resource is part of a hierarchy, it delegates its automation, if any, up the chain until it finds an agent.

Resources, just like the items they represent, can have properties tags.

Related topics:

- How to add tags to resources; see Adding tags to objects on page 2521.
- How to provide user credentials to resources; see Defining default user impersonation credentials on page 2332.

Modifying the resource tree

You can create, delete, and modify the contents of the resource tree.

Creating groups

Resource groups organize resources into logical groupings.

About this task

Resources are created on the **Resource Tree** page. The **Resource Tree** page displays resources in a hierarchical tree structure. Each row represents a resource and has a context-sensitive **Action** menu that is associated with it. The available actions depend on whether the resource represents an agent, agent pool, component, or organizational group.

In addition to the **Resource Tree** page, resources might be displayed in several ways, such as by adding resources to an environment.

1. Open the **Resource Tree** page.
2. Perform one of the following steps:

    a. To create a top-level group, click **Create Top-Level Group**.
    The top-level groups are ordered alphabetically.

    b. To create a resource group beneath an existing resource, display the **Action** menu for the resource, and then use the **Add Group** command.

    Result

    The **Create Resource** dialog box is displayed.
3. Enter a name and an optional description.
4. **Optional:** To specify criteria that are used to automatically populate the resource, select the **Include Agents Automatically** check box.

    Note: To automatically include agents, you must be a member of either the agent's team or the system team, such as the admin user. You must specify the team that will access the group, and that group must have access to the agent that you describe. You cannot assign the system team to the group. Existing agents matching the criteria are automatically included upon saving. The default interval for including new agents matching the criteria is every 5 minutes.

    Select **Name** or **Property**, and then select a filter criterion from the list. The available criteria are listed:
    - **Equals**
    - **Doesn't Equal**
    - **Contains**
    - **Doesn't Contain**
    - **Matches Regex** (match a regular expression)

    You can set more than one condition.
    If any agent-type resource in the filtered group satisfies the condition, it is preserved, otherwise it is removed. If agents that satisfy the condition exist, but they are not in the group, agent-type resources are created and added to the group.
5. **Optional:** If you added the group beneath an existing resource, perform one of the following steps:

a. If you want the team that manages the resource's parent to manage this resource, select the **Inherit Teams From Parent** check box.
The **Inherit Teams From Parent** check box is selected by default.

b. If you do not want the parent team to manage this resource, clear the **Inherit Teams From Parent** check box.
You can add a team by using the **Teams** action, then selecting a team.

6. **Optional:** If you added the resource below an agent, agent pool, or a component, the option to define default user impersonation credentials is available. See Defining default user impersonation credentials on page 2332 for information about setting impersonation credentials.
7. Save your work.

What to do next

For information about using resources in applications, see Mapping resources and components to environments on page 2363.

Creating agent-type and agent pool-type resources

Agent-type and agent pool-type resources represent the computers where components are deployed.

About this task

Resources are created on the **Resources** page. The **Resources** page displays resources in a hierarchical tree structure. Each row on the **Resources** page represents a resource and has a context-sensitive **Action** menu that is associated with it. The available actions depend on whether the resource represents an agent, agent pool, component, or an organizational group.

1. Open the **Resource Tree** page.
2. To create a resource, open the **Action** menu for the resource where you want to create the resource and click **Add Agent** or **Add Agent Pool**.
New resources are inserted below the selected resource. Agents and agent pools can be added below group-type resources.
3. From the Agent list, select the agent or agent pool that you want to associate with the resource.
4. In the **Name** field, enter a name for the resource.
By default, the resource name is the same as the agent or agent pool name.
5. Perform one of the following steps:

a. If you want the team that manages the resource's parent to manage this resource, select the **Inherit Teams From Parent** check box.
The **Inherit Teams From Parent** check box is selected by default.

b. If you do not want the parent team to manage this resource, clear the **Inherit Teams From Parent** check box.
You can add a team by using the **Teams** action, then selecting a team.

6. **Optional:** Define default user impersonation credentials.

For information about setting impersonation credentials, see Defining default user impersonation credentials on page 2332.

7. Save your work.

What to do next

For information about using resources in applications, see Mapping resources and components to environments on page 2363

Creating component-type resources

Component-type resources represent the components that are deployed to target environments.

About this task

Component-type resources are created on the **Resource Tree** page. The **Resource Tree** page displays resources in a hierarchical tree structure. Each row on the **Resource Tree** page represents a resource and has a context-sensitive **Action** menu that is associated with it. The available actions depend on whether the resource represents an agent, agent pool, component, or an organizational group.

1. Open the **Resource Tree** page.
2. To create a resource, open the **Action** menu for the resource where you want to create the resource and click **Add Component**.
   New resources are inserted below the selected resource. Components can be added below agents, agent pools, and other components.
3. From the **Component** list, select the component to associate with the resource.
4. In the **Name** field, enter a name for the resource.
   By default, the resource name is the same as the component name.
5. Perform one of the following steps:

   a. If you want the team that manages the resource's parent to manage this resource, select the **Inherit Teams From Parent** check box.
      The **Inherit Teams From Parent** check box is selected by default.

   b. If you do not want the parent team to manage this resource, clear the **Inherit Teams From Parent** check box.
      You can add a team by using the **Teams** action, then selecting a team.

6. **Optional:** If you added the component resource below an agent, agent pool, or another component, the option to define default user impersonation credentials is available. See Defining default user impersonation credentials on page 2332 for information about setting impersonation credentials.
7. If the component associated with the resource has any resource properties defined for it, they are displayed in the **Role Properties** area where you can set their value. If you change the default value, the **Reset to Default** action is displayed in the **Actions** field.
8. Save your work.

What to do next

For information about using resources in applications, see Mapping resources and components to environments on page 2363.

Adding agents to resource groups

You can find agents that are not associated with a resource and add them to a resource group.

1. Open the **Resource Tree** page.
2. Click **Show > Agents With No Resource**.
   Result
   The **Agents With No Resource** panel opens.
3. From the list of agents, select an agent by clicking the : : field in the first column of the list.
   The list is empty if all agents are associated with resources.
4. Drag the agent to the resource group to add the agent to that group.
5. Click **Hide Panel** to close the list of agents.

Moving and copying resources

Resource tree structures in the **Resources Tree** page can be configured by moving and copying the resources using the drag and drop feature.

About this task

Each row on the **Resource Tree** page represents a resource. Resources that are grouped under other resources are referred to as *subresources*. You can edit your organizational group nesting by moving and copying existing resources. Components and agents within a resource tree are also moved and copied along with the resource.

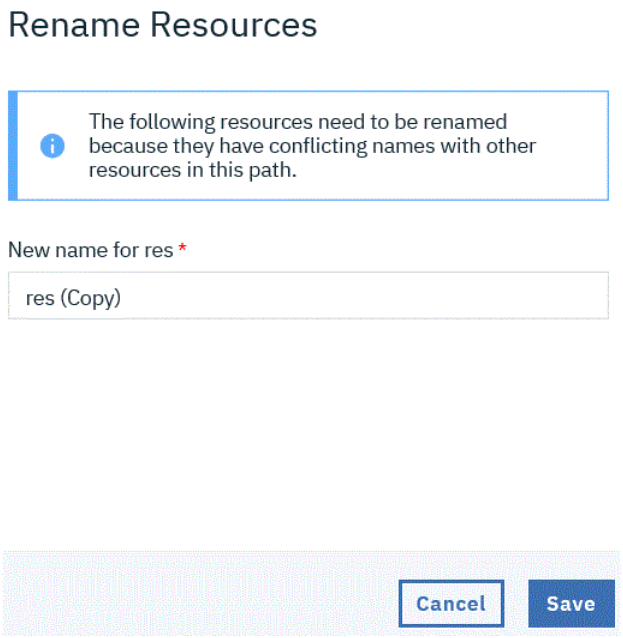
Procedure

1. Open the **Resource Tree** page.
2. Click and hold the mouse in the first column of the resource that you want to reposition.
   This column has small dots that are arranged in a box.
3. Move a resource by dragging the resource to a new location.
   Result
   While you are dragging the resource, a window appears to show the resource, as shown in the following figure:

   The left arrow sign (←) indicates that the row can be moved to the new location. The minus sign (–) indicates that row cannot be moved to the location.
4. Copy the resource by holding the Ctrl key while you drag it.
5. Position the pointer over the row where you want to copy the selected resource.

While holding the Crtl key, the plus sign (+) indicates the resource can be copied to the location, otherwise it shows minus sign.

6. Release the mouse button.
   The resource and any subresources that are associated with it are copied beneath the target row.
   When you copy a resource with a name that matches with an existing resource in the target location, the following window is displayed:



7. Save the resource with a new name.

Results

Results

The resources are moved or copied to the new location. Click the expand icon ▶ to expand the tree.

Deleting resources

When you no longer require the resources, you can remove them from the **Resource Tree** page and choose to delete them permanently.

Before you begin

You must be logged in as an administrator or must have the permissions to **Execute on Resources** and **Manage Children**.

About this task

A deleted resource is removed from the **Resource Tree**, but not from the system. The deleted resources are moved to the **Recycle Bin**. The deleted resources remain in the **Recycle Bin** for 14 days, after which they are deleted permanently from the system.

Notes:

- Resources that are part of resource template and dynamic resources, if deleted, are not moved to **Recycle Bin** and cannot be restored.
- If the deleted resource is mapped to an environment, the resource is deleted from the environment also. In case you still require the deleted resource, restore the resource, and map it to the environment again.
- In addition to the **Resource Tree**, resources might be displayed in several ways, such as by adding resources to an environment.

1. Login to HCL DevOps Deploy (Deploy).
2. Go to **Resources > Resource Tree**.
3. Select the checkbox that is associated with the resource to delete.

   Note: You can also select multiple resources that you want to delete.

4. From the **Actions** list, click **Delete**.
   The deleted resources are moved to the **Recycle Bin**.

   Note: The subresources that are associated with the selected resources will also be deleted.

Results

You have deleted the selected resources.

Related information

Deleting resources from the Recycle Bin on page 2320

Restoring the resources from the Recycle Bin on page 2321

Deleting resources from the Recycle Bin

When you no longer require the resources permanently, you can delete the resources from the **Recycle Bin** by setting up time and duration for the cleanup.

Before you begin

You must be logged in as an administrator or must have the permissions to **Execute on Resources** and **Manage Children**.

About this task

You can set up the time and duration for resources to get permanently deleted from the **Recycle Bin**.

Note: The deployment history cleanup process deletes all records in the database and the file system that are related to the deployments that you are deleting. The cleanup cannot be undone. Carefully choose the items that you delete.

1. Login to HCL DevOps Deploy (Deploy).
2. Go to **Settings > System Settings > Process History Cleanup** pane.
3. Turn on **Enable Deployment History Cleanup**.
4. Set up the time and duration in **Daily Cleanup Start Time** and **Daily Cleanup Duration** fields.

   The resources get permanently deleted according to the time and duration set by you.

Results

You have achieved to permanently delete the resources.

Related information

Cleaning up deployment history files on page 2133

Deleting resources on page 2319

Restoring the resources from the Recycle Bin on page 2321

Restoring the resources from the Recycle Bin

When needed, you can choose to restore the resources to their original locations in the **Resource Tree** after you delete them. When restored, the resources are restored as a child resource of the original parent resource. If the parent is moved, the resource is restored to the parent's new location. However, after resources are deleted from the **Recycle Bin**, they cannot be restored.

Before you begin

You must be logged in as an administrator or must have the permissions to **Execute on Resources** and **Manage Children**.

About this task

The **Recycle Bin** lists retained resources after you delete them. The recycle bin contains information such as the user who deleted the resource, the date, and the original path. You can sort and filter the resources by using this information and restore multiple retained resources at once.

Notes:

- You cannot restore a resource if the parent is also deleted. Therefore, you must restore the parent resource along with the child resource.
- Resources that are part of the resource template and dynamic resources, if deleted, are not moved to the **Recycle Bin**.

1. Login to HCL DevOps Deploy (Deploy).
2. Go to **Resources > Recycle Bin** tab.
3. Select the checkbox that is associated with the resource to restore.

   Note: You can also select multiple resources that you want to restore.

4. From the **Actions** list, click **Restore**.
   The resources are restored and available on **Resource Tree**.

Results

You have restored the resources.

Deleting resources on page 2319

Comparing and synchronizing resources

You can compare the contents of a resource group to another group or a resource template and then apply changes to the group or template.

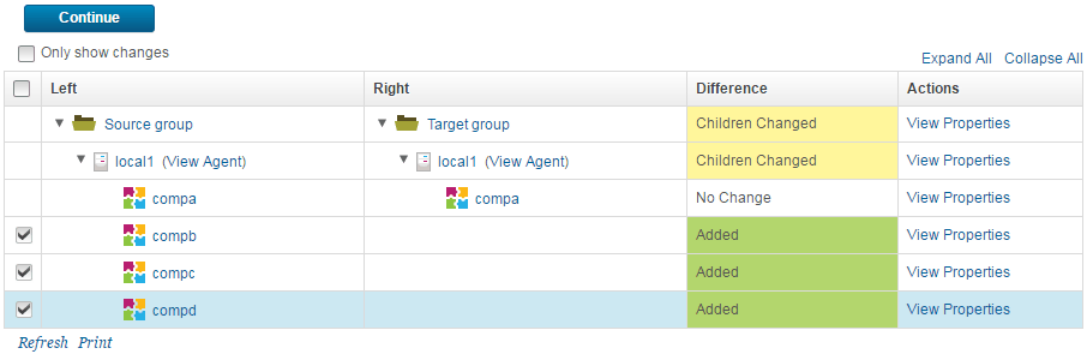
About this task

You can compare a group in the resource tree to another group or a resource template. You can apply changes, including properties and their values, from the first group that you select to the resource tree or second group.

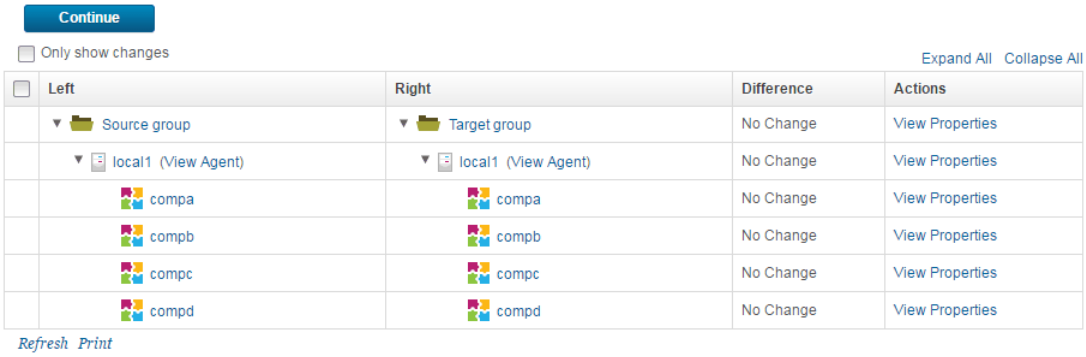
1. Open the **Resource Tree** page.
2. Display the **Action** menu for the folder that contains the source group and click **Compare or Synchronize**.
3. Compare the contents of a resource to either a resource template or another resource.
   Choose from:
   - To compare the contents of the resource to the contents of a resource template, take the following actions:
     a. From the **Compare Resources** window, select **Compare With Resource Template**.
     b. From the **Resource Template** list, select the name of the target resource template.
     c. Click **Save**.
   - To compare the contents of the resource to the contents of another resource, take the following actions:
     a. From the **Compare Resources** window, select **Compare With Resource**.
     b. From the **Compare Resources** list, click **Set**.

c. From the **Select Resource** window, select the target resource. You can expand resources and select a nested resource for the comparison.
d. Click **OK**.
e. Click **Save**.

4. On the **Resource Comparison** page, expand both resource trees.
5. Clear **Only show changes**.
6. Select each different resource from the left-hand, or source, resource to apply to the right-hand, or target, resource.
   The differences between the two resource trees are displayed. Each line of the resource tree can be one of the following states: **Children Changed**, **Added**, **Deleted**, or **No Change**.
   Example
   For example, the following image shows that the source resource tree contains three more agents than the target resource tree. All three additional agents will be added to the right-hand, or target, resource tree.



7. To review your changes, click **Continue**.
   Result
   The changes to the right-hand resource tree are displayed in the **Preview Changes** window.
8. Click **Apply Changes**.
   Result
   An **Alert** window confirms that the resource changes were applied successfully.
9. Click **Close**.
   Result
   The **Resource Comparison** page displays the updated status of the right-hand resource tree, as shown in the following image.



Since the contents of the groups are now identical, the statuses in the **Difference** column are all **No Change**.

Synchronizing resources from a template

You can add the contents of a resource template to the top-level resource group.

About this task

To add a resource hierarchy to a top-level group in the resource tree, synchronize the group to a resource template. You might complete this task to add a standard group of resources to an existing top-level group. The contents of the resource template are added directly to the group.

1. Open the **Resource Tree** page.
2. Display the **Action** menu for an empty group and click **Synchronize With Template**.
3. From the **Resource Template** list, select a resource template.
4. Click **Save**.

   Result

   The resource structure from the resource template is added to the group.

> **Note:** If you subsequently modify the resource template and then repeat the **Synchronize With Template** action, the modified resource structure is added to the group and the original resource structure is preserved. That is, the group will have two resource structures.

Adding resources from a template

You can add the structure from a resource template to a new group within an existing resource group.

About this task

To add a hierarchy of resource to a new group within a group in the resource tree, add resources from a template. You might complete this task to add a new node to an existing resource group.

1. Open the **Resource Tree** page.
2. Display the **Action** menu for the group and click **Add From Template**.
3. Provide a name for the new resource group.
4. From the **Resource Template** list, select a resource template.

5. Click **Save**.
   Result
   The resource structure from the resource template is added to the new group within the existing group.

Importing resources from WebSphere® Application Server

Use the WebSphere® Application Server - Deploy plug-in to import information about an IBM® WebSphere® Application Server system into a collection of resources. Typically, importing information by using the plug-in takes less time than manually creating resources to match the IBM® WebSphere® Application Server.

Before you begin

- Install the WebSphere® Application Server - Deploy plug-in. To download plug-ins, see the HCL™ Plug-ins website. Use the most recent version of the plug-in.
- Create a top-level resource group to contain agents. See Creating groups on page 2315.
- Install an agent on the WebSphere® Application Server system and add the agent as an agent resource under the top-level resource group.

About this task

Plug-ins can be developed and updated more frequently than Deploy provides release cycles. For the latest version of the WebSphere® Application Server - Deploy plug-in and the latest documentation, see the HCL ™ Plug-ins website.

1. On the Deploy server, click **Resources** to view the **Resource Tree** page.
2. If the `wsadmin` file is in a different location than one of the default locations, specify the file location as the value of the **wsadmin.path** property on the agent resource.

   The default location of the `wsadmin` file on Linux™ is `/opt/IBM/WebSphere/AppServer/bin/wsadmin.sh`. The default locations on Microsoft™ Windows™ are `C:\IBM\WebSphere\AppServer\bin\wsadmin.bat` and `C:\Program Files\IBM\WebSphere\AppServer\bin\wsadmin.bat`.
3. Click the **Actions** push button that is associated with the top-level group, and then click **Add Agent**.
4. In the **Create Resource** window, select the agent and then click **Save**.
   Result
   The new agent resource is displayed in the resource tree. Eventually, another resource is displayed under the agent resource. This resource is named `WebSphereCell` and represents the WebSphere® Application Server cell. You might need to click **Refresh** to see the cell resource, and it can take several minutes for the cell resource to be displayed.
5. Click the WebSphere® Application Server cell resource and then click **Configuration > Basic Settings**.
   The cell resource has the `WebSphereCell` role, which includes several properties that are related to the cell.
6. In the section that is labeled **Role Properties** for the `WebSphereCell` role, specify the connection information for the cell, including the locations of the profile and `wsadmin` file and the user name and password for the WebSphere® Application Server system, as in the following figure:

7. Click **Save**.
8. On the **Resources** page, click the **Actions** push button that is associated with the cell resource, and then click **Configure using WebSphere Topology Discovery**.

   Result

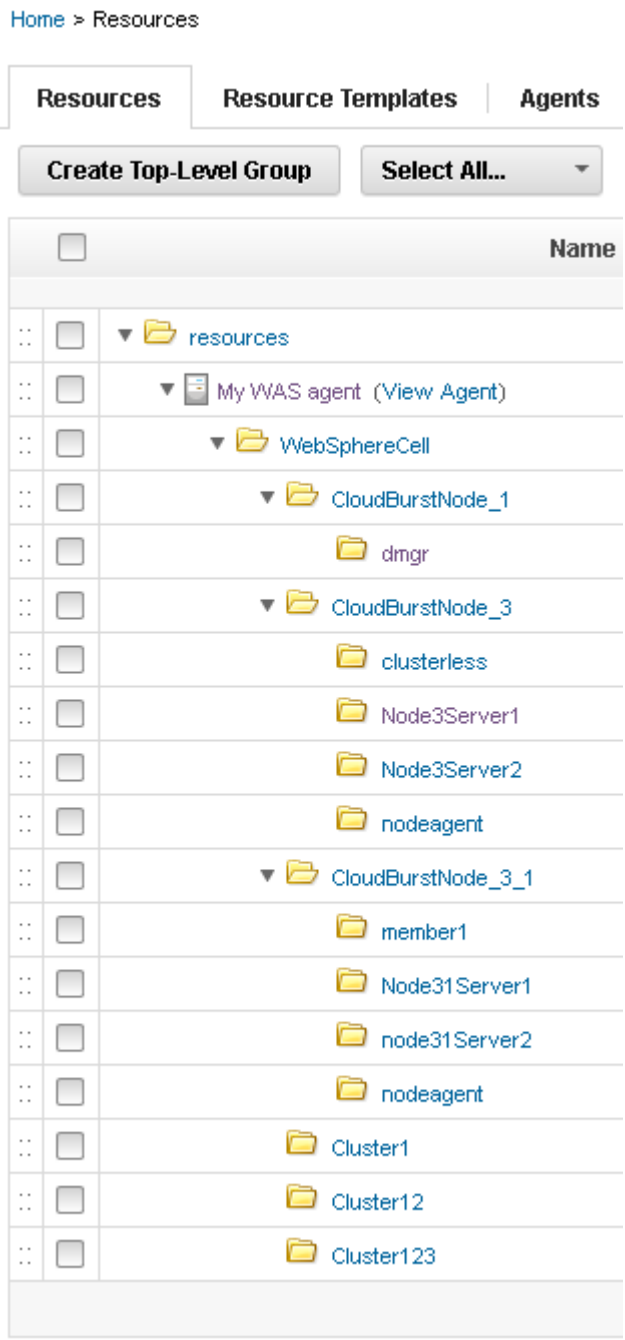
   The discovery step runs. This step might take several minutes. A log is displayed to show progress.
9. When the discovery process completes, close the log window, and then refresh the resource tree.

   Result

   Note: If you have multiple profiles defined for your WebSphere installation, you may discover all the profiles by using the `websphere.profilePath` property. See, https://hcl-software.com/plugins/666-2/

Results

Resources that represent the WebSphere® Application Server components are displayed in the resource tree. These new resources are displayed under the agent resource that you used to import the WebSphere® Application Server components. Each node, cluster, and server has a matching resource. The following figure shows resources that represent a WebSphere® Application Server system with three nodes:



What to do next

Add these resources to an environment by opening the **Resources** page for the environment and then clicking **Add Base Resources**.

Importing resources from WebSphere® Portal

With the WebSphere® Portal plug-in, you can discover resources for a portal cell and use plug-in steps to deploy artifacts.

Before you begin

- Create a top-level resource group to contain agents. See Creating groups on page 2315.
- Install an agent on the system that hosts the portal node.
- If IBM® WebSphere® Application Server is deployed in a directory other than the default directory, specify the **wsadmin.path** property on the agent.
    1. Click **Resources > Agents > *agent name* > Configuration > Agent Properties**.
    2. Add a property named **wsadmin.path**.
    3. Set the **wsadmin.path** property to the fully qualified path to the `wsadmin` script, including the script name.

       The default location of the `wsadmin` file on Linux™ is `/opt/IBM/WebSphere/AppServer/bin/wsadmin.sh`. The default locations on Microsoft™ Windows™ are `C:\IBM\WebSphere\AppServer\bin\wsadmin.bat` and `C:\Program Files\IBM\WebSphere\AppServer\bin\wsadmin.bat`.
- Install the WebSphere® Portal plug-in.
- Install the WebSphere® Application Server - Deploy plug-in.

About this task

Plug-ins can be developed and updated more frequently than HCL DevOps Deploy (Deploy) provides release cycles. For the latest version of the WebSphere® Portal plug-in and the latest documentation, see the HCL Plug-ins site.

1. On the Deploy server, click **Resources** to view the **Resource Tree** page.
2. Click the **Actions** push button that is associated with the top-level group, and then click **Add Agent**.
3. In the **Create Resource** window, select the agent and then click **Save**.

   Result

   The new agent resource is displayed in the resource tree. Eventually, another resource is displayed under the agent resource. This resource is named `WebSphereCell` and represents the WebSphere® Application Server cell. You might need to click **Refresh** to see the cell resource, and it can take several minutes for the cell resource to be displayed.
4. Click the WebSphere® Application Server cell resource and then click **Configuration > Basic Settings**.

   The cell resource has the `WebSphereCell` role, which includes several properties that are related to the cell.
5. In the section that is labeled **Role Properties** for the `WebSphereCell` role, specify the connection information for the cell, including the locations of the profile and `wsadmin` file and the user name and password for the WebSphere® Application Server system, as in the following figure:

The Discovery Address Endpoint Name for this
Using

Note: Leave the **Cell Name** property blank.

6. Click **Save**.
7. On the **Resources** page, click the **Actions** push button that is associated with the cell resource, and then click **Configure using WebSphere Topology Discovery**.
   Result
   The discovery step runs. This step might take several minutes. A log is displayed to show progress.
8. Click **Save** to close the **Auto Configure** window.
9. Wait 30-60 seconds, and then click **Refresh**.
   A twistie is now displayed next to **WebSphereCell**. Expand the twistie and verify that the resource tree matches your WebSphere® Application Server topology. The resource tree contains deployable artifacts for WebSphere® Portal (theme, PAA, WAR, ConfigEngine command, and XMLAccess script).
10. On the **WebSphereCell** entry, click **Edit** and verify that **Cell Name** is correct.
11. Define properties for resources.
    Click the resource, then the **Configuration** tab, then **Resource Properties**.
    - For an ND topology, define the properties for Portal Cluster, Portal Primary Node, and Portal Secondary Node resources.
    - For a stand-alone topology, define the properties for the Portal Node resource.

    Define the following properties:
    - **portal.home**: Portal installation directory
    - **portal.profile.home**: Portal profile directory
    - **portal.admin.user**: Portal administrator user name
    - **portal.admin.password**: Portal administrator password
    - **portal.config.port**: Portal configuration port
    - **websphere.password**: WebSphere® administrator password
12. Create components for the resources.
    Create one component for each resource to deploy.
13. Add the components to the resources.
    a. Navigate to the resource.
    b. Click **Actions > Add Component**.
    c. Select the component to add to the resource.
14. Create the application.

    a. Click **Applications**.

    b. If you do not plan to use an existing application, click **Create Application**.
       You can also use an existing application that is attached to the cell to manage.

c. Enter an application name, and then click **Save**.

d. Click the **Components** tab, and then add the component that was created by the template generation procedure.

15. Create an application environment.

    a. On the **Environments** page, click **Create Environment**.

    b. Enter an environment name, and then click **Save**.

    c. Navigate to the environment editor.

    d. Click the environment name, and then click **Add Base Resource**.
    Select the group for your example cell and environment.

    e. Edit the environment properties for the component.
    Click **Configuration > Environment Properies**. In the **Component Environment Properties** list, enter values for each property shown. If you provided values previously, the values are already completed with default values.

16. Create an application process of the **Deployment** type for configuration and deployment.

    a. Click the **Processes** tab.

    b. Add a deployment step.

    c. Drag the **Install Component** step onto the process editor.
        i. Select the component that you created for the resource.
        ii. Choose the process for the component.

    Example
    For example, if you created a component to contain a Portal WAR file to deploy, select that component, and then choose the Deploy Portal WAR file process.

    d. Click **Save**.

    e. Save the process.

17. Run the process to test the newly created component.

Defining default user impersonation credentials

You can define default user impersonation credentials for a resource.

About this task

To access resources on a target system, you might need to access a specific user account on that system. Typically, the required credentials are defined in plug-in steps, but default credentials can be defined on resources. Steps that do not have their own credentials use credentials that are defined on associated resources.

1. Click **Resources**, and then click the resource's name.
2. Click the **Configuration** tab that is associated with the resource, not the **Configuration** tab at the top of the page.
   Result
   The resource's **Basic Settings** page is displayed.
3. Select the **Default Impersonation** check box.
4. In the **User** and **Password** fields, enter the target system user name and password that can access the resource.
   The password is encrypted as it is entered.
5. In the **Group** field, enter the authentication realm group.
6. To use the sudo command for impersonation, select the **Use Sudo** check box.
   If the target system uses a UNIX™ or Linux™ operating system, you can use this option. If the target system uses a Windows™ operating system, this option has no effect.
7. To always use the credentials that are defined on the resource and override any credentials that are defined in process steps, select the **Always Use Default Impersonation** check box.
8. Click **Save**.

Resource templates

A resource template is a model for a group of resources. The template contains a hierarchy of resources, groups, and agent prototypes that is a starting point for creating new resources.

Resource templates contain *agent prototypes*, which represent agents that are not yet installed or connected to an environment. When you create an environment, you can use a resource template as a model for the environment. Then, you can map real agents to the agent prototypes in the template.

Resource templates provide a pattern for an environment. For example, you can use resource templates to represent dynamic cloud environments. If you define environment templates in an application template, you must use resource templates to define the resource models for the environment templates. See Creating application templates on page 2369.

Note: If you create an environment with an environment template and then add component mappings to the resource template used by the template, the new component mappings are added to the environment. However, if you remove component mappings from the resource template, the component mappings are not removed from the environment.

Creating resource templates

To create a resource template, specify the contents and organization of the template, including resources, groups, and agent prototypes.

1. Click **Resources > Resource Templates** and then click **Create Resource Template**.
2. Specify a name for the template.

   Restriction: If you use this resource template with a blueprint that you provision to a cloud that uses virtual system patterns, the name cannot contain asterisk (*), backslash (\), or forward slash (/) characters.

3. **Optional:** In the **Teams** fields, specify the access information for the new resource template.

4. **Optional:** Check the box next to **Copy Teams to Root Resource** to make the root resource available to the same teams as the resource template.

   Note: This checkbox only affects creating resources from a resource template, not resources that are created by an environment template.

5. **Optional:** Under **Root Resource Teams** click the plus sign to add the teams that should be able to use the root resource of the resource template.
6. Click **Save**.
   Result
   The resource hierarchy for the new template opens in the editor. The hierarchy contains a top-level group.
7. Add resources to the template hierarchy by selecting the top-level group or another resource or group in the template, clicking **Actions**, and clicking a task, such as **Add Group**.
   The template can contain any number of resources.
8. **Optional:** Add agent prototypes to the resource template.
   An *agent prototype* is a resource that represents one or more agents that are not yet installed or connected to an environment.

   a. Next to a folder in the resource template, click **Actions (...) > Add Agent Prototype**.
      You can add only one agent prototype to each folder.

   b. In the **Create Resource** window, specify a description for the agent prototype.

   c. **Optional:** Specify a name pattern for the agents that the agent prototype represents.
      You might use an agent name pattern if you have a system for provisioning agents that is not cloud-based. When you create an environment from an application blueprint that is based on this resource template, you map agents that match the name pattern to the corresponding agent prototypes in the blueprint. For any agent prototypes that do not match existing agents, an entry is created in the environment for an agent with the expected name.

      Note: When you specify an agent name pattern, you can not use wildcards or regular expressions. You can use the following special properties as variables that represent the application name and the environment name: `${p:application.name}` and `${p:environment.name}`.

   d. Click **Save**.

9. **Optional:** Add components to the agent prototypes.

   a. Next to an agent prototype in the resource template, click **Actions > Add Component**.

   b. From the **Component** list, select a component that runs on the agent prototype.

   c. Enter a description.

   d. Define default user impersonation credentials.

For information about setting impersonation credentials, see Defining default user impersonation credentials on page 2332.

e. Click **Save**.

Components can be added to agents, agent pools, and agent prototypes.

Note:

- If you create an environment with an environment template and then add component mappings to the resource template, the new component mappings are added to the environment. However, if you remove component mappings from the resource template, the component mappings are not removed from the environment.
- Changes in a resource template structure are automatically picked up by the resource sync service but any change in the role properties of a resource template will not be synchronized.

10. **Optional:** Add component tags to the agent prototypes.

Note: If you use this resource template in an application template and assign component tags to the application template, add those component tags to agent prototypes.

a. Next to an agent prototype in the resource template, click **Actions > Add Component Tag**.

b. From the **Component Tag** list, select a tag for the component that runs on the agent prototype.

c. Enter a description.

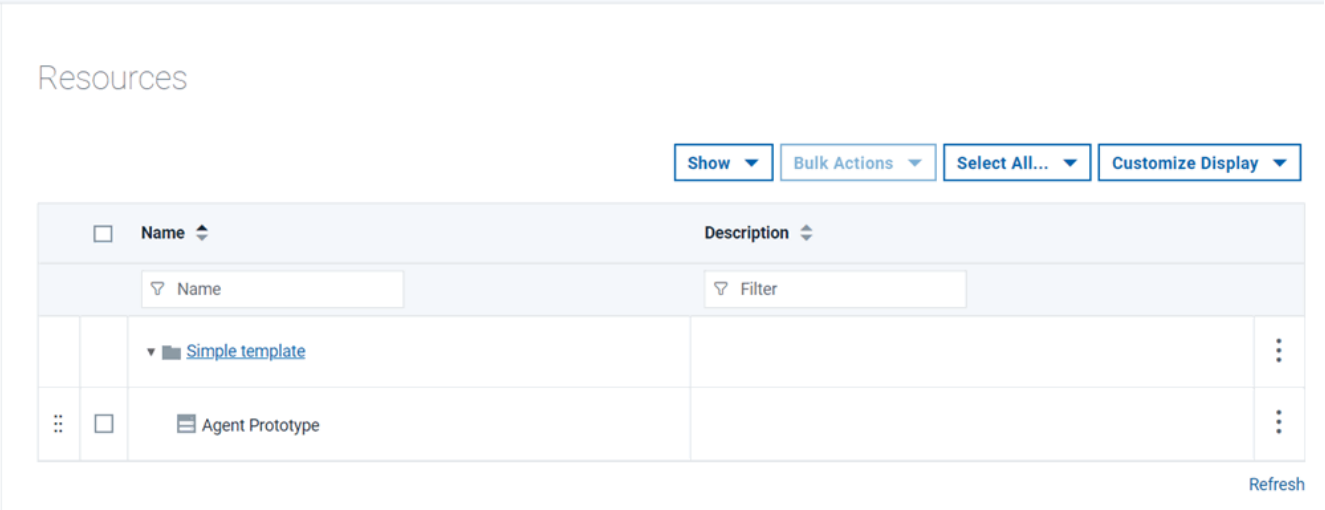
d. Define default user impersonation credentials.
For information about setting impersonation credentials, see Defining default user impersonation credentials on page 2332.

e. Click **Save**.

11. **Optional:** Add agent pool into resource template.
    a. Click the . . . icon next to the base resource of the resource template which appears on hover.
    b. Select **Add agent pool** option in the drop-down. Dialog will appear that lets you choose agent pool.
    c. Click **submit** and agent pool will be a child of the base resource.
    d. Select the . . . icon next to the new agent pool resource to **Add Component** and **Add Component Tag**.
12. **Optional:** Add agent into resource template.
    a. Click the . . . icon next to the base resource of the resource template which appears on hover.
    b. Select **Add agent** option in the drop-down. Dialog will appear that lets you choose agent.
    c. Click **Save** and agent will be a child of the base resource.
    d. Select the . . . icon next to the new agent resource to **Add Component** and **Add Component Tag**.

Example

For example, the following resource template contains a single agent prototype.



Note: Resource templates cannot be deleted if in use by an environment template, or if it's a parent of another resource template. When you delete a resource template all resources in that template will also be deleted.

Defining a new template from the resource tree

You can create a resource template from an existing resource group in the resource tree.

You might complete this task to reuse the hierarchy of a resource group in another location.

Note: If the group contains agents, the agents are included in the new resource template. The agents are not replaced with agent prototypes. Ensure that you use the new resource template appropriately.

1. Open the **Resource Tree** page.
2. Display the **Action** menu for a group, and then click **Define New Template**.
3. In the **Define New Template** window, set the resource template name.
4. **Optional:** Set the **Description**, **Parent Template**, and **Teams** for the resource template.
   See Creating resource templates on page 2333.
5. Click **Save**.
   Result
   The resource template is displayed.

Agents

An agent is a lightweight process that runs on a deployment-target host and communicates with the HCL DevOps Deploy (Deploy) server.

Agents are installed as Web agents on page 2096. Web agents use WebSocket connections and HTTPS for agent-server communication.

Agents do the actual work of deploying components and so relieve the server from the task, making large deployments that involve thousands of targets possible. Usually, an agent runs on the same host on which the resources it handles are located. A single agent can handle all the resources on its host. If a host has several resources, an agent process is started separately for each one. Depending on the number of hosts in an environment, a deployment might require many agents. For example, a test environment might contain a single web server, a single middleware server, and a single database server all running on the same host. A deployment to this environment might have one agent and three separate resources.

Agents have one or more matching *agent resources*, which represent the agents in the resource tree.

Agents are installed with the batch files that are provided with the installation files, see Installing agents from the command line. You can install agents on UNIX™ systems with the web application. Agents are run with the batch files that are included with the installation package.

Agents are unobtrusive and secure. Agent communications use SSL encryption and mutual key-based authentication for server-agent communication and employ HTTP, and HTTPS protocols to communicate with the server. See Agent security and communication on page 2095.

Agent configuration consists of assigning an agent to at least one environment; agents can be assigned to multiple environments. If an agent is assigned to several environments, it can do work on behalf of all of them.

Agent prototypes

An *agent prototype* is a resource that represents one or more agents that are not yet installed or connected to an environment. You can use agent prototypes in resource templates to represent resources that are not yet available. When you import a resource template from the cloud, an agent prototype is created for each node in the cloud pattern.

If you create a resource template instead of importing a resource template from the cloud, you can specify an **Agent Name Pattern** for any agent prototype that you add to the resource template. The agent name pattern can include the properties `${p:application.name}` and `${p:environment.name}`, but no other properties or wildcards.

Agent IDs

Each agent has a Universally Unique Identifier (UUID) that is created the first time you run an agent and it connects to the Deploy server. You can obtain an agent UUID from the **Agents** page by selecting an agent. The UUID is managed on the server. There is a one-to-one relationship between an agent name and its UUID. You can use either agent name or its UUID to delete an agent.

In addition to an agent's UUID, an agent has an endpoint ID that is generated as part of an agent installation process. An agent's endpoint ID is found in the `conf/agent/installed.properties` file of your agent installation directory with the property name **locked/agent.id**. This endpoint ID is broadcast to the server when the agent connects, and the server uses it to uniquely identify any given agent. When an agent is restarted and reconnects to the Deploy server, the Deploy server identifies the connecting agent by its endpoint ID and matches it with the agent UUID.

In REST API calls, APIs that require the agent's UUID or agent name, accepts the agent's endpoint ID as well.

Compact agents

Starting with V7.2.1, the agents are installed as compact agents.

A compact agent is a single-process mode for agents that enables a full upgrade of the agent software stack. It allows a Java upgrade, which was impossible without workarounds previously. In addition to this capability, compact agents also complete several other minor cleanups to the organization of the agent and its operation on Windows in particular.

Compact mode is supported on agents that run on Linux, Mac, and Windows platforms. On upgrade, the agents are switched to compact mode only on a supported platform.

Compact agent changes: Summary

A new installation or upgrade establishes the following changes:

• Running a compact agent doesn't show any monitor process.

• Restarting or upgrading changes the worker process identifier (PID).

• The `/monitor` directory is removed.

• The *JAVA_HOME* variable is set to the content of the *<DEPLOY_AGENT_HOME>*`/conf/agent/javahome.conf` file. The **set_env** setting is ignored.

• File changes in the agent installation directory are as follows:

File or folder	Previous location	New location	Description
shutdown.sh	/bin/shutdown	/var/shutdown	
restart.sh	/bin/restart	/var/restart	
classpath.conf	/bin/classpath.conf	/conf/agent/classpath.conf	Content is unmodified.
worker-args.conf	/bin/worker-args.conf	/conf/agent/javaopts.conf	The javaopts.conf file contains a list of options for the Java executable file that runs the agent.
upgrade.out	/bin/upgrade.out	/var/log/upgrade.log	
agent-upgrade	/agent-upgrade (or /bin/agent-upgrade	/var/upgrade/unpack	
air-agentupgrade.jar	/bin/air-agentupgrade.jar	/var/upgrade/air-agentupgrade.jar	
launcher.jar	/monitor/launcher.jar	/lib/launcher.jar	

The *<DEPLOY_AGENT_HOME>*`/conf/agent/javahome.conf` file contains a single line that is the path to the Java installation that runs the agent.

The following list identifies Windows-specific changes after a new installation or upgrade:

• The `/bin/agent.cmd` and `/native/<cpu>/winservice.exe` files replace the `/bin/agent.exe` file.

• The process removes the `/bin/run_agent.cmd`, `/bin/start_agent.cmd`, `/bin/stop_agent.cmd` files.

• If you run the agent as a service, restarting it restarts the entire service. Therefore, changes to the system environment are reflected in the agent's environment.

• The agent service configuration is no longer stored in the registry. Environment variables are defined in the `/bin/set_env.cmd` file and reflected in the agent's environment. This means that the service mode and `agent run` or `agent start` are more consistent.

• The process does not migrate the custom environment variables that are defined in previous service registry entries.

• Some side-effects of scripting in the `set_env.cmd` file might no longer apply. Changes to the environment are explicitly detected and saved. Other script continues to run and side-effects affects the entire system. For example, modifications to the file system still apply to the agent.

• The following files are replaced by the `/var/log/stdout` log file:

```
/var/log/stdout_XXXXXXXX.log
/var/log/stderr_XXXXXXXX.log
/var/log/service_XXXXXXXX.log
```

Note that the previous files are not removed but new files are not created.

• The service name cannot be customized. The service name is generated from a hash of the agent installation path and is unique to each installation on a computer.

Agent executable command-line commands

These are the command-lines that compact agent executable file accepts. The agent executables are the UNIX script or the Windows executable file.

Command	Description
run	Runs the agent from the console.
start [<pidfile>]	Runs the agent in the background. UNIX: The pidfile argument is optional but is typically used when it runs from an init script. Windows: The pidfile argument is not used.
stop	Stops the agent.

Command	Description
	It creates the "var/shutdown" file. The agent itself monitors for the existence of this file and terminates itself if it is detected. This means the user must have sufficient permission to write that file.
install-service	Windows-only command. This command installs the windows service. It must be run as an administrator with elevated privileges.
uninstall-service	Windows-only command. This command uninstalls the windows service. It must be run as an administrator with elevated privileges.
start-service	Windows-only command. This command starts the windows service. It must be run as an administrator with elevated privileges.
stop-service	Windows-only command. This command stops the windows service. It must be run as an administrator with elevated privileges. This command does not directly use the mechanism of the "stop" command. It requests the Windows service control manager (SCM) for the service to stop.

Agent metadata

The **Agent Metadata** tab provides additional information about the agent.

The **Agent Metadata** page contains agent information categorized into the following information types:

Category	Description
Java Homes	Lists all Java packages installed on the agent. Available attributes include name, vendor, version and status.
Configured Server URLs	Lists all server URLs configured with the agent. Server URLs can be used for proper assignment between the certificates and server hosts.
Configured Relay URLs	Lists all relay URLs configured with the agent.
Server Public Key Pins	Lists all server public keys pinned with the agent. Server key pin information is required to remove obsolete pins, and verify that the new pins are deployed.

Metadata	Lists metadata collected by web agents. An example agent metadata is shown below:
	
	`activeJavaHome C:\Program Files\Java\jdk-15.0.2`
	`verifyServerIdentityEnabled false`
	`serverRemotePort 51665`
	`serverRemoteIp 127.0.0.1`
	`serverPort 7919`
	`serverPinPerHostLimit 8`

Agent relays

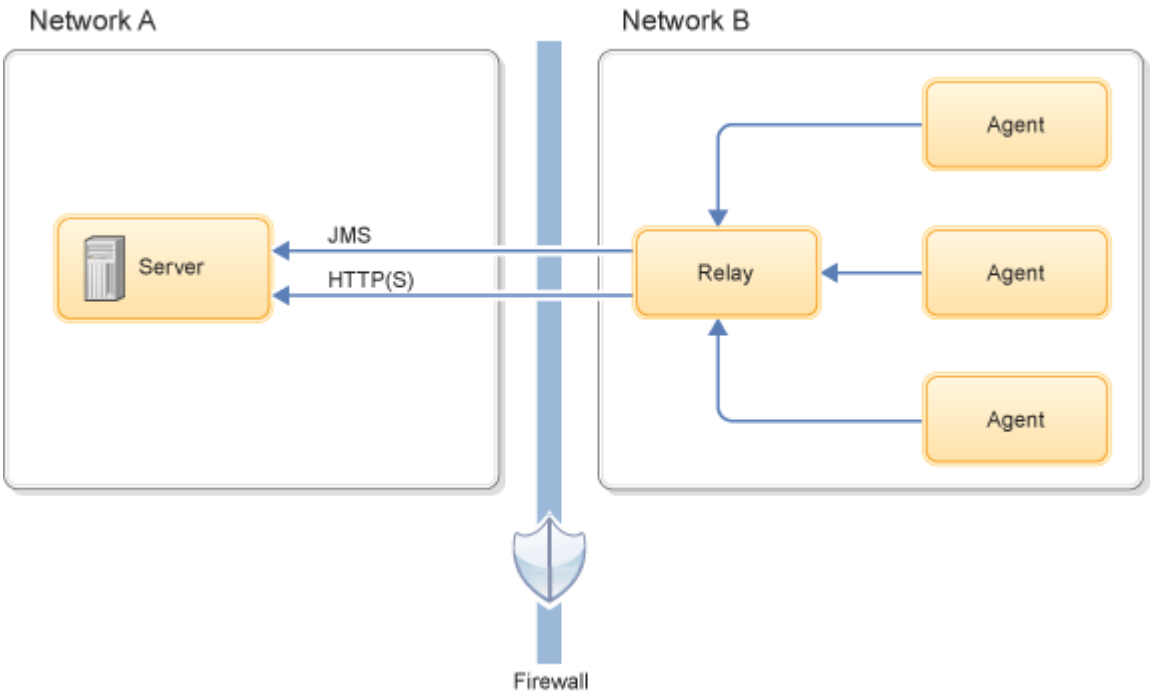
Agent relays coordinate communication between agents and the HCL DevOps Deploy (Deploy) server. Agent relays improve the performance of communication between the server and agents. Relays also allow agents to communicate through firewalls.

To enhance performance and reduce maintenance, Deploy can use *agent relays* to communicate with remote agents. Instead of each agent connecting directly to the server, agents connect to agent relays, which then connect directly to the server. Using agent relays in this way reduces load on the server because the server has fewer direct connections.

Agent relays also simplify communication across networks and firewalls. If multiple agents are in a remote network without an agent relay, each agent must connect to the server individually. In this case, each agent must have network permission to connect to the server, including firewall permissions. With an agent relay, the agents connect only to the relay, and the relay is the only system that contacts the server directly, such as with a VPN or tunnel.

Agent relays are often convenient when the agents are on cloud systems, because cloud systems are often separated from the Deploy server by a firewall or require a VPN or tunnel to reach the server.

The following figure is a simple diagram of communication between agents, an agent relay, and the server across a firewall. The agents connect directly to the agent relay, and the agent relay is the only system that connects to the server through the firewall.



The agent relay communicates with the server and the agents by using the same combination of HTTP, and HTTPS communication protocols that the agents use. As long as there is at least a low-bandwidth WAN connection between the server and agent relay, the Deploy server can send work to agents in other locations.

Note: Starting with version 7.0.5. the agent relay uses a new proxy by default. Only HTTPS traffic can be proxied with this new proxy, but the relay has historically used HTTPS. If for any reason the relay needs to be able to proxy HTTP traffic then the old proxy can be enabled by including the following line in the relays `agentrelay.properties` file: `agentrelay.http_proxy.use_rabbit=true` The new proxy can now support up to 10,000 connected web agents, although to reach maximum scalability, OS file descriptor and ephemeral port limits may need to be raised.

Agent relays open the connections to the Deploy server; the server never opens connections to the agent relays. Agents open the connections to the agent relay; the agent relay never opens connections to the agent. Agent to server communication is always encrypted. HTTP 20080 port is used to establish a tunnel between agent and server to transfer encrypted data. By default, agent relays open connections on the following ports for communication:

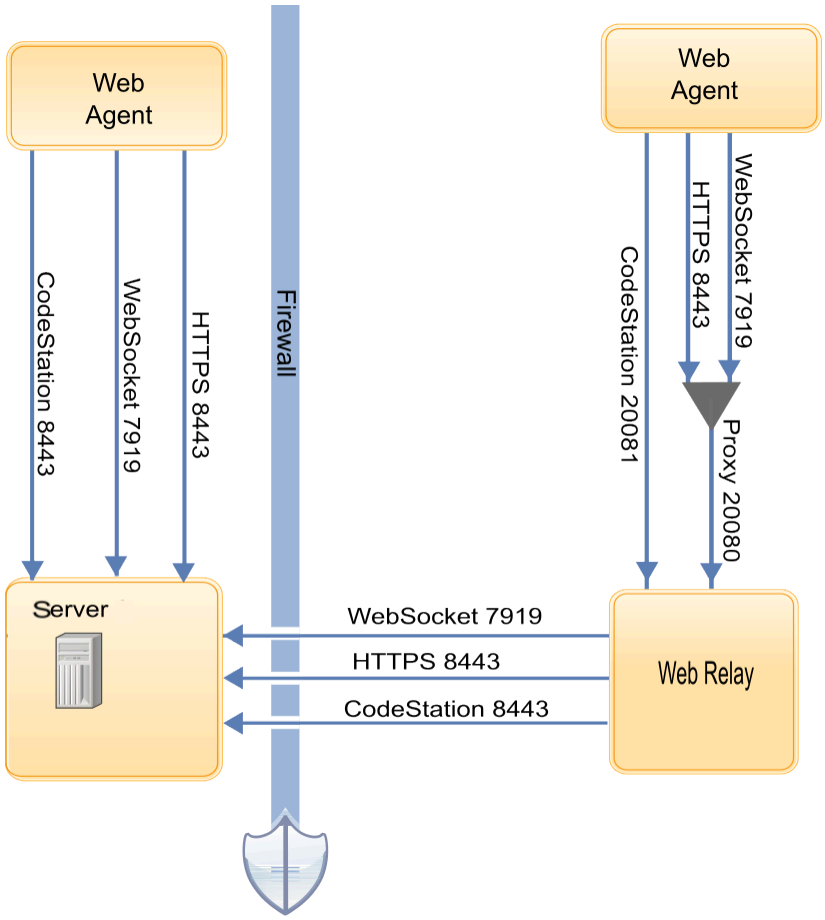
- 8080 and 8443 for HTTP and HTTPS connections to the server

Agent relays accept connections on the following default ports:

- 20080 for HTTP proxy connections from agents.
- 20081, the encrypted port, for artifact cache requests from agents.

The server does not open connections to agents or agent relays.

The following diagram shows the main default ports that are involved in communication between agents, agent relays, and the server.



You can also cache artifacts on agent relays to improve system performance. See Caching artifacts on agent relays on page 2125.

Example

Example

The following simple artifact move illustrates the mechanics of remote communications:

1. A remote agent starts and establishes a connection to the agent relay through WebSocket
2. The agent relay alerts the Deploy server through WebSocket that the remote agent is online.
3. The server sends an artifact download command to the relay through WebSocket, and the relay delivers the message to the remote agent, also through WebSocket.
4. The server locates the artifacts. If the artifacts are not in the relay's CodeStation cache, the server sends the artifacts to the relay over HTTP or HTTPS.
5. The agent relay streams the artifacts directly to the agent over the server-relay HTTP or HTTPS connection.
6. After the remote agent completes the work, it informs the server through the agent relay WebSocket connection.

Applications

Applications are responsible for bringing together all the components that must be deployed together.

Applications do this task by defining the different versions of each component and defining the different environments that the components must go through on the way to production. In addition, applications also map the constituent hosts and systems (called resources) that a component needs within every environment.

Applications also implement automated deployments, rollbacks, and similar tasks. These tasks are called processes. However, at the application level, processes are concerned only with the components and resources that are necessary for deployment, and related tasks. By contrast, component processes are concerned with running commands and related tasks.).

Applications also introduce snapshots to manage the different versions of each component. A *snapshot* represents the current state of an application in the environment. Typically, the snapshot is generated in an environment that has no approval gates. This type of environment is called an uncontrolled environment. For most users, the snapshot is pushed through the pipeline.

Note: Before you configure an application, install at least one agent in a target environment. For evaluation purposes, the agent can be on the same system as the server. In addition, you must also add at least one resource group to the agent. See Resources on page 2312.

Environments

An environment is a collection of resources that host the application. Environments typically include host systems and HCL DevOps Deploy (Deploy) agents. When a deployment is run, it is always done so in an environment. While environments are collections of resources, resources can vary per environment.

For example, environment 1 might include a single web server, a single middleware server, and a single database server. Deploy represents these systems as three separate resources that are running in environment 1. Environment 2, however, might include several clustered databases and servers. To deploy the same components on these different environments, Deploy organizes the resource elements with resource groups. The server also keeps an inventory of everything that is deployed to each environment. In this way, the Deploy server manages the contents of each environment and tracks the differences between those environments.

Processes

A *process* plays a coordination role. They are authored with a visual drag-and-drop editor, and composed of steps that call the component processes. For example, to deploy the application you might run a process that is called Deploy. This Deploy process would in turn run the requisite components and run the deployment.

Snapshots

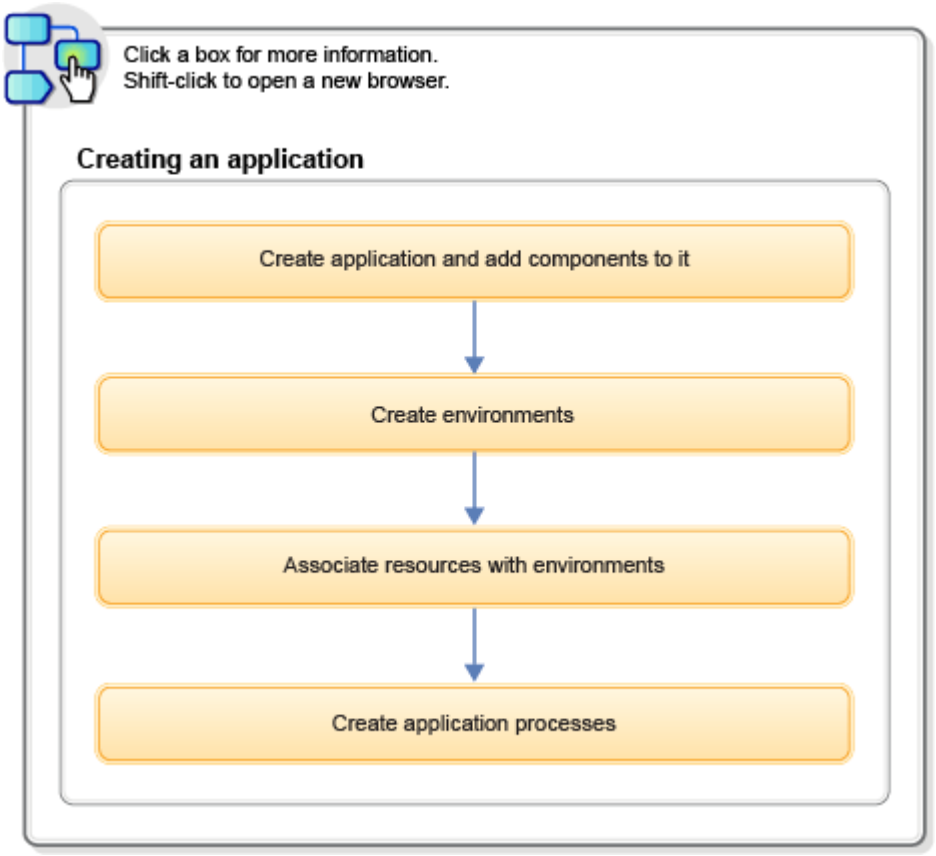
Snapshots specify what combination of component versions you deploy together. They are models that you create before you deploy the application. A snapshot specifies the exact version for each component in the application. When a snapshot is created, Deploy gathers together information about the application, including the component versions, for an environment. Typically, the snapshot is generated in an environment that has no approval gates. This kind of environment is called an

uncontrolled environment. For most users, the snapshot is pushed through the pipeline. Typically, one of the environments remains uncontrolled to allow for snapshots. When a successful deployment runs in the uncontrolled environment, a snapshot is created based on the state of the application within the environment: thus capturing the different versions of the components at that time. As the application moves through various testing environments, for example, Deploy ensures that the exact versions (bit for bit) are used in every environment. After all the appropriate stages and approvals for a snapshot are complete, the snapshot is pushed to production.

Getting started with creating applications

Applications associate resources with environments and define processes to run deployments.

The following diagram summarizes the steps for creating applications:



1. Click this area for information about creating applications. on page 2346
2. Click this area for information about creating application environments. on page 2354
3. Click this area for information about mapping resources to environments. on page 2363
4. Click this area for information about creating application processes. on page 2428

After defining the application itself, you identify the components that it manages, and create application processes that coordinate their deployment. Finally, you create the environments that serve as deployment targets, and map resources to them.

Related topics:

- About HCL DevOps Deploy (Deploy) properties; see Properties on page 2500
- How to create snapshots; see Snapshots on page 2383
- How to import applications; see Importing applications on page 2347

Creating applications

You can create an application from scratch or import an existing one.

Before you begin

Before you configure an application, ensure that at least one agent is installed in a target environment. For evaluation purposes, the agent can be on the same system as the server. See Resources on page 2312.

Some of the configuration options might be restricted based on the role assigned to you. Check with your administrator, if you need a specific option enabled.

About this task

See Importing applications on page 2347 for information about importing applications.

1. Display the **Create Application** dialog box **Applications > Create Application**, and enter the following information:
   - Typically the **Name** and **Description** correspond to the application you plan on deploying.

     Restriction: If you deploy this application to a cloud that uses virtual system patterns, the application name cannot contain asterisk (*), backslash (\), or forward slash (/) characters.

   - To grant teams access to the application and set its security type, click the **plus sign** icon by **Teams**, select values from the **Team** and **Type** lists, and click **Add**.
   - To create an application from a template, from the **Application Template** list, select the application template name. Then, from the **Application Template Version** list, select either the application template version number or to ensure that the application always meets the latest requirements of the template, **Always Use Latest**. See Creating applications from application templates on page 2371.
   - **Notification Scheme**. HCL DevOps Deploy (Deploy) includes integrations with LDAP and email servers that enable it to send out *notifications that are based* on events. For example, the default notification scheme sends out an email when an application deployment fails or succeeds. Notifications also play a role in approving deployments: Deploy can be configured to send out an email to either a single individual or to a group or people (based on their security role) notifying them that they must approve a requested deployment. See Creating Notifications in a Notification Scheme on page 2081.
   - If you want the application to require that every component is versioned, click the **Enforce Complete Snapshots** check box.
   - If you want the application to only deploy changed versions by default, click the **Only Changed Versions Default** check box.
2. Click **Save**.

   Result

The new application opens.

3. Add one or more components to the application:

    a. Within the application, click the **Components** tab, which is not to be confused with the global **Components** tab.

    b. Click **Add Component**.

    c. In the **Add a Component** window, expand the **Select a Component** list and select the check boxes next to one or more components, as shown in the following figure.
    Example

    d. Click **Save**.

What to do next

After you create an application, you:

- Create an environment (Creating environments on page 2354)
- Associate an agent with the environment (Mapping resources and components to environments on page 2363)
- Create an application process (Application processes on page 2428)

Importing applications

If you exported an application, you can import the application on a different server. When you import an application, you can create a new application or upgrade an existing application.

Before you begin

Ensure that you have exported an application from the source server and copied the JSON or YAML file to the destination server. See Exporting applications on page 2352.

Additionally, you must know that:

- To share applications that have secured properties among Deploy servers, you exchange keys from each server's encryption keystore. See Sharing secured properties among servers on page 2350.
- The version of the destination server must be the same as of the source server.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

About this task

To move applications between servers, you export the applications and import them to a different server. When you import an application, components and other items that are associated with the application are also imported, including their properties and processes (if they are available to the importing server).

Note: Notification schemes are not imported.

For information about templates that are associated with the imported components, see Importing components on page 2296.

Notes:

- If imported components have the **Import Versions Automatically** parameter set to true, Deploy automatically imports component versions if the artifacts are accessible to the importing server.
- You might receive an error message that indicates the Java™ heap space is out of memory when you attempt to import an application. To resolve the issue, increase the Java™ heap size. Open the `server_directory/bin/set_env` file, and set the Java™ heap size to a higher value, such as 2 GB.

1. Open the **Import Applications** dialog box by clicking **Applications > Import Applications**.
2. To upgrade an existing application, enable the **Upgrade Application** option. To create a new application, leave **Upgrade Application** cleared.
   If the name of the application in the JSON file (not the name of the file itself) matches an existing application name, then the application parameters are updated. If items such as processes or properties exist, new versions are created. New items, such as processes, environments, components, or properties, are also added. If the name of the application is not found, the import action has no effect.

   Note: The application name is the first parameter in the defined file. This example shows the first parameter in the respective file:

   ```
   "name": "helloWorldApplication",
   ```

3. To import the application with snapshots, enable the **Import with Snapshots** option.
4. To import the full base resource trees mapped to the application environments, enable the **Import Full Base Resource Trees** option.

   When selected, the resource mapping of the imported application environment matches with existing resources on the source server.

Note: The resources must exist on the source server for the application environment to map to.

5. Configure how to import the items that are associated with the application.
   When you import an application, all application templates, components, generic processes, and resource templates that are associated with the application are also imported. For each item type, you must select the option from the list that determines how each item type is imported or upgraded. If your application does not contain items of a type, accept the default value.

   Application Template Upgrade Type

   If the application was created from an application template, you must specify how to import the application template.

   Component Upgrade Type

   If the application contains components, you must specify how to import them.

   Note: The components must be on the importing server.

   Process Upgrade Type

   If the application processes contain generic processes, you must specify how to import them. If you are also upgrading components, then the generic processes that are called in the component processes are also affected. The import process has different results if the generic processes exist or not.

   Note: The server tracks generic processes by name. If a generic process on the server is assigned the same name as a generic process that is imported, then the generic process exists on the server.

   Resource Template Upgrade Type

   The application template might also contain resource templates. Specify how to import resource templates that have the same names as existing resource templates.

The following table lists the options available for the above upgrade types:

Table 730. Upgrade options that are available for each item type

Option	Description
Use Existing *Item Type*	To use the same item that is used by the imported application, select this option. The new application contains references to the item. If you are upgrading, the application uses the imported item.
Create *Item Type*	To create an item that is based on the item that the imported application uses, select this option. A new item is created that is based on the item of the imported application. If you are upgrading, the application uses the newly created item, and it no longer uses the item that it previously used.

Option	Description
Fail If *Item Type* Exists	When you want to create a fresh installation, select this option. If you are creating an application, Deploy creates both a new application and item unless the item exists, in which case the application is not imported. If you are upgrading, the upgrade fails if the item exists on the importing server.
Fail If *Item Type* Does Not Exist	To ensure that an item is on the importing server, select this option. If you are creating an application, Deploy creates both a new application and item unless the item does not exist, in which case the application is not imported. If you are upgrading, the upgrade fails if the imported item does not exist on the importing server.
Upgrade *Item Type* If Exists	To upgrade the existing item, select this option. This option creates an application and upgrades the existing item with data from the imported application. If you are upgrading and an existing item matches an imported one, the item is upgraded. If the imported item matches the existing one, the imported item is used.

6. Click **Choose File**, and then select the name of the JSON or YAML file that contains the application definition.

   Note: You must create the JSON or YAML file that contains the application definition on a server that uses the same version of Deploy as the destination server.

7. Click **Submit**.

Sharing secured properties among servers

To share applications that have secured properties among HCL DevOps Deploy (Deploy) servers, exchange keys from each server's encryption keystore.

Before you begin

Make sure that the location of the Java™ keytool command is on the **PATH** variable of the servers. The `keytool` application is included in the Java™ developer kit and is not part of Deploy.

About this task

To share applications that have secured properties, export the server's key and import it into each target server. This process enables applications from the exporting server to be used by the other servers. Repeat the process for each server with applications that you want to share.

1. On the first server, open a command-line window, and go to the server installation `conf/server` directory.
2. Find the value of the **encryption.keystore.alias** property in the *`install`*`/conf/server/installed.properties` file.

   Example

For example, the following code shows a value of `abcdkey1234`:

```
encryption.keystore=../app_data/conf/encryption.keystore
encryption.keystore.alias=abcdkey1234
```

You must have this alias to complete the next steps.

3. Go to the folder that contains the keystore file `encryption.keystore`.
   The default location is *appData*`/conf/encryption.keystore`, where *appData* is the application data folder.
4. Run the following command to import the server key into a temporary keystore.
   You must enter this command on a single line.

```
keytool -importkeystore -srckeystore encryption.keystore
  -srcstorepass srcPassword
  -srcstoretype pkcs12
  -alias alias
  -destkeystore temp.keystore
  -deststorepass tempPassword
  -deststoretype pkcs12
```

   - For the *srcPassword* variable, specify the password for the server keystore. The default password is `changeit`.
   - For the *alias* variable, specify the value of the **encryption.keystore.alias** property.
   - For the *tempPassword* variable, specify a password for the temporary keystore. You will use this password later.
5. Copy the temporary keystore, which is named `temp.keystore` in the previous example and store it in the appropriate folder on the second server.
   Check the **server.appdata.dir** property in the `installed.properties` file to determine where to store the keystore.
   - If the **server.appdata.dir** property has a value of two periods (..), copy the keystore to the *install*`/conf/` folder on the second server.
   - If the property has a value other than two periods, the server uses an application data folder. Copy the keystore to the *appdata*`/conf/` folder on the second server.
6. On the second server, open a command-line window, and go to the server installation *install*`/conf/server` directory.
7. Run the following command to import the key in the temporary keystore into the server keystore.
   You must enter this command on a single line.

```
keytool -importkeystore -srckeystore temp.keystore
  -srcstorepass tempPassword
  -srcstoretype pkcs12
  -alias alias
  -destkeystore encryption.keystore
  -deststorepass destPassword
  -deststoretype pkcs12
```

   - For the *tempPassword* variable, specify the password for the temporary keystore.
   - For the *alias* variable, specify the **encryption.keystore.alias** property of the first server, not the current server.
   - For the *destPassword* password, specify the password for the current server keystore.
8. Restart the second server.
9. **Optional:** Delete the temporary keystore file from each server.

Results

The encryption key from the first server keystore is now on the second server keystore. As a result, the second server can now decrypt applications from the first server.

You can verify that the second server keystore has the key by running the following command on the second server:

```
keytool -list -keystore encryption.keystore
  -storepass password
  -storetype pkcs12
```

For the *password* variable, use the password of the server keystore.

This command lists the keys in the server keystore. If you copied the keys successfully, the list includes at least two keys: one from each of the servers. These keys are listed according to the **encryption.keystore.alias** properties of the respective servers. For example, the following output shows two keys:

```
Your keystore contains 2 entries

efghkey5678, Oct 15, 2013, SecretKeyEntry,
abcdkey1234, Nov 22, 2013, SecretKeyEntry,
```

What to do next

Repeat this process to copy keys between other servers.

Exporting applications

Exporting applications creates a JSON file (file extension `json`) that contains the properties, components (and their associated properties and processes), and processes of the applications.

About this task

For information about JSON, see http://www.json.org/.

Note: Exporting applications in this way includes only the most recent version of each component process and application process.

When you export an application, components, snapshots and other items that are associated with the application are also exported, including their properties and processes (if they are available to the exporting server). Notification schemes are not exported.

To export one or more applications:

1. On the **Applications** pane (**Applications**), select the check box next to one or more applications.
2. At the top of the table, click **Actions** and then click **Export**.

   Result

   The file is saved in the default download location for your browser.

What to do next

You can import the application to another server that uses the same version of HCL DevOps Deploy (Deploy). See Importing applications on page 2347.

Rational Team Concert™ Build

The Rational Team Concert™ Build system defines resources that are used to describe and manage builds.

The Rational Team Concert™ Build system in IBM® Rational® Team Concert™ defines the following types of logical resources that are used to describe and manage builds:

Build definition

A build definition describes:

- The workspace to process.
- The Ant scripts and targets to run against the workspace.
- The schedule for the build.
- The properties to simplify the configuration of the build.
- The build engines that can handle build requests for the build definition.

Build engine

A build engine represents a Build System Toolkit Jazz™ Build Engine running on a designated build computer. A Jazz™ Build Engine running on a build computer correlates itself to a build engine in Rational® Team Concert™ by specifying the unique identifier of the build engine.

Build request

A build request represents a scheduled or explicitly issued request to run a build according to a specified build definition. Build definitions are submitted to a build queue. A Jazz™ Build Engine receives and processes the build request if its corresponding build engine in Rational® Team Concert™ is listed as a supporting build engine for the build definition.

Build result

A build result represents the output of a build.

Build System Toolkit

Each build computer contains an installation of the Rational® Team Concert™ Build System Toolkit.

The Build System Toolkit consists of the following major components:

Jazz™ Build Engine

The Jazz™ Build Engine is a command-line tool that polls for and processes build requests from Rational® Team Concert™. When the Jazz™ Build Engine is started, it must identify a corresponding build engine in Rational® Team Concert™. TheJazz™ Build Engine can then accept any build request whose build definition is supported by the build engine. The Jazz™ Build Engine runs the Ant script and targets that are specified in the build definition. Each build is represented in Rational® Team Concert™ by a build result.

Build toolkit

The build toolkit is a collection of Ant tasks. Ant scripts can use these tasks to send information (such as build progress, results, links, artifacts) to Rational® Team Concert™ to include in the build result.

Build agent

The build agent is a lightweight process that handles agent-based builds that support z/OS® or IBM® i build scenarios. Jazz™ Build Engine

Note: The Jazz™ Build Engine is a component of the Build System Toolkit; it refers to the process that runs on a build computer and runs Ant scripts.

Application environments

An *environment* is a user-defined collection of resources that hosts an application.

An environment is the application's mechanism for bringing together components with the agent that deploys them. Environments are typically modeled on some stage of the software project lifecycle, such as development, QA, or production. A resource is a deployment target, such as a database or Java™ Platform, Enterprise Edition container. Usually, resources are found on the same host where the agent that manages them is located. A host can be a physical system, virtual machine, or be cloud-based.

Environments can have different topologies, for example: an environment can consist of a single server; be spread over several servers; or spread over clusters of servers. Environments are assigned to specific applications. Although multi-tenant systems can be the target of multiple applications, most IT organizations use application-specific environments. Additionally, approvals can be assigned to specific environments.

HCL DevOps Deploy (Deploy) maintains an inventory of every artifact that is deployed to each environment and tracks the differences between them.

Environment properties can be created with the environment's **Properties** pane (**Applications > *selected application* > Environments > *selected environment* > Properties**).

A value that is set on a component environment property overrides an environment property that has the same name.

Referenced: `${p:environment/propertyName}`.

Creating environments

Before you can run a deployment, you must define at least one application environment that associates components with an agent on the target host.

Before you begin

Ensure that you have at least one base resource to associate with the new environment. See Mapping resources and components to environments on page 2363.

Some of the configuration options might be restricted based on the role assigned to you. Check with your administrator, if you need a specific option enabled.

About this task

The initial environment is typically uncontrolled and often is used to create snapshots. You create an environment for each location to which you deploy an application.

1. Click **Applications**, click your application's name, and click **Create Environment**.
   Result
   The **Create Environment** dialog box opens.
2. Specify the environment name.
   The name is used as part of the deployment process and typically corresponds to the target environment.
   Example
   If you deploy to an integration environment, you might name the environment `SIT`.
3. **Optional:** Provide the following information:

   a. Specify a description.

   b. Assign teams to the environment and set its security type. Click **Add Team**, select values from the **Team** and **Type** lists, and click **Add**.

   c. Enable the **Show Compliancy on Load** option to load the environment's compliancy automatically on the application environment page.
   If disabled, the **Load Compliancy** option will still be available that allows you to load the environment's compliancy on demand.

   d. If you created the application from an application template, in the **Environment Template** list, select the environment template to use for the environment.
   You can assign any security type to this environment.

   e. To ensure that components cannot be deployed to the environment without first being approved, specify the **Deployment Approvals** information. If specified, Deploy enforces an approval process before the deployment can be deployed to the environment. Initial deployments are typically done in uncontrolled environments. After the deployment works as designed, you can configure an approval process as the application moves along the development pipeline. If you are setting up more than one environment, consider creating an approval process for at least one of them.
   You can apply two types of approvals to an environment, that is, external and manual approvals.
      - Specify a **Resource Type to Run External Approval**. You can select **System Default** for the values specified in the system settings, an **Agent Pool** to specify a group of agents, or an **Agent**.
      - Choose an existing **External Approval Process** to run. See Managing external approval processes on page 2392 for information about how external approval processes are created.
      - You can **Exempt Processes** from approvals even if it is required by an environment.
      - Enable **Require Manual Approvals** to allow approvals from users in a role specified by the approval process created for the environment. See Creating an approval process on page 2388 for information about how manual approval processes are created. To prohibit the user who makes an approval request from approving the same request, select **No Self-Approvals**.

f. To prevent changes to snapshots in this environment after you deploy them, select the **Lock Snapshots** check box.

g. If you selected the **Lock Snapshots** check box, from the **Snapshot Lock Type** list, select the lock type:
   - To lock only component versions, select **Only Component Versions**.
   - To lock snapshot configurations, select **Only Configuration**.
   - To lock both component versions and configurations, select **Component Versions and Configuration**.
   - To use the system default value, select **System Default**. The default value is determined by the **Default Snapshot Lock Type** field on the **System Settings** page. For information about system settings, see System settings on page 2086.

h. Select **Require Snapshot** to require that snapshots are deployed to the environment.
   When this option is selected, only snapshots can be deployed to the environment.

i. Select a color to apply to the environment. Default is Bright Cerulean (Blue).

j. To apply the component version and snapshot cleanup settings that are specified on the **System Settings** page, select the **Use Default Artifact Cleanup Settings** check box.
   If this check box is cleared, you must specify how long to keep snapshots and component versions. For more information about cleaning up snapshots, see Cleaning up snapshots on page 2143.

   To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Use Default Artifact Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

k. To apply deployment history cleanup, select the **Use Deployment History Cleanup** checkbox.
   You can use the default settings that are specified on the **Systems Settings** page by clicking **Use Default Deployment History Retention**, or in **Days to Retain Deployment History** you can specify a number of days to retain deployment history records. For more information about cleaning up deployment history, see Cleaning up deployment history files on page 2133.

l. To apply process step logs cleanup, select the **Use Process Step Log Cleanup** checkbox.
   You can use the default settings that are specified on the **Systems Settings** page by clicking **Use Default Step Log Retention**, or in **Days to Retain Step Logs** you can specify a number of days to retain step logs. For more information about cleaning up process step log, see Cleaning up process step log files on page 2145.

4. Click **Save** or **Next**.
5. Click **Create** to submit the request.

Results

The new environment is displayed in the **Environments** pane.

Note: An environment template cannot be deleted if it is being used by an environment.

Creating environments from WebSphere® Application Server cells

You can import information about a WebSphere® Application Server cell into resources and then use those resources in an environment.

Before you begin

You must have a WebSphere® Application Server cell and an application in the HCL DevOps Deploy (Deploy) server.

1. Import resources from the WebSphere® Application Server cell as described in Importing resources from WebSphere Application Server on page 2325.

   Result

   When you are finished, you have a collection of resources that represent the cell and the nodes, servers, and other artifacts in the cell. These resources are under the agent resource for the WebSphere® Application Server system.
2. In the Deploy server, create an application environment.
3. Add the resources to the environment:
   a. Open the environment and go to the **Resources** tab.
   b. Click **Add Base Resources**.
   c. Select the agent resource and click **OK**.

What to do next

Now you can run application processes on the environment, including processes that contain steps in the WebSphere® Application Server - Deploy plug-in.

Deployment triggers

Starting with v7.1.0, deployment triggers replace the run process after a version is created feature.

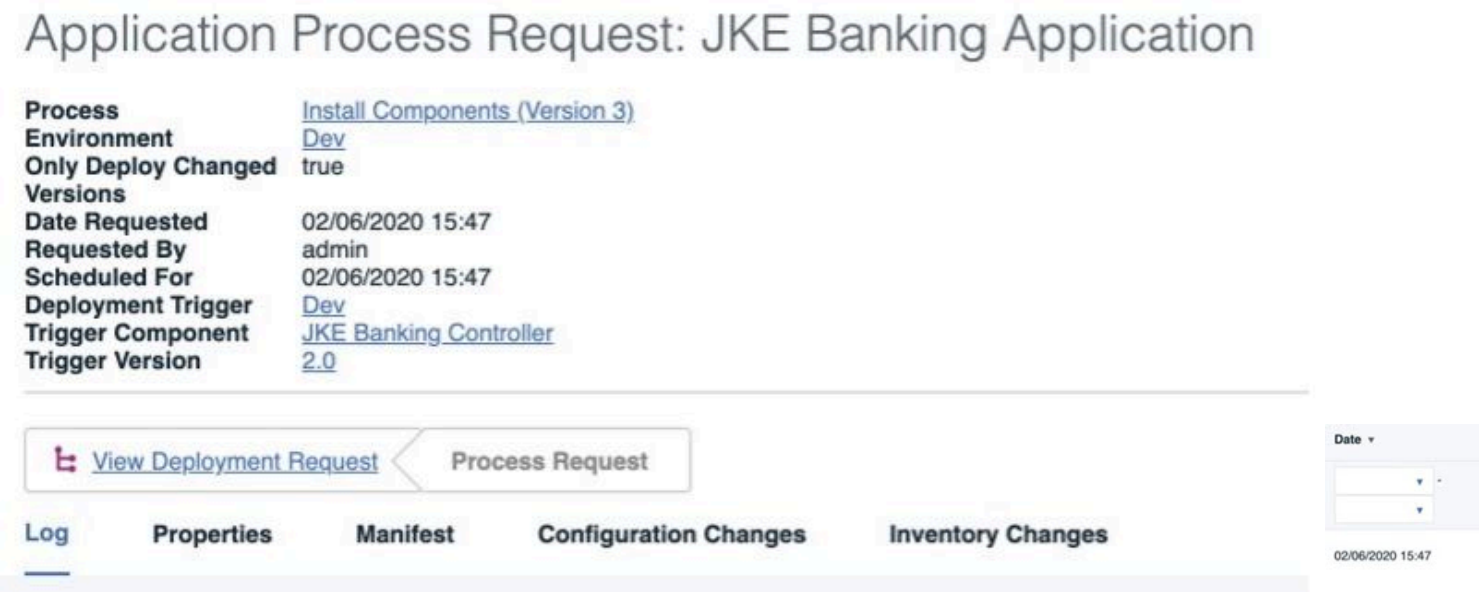
Deployment Triggers are ways for environments to subscribe to certain components. A trigger consists of a specified component, deployment process, and user. Whenever a component finishes importing a version, the server will automatically execute all deployment triggers relevant to that component and will run configured deployment processes against the triggers' environment, using the newly imported version as the deployment payload. With deployment triggers, development environments can be configured to get the latest build artifacts deployed as soon as they are received by the HCL DevOps Deploy (Deploy) server.

When you create a deployment trigger, you have to specify a user who has the run deployment triggers permission, but you do not require that permission yourself. Run deployment triggers is a system level permission that governs whether the a user is allowed to run the process that is the trigger specifies

The user who runs the deployment trigger also must have all permissions that are required to run an application process. Like the run deployment triggers permission, these permissions are also asserted at process run time and not when the trigger is created.

The default audit view is as follows:

- When the deployment trigger is created and who created it
- When the deployment trigger is deleted and who deleted it



Migration

Database upgrades transfer existing deployment triggers to a new table and remove the current constraints, indexes, and columns from the component table.

The specified user for these rows is admin by default.

Importing and exporting

Applications and snapshots that are imported or exported retain information about their deployment triggers.

Importing application snapshots that include component versions do not activate deployment triggers.

Copying an environment retains information about deployment triggers.

Approvals

An application process that requires approvals is still kicked off when a deployment trigger runs the process.

Note: When you update component versions on the command-line interface, a deployment trigger runs when the import is finished.

Before the deployment trigger request submission succeeds submitted, these conditions must be met:

- The component must be mapped to the application when the deployment trigger submits the process request.
- The application process and component must not be deleted.
- The user who runs the deployment must have run deployment triggers permission when deployment trigger runs.

Note: If the user who runs a deployment trigger does not have the required role for a process, then the application process cannot start the deployment by using the deployment trigger.

Creating deployment triggers

With the new deployment trigger feature, you can run an application process automatically on a specified environment after component versions have been added. Deployment Triggers also allow for user specification.

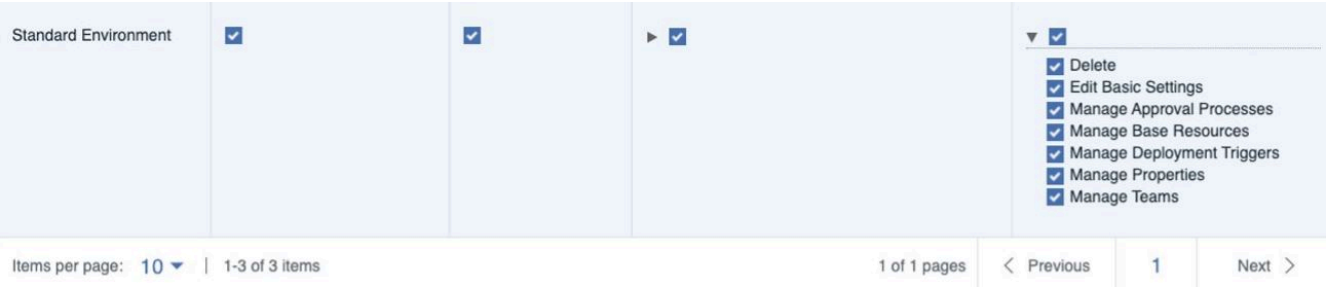
Before you begin

To create a deployment trigger you must have these permissions:

- Edit Basic Settings on environments
- Execute on environments
- Manage Deployment Triggers

To delete a deployment trigger, you must have these permissions:

- Edit Basic Settings on environments
- Manage Deployment Triggers



About this task

You can create deployment triggers for many components on a single environment.

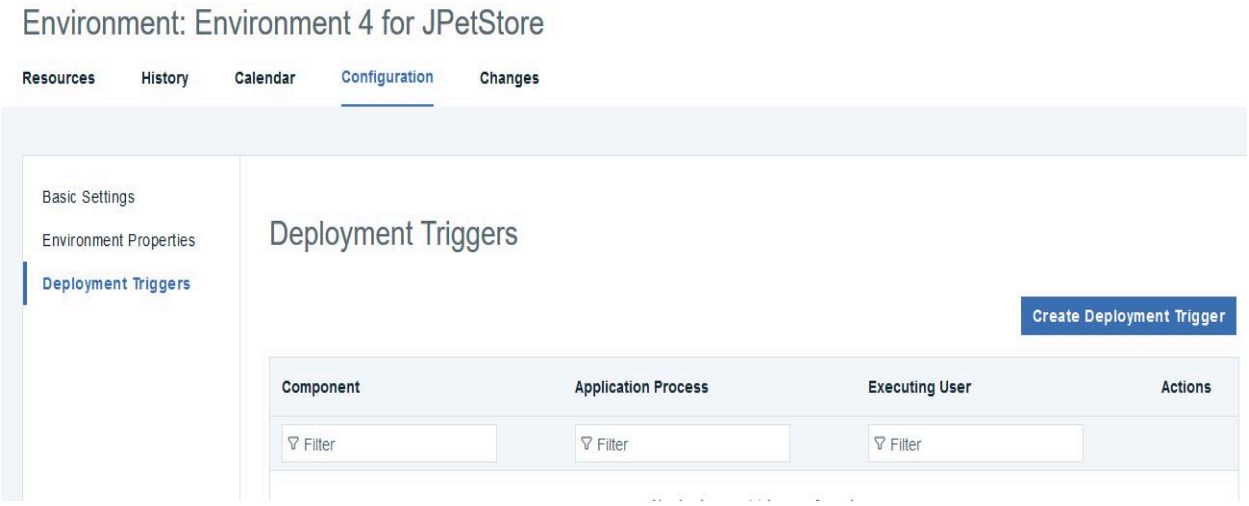
You can run multiple application processes on as many environments as you want.

A deployment trigger adds strict access to running an application process on selected environment through the permission system.

Note: You cannot have duplicate deployment triggers on component, application process, and environment. However, you may create nearly identical deployment triggers when you choose the same component and application process with a different executing user.

Procedure

1. On the Environment Configuration page click on **Deployment Triggers**.



2. Click **Create Deployment Trigger**.
3. In the **Create Deployment Trigger** window, select a component, application process, and executing user.
4. Click **Save** when done.

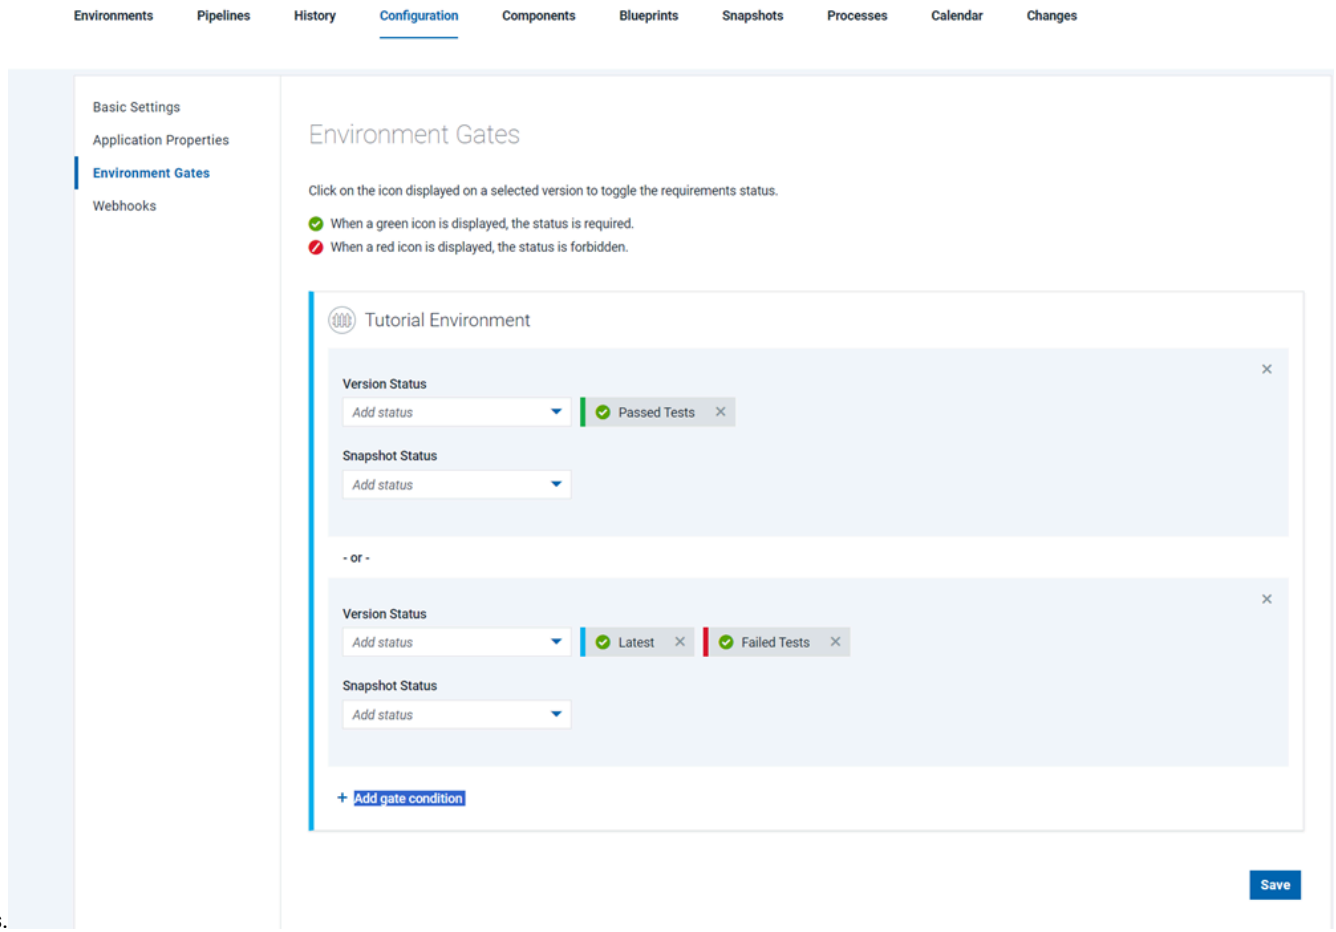
Environment gates

An environment gate is a requirement that must be met before component versions can be deployed to an environment. For example, a component version might need to pass certain tests or receive an approval.

Each environment gate can require a combination of version statuses. These statuses can be combined by using "and", "or" or "not" operators. When the component version has satisfied the statuses and operators, it can be deployed to the environment.

For example, the following figure shows the gate for an environment. The gate has three component version statuses: **Passed Tests** "*or*" both **Latest** "*and*" along with "*Not*" **Failed Tests**. In this case, a component version

cannot be deployed to the environment unless it has the **Passed Tests** status or the **Latest** status and not **Failed**



Tests.

To see the statuses on a component version, click **Components > *selected component*** **> Versions** and look in the **Statuses** field.

Creating environment gates

Create gates that specify the conditions that must be met before a component version or snapshot is deployed to the environment. The conditions are defined on the component version statuses and snapshot statuses.

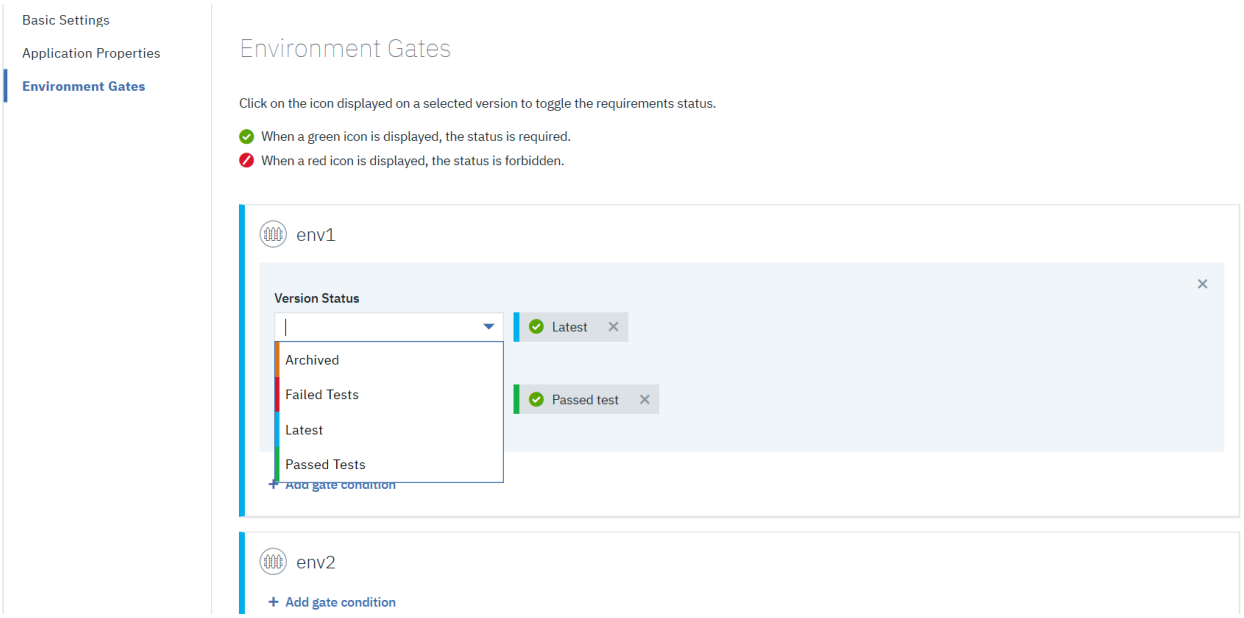
Before you begin

Create one or more component version and/or snapshot statuses. To create statuses, see Creating statuses on page 2243. Note that component versions cannot be deployed to the environments unless they have the specified statuses.

1. Display the **Environment Gates** pane for the target application or application template (**Applications > *selected application*** **> Configuration > Environment Gates** or **Applications > Templates > *selected application template*** **> Configuration > Environment Gates**).
   This pane lists the environments and the gates for each environment.

Note: You cannot modify environment gates if the environment was created by using an application template.

2. Next to an environment, click **Add gate condition**.
3. Select a component version and/or snapshot status by clicking the drop-down arrow from their respective fields.



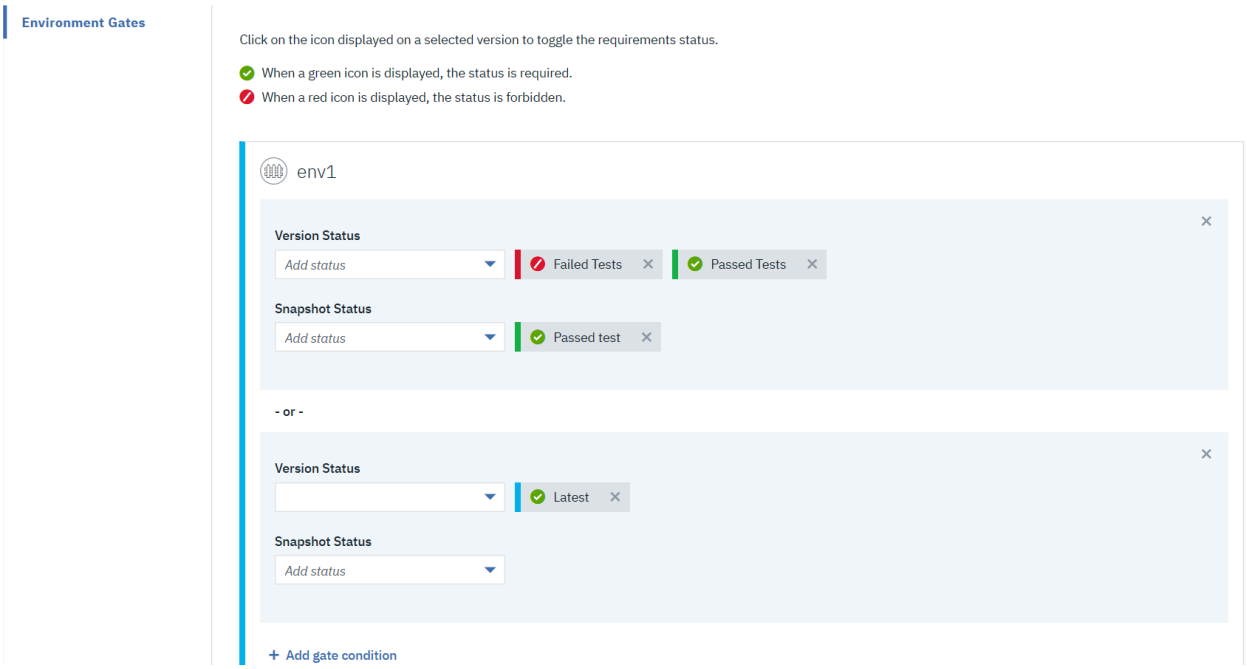
You can add more than one status to a gate condition that must be satisfied for the deployment. For example, if you define a gate with the statuses `Passed unit tests` and `Latest`, only component versions with both of these statuses can be deployed into the environment.

Adding another gate condition, applies the `-or-` operation to the gate. An environment with two or more gate conditions means that the component version can be deployed if it meets any of the conditions. For example, if you define a gate with the statuses `Passed unit tests` and `Latest`, a component version passes the gate if it has either status (or both). A single environment can have any number of gate conditions.

Once you add a status, you can click the green check mark that turns it into a circle-backslash symbol. It gives the status a `Not` operation. A status with circle-backslash symbol indicates that it will exclude the status from deployment. For example. if you define a gate with the condition `(circle-backslash symbol) Failed tests`, the component versions with this status will not be deployed into the environment.

Note: When deploying component versions without choosing a snapshot, the snapshot gates are ignored.

The following example screen capture shows how you can set the gate conditions for an environment.



4. Repeat these steps for other environments.
   Each environment can have different gates.
5. Save your changes.

Results

The environment deployments are executed when all of the specified gate conditions are met.

Mapping resources and components to environments

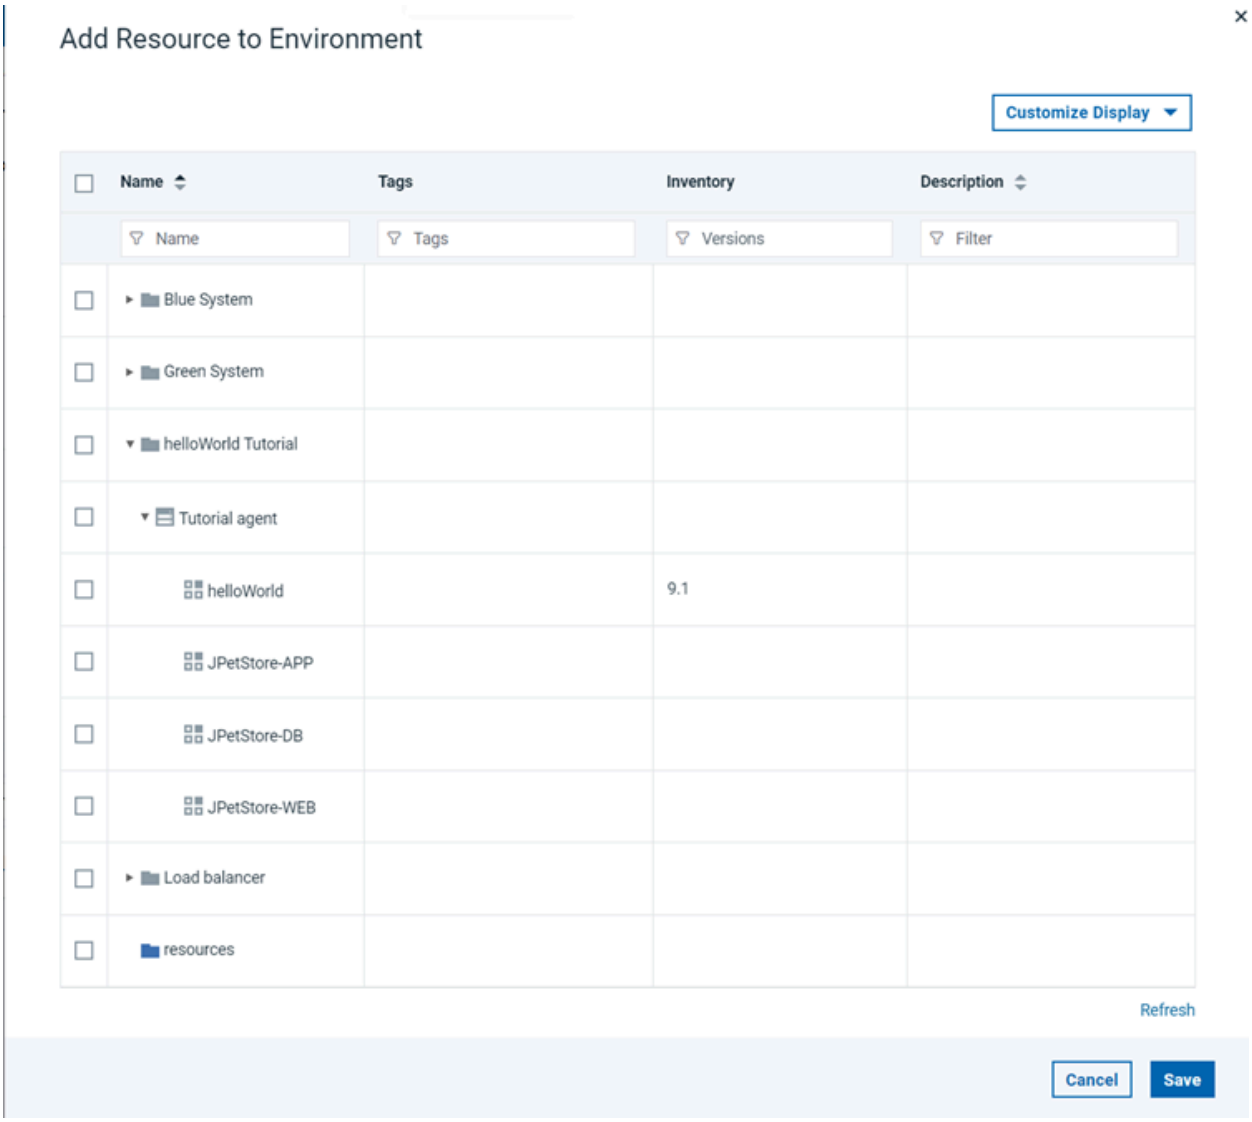
You can specify where components are deployed by adding a resource or resource group to the environment. Then, map the components to those resources.

About this task

Resources and resource groups identify the agents that do the work of deploying components and provide other configuration information. You must identify the resources for the environment and then specify which components run on which resources.

If you are using IBM® WebSphere® Application Server, you can import information from cells as resources; see Importing resources from WebSphere Application Server on page 2325.

1. To open the environment, click **Applications > application > environment**.
2. Click **Add Base Resources** to display the **Add Resource to Environment** window for the selected environment.
   All previously defined resources are available for use, as shown in the following figure:



3. Select the check box that is associated with the resource or resource group to use.
   You can select more than one resource. Selecting a resource that was previously added to the environment has no effect. Adding more than 10 base resources in an environment may result in performance issues.
4. Click **OK**. The selected resource or resource group is added to the environment.
5. To remove a base resource from the environment, in the same row as the resource, click **Actions > Remove From Environment**.
   Removing a base resource removes its child resources as well. Starting from v7.0.5.1, you can delete a resource from the environment. Note that deleting a resource from the environment resource tree deletes the resource from the system. Delete a resource from the system as follows:
   a. Go to **Settings > System Settings**.
   b. Enable **Deleting Resources from Environment Resource Tree**, confirm, and save your changes.
   c. Go back to your environment resource tree, in the same row as the resource, click **Actions > Delete**.
6. Map each component in the application to the resources.

Each component must be mapped to at least one resource. You can map the same component to multiple resources. Or to specify that the component is deployed more than once to the environment, you can map the component multiple times to the same resource. There are several ways to map components to resources:

Choose from:

- To add components one at a time, in the same row as the resource, click **Actions > Add Component**, and then select the component.
- To drag components, click **Show > Components**. Then, in the list of components that are associated with the application, drag one or more components to the resource.
- To add multiple components at once, ensure that each component has the same tag. Then, in the same row as the resource, click **Actions > Add Component Tag**, and specify the tag that identifies the components.

Results

The environment is populated with resources and components.

What to do next

Note: For z/OS deployments, you must use a one-to-one (1:1) mapping between environments and resources. This practice ensures that each resource is assigned exclusively to a single environment within the application context.

After mapping components and resources, create an application process. For information about creating application processes, see Creating application processes on page 2429.

Comparing environments

You can compare two environments to see differences in their inventories or property values.

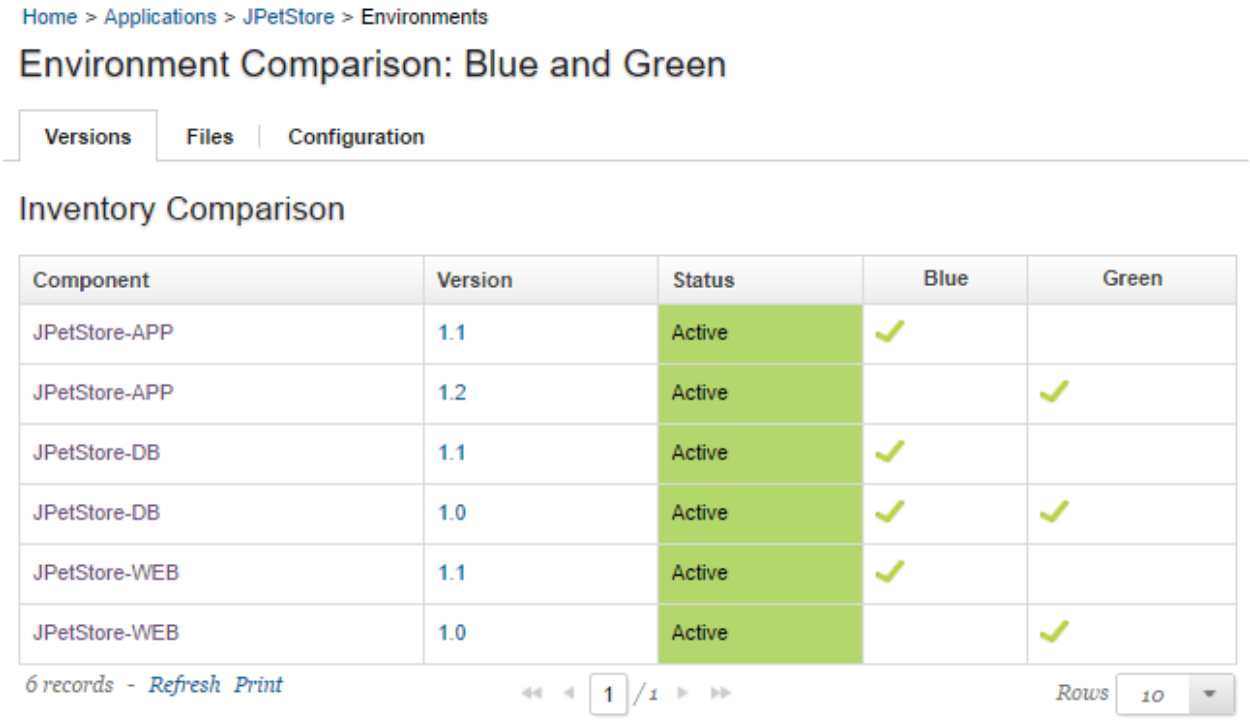
Comparing environment inventories

Comparing two environment inventories shows the differences in component versions between two environments. It also shows the differences in files and properties.

1. From the Deploy dashboard, click **Applications**, and then select an application.
2. Click **More** for one of the environments to compare, and then click **Compare**.
3. From the **Environment** list, select the other environment to compare, and then click **Save**.

   Result

   The **Environment Comparison** page opens. The component versions that are contained in each environment are displayed on the **Versions** tab, as shown in the following figure.



4. To see the differences between component environment properties in the two environments, click the **Configuration** tab.
5. To see the differences between files in the two environments, click the **Files** tab.

Comparing properties

You can run a detailed comparison of properties between environments. You use one environment as a reference point, select one or more other environments, and the server shows the differences in properties on the other environments.

1. From the Deploy dashboard, click **Applications**, and then select an application.
2. Click **Compare Environments**.
3. In the **Select Environments** window, select a reference environment and then select one or more other environments to compare with the reference environment.

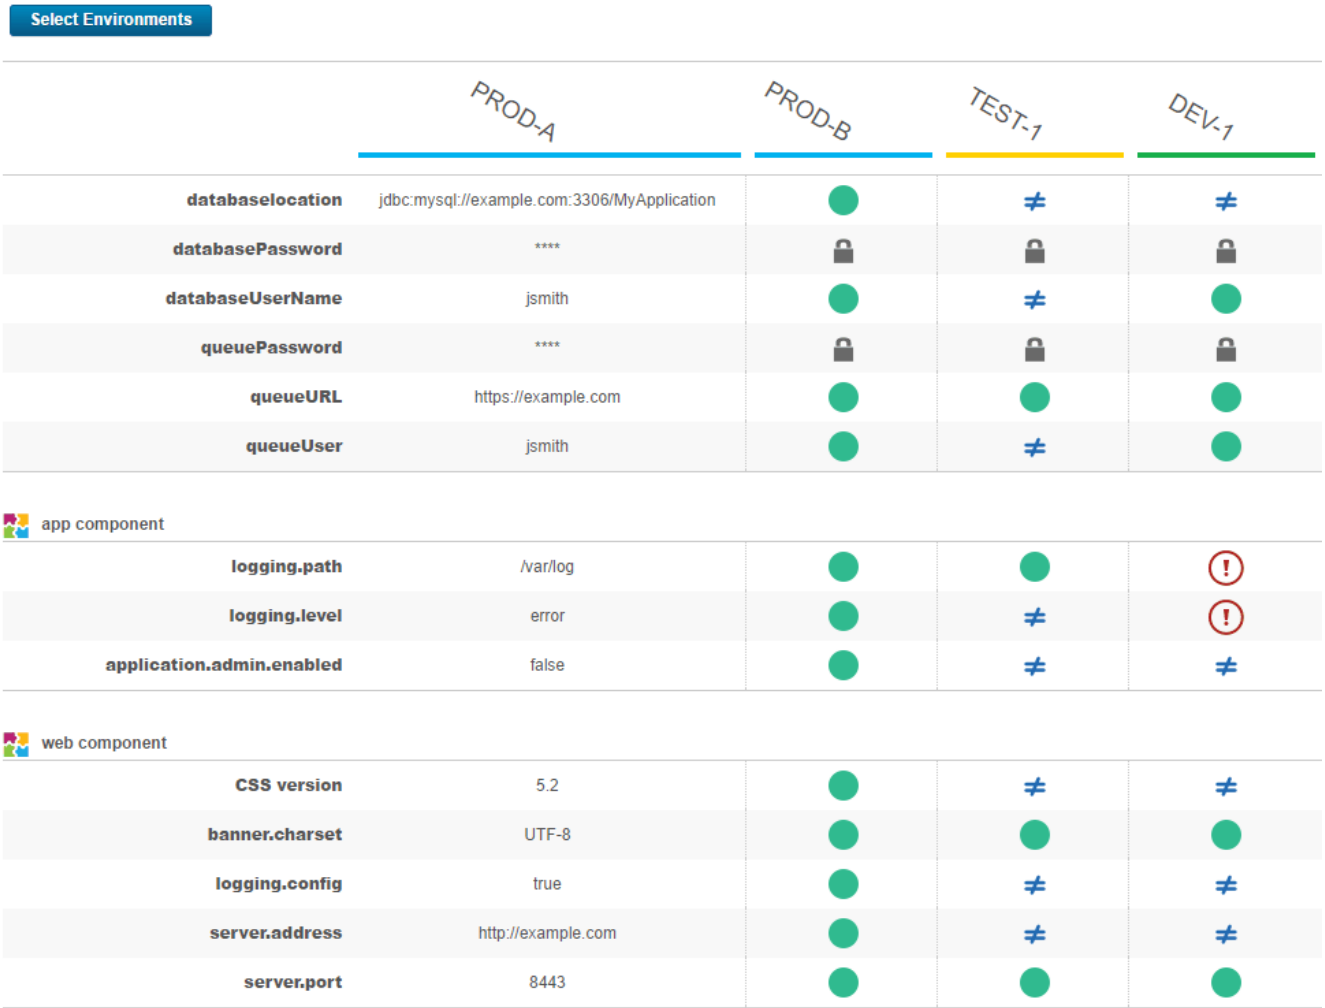
Results

The **Environment Comparison** page shows the differences in properties between the reference environment and the other environments. The reference environment is shown on the left side of the page and the other environments are shown in the columns to the right.

- A green dot indicates that the property has the same value as the reference environment.
- A not equals sign ≠ indicates that the property has a different value than the reference environment.

- An empty circle indicates that the property does not exist on the environment.
- An exclamation point indicates that the property is required, but it does not have a value on that environment.
- A lock indicates that the property is secure. The server does not compare secure properties.

The **Environment Comparison** looks like the following figure:



You can also export the results of the comparison to a CSV file by clicking **Download**. The output file escapes values that start with Excel function characters such as `=`, `+`, `-`, and `@` by prepending an apostrophe. Property values that are longer than 4,000 characters are truncated to 4,000 characters in the output.

Application templates

With an *application template*, you can save and reuse a collection of resources, environments, processes, and tagged components or component templates to create a standardized application.

An application template is a standard framework for users to employ when they create applications. In the application template, you can specify the application properties, environment properties, and environment gates for an application. You can also create a framework that describes attributes of the components, environments, and application processes that an application initially contains. Application templates can contain as many of these elements as required to guide users through the application creation process and to standardize their environments.

Application and environment properties

You specify which application and environment properties are included in applications that are created from the application template. Users must provide values for these properties when they create an application from the application template, and users cannot remove these properties from the application.

Environment gates

You specify which statuses a component version must contain before you can deploy it to an environment. The users cannot modify environment gates in environments that were created by using an application template. To add a version status to a component version, see Adding version statuses on page 2244.

Components

Instead of identifying which components must be used in the application, you can specify which tags that the components that users assign to the application must use.

To control which components users can assign to an application by using the template, you must create a naming scheme for component tags that is relevant to your company. You must also consistently apply the tags to components and component templates. See Adding tags to objects on page 2521.

For example, a simple three-tier web application uses a database, web interface, and application logic. You might tag these components with the following tags: `database`, `web_ui`, and `app_logic`. When you create an application template for this web application, you can specify that the application contain three components, one that uses each of those tags. When users create an application from the template, they can assign to the application one component per tag.

Environments

You can allow users to select environments from the application template. If you do, you must create resource templates that describe the resource tree for each environment. The resource tree can include any agent prototypes, and, if you specify component tags, you can assign the component tags to the agent prototypes. Upon application creation, the components that contain these tags are assigned to the resource tree for the environment. See Creating resource templates on page 2333.

Note: If you create an environment with an environment template and then add component mappings to the resource template, the new component mappings are added to the environment. However, if you

remove component mappings from the resource template, the component mappings are not removed from the environment.

Application process

You can define a simple application process that installs multiple components. Instead of specifying the component and selecting a process, you specify component tags.

To ensure that users can create only applications that adhere to templates, you might create a role for users who create applications from templates. See Creating roles and assigning permissions on page 2188. For more information about role permissions that prevent users from modifying applications to deviate from the application templates, see Application template permissions reference on page 2203.

Note: If users are granted the certain permissions, they can add or remove components, environments, and application templates after they create an application from the template.

Creating application templates

Define application templates so that users can create applications that contain the types of components, the environments, and the resource tree that you specify.

1. Click **Applications > Templates > Create Application Template**.
2. Define the application template:
    a. Enter a name and description, and select the teams that can access the application template.
    b. **Optional:** From the **Notification Scheme** list, select a notification scheme.
    c. **Optional:** To require that a version be provided for each component when a snapshot is created, select **Enforce Complete Snapshots**.
    d. **Optional:** To set the tags that components must use to be assigned to an application during creation, select tags from the **Required Component Tags** list. You specify the minimum, maximum, or exact number of components that contain the tag that the user must select.

        Note:

        By selecting component tags, you limit only the components that a user can assign to an application during its creation. If they have permission, users can add other components to an application after they exit the wizard.

    e. Click **Save**.
3. **Optional:** Define application properties.
   The application properties that you define are included in all applications that use this application template.

a. Click **Configuration**. This **Configuration** tab is associated with the application template that you created, not the main **Configuration** tab.
b. Click **Application Property Definitions**.
c. Click **Add Property**, define the property, and click **Save**.

4. **Optional:** Create an application process.
   The application process that you define is included in all applications that use this application template.

   a. Click **Processes**. This **Processes** tab is associated with the application template that you created, not the main **Processes** tab.

   b. Click **Create Process** to open the **Create an Application Process** dialog box, and create the application process. See Creating application processes on page 2429.

   c. Edit the process in the process editor. See Editing processes on page 2453.

   Note: In the process editor, you can select only a limited number of process steps, such as the **Install Multiple Components** and **Run Operational Process for Multiple Components** steps.

5. **Optional:** Create environment templates.
   The environments that you define can be used by all applications that use this application template. When applications are created from application templates, multiple environments can be created from each environment template. You must assign a resource template to an environment template.
   See Creating environment templates on page 2372.

   Note: To minimize additional steps after you create an application from this template, ensure that the resource template that you select specifies both agent prototypes and the component tags that you selected.

   Note: If you create an environment with an environment template and then add component mappings to the resource template used by the template, the new component mappings are added to the environment. However, if you remove component mappings from the resource template, the component mappings are not removed from the environment.

6. **Optional:** Create environment gates.
   The environments gates that you define must be used by all applications that use this application template and cannot be removed from these applications.
   See Creating environment gates on page 2361.

What to do next

By using team object mapping, grant the team access to application template, agents, component instances, component templates, environment templates, and resource templates. See Mapping teams to objects on page 2215.

Creating applications from application templates

Create an application from a template to apply a set of tagged components, environments, and the specified resource tree to the application.

Before you begin

Confirm that your role has access to an application template and the permissions that are needed to create an application from a template. See Permissions reference for using application templates on page 2203.

1. Click **Applications**, and then click **Create Application**.
2. Complete the information in the **Create Application** dialog box.
   See Creating applications on page 2346.

   Note: You must select the application template from the **Application Template** list.

3. If the application template specifies application properties, you must complete them.
   Application properties are listed at the bottom of the dialog box, after the **Enforce Complete Snapshots** option.

   Note: You cannot delete application properties that you create with the application template. After you create the application, you can view and edit these properties. Open the application, click the **Configuration** tab (not the **Configuration** tab at the top of the page), and then click **Basic Settings**.

4. Click **Next**.
5. Select components from the appropriate lists or create components to satisfy the listed requirements.
   You must select or create the number of components that is specified for each tag type.

   Note: To create components, you must have permission to create components from templates. You can only create components from component templates that contain the tag that is specified in the application template.

6. Click **Next**.
7. **Optional:** Create the environments to use in this application.
   By default, one environment is shown for each environment template in the application template. You can create more environments that use the same template or remove any environments, including those environments provided by default.
   Choose from:
   - To create another environment, click **Create an environment from a template** , and then select the environment from the list. An environment is added to the **Environment list**. The environment name contains the name of the environment template and a unique number.
   - To create a copy of an environment, select the environment and click **Duplicate the selected environment** . An environment is added to the **Environment list**. The environment name contains the name of the

source environment name and "copy." The new environment contains the same values for the description and properties values as the source environment.

- To remove an environment, select the environment from the **Environments** list, and then click **Delete the selected environment** .

Note:

When creating an application from an application template and no environment is selected, a resource named after the application is also created.

Note: You cannot delete an application template if it is in use by an application. You cannot delete environment properties that you create with the application template. After you create the application, you can view and edit these properties. Open the environment, click the **Configuration** tab (not the **Configuration** tab at the top of the page), and then click **Basic Settings**.

8. If an environment template contains environment properties, provide values for them.
   You must provide values for required environment properties. If an environment contains required properties, a blank circle is displayed in the same row as the environment name. When all required environment properties are provided, the circle is shaded.
9. Click **Next**.
10. **Optional:** If you specified environment templates, add agents or agents pools to them.
    Drag an agent/agent pool onto each agent prototype that is shown in the **Environments** pane. If you drag multiple agents onto an agent prototype, a copy of the resource tree for the agent prototype is created for each agent.
11. Click **Save**.

Creating environment templates

When you create an application template, you can define environment templates that model environments for the applications that you create by using the application template.

Before you begin

Ensure that you have a resource template that describes the resource tree for this environment in the application. Include both the component tags that the application templates uses and agent prototypes. See Resource templates on page 2333.

Some of the configuration options might be restricted based on the role assigned to you. Check with your administrator, if you need a specific option enabled.

Create environment templates as follows:

1. Click **Applications > Templates**, select your application template, and then click **Environment Templates > Create Environment Template**.
2. Specify the environment name.

If you create an environment from this template, the environment is assigned this name by default. The name is used as part of the deployment process and typically corresponds to the target environment.

3. Provide the following information:

    a. Specify a description.

    b. **Required:** In the **Resource Template** list, select the resource template to use for the environment.

    c. To set the environment security type, from the **Type** list, select the security type.
    The security type is automatically assigned to environments that you create when you create an application from a template. If you specify an environment template when you add an environment to an existing application, you must manually assign the security type.

    d. To grant teams access to the environment and set the security type for the environment template, click **Add Teams**, select values from the **Team** and **Type** lists, and click **Add**.

    e. To ensure that components cannot be deployed to the environment without first being approved, specify the **Deployment Approvals** information. If specified, Deploy enforces an approval process before the deployment can be deployed to the environment. Initial deployments are typically done in uncontrolled environments. After the deployment works as designed, you can configure an approval process as the application moves along the development pipeline. If you are setting up more than one environment, consider creating an approval process for at least one of them.
    You can apply two types of approvals to an environment, that is, external and manual approvals.
        - Specify a **Resource Type to Run External Approval**. You can select **System Default** for the values specified in the system settings, an **Agent Pool** to specify a group of agents, or an **Agent**.
        - Choose an existing **External Approval Process** to run. See Managing external approval processes on page 2392 for information about how external approval processes are created.
        - You can **Exempt Processes** from approvals even if it is required by an environment.
        - Enable **Require Manual Approvals** to allow approvals from users in a role specified by the approval process created for the environment. See Creating an approval process on page 2388 for information about how manual approval processes are created. To prohibit the user who makes an approval request from approving the same request, select **No Self-Approvals**.

    f. To prevent changes to snapshots in this environment after you deploy them, select the **Lock Snapshots** check box.

    g. If you selected the **Lock Snapshots** check box, from the **Snapshot Lock Type** list, select the lock type:
        - To lock only component versions, select **Only Component Versions**.
        - To lock snapshot configurations, select **Only Configuration**.
        - To lock both component versions and configurations, select **Component Versions and Configuration**.
        - To use the system default value, select **System Default**. The default value is determined by the **Default Snapshot Lock Type** field on the **System Settings** page. For information about system settings, see System settings on page 2086.

    h. Select a color to apply to the environment.

i. To apply the component version and snapshot cleanup settings that are specified on the **System Settings** page, select the **Use Default Artifact Cleanup Settings** check box.
If this check box is cleared, you must specify how long to keep snapshots and component versions. For more information about cleaning up snapshots, see Cleaning up snapshots on page 2143.

To apply the component version cleanup settings that are specified on the **System Settings** page, select the **Use Default Artifact Cleanup Settings** check box. If this check box is cleared, you must specify how long to keep component versions. For more information about cleaning up component versions, see Cleaning up component versions on page 2136.

j. To apply deployment history cleanup, select the **Use Deployment History Cleanup** checkbox.
You can use the default settings that are specified on the **Systems Settings** page by clicking **Use Default Deployment History Retention**, or in **Days to Retain Deployment History** you can specify a number of days to retain deployment history records. For more information about cleaning up deployment history, see Cleaning up deployment history files on page 2133.

k. To apply process step logs cleanup, select the **Use Process Step Log Cleanup** checkbox.
You can use the default settings that are specified on the **Systems Settings** page by clicking **Use Default Step Log Retention**, or in **Days to Retain Step Logs** you can specify a number of days to retain step logs. For more information about cleaning up process step log, see Cleaning up process step log files on page 2145.

4. Click **Save**.

Note:

- If you create an environment with an environment template and then add component mappings to the resource template, the new component mappings are added to the environment. However, if you remove component mappings from the resource template, the component mappings are not removed from the environment.
- Changes in a resource template structure are automatically picked up by the resource sync service but any change in the role properties of a resource template will not be synchronized.

Results

The **Configuration** tab for the environment template is displayed. When you use the application template to create an application, you can create environments by using this environment template.

Exporting application templates

Exporting a template creates a JSON file (file extension `.json`) that contains the template's configuration information, resource templates, environment templates, approval processes, application processes, and generic processes.

About this task

To move application templates between servers, you can export the template and import it on a different server. When you import an application template, all resource templates, environment templates, approval processes, application processes, generic processes, and tags that it uses are also imported.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

Note: Exporting application templates in this way includes only the most recent version of each embedded application process.

For information about JSON, see the JSON website.

1. Go to the **Application Templates** pane (**Applications > Templates**).
2. In the same row as the application template to export, click **Actions > Export**.
   Result
   In the default download location for your browser, a file with the same name as the application template is saved. For example, if the application is named `JPetStore`, the JSON file is named `JPetStore.json`.

What to do next
You can import the application to another server that uses the same version of HCL DevOps Deploy (Deploy). See Importing application templates on page 2375.

Importing application templates

If you exported an application template, you can import the template to a different server. When you import an application template, you can create an entirely new template or upgrade an existing one.

About this task
To move application templates between servers, you export the templates and import them to a different server.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

Note: You must create the JSON file that contains a template on a server that uses the same version of HCL DevOps Deploy (Deploy) as the destination server.

When you import an application template, all resource templates, environment templates, approval processes, application processes, generic processes, and tags that it uses are also imported.

1. Open the **Import Application Template** dialog box by clicking **Applications > Templates > Import Application Template**.
2. Click **Choose File**, and then select the name of the JSON file that contains the template.
3. To upgrade an existing application template, select **Upgrade Template**. To create a template, leave **Upgrade Template** cleared.
   If the name of the application template in the JSON file (not the name of the file itself) matches an existing template name, then the template parameters are upgraded. If items such as processes or properties exist, new versions are created. New items, such as processes, environment templates, resource templates, or properties, are also added. If the name of the application template is not found, the import action has no effect.

Note: The application template name is the first parameter in the JSON file. For example,

```
"name": "JPetStore",
```

4. If the application template's processes contain generic processes, use the **Generic Process Upgrade Type** list to specify how the generic processes that are called in the application processes are upgraded or created.
   This selection affects only generic processes, not the application processes in the application template. The import process has different results depending on whether the generic processes exist.

   Note: The server tracks generic processes by name. If a generic process on the destination server is assigned the same name as a generic process that is imported, then the generic process exists on the server.

   - To import an application template without updating the generic processes that are on your server, select **Use Existing Generic Process**. If the generic process does not exist, a generic process is created. If a generic process with that name exists, another version is not created.
   - To create generic processes, select **Create Generic Process**. A copy of the generic process is always created. If a generic process with that name exists, a unique string is added to the new generic process's name. When run, the application process calls the new generic process.
   - To create a fresh installation and ensure that generic processes are not on the importing server, select **Fail if Generic Process Exists**. If you are creating an application template, it creates both an application template and generic processes unless generic processes exist, in which case the import action fails.

     If you are upgrading an application template, the upgrade fails if the imported application template's generic processes exist.
   - To ensure that generic processes are on the importing server, select **Fail if Generic Process Does Not Exist**. If you are creating an application template, it creates both the application template and generic processes, unless the generic processes do not exist, in which case the import action fails.
   - To upgrade the generic processes, select **Upgrade if Generic Process Exists**. This option creates an application template and versions of the generic processes on the importing server. If the generic processes do not exist, processes are created.
5. In the **Resource Template Upgrade Type** list, specify how to handle resource templates that are being imported, along with the application templates that have the same names as existing resource templates.
   - To import an application template without updating the resource templates that are on your server, select **Use Existing Resource Template**. If the resource templates do not exist, resource templates are created. If a resource template with that name exists, another version is not created.
   - To create resource templates, select **Create Resource Template**. Copies of the resource templates are always created. If a resource template with that name exists, a unique string is added to the new resource template's name. When run, the application process calls the new resource template.
   - To create a fresh installation and ensure that resource templates are not on the importing server, select **Fail If Resource Template Exists**. If you are creating an application template, it creates both the application template and resource templates unless resource templates exist, in which case the import action fails.

If you are upgrading an application template, the upgrade fails if the imported application template's resource templates exist.

- To ensure that resource templates are on the importing server, select **Fail If Resource Template Does Not Exist**. If you are creating an application template, it creates both the application template and resource templates unless the resource templates do not exist, in which case the import action fails.
- To upgrade the resource templates, select **Upgrade Resource Template If Exists**. This option creates an application template and versions of the resource templates on the importing server. If the resource templates do not exist, resource templates are created.

6. Click **Submit**.

Application processes

Application processes, like component processes, are created with the process editor. You use application processes to deploy or to roll back components.

Tip: For full coverage of application processes, see Application processes on page 2428 and its subtopics.

HCL DevOps Deploy (Deploy) provides several common process steps. Otherwise, application processes are assembled from processes that are defined for their associated components.

Application processes can run manually, automatically on some trigger condition, or on a user-defined schedule. When a component has several processes, the application determines which ones run and in which order. For instance, an **n**-tiered application might have a web tier, a middleware tier, and a database tier. And, continuing the example, the database tier must be updated before the other two, which are then deployed concurrently. An application can orchestrate the entire process, including putting target servers online and offline for load balancing as required.

Importing specific application processes

Application processes define the steps required to deploy, manage, or rollback specific application. You can import specific application processes to reuse a standardized deployment across multiple applications or environments without recreating a process each time.

Before you begin

You must have ensured that the application process source file to be imported is a JSON or YAML file.

About this task

By importing processes in HCL DevOps Deploy (Deploy), you can incorporate specific deployment logic for applications and reuse them across different environments.

Note: When you export components, applications, processes, or templates, and then import them on a different computer, you must ensure that you install the same versions of the same plug-ins on both computers.

1. Log in to Deploy.
2. Click **Applications**.
   The list of Applications is displayed.
3. Select the application to which you want to import the process.
4. Click **Processes > Import application process**.
   The **Import application process** dialog is displayed.
5. Select **Process Upgrade Type** from the dropdown list.
6. Click **Choose File** to upload the import process source file that you want to import.

   Notes:
   - You must create the JSON file that contains the component definition on a server that uses the same version of Deploy as the destination server.
   - Only JSON and YAML file types are supported.

7. Click **Submit**.

Results

You have imported the specific application process. The imported application process is listed in the **Processes** tab for the application.

What to do next

You can set environment-specific properties by editing the process in the process editor. See Editing processes on page 2453.

Related information

Applications on page 2344

Processes on page 2398

Exporting specific application processes

You can export specific application processes to save and share deployment configurations for reuse across environments.

Before you begin

You must have identified the application processes that are to be exported.

About this task

Exporting application processes creates JSON or YAML file (file extension), that contains processes for the applications. For more information about JSON, see http://www.json.org/. You can export one or more specific application processes as YAML or JSON files.

Note: When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

1. Log in to Deploy.
2. Click **Applications**.
   The **Applications** page is displayed.
3. Click the appilcation from which you want to export specific application process.
4. Click **Processes**.
   The list of associated processes with the selected application are displayed.
5. Export the processes using any of the following methods:.
   - To export processes in bulk:
     a. Select the processes to be exported.
     b. Click **Bulk Actions**.
     c. Select **Export to JSON** or **Export to YAML**.
   - To export a latest promoted process:
     a. Click the menu option of the process to be exported.
     b. Select **Export to JSON** or **Export to YAML**.

Results

You have exported the specified application processes to your local system in the selected file format.

What to do next

After exporting, you can import them into other instances for future use.

Processes on page 2398

Application blueprints

An application blueprint maps application components to a resource template. When you create an environment or provision one from the cloud, you can use the blueprint as a model.

A blueprint begins with a resource template. This resource template specifies a collection of resources, typically including agent prototypes. In the blueprint, you place components on these agent prototypes. The resulting blueprint provides a pattern for an environment, including which components are deployed on which agents.

Creating application blueprints

To create an application blueprint, map the components of the application to a resource template.

Before you begin

Create a resource template as described in Creating resource templates on page 2333.

1. Click **Applications**, click your application, and then click **Blueprints**.
2. Click **Create Blueprint**.
3. Specify a name for the blueprint and select the resource template.
4. Click **Save**.

   Result

   The new blueprint opens, showing the contents of the template, including the agent prototypes.
5. Map the components of the application to the agent prototypes:

   a. Hover the mouse over an agent prototype and then click **Actions > Add Component**.

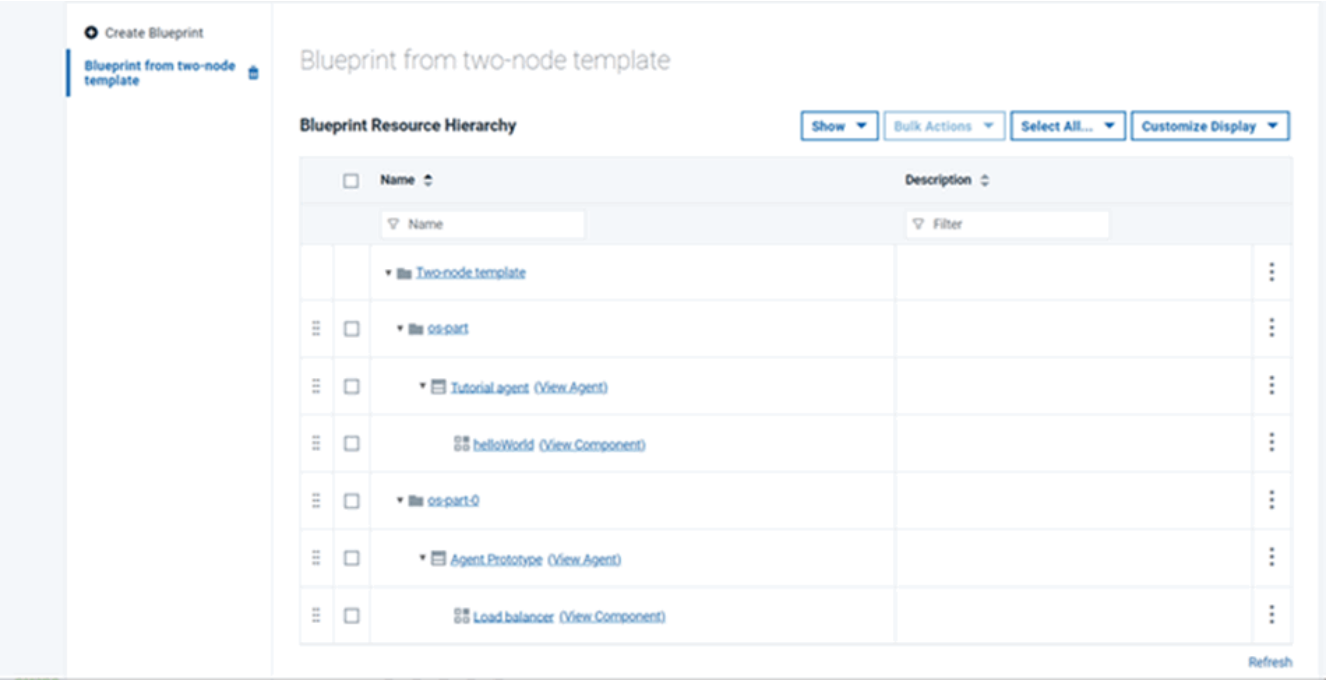
   b. In the window that opens, select a component, specify its information, and click **Save**.

   c. Repeat this process to add the application components to the agent prototypes.
   Depending on how your application is organized, you can add the same component to multiple agent prototypes or multiple components to the same agent prototype.

Note: If you create an environment from this blueprint and then add component mappings to the blueprint, the component mappings are also added to the environment. However, if you remove component mappings from the blueprint, the component mappings are not removed from the environment.

Results

The complete application blueprint shows how the components are mapped to the agent prototypes. The following example shows a simple blueprint. The resource template contains two agent prototypes. In the blueprint, one component is mapped to each agent prototype.



What to do next

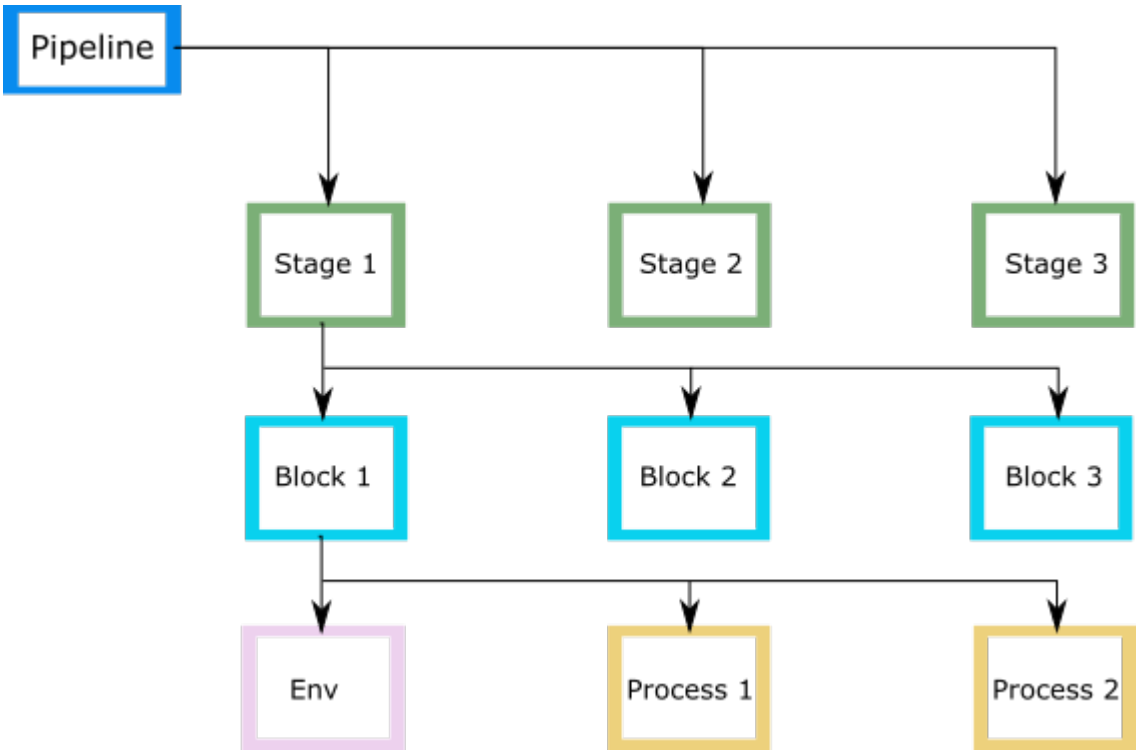
Create environments that are based on this blueprint.

Application pipelines

Allows you to run application processes in multiple environments and promote versions through a set of stages.

Application pipelines includes an ordered list of stages. Each stage in a pipeline is comprised of blocks. A block consists of environments and an ordered list of processes that you want to execute in this block.

The following chart is a graphical representation of an example pipeline definition.



You can create and run multiple pipelines in an application. The pipelines are executed manually.

Managing pipelines

You manage pipelines by defining, editing, deleting, and tracking the execution history of pipelines.

About this task

The structure of a pipeline is defined using JSON format. You can use the following example JSON format to define a pipeline per your requirement:

```
{
    "name": "pipeline-name",
    "stages": [
        {
            "name": "stage-name",
```

```
            "blocks": [
                {
                    "environment": "environment-name",
                    "processes": [
                        "application-process-name-1",
                        "application-process-name-2"
                    ]
                }
            ]
        }
    ]
}
```

Here, `pipeline-name` and `stage-name` are custom names. The `stage-name` can be named to signify the environments you want to deploy. The environment name and application process names must match with the ones existing in the application.

Note: You cannot set properties in the application pipelines. The properties must be preconfigured on the process, environment, and so on.

Manage pipelines from the Applications page as follows:

1. Go to ***application_name*** **> Pipelines > Create Pipeline**.
   The **New Pipeline** window is displayed.
2. Enter a name for the new pipeline and save it.
   The **Code View** tab of the new pipeline is displayed.
3. Define the structure of the pipeline using the JSON format as described above and save it.
   The new pipeline is listed in the **Pipelines** tab. You can manage pipelines by running, editing, or deleting a pipeline. Each pipeline includes its execution history. You can view or cancel a pipeline execution. Note that you can cancel pipelines with Started, Not Started, and Running status only. To run a pipeline, see Executing pipelines on page 2382.

Executing pipelines

After you define a pipeline, you can execute it using the Web UI.

Before you begin

Before executing a pipeline, understand how runtime objects such as stage and blocks act in a pipeline exection:

- Pipeline execution:
  - Stages are executed sequentially.
  - The next stage starts only when the previous stage is completed successfully.
  - A pipeline completes successfully only when all stages are completed successfully.
- Stage execution:
  - Each block in a stage is executed concurrently.
  - A stage completes successfully only when all blocks complete successfully.

- Block execution:
  - Each process is executed sequentially.
  - The next process starts only when the previous process is completed successfully.
  - A block completes successfully only when all processes are completed successfully.

About this task

Execute a pipeline from the Application page as follows:

1. Go to ***application_name*** **> Pipelines > Pipeline Execution** or click on play button next to a pipeline.
2. Select a snapshot or choose a component version that you want to deploy.
3. Click on **Submit**.
   The pipeline executes and shows the runtime objects that further represents the execution status. An execution have statuses such as Not Started, Starting, Running, Canceling, Completed, and Canceled.

Results

The historical record of completed pipelines or any running pipeline execution is listed in the **History** tab. A pipeline execution can be tracked for the details such as Status, Started date and time, Completed date and time, Payload, and Initiated By.

Snapshots

A *snapshot* is a collection of specific versions of components and processes. Typically, a snapshot represents a set of component versions that are known to work together. In most cases, snapshots include all of the components in an application.

A snapshot is typically created when a successful deployment runs in an uncontrolled environment, where there are no approval gates. Snapshots can be created in controlled environments too. When a snapshot is created, a picture of the application's current state is captured. As the application components move from one environment to another, HCL DevOps Deploy (Deploy) ensures that the exact versions and processes that you selected are used in each environment.

Snapshots can help manage complex deployments, which have multiple environments and development teams. For example, after you test and confirm that team A's component works with team B's component, you can create a snapshot. Then, as development progresses, you can create more snapshots to model the effort and drive the entire deployment, coordinating versions, configurations, and processes.

Creating snapshots

To create a snapshot, you specify which version of components and processes to include in the snapshot. Typically, to create a snapshot you copy the components and processes from an environment where you deployed the application without errors.

1. From the dashboard, click **Applications**, and then select an application.
2. On the application page, click **Snapshots**, and then click **Create Snapshot**.
3. Type the name of the snapshot in the **Name** field, and type a description in the **Description** field.

4. Click **Save**.

   Result

   The **Component Versions** page opens for the new snapshot. All the components in the application are listed.
5. Add component versions to the snapshot.

   Choose from:

   - Typically, you create a snapshot by copying versions of components from an environment in which you deployed and tested the application without errors. To copy the component versions in an environment, click **Select For All**, and then click **Copy from Environment**. Select the environment from which to copy component versions and processes. This procedure copies the currently deployed versions of the components from that environment.
   - To create a snapshot that includes the component versions from another snapshot, click **Select For All**, and then click **Copy from Snapshot**.
   - To select component versions individually, for each component click **Add** in the **Versions** column. After you click **Add**, click the **Versions** field to select a version of that component that is available in CodeStation. To select all the latest versions or to select all versions that match a name pattern, click **Select For All** and then select the appropriate option from the list.
6. **Optional:** To refine the versions of the component processes in the snapshot, click **Configuration > Advanced Settings**. By default, the most recently defined version of each component process and property is used. `Latest` is displayed in the **Versions** column, with the actual version in parentheses.
   - To select a specific version of a process or property, click **Set Version** in the **Actions** column.
   - To set all processes and properties to use the latest versions at the time of deployment, click **Reset All to Latest**. In this case, the processes and properties use the most recent versions that are available at the time you run the deployment.
   - To set all processes and properties to use the most recent version that is currently available on the server, click **Set Latest Entries to Current**. In this case, the processes and properties use the most recent versions that are available at the time that you click **Set Latest Entries to Current**. Any changes that are made to processes and properties after this operation are not automatically absorbed into the snapshot.
   - To permanently prevent any changes to the snapshot, click **Lock Configuration**.

     Warning: After you click this button, no changes can be made to the snapshot. This setting cannot be reversed.

7. **Optional:** To lock snapshot component versions, using the **Applications** page, select an application, then click **Snapshot > *snapshot name* > Component Versions**. By default, the lock setting is determined by the option selected in the **Lock Snapshots** field on the **Create Environment** window. To lock previously unlocked component versions, click **Lock Versions**.
8. **Optional:** To lock a snapshot configuration, using the **Applications** page, select an application, then click **Snapshot > *snapshot name* > Configuration > Advanced Settings**. By default, the lock setting is determined by the option selected in the **Lock Snapshots** field on the **Create Environment** window. To lock an unlocked snapshot configuration, click **Lock Configuration**.

Alternately, you can automate snapshot locks within a process by using the **Lock Snapshot** process step. See Lock Snapshot on page 2480.

Note: When you add a new configuration to a snapshot that is locked, that new configuration will not be locked automatically.

Lock Snapshot on page 2480

Deploying snapshots

After you create a snapshot, you can deploy the snapshot to an environment.

About this task

Deploying a snapshot deploys the components in the snapshot. The components are deployed in the order in which they were added to the snapshot or to the environment on which the snapshot is based.

1. From the dashboard, click **Applications**, and then select an application.
2. On the application page, click **Snapshots**, and then select a snapshot.
   Result
   The environments that are defined for the application are listed at the bottom of the **Dashboard** page.
3. For the environment where you plan to deploy the snapshot, click the **Request Process** icon.
4. To deploy component versions whether or not they are already deployed, clear the **Only Changed Version** check box. By default, the **Only Changed Version** check box is selected so that only changed versions of components are deployed.
5. Select the deployment process to run from the **Process** list.
6. To run the process in the future, select the **Schedule Deployment** check box.
   Result
   If you select the **Schedule Deployment** check box, more fields become available so that you can specify the date and time to run the process, and configure the process to run on a recurring basis.
7. Click **Submit**.
   Result
   Unless you scheduled the process to run in the future, the application process starts and deploys the snapshot.

Comparing snapshots

You can compare two snapshots to see differences in the files that they contain.

1. From the dashboard, click **Applications**, and then select an application.
2. On the application page, click **Snapshots**.
3. In the **Actions** column, click **Compare** for one of the snapshots to compare.
4. From the **With Snapshot** list, select the other snapshot to compare, and then click **Save**.

Result

The **Snapshot Comparison** page opens. The component versions that are contained in each snapshot are displayed.

5. To see the differences between processes and properties in the two snapshots, click the **Configuration** tab.
6. To see the differences between files in the two snapshots, click the **Compare Files** tab.
7. To see the differences between properties in the two snapshots, click the **Properties** tab.

Previewing snapshots

You can preview an application snapshot before you deploy it to see the upcoming changes in resources and properties.

1. From the dashboard, click **Applications**, and then select an application.
2. On the application page, click **Snapshots**, and then select a snapshot.
3. Under **Environments**, for the environment in which to preview the snapshot, click **Preview**.

   Result

   The **Preview Deployment** window opens.
4. From the **Process** list, select a deployment process.

   Result

   The **Deployment Preview** page opens. The changes to be made to resources and components are displayed.
5. To see the changes to be made to properties, click the **Configuration Changes** tab.

Importing and exporting snapshots

You can import and export snapshots to transfer snapshots and component version artifacts to different servers.

Before you begin

Make sure that the application and the components in the snapshot exist on the target server.

Note: Exporting snapshots in this way includes only the versions of the components that are in the snapshot. However, the exported snapshot always includes the most recent versions of component processes.

About this task

To export a snapshot, go to the **Snapshots** tab for an application and next to the snapshot, click **Export**. The server stores the snapshot, the component versions, and the plug-ins that the components use in an archive file.

To import the snapshot on another server, open the application, go to the **Snapshots** tab, and click **Import Snapshots**.

Note: You must create the archive file that contains the snapshot on a server that uses the same version of HCL DevOps Deploy (Deploy) as the destination server.

Viewing snapshot history

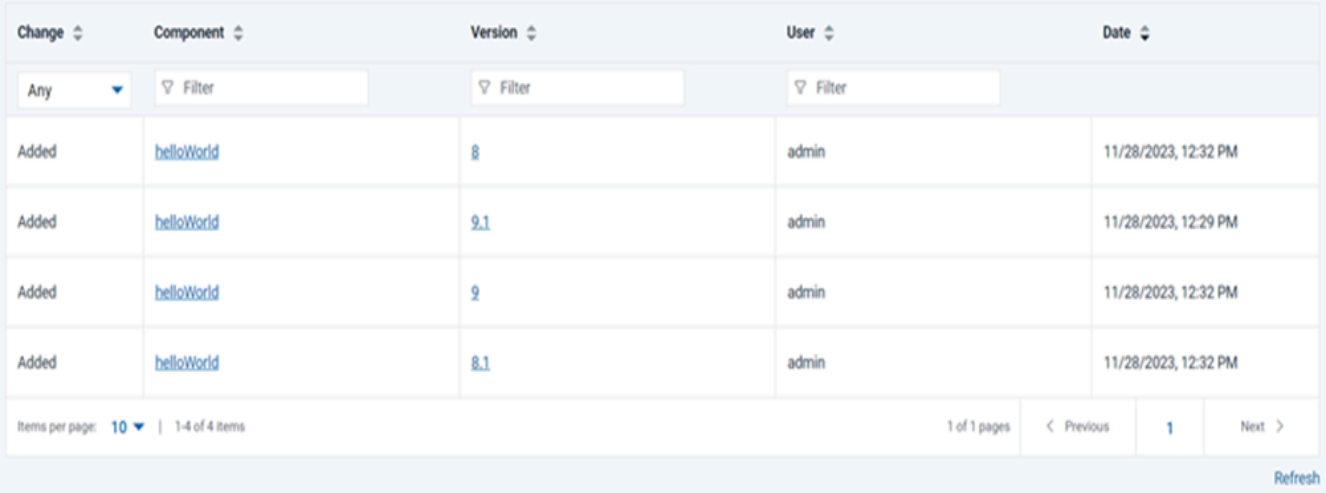
You can track changes to component versions included in a specific snapshot from the **Changes** tab.

Before you begin

Make sure that the application and the components in the snapshot exist on the target server.

About this task

To view a snapshot history, select an application, click **Snapshots > *snapshot name* > Changes**. The **Changes** tab displays the list of changes made to the selected components versions of the snapshot.



You can view the following changes for a snapshot:

- Whether the version is added or removed.
- Impacted component name.
- Impacted component version.
- User responsible for change.
- Time and date of the change.

Manual application tasks

A manual application task interrupts an application process until manual intervention is done. To create a manual task, add a manual step to an application process and select a notification template.

1. Open an application process in the process editor.
2. From the **Utility Steps** folder, add a **Manual Application Task** step to the process.
3. In the **Edit Properties** window, specify the following properties for the step:

Table 731. Manual Application Task properties

Field	Description
Name	The name for the manual task.
Notification Template	Specify a notification template. The individual tasks map to the notification scheme used by the application (see Creating Notifications in a Notification Scheme on page 2081). If you do not want notifications created for the task, select **None**.

Field	Description
Require Comment	Enforces the approver to give a reason for approving or rejecting the task.
Comment Prompt	Type a comment for the approver before they approve or reject the task. You can add properties to the comments. For example, you can use the **snapshot.name** property for approver to identify for which snapshot the approval is required. See Properties on page 2500.
Approver requirements	**Only the deploying user** Restricts approval to the user who started the deployment. **Specific users or group** Allows you to select users or groups that can approve the task.
Add Property	Add one or more properties to the task. You can use these properties later in the process just like output properties from other steps.

4. Click **Save** to save the properties for the step.
5. Include the manual task in the process as with any other step.
6. Save the process.

Results

When you run the process, it pauses at this step, sends a notification, and waits for approval before the process continues. To approve the task and resume the process, click the **Respond** link for the step in the process log, click **Approve**, and then click **Submit**. You can also resume the process from the **Work Items** tab.

Approval Process

You can add approval requirements to deployments. Deployments with approvals cannot be completed until all approvers respond. Approvers can respond to requests on the **Work Items** tab, or by email.

Approval processes are created when you want a manual intervention in executing a particular task or process step. There are two ways in which you apply approval process:

- Generic approval process
- External approval process

Notifications such as an email message can be sent to the approver assigned for each approval process. Configure notification schemes from the Notifications tab of the Settings page.

Creating an approval process

You can add approval requirements to deployments. The approval process identifies the deployment and the role of the approver. You respond to approval requests on the **Work Items** page, or, depending on the configuration, through email.

Before you begin

Before an approval process can be configured, these prerequisites must be met.

- An **ApprovalCompleted** notification template exists for use in the approval process.
- **Require Approvals** is enabled for an environment. In the application environment, select **Configuration** at the task bar and ensure that the **Require Approvals** check box is enabled in the **Basic Settings** window. **Approval Process** will be enabled in the environments task bar.
- The email approval feature is available in notification templates created in V7.1.1 and later. Because templates are not overwritten when you upgrade, you must manually add the email approval feature to your template if you upgrade from a version prior to 7.1.1. To add the feature to your template, paste the following script into your email templates:

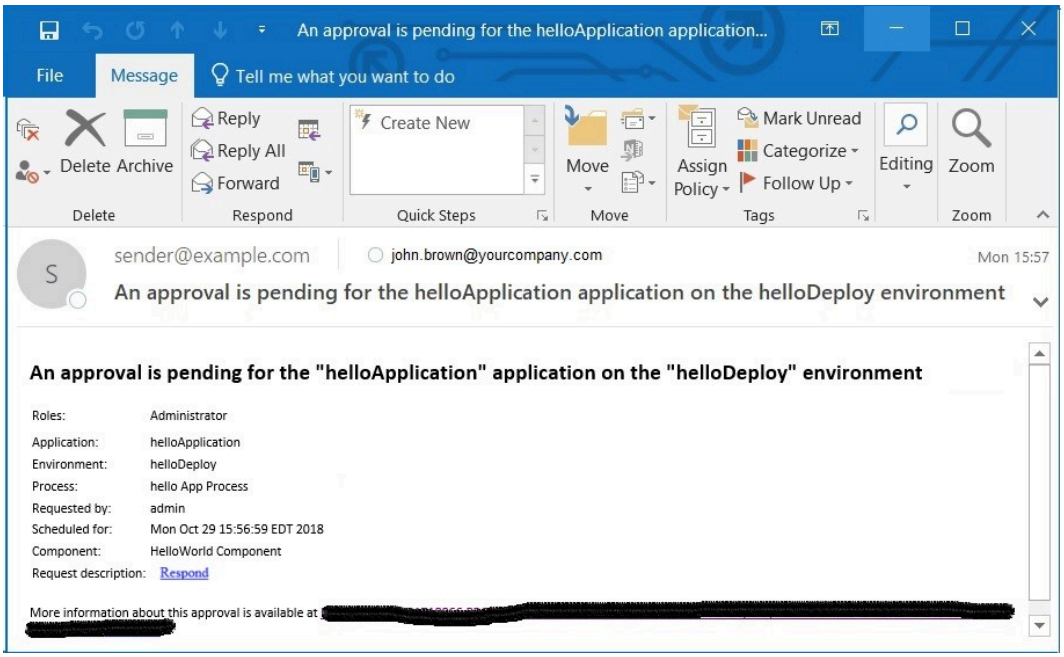
```
#if ($respondUrl)
      <tr>
          <td><a href="$respondUrl">Respond</a></td>
      </tr>
  #end
```

Note: You can add the script to all email templates but currently the `respondUrl` property is only available for TaskCreated and ApprovalCreated notifications.

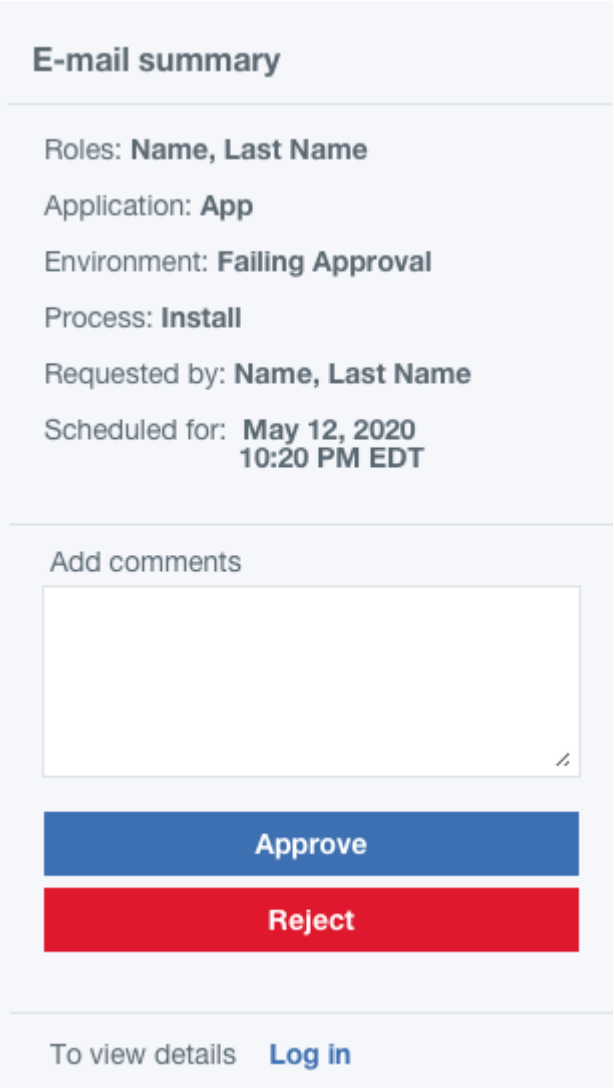
Tip: You can also select the **No Self-Approvals** check box that follows the **Require Approvals** check box. When this check box is selected, the user who sets up of the approval process cannot subsequently approve the process.

1. To create an approval process, display the **Approval Process Design** pane (**Applications > *application name* > Environments > Environment: *environment name* > Approval Process**.
2. Configure the steps that need approval from the process editor. The steps are based on job type and the role of the approver. You have the option of selecting three job types: the application, component, or environment. For help on the process editor, see Processes on page 2398.

   When the process runs, the approver is notified with an e-mail that an approval is required. An example of a default **ApprovalCreated** notification template is shown below.



The e-mail notification includes the **Respond** option that directs the approver to the E-mail summary page. An example of the E-mail summary page is shown below:



This allows the approver to take appropriate action without logging into the Deploy.

Note: The Approve and Reject links expire in 5 days from the date of approval is requested.

Note: If a scheduled deployment that requires approval reaches its start time and the approval is not given, the process does not run and acts as a rejected request. To resubmit a request, you must request a new process. If a process with an approval does not have a scheduled deployment time, the process remains idle until a response is made.

What to do next

- View the status of the request by displaying the **Deployment Detail** pane on the **Reports** tab. If a request is approved, it is displayed as a success. However, if the request was rejected, it shows as failed. If a request is failed, display the **Application Process Request** by clicking **view request**.
- If a comment is made regarding the process, you can view it by clicking the log push button in the actions column on the **Application Process Request**.

Managing external approval processes

If you have a process step that requires validation on an external application before deployment, you can create an approval process and assign it to environments. With this approval process, the deployment runs automatically and only when it is approved.

Before you begin
Ensure that the:

- Notification templates such as Approval Created, Approval Failed, and Approval Completed exist for use in the approval process. For information about how to create notification templates, see Creating Notifications in a Notification Scheme on page 2081.
- **External Approval Settings** in the **System Settings** are configured to use an agent or an agent pool for the external approval process.

1. Navigate to **Processes > External Approval Process**.
2. Click **Create**.
3. Enter a name for the approval process and specify the working directory.
   Optionally, you can provide a process description and add teams to the process.
4. In the process editor, configure the steps that require approval. For help on the process editor, see Processes on page 2398.
   The external approval process definition is complete.
5. Assign the external approval process to an environment.
   a. Click **Applications > *application name* > Environments > Environment: *environment name* > Configuration**.
   b. Enable **Require Approvals**.
   c. Enable **No Self-Approvals** to prevent yourself from approving the process.
   d. Activate **Use Agent Pool for External Approvals** to run the approval process on a group of agents.
      If you turn on this option, specify an agent pool in the **Agent Pool for External Approvals** field.
   e. Select the external approval process to use.
   f. Specify an agent for the approval process in the **Agent for External Approvals** field.

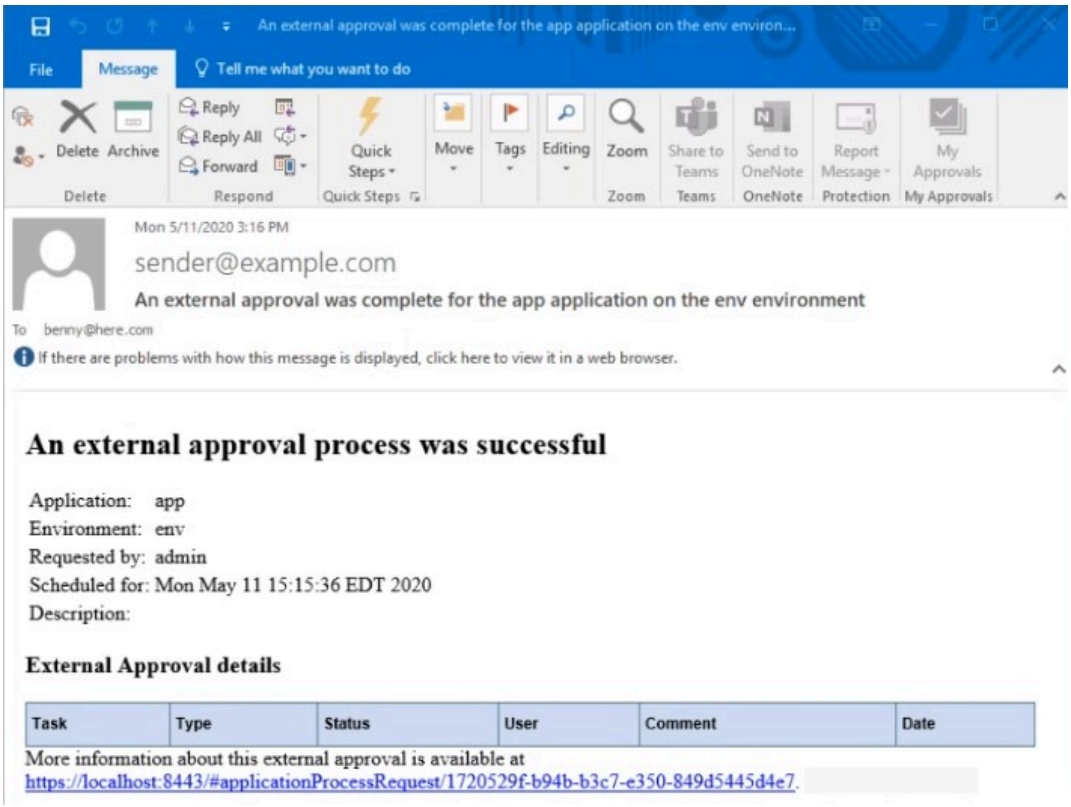
g. Exclude other processes of the environment from the approval process by choosing processes in the **Exempt Processes** list.

h. Save your changes.

The approval process is assigned to the environment.

Result

When an application process runs on the environment, the approver gets an e-mail notification and can approve or reject the request via e-mail. Subsequently, when the request is approved or rejected, the requestor is notified with an email. An example of a default **Approval Completed** notification template follows.



The deployment starts immediately when the request is approved or runs at the scheduled time. If a request is rejected or failed, open the **Application Process Request** by clicking **View Request** and check comments on the approval by clicking the Comment icon in the **Actions** column.

What to do next

You can verify the status of the request by using any of these methods:

- Go to the **Deployment Detail** pane on the **Reports** tab.
- Check the environment history.

An approved request status is displayed with a `Success` label. A rejected request is shown with a `External Approval Failed` label.

Note: While you export or import an application, the approval processes are also included in the export or import.

You can also export and import external approval process individually. While importing, select **Upgrade Process** to import an updated and existing approval process.

Responding to approval requests

If a deployment requires approval, create an approval process that generates an approval request. Approvers respond to the requests on the **Work Items** tab where they approve or deny requests. You can also allow approvers to respond to requests through email.

Until a job is approved, an unscheduled deployment remains idle. If time elapses on a scheduled job that needs approval, the job fails. This control allows the approver to verify the deployment details, and choose the time that it is deployed. Notifications are sent to users who are eligible to complete an approval step if the system is configured with an email server and the user has an email address set.

You can review your approval requests in the **Works Items** tab. This page displays the name of the process, when the request was submitted, who requested the process, and the snapshot or version used. You can also view details of the environment or resource by clicking the link in the **Environment/Resource** column. They can view the details of the target by clicking the link in the target column. Or they can view details on the request by selecting the View Request in the Actions column. The Actions column is also where the approver can respond to the request.

Beginning with version 7.1.1, you can also respond to approval requests through email. An email request provides a link where you can approve or deny the request. The linked-URL does not require a logon to the Web application. If a request requires several approvals, each approver receives a unique link where they can respond.

An open request displays the status as Pending Response. To respond to a request, click actions, and then **Respond**. The approver has the option of leaving a comment. If a request is rejected, the process does not run. If approved, the process begins.

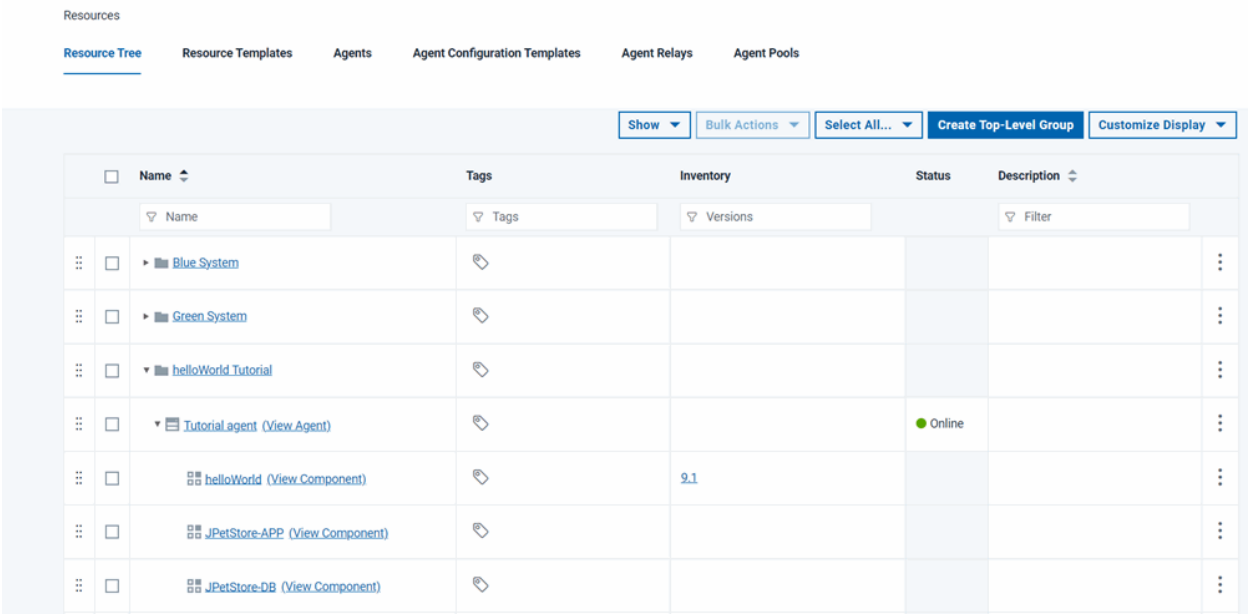
Inventories

You use different *inventories* to track installed components and properties in HCL DevOps Deploy (Deploy) elements.

Inventories provide a complete view of the status and contents of your components. There are different views of the current inventory, depending on your location in Deploy. Inventory information is available on individual components, for every application environment, for each agent resource, and for each component resource.

- The component inventory lists all the resources on which a component is deployed. To see the inventory for a component, click **Components**, click the component, and look on the **History** tab, under **Inventory for Component**.
- The environment inventory lists all the component versions that are deployed to an environment. To see the inventory for an environment, click **Applications**, click the application, and on the **Environments** tab, expand the environment.

- The resource inventory lists all the components that are deployed to an agent resource. To see the inventory for an agent resource, click **Resources**, and expand the resource tree to see which components are installed on which agent resources, as shown in the following figure.



- The resource configuration inventory lists all the properties that are associated with a component resource's elements. To view the configuration inventory for a component resource, click **Resources**, expand the resource tree, select a component, and, from within the component, click the **Inventory** tab. Locate the properties within the **Configuration Inventory**, and click **View** to display the **Property Details** dialog box.

When you create application processes, you have the option of allowing the server to manage the environment inventory and compliance automatically, or to manage the inventory yourself. See Managing environment inventory and compliance on page 2396. Deploy always tracks the component, resource, and resource configuration inventories automatically.

Environment inventory and compliance

The *inventory* for an environment lists the component versions that are intended to be deployed to that environment. *Compliance* shows whether the environment contains those component versions.

The inventory and compliance for an environment are updated each time that you run an application process or deploy a snapshot to the environment. For example, assume that you run an application process that deploys two component versions to an environment. Regardless of whether the application process completes successfully, the environment inventory shows that the two component versions are deployed. The compliance shows how many of the components are installed successfully. In this way, the inventory shows the intended state of a resource or environment, while the compliance shows how closely the resource or environment matches the intended state. By reviewing the difference between the environment inventory and compliance, you can determine whether another deployment is necessary to bring an environment into compliance.

The environment compliance status appears green for compliant environment and red for non-compliant environment. Inventory count is displayed along with the compliance status in the format `number of actual inventory/number of desired inventory`. Here are a few examples of environment inventory and compliance statuses and what they mean:

Status	Description
Inventory: 5/5	The desired inventory is the same as the actual inventory.
Inventory: 2/5 (3 missing)	The desired inventory has more component versions than the actual inventory.
Inventory: 5/5	The desired inventory has the same amount of component versions as the actual inventory, but some versions in the list don't match.
Inventory: 7/5	The desired inventory has less component versions than the actual inventory.
Inventory: 2/2+1	The desired inventory has one fewer version when an attempted uninstall or rollback of a component fails. When a deployment or rollback fails, the incomplete version is removed from the list of desired versions. To troubleshoot component process errors, the inventory display is updated with a "+1" indicator, signifying that a version was removed due to the failure.

The environment inventory and compliance track components but not snapshots or applications. For example, if you successfully deploy a snapshot with two component versions, the inventory is two components and the compliance is two components. If you successfully deploy a different snapshot with versions of two different components, the inventory is four components and the compliance is four components. In this way, the server counts component versions for inventory and compliance, not the versions in a snapshot or applications.

Managing environment inventory and compliance

You can allow the server to manage the environment inventory and compliance automatically, or you can manage the environment inventory and compliance with steps in an application process.

About this task

The inventory for an environment shows the component versions that are intended to be deployed to an environment. The compliance level shows the component versions that are successfully deployed to that environment. For more information about the concepts of inventory and compliance, see Environment inventory and compliance on page 2395.

When you create application processes, you can allow the server to manage the environment inventory and compliance automatically, or you can manage the inventory and compliance yourself. If the inventory management is automatic, the server automatically updates the inventory and compliance for each environment. When you run an application process, the server adds the selected component versions to the environment inventory. Similarly, when component processes run, the server updates the inventory to show which component versions were deployed and which component versions were not.

For example, assume that an application process deploys one component version, but the component deployment process for another component version fails. In this case, the server sets the environment inventory to include the two component versions. The server also sets the compliance to include only the component version that was deployed.

As an alternative, you can manage the environment inventory and compliance manually. In this case, you add steps that make specific changes to the inventory and compliance.

1. In the settings for the application process, set **Inventory Management** to **Advanced**.
2. In the application process, add steps to install, uninstall, or configure component versions as usual.
3. Add the **Component Inventory Update** utility step, and then specify the properties for the step as described in Inventory Update on page 2479.
   Specifically, specify the component to update the inventory for and the changes to make to the inventory and compliance. You can add as many Component Inventory Update steps to the process as you need.
   Example

   For example, to add a component version to the inventory and set the compliance to active, specify the following properties: select the component; from the **Action** list, select **Add Desired Inventory**; and from the **Status** list, select **Active**.

   Note: The Component Inventory Update and Snapshot Inventory Update steps are available only in application processes that have **Inventory Management** set to **Advanced**.

4. **Optional:** If you use snapshots in application processes, add the **Snapshot Inventory Update** utility step. Specify whether to add a snapshot version to or remove a snapshot version from the inventory, as described in Snapshot Inventory Update.

Viewing resource configuration inventories

You can view the configuration inventory for a component, which includes all properties that are associated with the component resource.

About this task

When you deploy a component, you store all the properties that are associated with the component, its application, and its environment on your deployment's resource target. From the resource tree, you can view which properties are active on the component resource.

1. To view the resource tree, complete one of these steps:
   Choose from:
   - To view the entire resource tree, click **Resources**.
   - To view the resource tree for a specific application environment, click **Applications > *application name* > *environment name***.
2. Click the component's name.
3. From within the resource, click the **Inventory** tab.
4. In the **Configuration Inventory** pane, locate the property to examine.
   You might have to expand several levels to locate the properties.
   Example
   To view the properties that are associated with the component, expand both **Components** and the component itself.
5. In the same row as the properties, click **View**.

Result

The **Property Details** dialog box is shown.

6. Review the contents of the **Property Details** dialog box.
   The dialog box contains the following information:
   - The versions of properties that are stored on the resource target
   - The name and value of each stored property
7. Click **Cancel** to return to the resource tree.

What to do next

If the resource target does not contain the correct version of the properties, you can configure a component process to update the properties. See Component process types on page 2423.

Processes

Processes are automated tasks that run on agents.

There are three types of processes:

- Generic processes run outside the context of components or applications. Generic processes are shown on the top-level **Processes** tab. You can use generic processes in these instances, for example:
  - In conjunction with a number of different component processes that do not fit well into a component template
  - When you want to run processes that directly affect HCL DevOps Deploy (Deploy) agents that are unrelated to component, such as changing the agent configuration
- Application processes run within the context of applications. In many cases, application processes call component processes. For example, an application process can call the component processes that deploy their associated components.
- Component processes run tasks on a single component, such as deploying it, uninstalling it, or running configuration tasks on it.

Processes are lists of steps and connections between those steps. Each step is an individual command that runs on a target computer. Steps can manipulate files, run system commands, download files, and run programs. Plug-ins contribute most of these steps; plug-ins are available that work with many different types of software.

You use the process editor to work with processes. See Editing processes on page 2453.

Each time you request a process, the server keeps a log of information about the process and the individual logs from each step. To download these logs, open the process request and click **Download All Logs**.

Process step types and logic

When you design processes, you use different kinds of process steps and joining techniques. You can assign properties to process steps and use them to control step execution.

Conditional processes

Every connection (except connections from the Start step) has a delete tool and conditional flag. The conditional flag sets a condition on a connection.

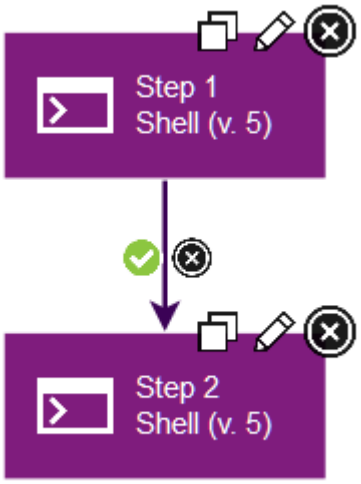
To change a flag value, cycle through possible values by clicking the flag.

The possible conditional flags are as follows:

- `success`: The process is complete.
- `fail`: The process did not finish.
- `both`: The process is complete or the process did not finish. Either status is acceptable, and the next step can start.

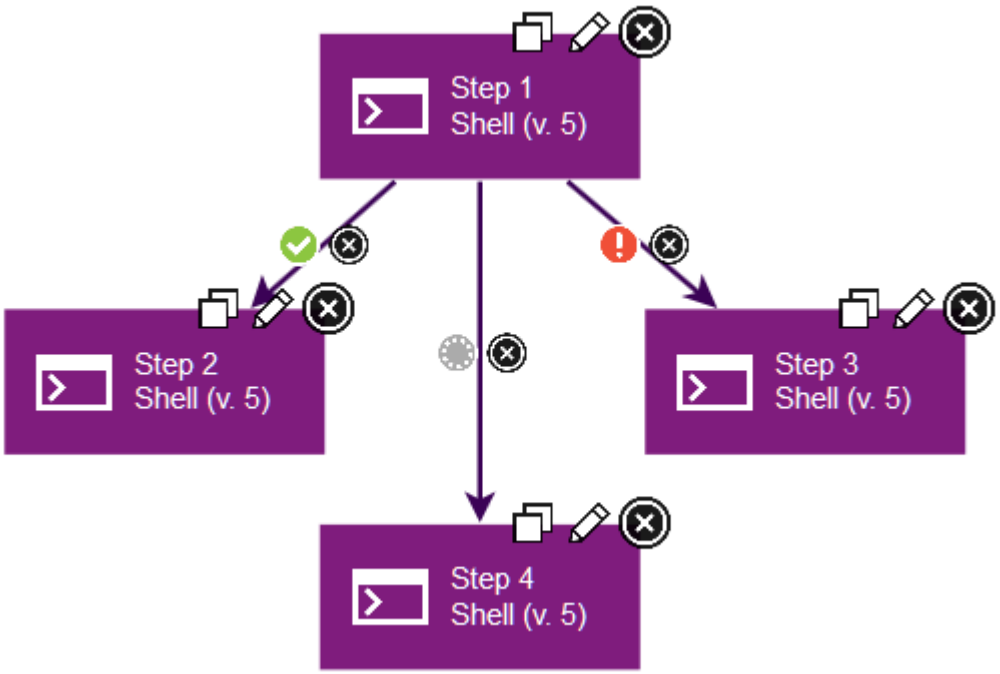
By default, all connections have the flag set to checked (success), meaning the originating step must end processing before the target step starts to process.

The following figure shows two steps that are connected with a `success` conditional flag, which is the default for new connections. In this case, if the first step finishes, the process follows the connection to the second step. If the first step fails, the process ends, and the second step does not run.



A step can have multiple connections with different conditional flags. For example, the following figure shows a step with three connections:

- The connection to step 2 has a `success` flag. Step 2 runs if the first step finishes.
- The connection to step 3 has a `failure` flag. Step 3 runs if the first step fails.
- The connection to step 4 has a `both` flag. Step 4 runs regardless of whether step 1 finishes or fails.



Note: If a step has multiple connections that eventually reach the same target step, determining whether the target runs depends on the value of the intervening flags. If all of the intervening connections have success flags, the target runs only if all the steps are successful.

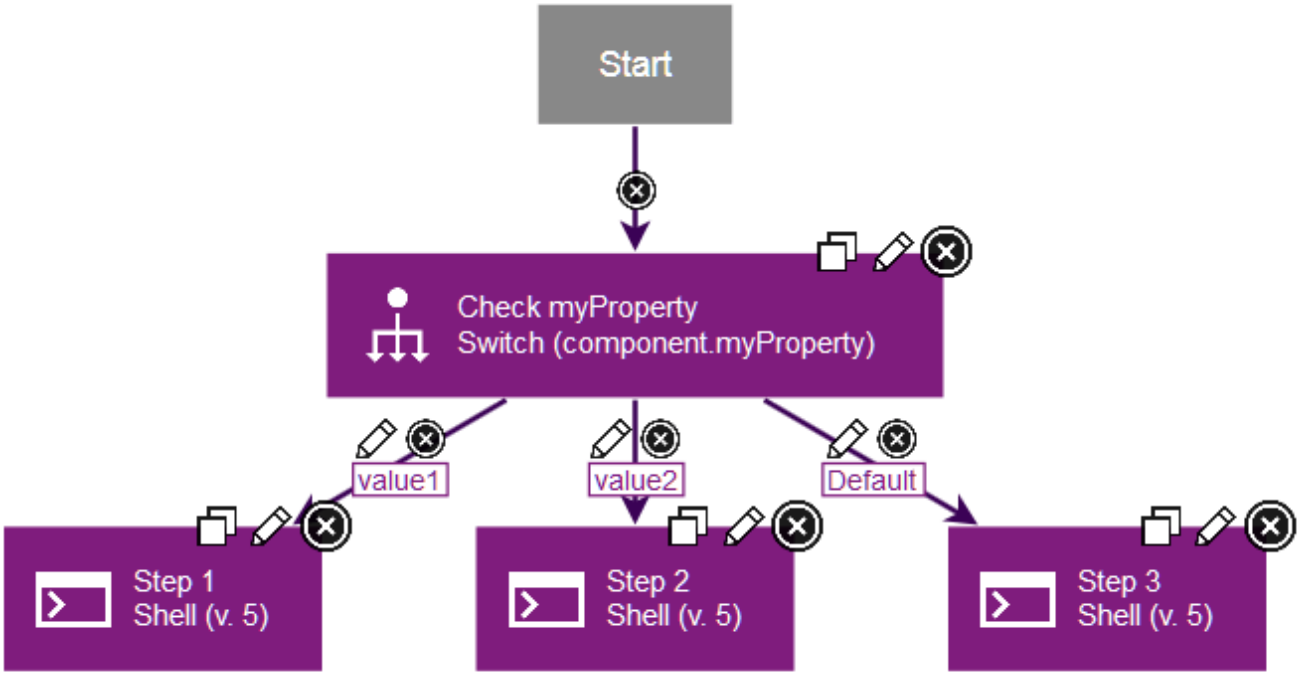
For an entire process to succeed, it must reach a Finish step. If it does not end with Finish, the process fails.

Switch steps

A *switch step* is a utility step that you use to branch process, based on the value of a property.

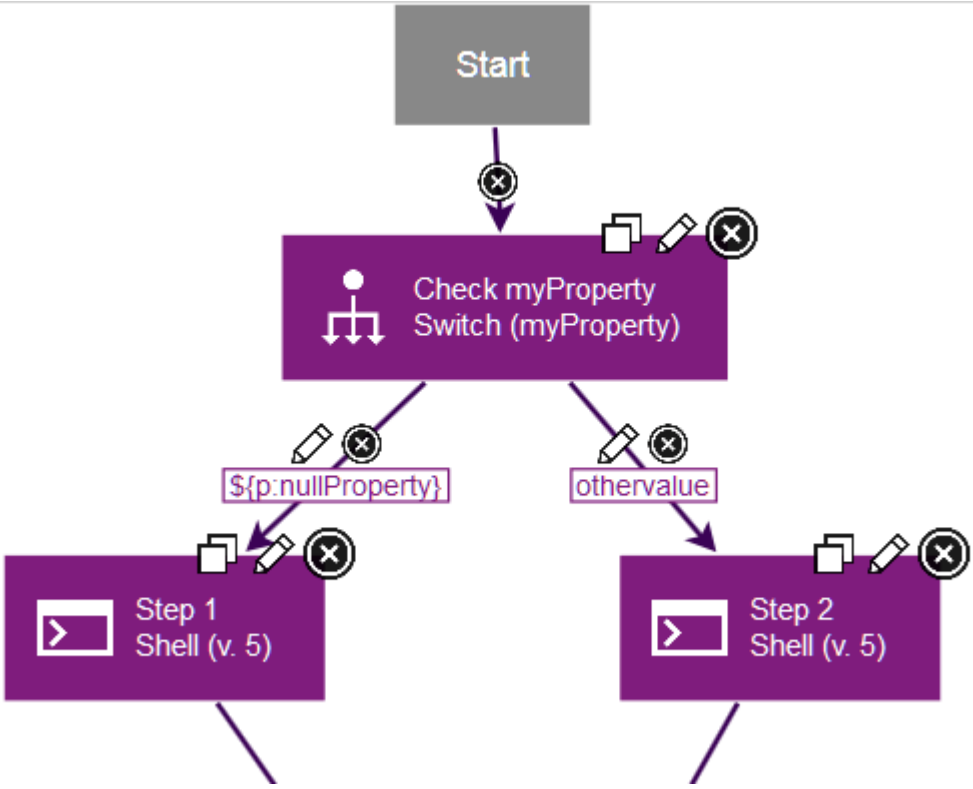
When you add a switch step, you specify a property, either as the property name itself or in the same form as you would use in other steps, such as `${p:propertyName}`. Then, you add two or more outgoing connections from the step, each with a possible value for that property. At run time, the process follows the connection with the matching property value. The process also follows any connections with `fail` or `both` conditional flags.

For example, the following figure shows a switch step for the **myProperty** component property. Two outgoing connections have different values for that property, including `value1` and `value2`. The third connection has the `default` value, which means that the process follows this connection if no other values are matched.



To set the property to use, add the Switch step to the process and click the edit properties icon . In the step properties, specify the property, either by specifying the property name by itself or in the same form as you would use in other steps, such as `${p:propertyName}`. You cannot use a secure property in this step.

To check whether a property is defined, create a second property, and give that property a null value. Then you can compare other properties to that property to see whether they are defined. For example, the following process contains a property that is named **nullProperty**; this property is not defined. In the process, the switch step compares a property that is named **myProperty** to this null property. If the property is not defined, step 1 runs. If the property has the `othervalue` value, step 2 runs.



Pausing a process

You can pause a process to include some updates in an already running process and then resume it. This allows you to apply multiple fixes in between pausing and resuming without requesting a new process.

During the execution of a process with multiple steps, you can press the **Pause** button from the deployment execution log. Pausing a process execution stops the deployment at the next step and results in the following behavior:

- The step which was running, continues to run and retains the Running label.
- The subsequent steps are marked as Not Started.
- The overall process status is marked as Paused at bottom of the page.
- When the current running step terminates processing, as you can see from its output, it still stays in Running state.
- If you click Resume, the currently running step terminates successfully and the next step begins.

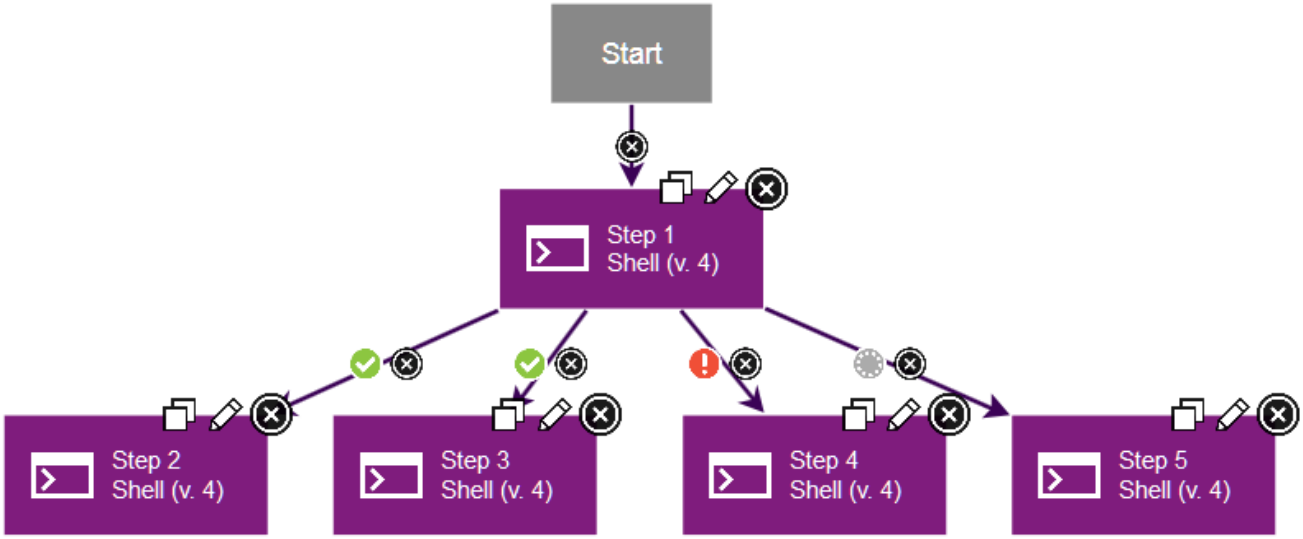
Branching and joining steps

You can branch processes so that multiple steps run at the same time. You can also merge processes to return to running a single step at a time.

Default branching and joining

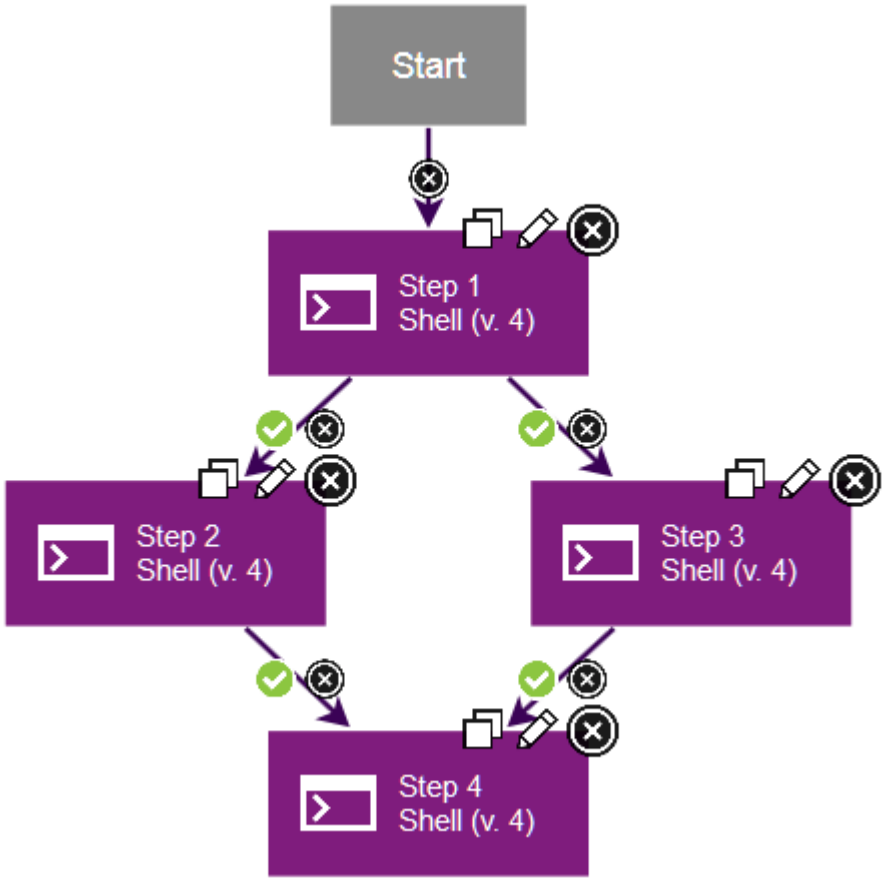
To branch a process and run multiple steps at the same time, add multiple outgoing connections from a step. You can use any combination of `success`, `fail`, and `both` conditional flags, as described in Conditional processes on page 2399. For

example, the following process shows a step that branches into four steps. Two connections have `success` flags. One has a `fail` flag, and one has a `both` flag.

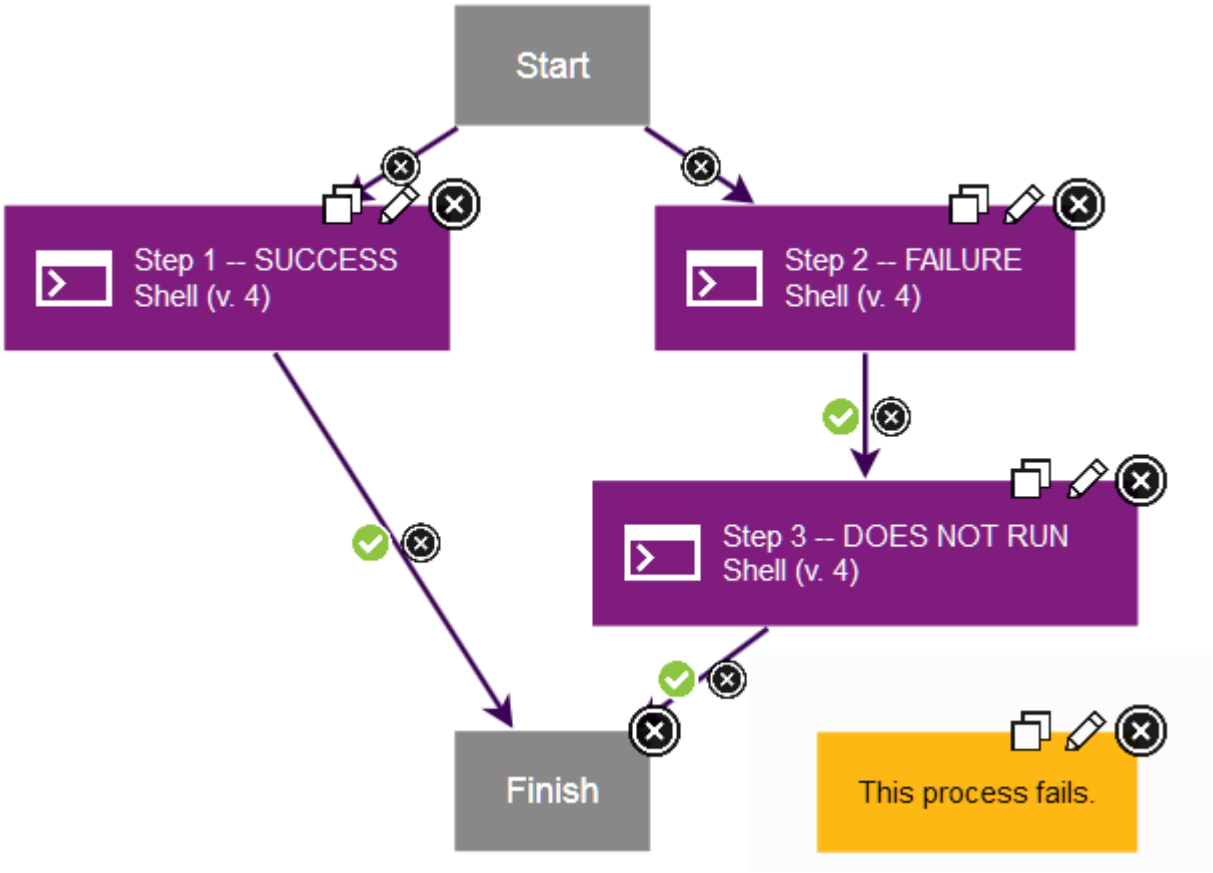


In this case, if the first step finishes, three steps run at the same time: the connections with the `success` flags and the connection with the `both` flag. If the first step fails, two steps run at the same time: the connection with the `fail` flag and the connection with the `both` flag.

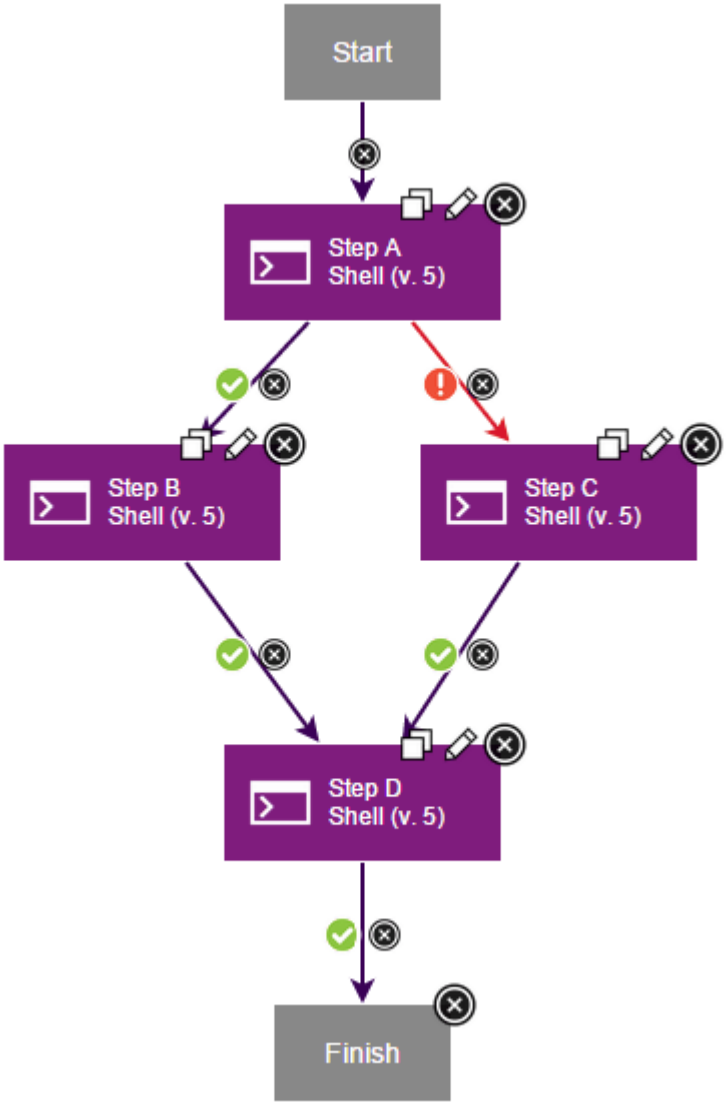
If a process has multiple steps that run at the same time, you can use connections to merge the process into a single step. For example, the following process shows two steps that are running at the same time. Both steps have a connection to a third step, and both of those connections have a `success` conditional flag. In this case, if either step 2 or step 3 fails, step 4 does not run. Because all the parallel processes that branch from step 1 have `success` flags, all the processes that merge at step 4 must succeed for step 4 to run.



How you branch and merge steps can change whether the process finishes or fails. For example, the following process has three steps. Step 1 runs on its own parallel path. In another parallel path, step 2 runs first and then links to step 3. Step 1 and step 3 then connect to the Finish step. If step 2 fails, step 3 does not run. Because step 2 failed, the entire branch is invalid, and the process fails.

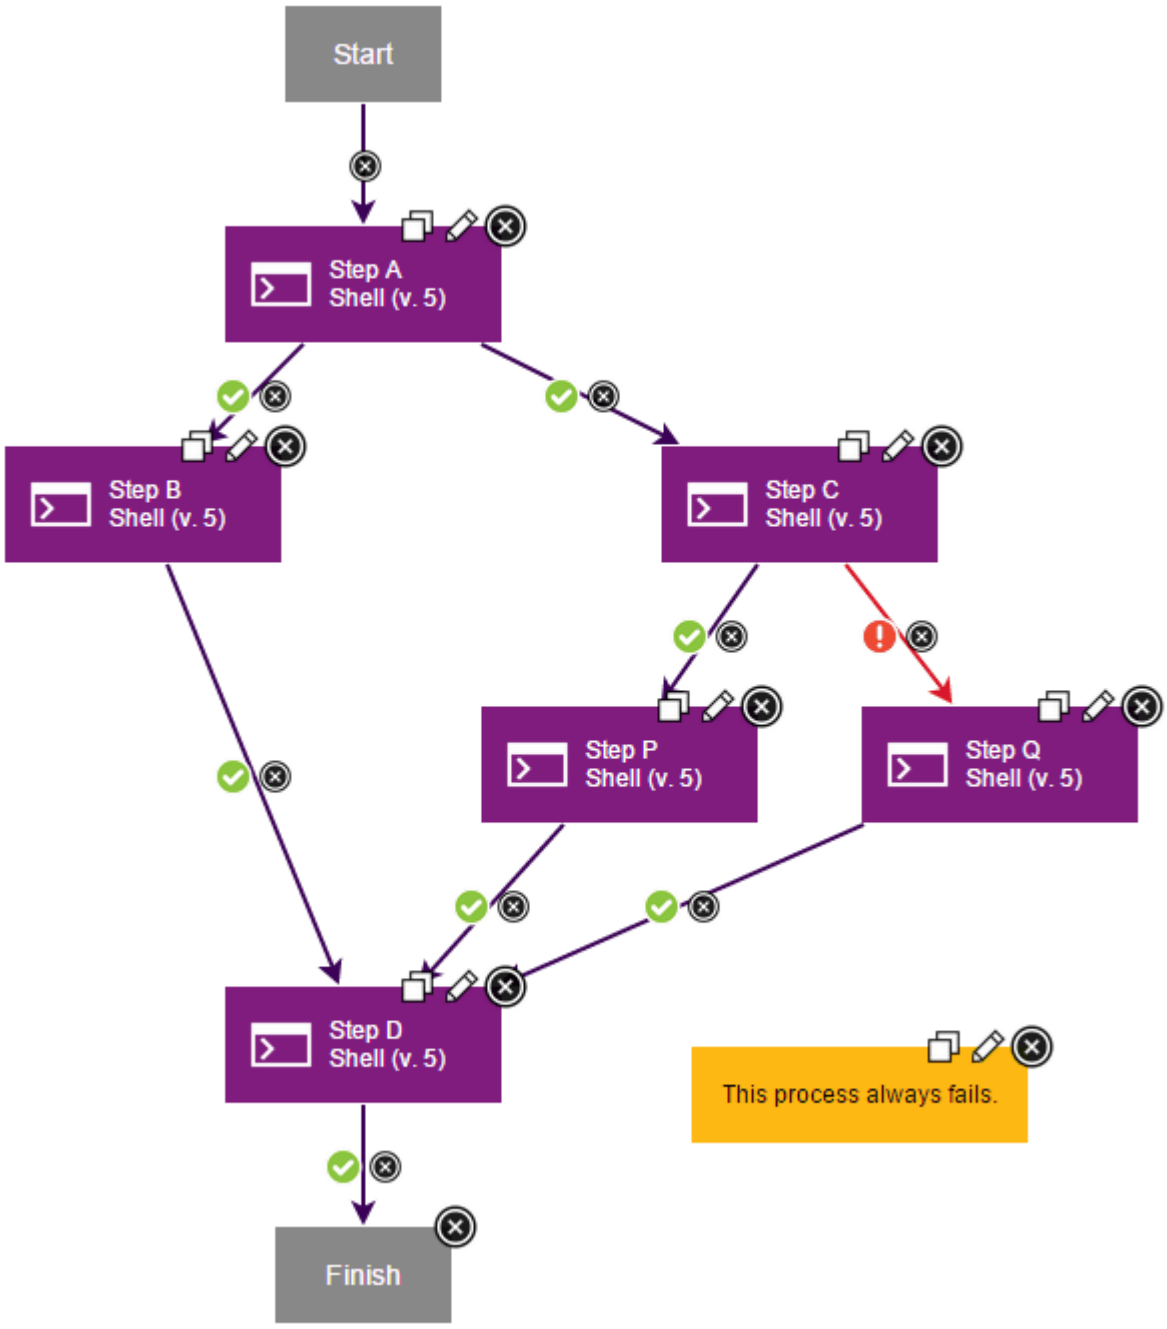


If you assign a `success` flag to one parallel process and a `failure` flag to another parallel process, only one parallel process can run. Because only one parallel process can run, only one of the processes that merge at the merging step must succeed for that step to run. In the following example, if step A succeeds, step B runs. If step A fails, step C runs. Step D runs if either step B or C succeeds.

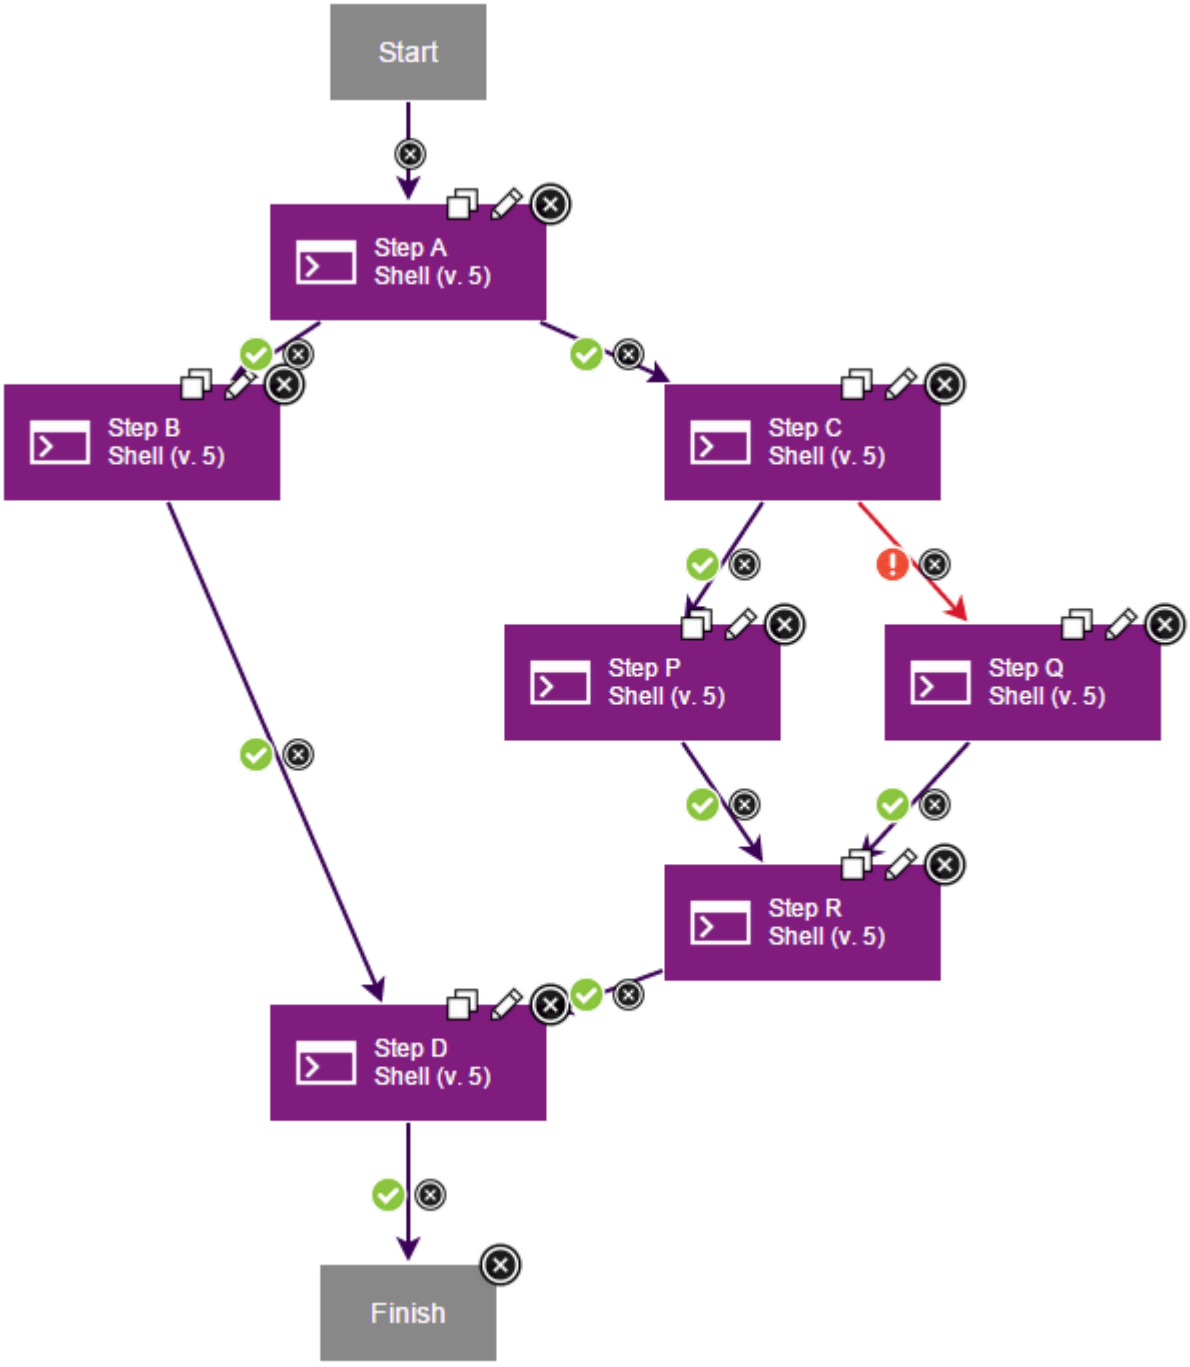


Your process can include nested parallel paths, but you must carefully plan how the parallel paths merge. The rules for the `success` and `failure` flags that you assign at the branching step control how the parallel paths must merge. If you mark all the steps at the branching step with `success` flags, then all the steps that are attached to the merging step must succeed.

The following process contains two branching steps but only one merging step. Because both branches from step A have `success` flags, all the steps that merge at step D must succeed for it to run. Step P runs only if step C succeeds and step Q runs only if step C fails. Because both step P and step Q merge at step D, it is impossible for all the steps that join at step D to succeed. This process always fails.



The following process adds a separate merging step to resolve the parallel paths that branch at step C. As in the previous example, either step P or step Q runs. Unlike the previous example, steps P and Q merge at step R, which follows the rules for its branching step and runs if either step P or Q succeeds. Step D still follows the branching rules for step A and runs only if all the processes that it merges succeed. If both step B and step R succeed, step D can run. By resolving each set of parallel paths separately, your process runs as planned.

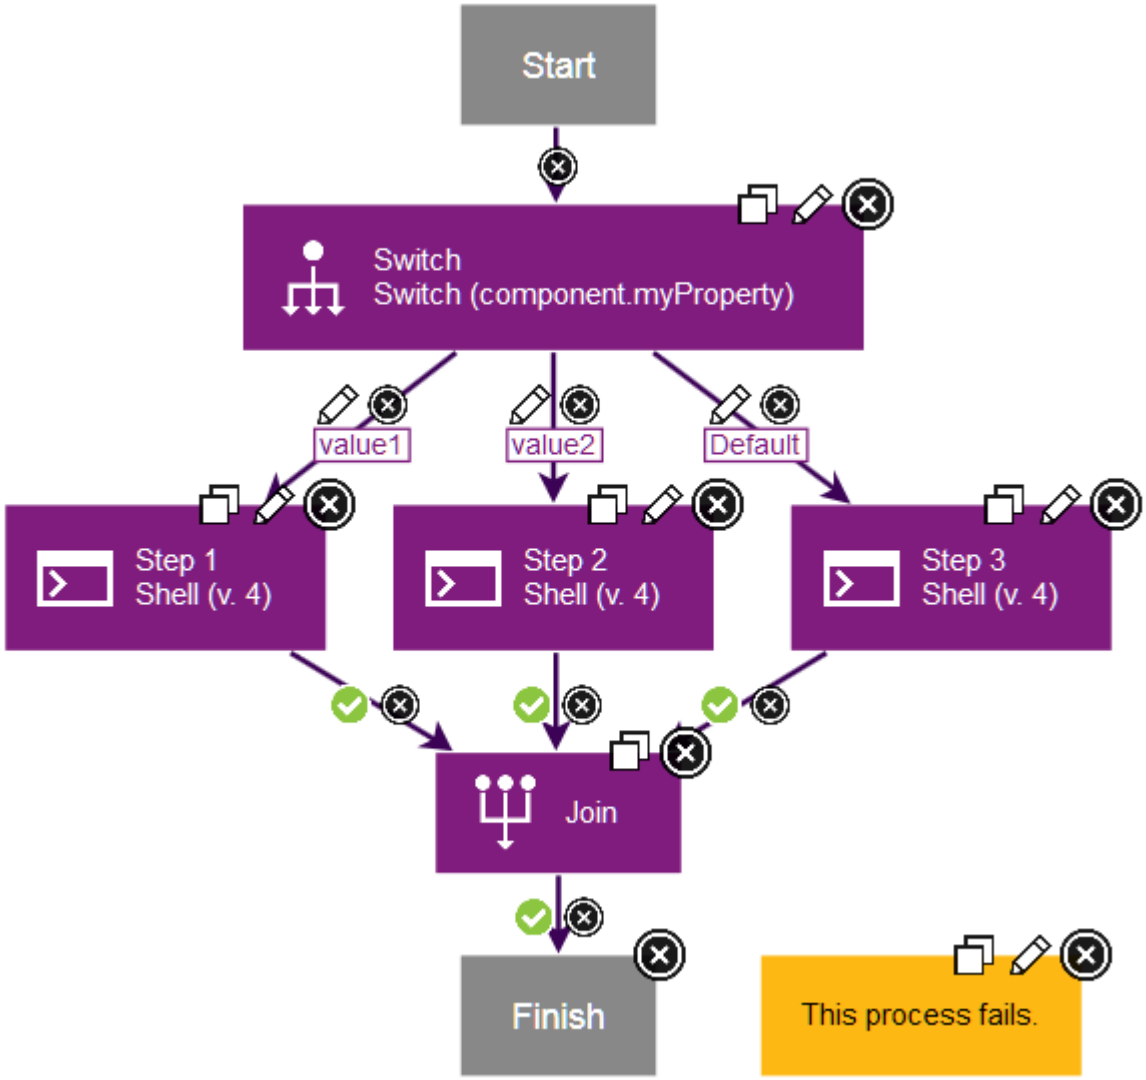


By carefully planning the location of your branching and merging steps, you can ensure that your processes run correctly.

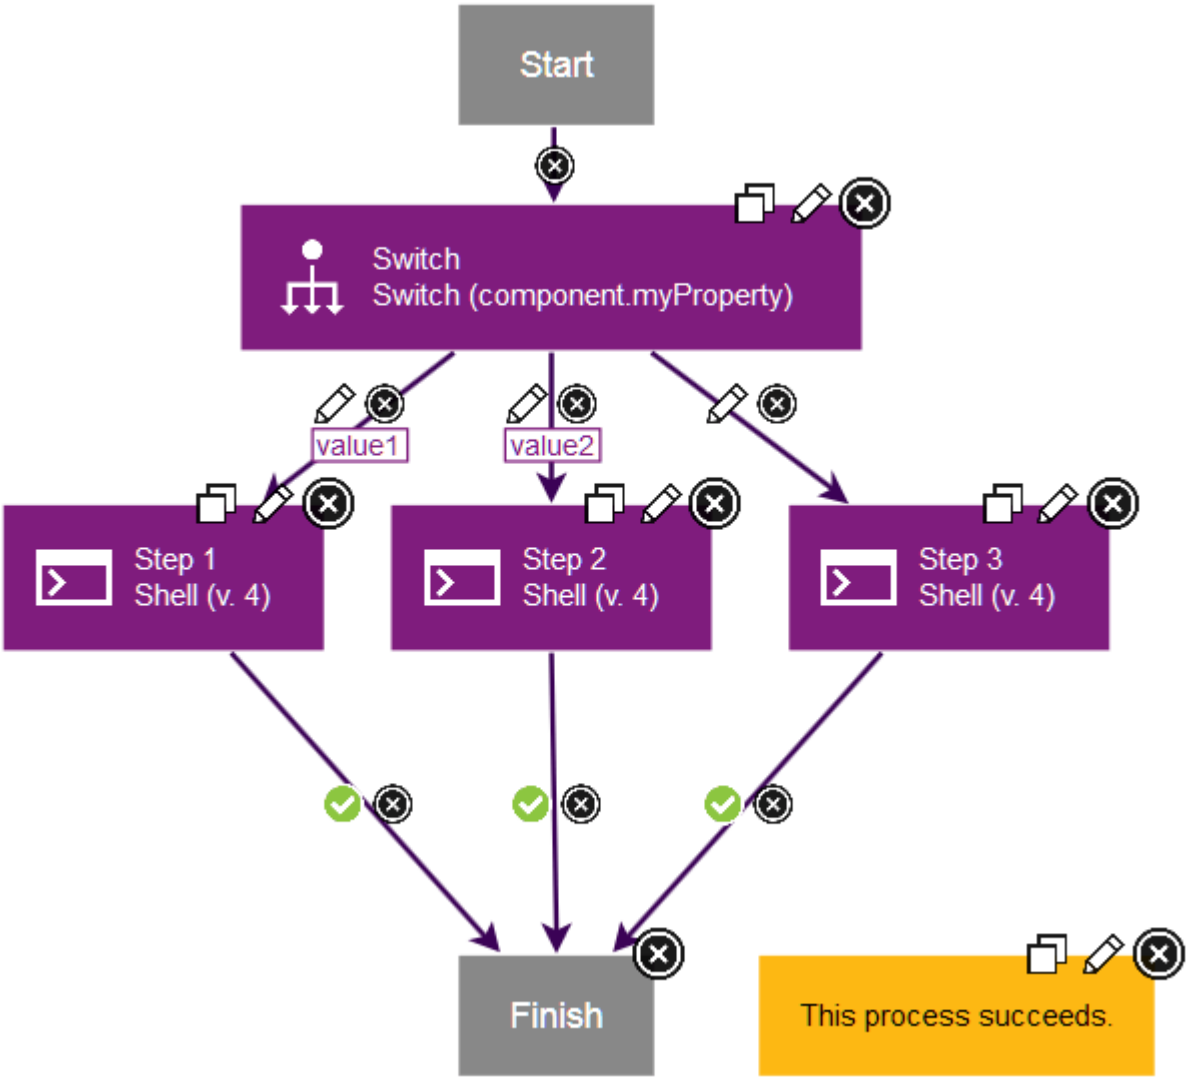
Branching and joining with the Switch and Join step

Use a Join step to explicitly indicate that all connections to the Join step must succeed. The Join step fails if any of the connections to it fail or do not run. For example, the following process uses a Switch step to branch the process. The Switch step has three outgoing connections, each for a different possible value of a property. Thus, only one of these outgoing

connections runs. The three outgoing connections are merged at a Join step. The Join step always fails because only one of the outgoing connections runs. The two other step chains do not run, and therefore the Join step fails.



In these cases, when you do not intend for each step chain to run, do not use a Join step. Instead, merge the step chains by connecting the chains to a single step, as shown in the following process.



Process step properties

All steps have the following properties: `exitCode`, `status`, and `lines of interest` (LOI, which are items that the post-processing script finds in the step's output log).

You can view the properties by using the component's **Log** pane to examine the step's output log (**Components > *selected component*** **> Component request history > View Request > Properties**).

Inventory and versions statuses, which are defined with the **status** property, can be used in application approval gates (see Environment gates on page 2360). The other properties can be used by post-processing scripts, see The post-processing element on page 2576.

Process step preconditions

Most steps in a process can have a precondition. If the **Precondition** field is available, the process supports a precondition. This precondition determines whether the step runs. Like post-processing scripts, preconditions use JavaScript™ 1.7.

Note: The syntax for preconditions is similar to the syntax for post-processing scripts. See Post-processing scripts on page 2415.

Preconditions return Boolean values. If the precondition returns `True`, the step runs as usual.

If the precondition returns anything other than `True`, the process skips that step. In the process request, the step is labeled "Precondition Failed." However, in this case, the process continues to run; the process follows the success links from that step as though the step succeeded.

The precondition has access to the same properties that the step does. Application processes have access to the following properties:

- Application properties
- Application process properties
- Environment properties, including component environment properties
- System properties
- Output properties from previous steps. See Output properties on page 2516.

Property availability depends on your context. See Property availability on page 2519 for information about which properties you can access.

After you run a process, you can see the properties that the process had access to by opening the process request and clicking the **Properties** tab.

To access a property, use the properties.get() command. For example, the following code retrieves the value of an application property:

```
properties.get("application/property1")
```

The following example precondition allows the step to run only if the application property `property1` exists and is not null:

```
properties.get("application/property1") !== undefined &&
properties.get("application/property1") !== null &&
properties.get("application/property1") !== ""
```

Important: Do not use notation such as `${p:component.myProperty}` in the precondition script. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`.

Precondition scripts can access the process properties. For example, if the process has a property that is named `processProperty1`, you can access that property with the following code:

```
properties.get("processProperty1")
```

Precondition scripts in component processes and generic processes can access the output properties of previous steps. For example, assume that the post-processing script of a step that is named `Step1` specifies a property that is named `OutputProp1`. The following precondition script allows another step to run only if the value of this property is `value1`:

```
properties.get("Step1/OutputProp1") == "value1"
```

Preconditions have access to a property that is named `hasFailures`. This property is `True` if any of the steps in the process fail. It is undefined if no steps fail. For example, to run a step only if no other steps in the process fail, use the following precondition:

```
properties.get('hasFailures') == undefined
```

Adding deployment warnings

Warning statuses provide a way to easily identify deployments that require closer inspection that had been marked during the process execution.

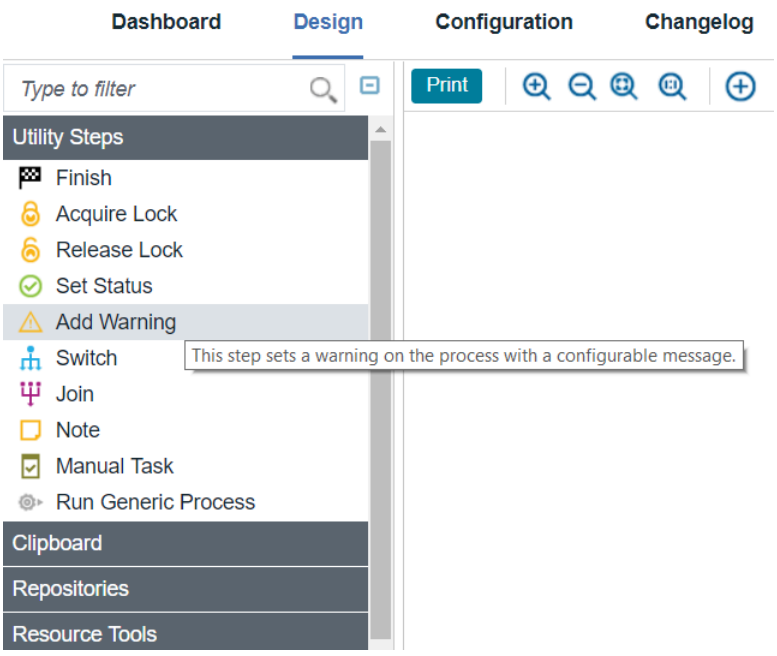
Adding warnings

The warning message will be determined by the process author at design time.

Warnings can be set on an execution by either of the following:

1. Through the `Add Warning` plug-in step.

   This step requires a warning message as its only field. The warning message has a minimum length of 1 and maximum length of 2000. Empty string messages will be discarded.



2. In the post processing script.

The default post-processing script is an example of how this is done:

```
// post-processing script
var exit = properties.get('exitCode');

/* Set a warning
scanner.register('^Warning: ', function(lineNumber, line) {
    properties.put('ucdWarning', line);
});

scanner.scan();
*/

if (exit == 0) {
    properties.put('Status', 'Success');
}
else {
    properties.put('Status', 'Failure');
}
```

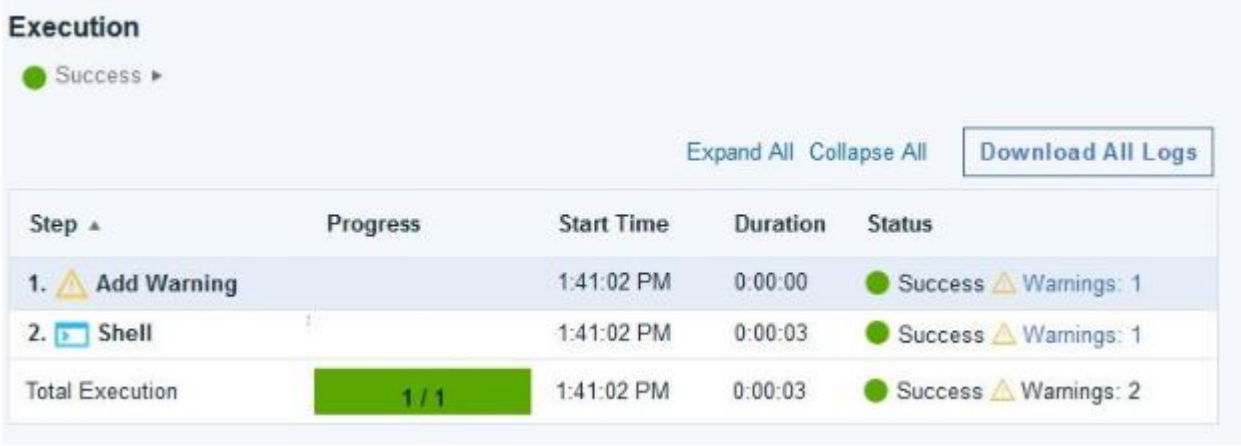
View process requests with warnings

Scan the request history to locate executions that have warnings set and easily trace the warnings back to their originating plug-in step. The **history** and **execution log** pages will display the status of the execution alongside a warning indicator with count of warnings. This indicator will only display if there are any warnings from child activities that have not been ignored. Users can click warning count to view the list of warning messages from the plug-in steps of the executed process activity.

The **history** page will display a `Status` column that shows the execution status (Success or Failure) and also the count of warnings that had been set for that process. No count will be given if no warnings were set.

The **execution log** page displays each step and child execution. When the steps have completed the Status column will display the count of warnings in the same manner as the **Request History** page. In addition to displaying how many warning messages were set on a step/execution, you can bring up the warning messages for that step and any child steps underneath it. Below is an example of what messages would be available at each step in the **execution log** page. The `shell with warning` steps set a warning message.

Figure 6. Execution log showing warnings



Steps	Warning Messages
(application process (execution))	"warningA, warningB"
1. Install Component "myComponent"	"warningA, warningB"
__ i. myComponent	"warningA, warningB"
____ A. myComponentProcess	"warningA"
______ a. Shell with warning	"warningA"
______ b. Shell	""
____ B. myOtherComponentProcess	"warningB"
______ a. Shell with warning	"warningB"

Success/Failure notifications include warnings

In addition to displaying the result status, the default deployment or process notification templates include the total count of warnings that have not been ignored. You have access to the warning messages if you choose to modify the default notification templates. Server upgrades will not modify existing notification schemes.

Behavior

Warnings set on plug-in steps are passed up to parent process. For example, if you have a component process which uses the plug-in step `Add Warning` and this component process is used in an application process, the warning would be available in the application process **execution log** and **history**.

Warning messages are stored in the workflow trace. Each activity trace may contain a field `warningMessage`containing the warning message if one is set. Workflow metadata will contain a count of warnings generated for each execution context to allow accessing the warning count without loading the workflow trace.

Activities can optionally ignore warnings from its child activities. An activity that can spawn child activities can be configured to ignore the warnings from its child activities. The UI has an option to ignore warnings from child activities. If the activity is configured to ignore warnings then any warnings set from child activities should not be included in the spawning-activity's execution log and process request history.

For example, a component process `deployWithWarning` will always set a warning message. There is an application process `appProcess` that runs an `Install Component` step that runs `deployWithWarning` but ignores warnings. After execution completion, the execution log and deployment history will show `appProcess` and the `Install Component` step was successful with no warnings. However if the execution log is expanded, `deployWithWarning` will show successful with 1 warning.

Specific activities that have the option to ignore child warnings are:

- Run Generic Process
- Run Generic Process for Each Affected Resource
- Run Component Process
- Run Application Process

- Run Operational Process for Multiple Components
- For Each Agent
- For Each Tag
- Run Process for Each Version
- Install Multiple Components
- Install Component

Existing History and Execution Log

The existing process request history and execution logs are not affected as they will not have the new plug in step `Add Warning` and post-processing script actions.

Post-processing scripts

Post-processing scripts run after a step finishes. Typically, post-processing scripts ensure that expected results occurred.

Notes:

- Use JavaScript™ 1.7 to write post-processing scripts.
- In the script, do not use the `${p:component.myProperty}` notation. For example, to set a property named `myProp` whose value is included in the output log, enter this script:

```
var exit = properties.get('exitCode');

scanner.register("regex", function(lineNumber, line) {
     var thing = 'do stuff';
});
scanner.scan();

if (exit == 0) {
    properties.put('Status', 'Success');
}
else {
     properties.put('Status', 'Failure');
}
```

- The syntax for post-processing scripts is similar to the syntax for preconditions. See Process step preconditions on page 2411.

Steps in component processes and generic processes can have post-processing scripts, but steps in application processes cannot.

Post-processing scripts come from the following sources:

- Steps can have default post-processing scripts. These scripts are included with the plug-in. See Creating plug-ins on page 2561.
- You can override the default post-processing script for a step or provide a post-processing script for a step that does not have one. See Editing processes on page 2453.
- You can store post-processing scripts on the server for reuse. See Storing reusable post-processing scripts on page 2242.

Post-processing scripts must set the **Status** property to specify the status of the script. The script can specify any value for the **Status** property. For example, to specify that the script was a success, run the following command in the post-processing script:

```
properties.put("Status","Success");
```

See The post-processing element on page 2576 for examples and more information.

Storing reusable post-processing scripts

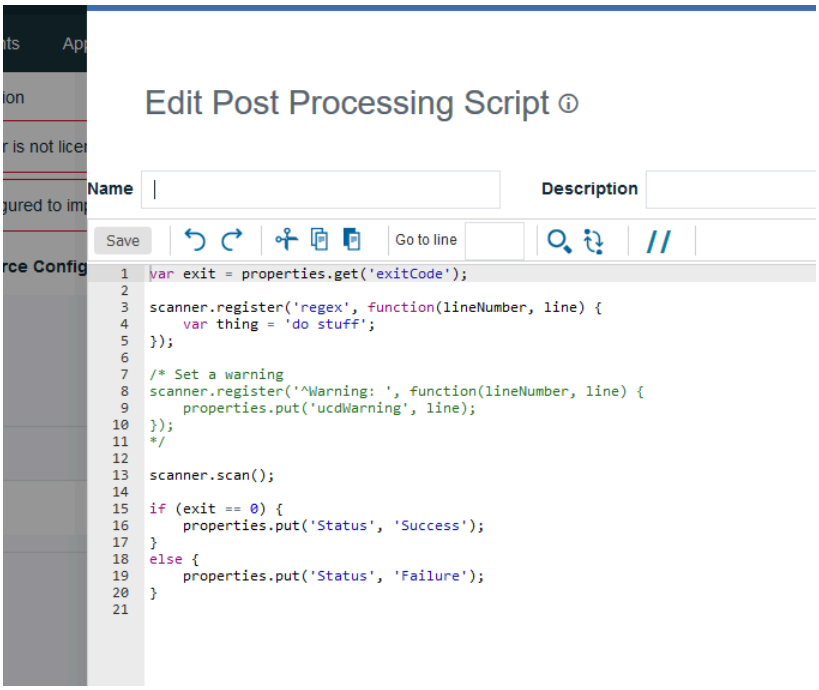
You can store post-processing scripts on the server so you can reuse them in component processes and in generic processes.

About this task

When a step finishes, the agent runs the post-processing script for that step. When the agent runs the script, it first loads the server log file. It finds the exit code property of the target step with regular expressions that are defined in the script. It then applies any actions that are defined in the script before it runs the next step.

The HCL DevOps Deploy (Deploy) server log file is normally found in the following location: *server_installation_directory*`/var/log/deployserver.out`.

1. Click **Settings > Post Processing Scripts** and then click **Create Script**.
   Result
   The **Edit Script** window opens, as shown in the following figure.



2. Specify a name for the process step.
3. Give a description for the process step.
4. Specify the teams that can access and edit the script.
5. Enter or paste the script into the **Script Body** field.
   See the roll-over help next to the field for information about the properties and variables that are available for user-defined scripts.

   Post-processing scripts must set the **Status** property to specify the status of the script. The script can specify any value for the **Status** property. For example, to specify that the script was a success, run the following command in the post-processing script:

   ```
   properties.put("Status","Success");
   ```

Examples of post-processing scripts

Post-processing scripts are written in JavaScript™.

Post-processing scripts must set the **Status** property to specify the status of the script. The script can specify any value for the **Status** property. For example, to specify that the script was a success, run the following command in the post-processing script:

```
properties.put("Status","Success");
```

Writing to the log

You can write to the output log for the process with the following command:

```
commandOut.print("hello");
```

Checking the result of a step

The post-processing script can examine the step's output log and run commands based on the result. In the following code fragment, `scanner.register()` registers the strings `error at line` and `the value is` with a regular expression engine, then runs commands if those strings are found. After all strings are registered, it calls `scanner.scan()` on the step's output log line by line.

```
properties.put("Status", "Success");

//
// Evaluate the built-in exitCode property, which indicates the exit code
// of the script called by the plug-in step. Typically, if the value of
// the exitCode property is non-zero, the plug-in step failed.
//
if (properties.get("exitCode") != 0) {
     properties.put("Status", "Failure");
}
else {

     //
     // Register a scanner to search for the text "error at line" in the log.
     // The first argument is a regular expression.
     //
     // The second argument, an inline function, is invoked once for
     // every line in the log output that matches the pattern. The "lineNumber"
     // variable contains the line number where the match occurred, and the
     // "line" variable is the full text of the line.
     //
     scanner.register("(?i)ERROR at line",  function(lineNumber, line) {

         //
         // In this case, we build up an "Error" property which
         // contains the text of all errors that are found. We find every
         // line starting with "error at line" and add it to this list.
         //
         errors.put("Errors", errorString);

         //
         // If a line starting with "error at line" is found, the step has
         // failed, so we set the special "Status" property to "Failure",
         // indicating to the DevOps Deploy server that the step should
         // be marked as a failure.
         //
         properties.put("Status", "Failure");
     });

     //
     // Multiple searches can be registered with the scanner. We add a
     // second search to look for some interesting text to set as an output
     // property.
     //
     // For example, if there is a line "The value is BLUE", then we end up
     // with an output property, "Value", with a value of "BLUE".
     //
     scanner.register("The value is", function(lineNumber, line) {
```

```
            var value = line.replace("The value is ", "");
            properties.put("Value", value);
        });

        scanner.scan();

        //
        // Convert the collected list of error strings into a single string and
        // set that as an output property.
        //
        var errors = properties.get("Error");
        if (errors == null) {
            errors = new java.util.ArrayList();
            properties.put("Error", errors);
        }
        properties.put("Error", errors.toString());
    }
```

Retrieving a property from a previous step

The following scripts assume two steps that are in the same process. The post-processing script for the first step creates two output properties, which are named **Status** and **Step1Prop**:

```
if (properties.get("exitCode")==0)
  { properties.put("Status","Success"); }
else
  { properties.put("Status","Failure"); }

properties.put("Step1Prop","value1");
```

Then, a second step can access those properties. For example, if the first step was named `Step1` and specified the output properties **Status** and **Step1Prop**, you might create a Shell step with the following code to access those properties:

```
echo Properties of previous step:
echo "${p:Step1/Status}"
echo "${p:Step1/Step1Prop}"
```

The second step can also use those properties in its post-processing script. For example, the following post-processing script includes the **Status** property of the previous step in a property for the second step:

```
{
properties.put("Step2Prop","New property");
properties.put("Status","OK");
properties.put("StatusOfPreviousStep","${p:Step1/Status}");
}
```

Passing a value from one step to another

Passing a value from one step to another involves a few general steps:

1. In the first step, store the value in a place where the post-processing script can access it. You can store the value by writing it to the log file for the step. For example, if you are using a Shell step, you can write the value and a unique key to the log with an `echo` command:

   ```
   echo "myvalue=1234"
   ```

   As a result, the log for the step shows the key and value:

   ```
   myvalue=12345
   ```

2. In the post-processing script for the step, use the scanner object to scan the log for the key. Then, assign the value to an output parameter. The following example script searches the output log for the key `myvalue=` and then stores the value in the output property `myOutputValue`:

   ```
   var exit = properties.get('exitCode');

   scanner.register("my value=", function(lineNumber, line) {
        var value=line.replace("my value=","");
        properties.put("myOutputValue",value);
   });

   if (exit == 0) {
       properties.put('Status', 'Success');
   }
   else {
        properties.put('Status', 'Failure');
   }
   scanner.scan();
   ```

3. In future steps, refer to the output parameter of the first step. For example, if the first step is named `SetMyValue`, future steps can refer to the property with the following code:

   ```
   ${p:SetMyValue/myOutputValue}
   ```

Adding a deployment warning

A warning can be added by a post-processing script at design time using the process author. Here's the default post-processing script which is an example of how this is done:

```
// post-processing script
var exit = properties.get('exitCode');

/* Set a warning
scanner.register('^Warning: ', function(lineNumber, line) {
    properties.put('ucdWarning', line);
});

scanner.scan();
*/

if (exit == 0) {
    properties.put('Status', 'Success');
}
else {
```

```
    properties.put('Status', 'Failure');
}
```

Allowlisted in-line functions and objects

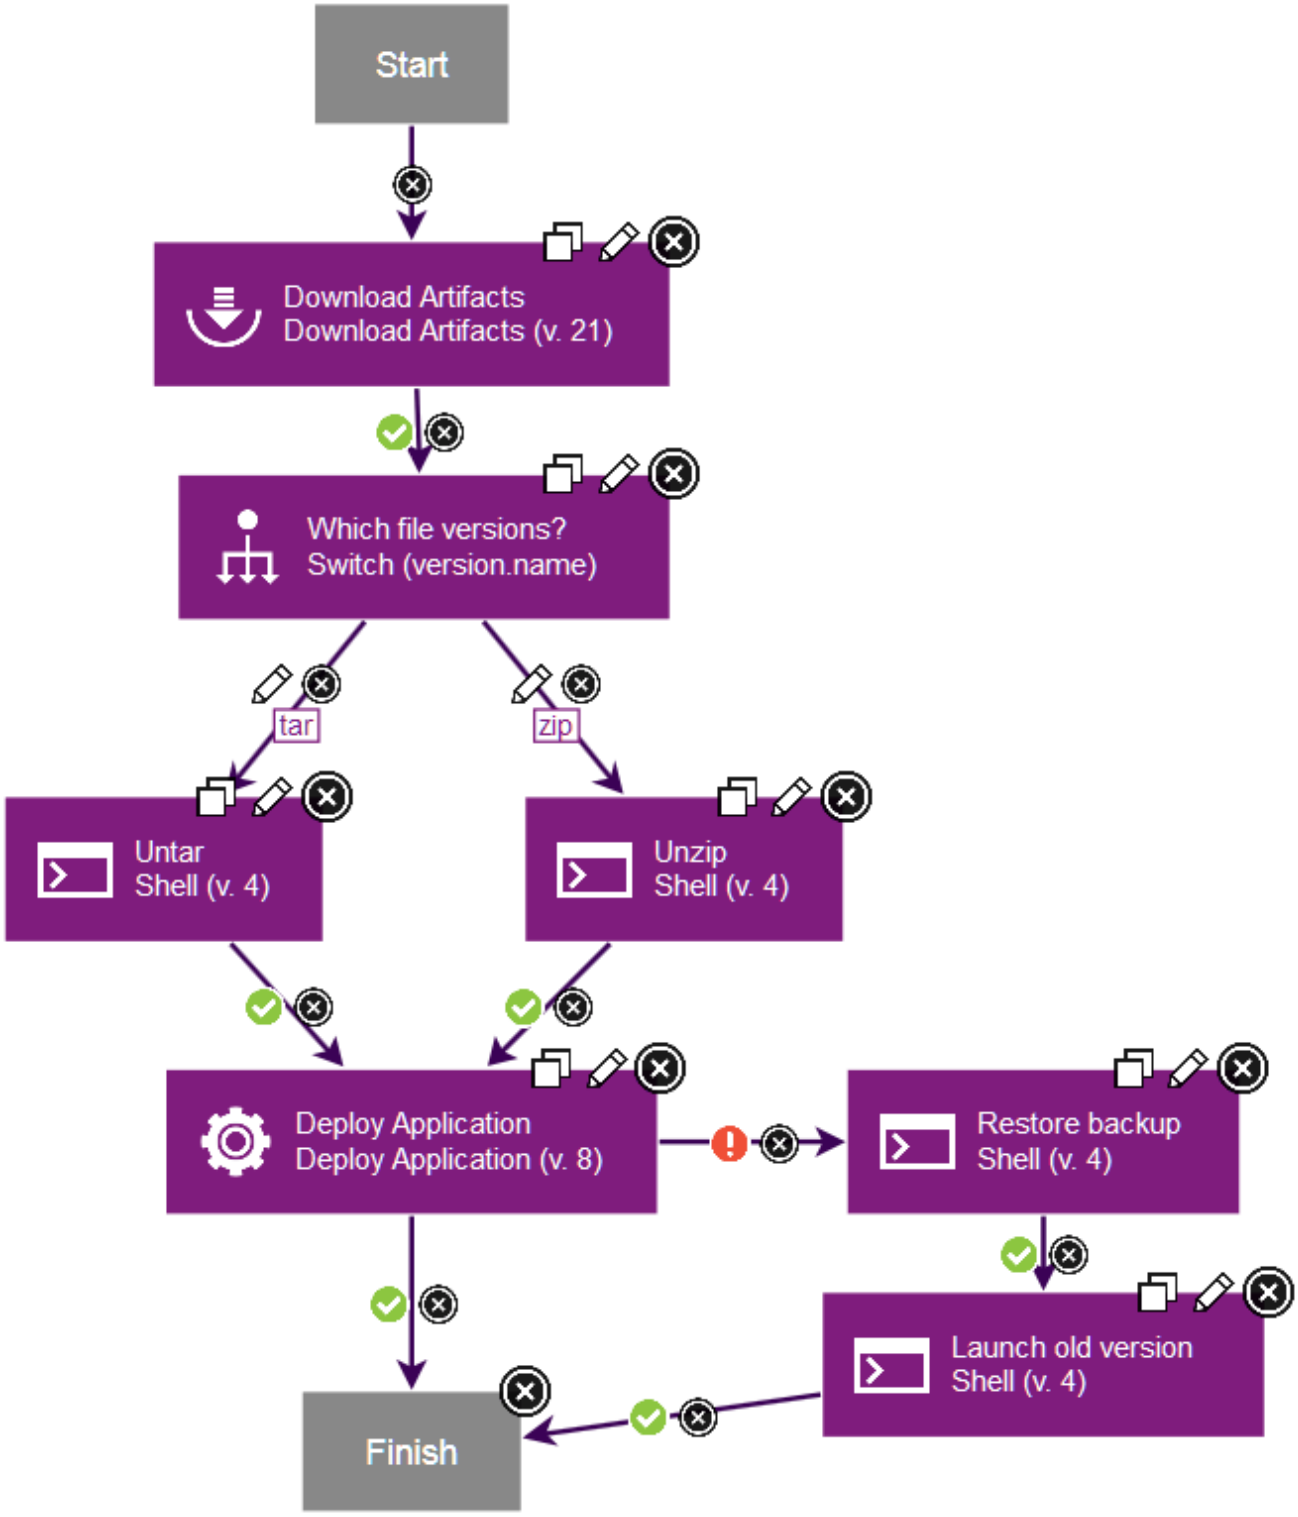
The following objects and functions are allowed to be used in the JavaScript runtime:

```
Function
Object
Error
decodeURI
decodeURIComponent
encodeURI
encodeURIComponent
escape
isNaN
unescape
NaN
isFinite
parseFloat
parseInt
Infinity
undefined
EvalError
RangeError
ReferenceError
SyntaxError
TypeError
URIError
Array
String
Boolean
Number
Date
Math
JSON
RegExp
```

Component processes

A *component process* is a series of user-defined steps that operate on a component's artifacts. Each component has at least one process that is defined for it and can have several.

A component process can be as simple as a single step or contain numerous steps and relationships. The *switch step*, for instance, creates conditional processes. For example, you might take artifacts from a source like an IBM® Anthill Pro project and map the artifacts that get deployed to an HTTP server into one component. Then, you might map the artifacts that get deployed to a Java™ Platform, Enterprise Edition container to another component. You might map the artifacts that get deployed to a database to yet another component. Or, to take another example, a single-component deployment might consist of two processes: the first moves component files to a target server on Friday night (a lengthy operation), while the second deploys the files Saturday morning.



Important: When you begin to create a component process, you must assign a type by making a selection from **Process Type** menu. The type that you select can determine whether the application process that you create later

functions as intended. For example, if the object of the component process you are creating is to deploy the current component and you select **Operational (with version)** in **Process Type**, the process will fail. See Component process types on page 2423.

Component processes are created with the *process editor*. The process editor is visual drag-and-drop editor where you can drag process steps onto the design space and configure them as you go. As more steps are placed, you visually define their relationships with one another. Process steps are selected from a menu of standard steps that replace typical deployment scripts and manual processes. HCL DevOps Deploy (Deploy) provides steps for several utility processes, such as inventory management, and workflow control. Other process steps are provided by plug-ins. Plug-ins provide integration with common deployment tools and application servers, such as WebSphere®, Microsoft™ IIS, and many others. Without any additions, Deploy provides plug-ins for many common processes, such as downloading and uploading artifacts, and retrieving environment information. A component process can have steps from more than one plug-in.

Like other processes, component processes begin with the Start step and must end with the Finish step.

A component process is defined for a specific component. A component can have more than one process that is defined for it, but each component requires at least one process.

For example, deploying an EAR file to an IBM® WebSphere® Application Server typically consists of the following operations:

1. Transfer the EAR file to the target server.
2. Stop the target server instance.
3. Run wsAdmin with deployment properties.
4. Start the target server instance.
5. Verify that the deployment succeeded by accessing a specified URL.

The WebSphere® Application Server - Deploy plug-in provides a configurable process step for each operation.

A frequently used component process can be saved as a template and applied later to new components.

Component processes are run by Deploy agents on hosts. One instance of a component process is started for each resource that is mapped to a component in the target environment. See Resources on page 2312.

Component process types

Different types of component processes deploy, configure, or uninstall component versions.

In most cases, you run component processes by adding them to application processes. However, you can also run component processes directly. For more information, see Running component processes on page 2427.

The Deployment and Operational (With Version) process types require a component version. If you do not specify a component version, the process does not run. In this case, the process is shown in the log with this message: `No Version Selected`. You can access the component version name with the **${p:version.name}** property. See Referring to properties on page 2509.

The other component process types do not use a specific component version; they run the same way regardless of the inventory of the target resource. Therefore, version-specific properties such as the **${p:version.name}** property are not available.

You use the following component process types:

Deployment

This type of component process deploys the specified component version to the target resource. It is the most common type of component process. If no component version is specified, the process does not run. For example, if the deployment manifest or snapshot does not contain a version of the specified component, the process does not run.

After the process runs, it updates the component inventory to include the component version, even if the process failed. If the process finishes, it updates both the component inventory and the configuration inventory, which contains all the properties for that component and its related elements. To view the updated properties, see Viewing resource configuration inventories on page 2397.

In most cases, this type of component process includes the Download Artifacts step, which downloads the component version artifacts to the target resource. Then, the process includes steps that install or configure the component version.

The most common way to run a deployment component process is to add it to an application process. In an application process, add the Install Component step, and then select the deployment component process.

Configuration Deployment

This type of component process applies a configuration inventory to a deployed component.

After the process runs, it updates the resource configuration inventory to contain updated properties. It does not change the environment or component version inventories.

For example, this type of process might use configuration templates to create configuration files, as described in Creating configuration files in component processes on page 2427. As another example, this type of process can update an application server with the most recent component properties, environment properties, and application properties. In this case, the process updates the configuration on the application server without reinstalling the component.

To include this type of process in an application process, add the Apply Configuration step, and select the configuration deployment process.

Uninstall

This type of component process removes the component version from the target resource. It also removes the component version from the environment inventory. It does not modify the configuration inventory.

To use this type of process in an application process, add the Uninstall Component step, and select the Uninstall component process.

This type of process can uninstall all the component versions in the inventory or only the specified versions. When you add a component with this component process to an application process, you specify the **Uninstall Type** field. The **All Existing** option removes all the versions of this component that are in the inventory. The **All Selected For Process** option removes only the versions that you specify when you start the application process.

Operational (With Version)

This type of process does not add or remove artifacts from the inventory; it runs steps on a currently deployed component. For example, this type of process can start or stop a service or change the properties on a deployed component.

By default, this type of process always runs when you include it in an application process, but you can restrict it to run only when certain components change.

To use this type of process in an application process, add a step that can call this type of process. For example, the Run Process for Each Version and Install Component steps can call this type of process.

Running this process step does not update the component's properties on the target resource.

Operational (No Version Needed)

This type of process is the same as the Operational (With Version) type, except that this type does not use a component version.

Each process of this type is listed as an available application process step, and you can add its step to call the process. You can also add a step that can call this type of process, such as the Apply Configuration step, to use this type of component process in an application process.

Creating component processes

A component process is a series of user-defined steps that operate on a component's artifacts. You create a component process in two steps: first, you configure basic information, such as name; second, you use the process editor to assemble the process.

1. Log in to the HCL DevOps Deploy (Deploy) application.
2. Click **Components > *selected component* > Processes > Create Process**.
   The **Create Process** window is displayed.
3. Provide the process details.

Field	Importance	Description
Name	Required	Enter a name (maximum 255 characters) that identifies the process. The process name appears in many UI elements.
Description	Optional	Conveys more information about the process.
Process Type	Required	Defines the process type.

Field	Importance	Description
		Selecting the correct process type is critical for the associated application process to run correctly. **Important:** If you are deploying components you must select the **Deployment** process type. If another type is selected for a component that you plan to deploy with an application process, the application process will fail. For more information, see Component process types on page 2423.
Inventory Status	Required	Status that is applied to component versions after being successfully run by this process. `Active` indicates that the component version is deployed to its target resource. The status appears on the **Inventory** panes for the component itself and environments that ran the process.
Default Working Directory	Required	Defines the location that the agent uses to run the process (for temporary files, and so on). The default value is `${p:resource/work.dir}/${p:component.name}`, where `${p:resource/work.dir}` is the default working directory for the agent and `${p:component.name}` is the component name. The default value resolves to *`agent_directory`*`\work\`*`component_name_directory`* and is stored in the `componentProcess.defaultWorkDir` property. The default properties work for most components; you might need to change it if a component process cannot be run at the agent's location.
Required Role	Optional	Restricts who can run the process. You can choose multiple roles associated with the team for the environment to run the process. The available options are derived from the Deploy security system. The default value is `None`, meaning anyone can run the process. For information about security roles, see Managing Security on page 2149.

4. Save the process details.

   Result

   The process is listed on the **Processes** pane for the associated component.

What to do next

You can edit the process in the process editor. See Editing processes on page 2453.

Running component processes

Component processes are typically run from within application processes. However, you can also run component processes directly to test the processes or to correct an error in an urgent situation.

About this task

To run a component process in an application process, add the appropriate step to the application process and specify the component process. For example, to run a deployment component process, use the Install Component step. The step that you use depends on the type of component process. For more information, see Component process types on page 2423.

You can run certain types of component process from generic processes. See Generic processes on page 2451.

You can also run component processes directly as follows:

1. Click an application, and go to the **Components** tab.
2. Next to the component, click **Run Process**.
3. In the **Environment** and **Resource** lists, select where to run the process.
4. In the **Process** list, select the component process.
5. If the component process requires a component version, in the **Version** list, select the component version.
6. If the component process requires other properties, specify values for those properties.
7. Click **Submit**.

Results

The component process is listed in the **Components > *selected component* > Component Request History**.

What to do next

You can search a component process by filtering any of the columns from the **Component Request History**:

- Resource
- Version
- Application
- Environment
- Scheduled For
- By
- Status

Creating configuration files in component processes

Configuration templates are templates for files that are created during a component process. Typically, the data is for configurations for web servers, but the files can be used for any application that you deploy.

About this task

A configuration template contains property names and property references. For example, the following line can be used in a configuration template:

```
database.username=@DB_USER@
```

When you deploy the component in an environment, the value of the **DB_USER** property that is defined for that environment is substituted for the `@DB_USER@` reference.

As an alternative to using configuration templates, you can also use the Create File step. In this case, you specify the contents of the file in the **Contents** field and include property references in the usual syntax of `${scope/propertyname}`, where `scope` is the scope of the property and `propertyname` is the name of the property.

1. Click **Components > *selected_component* > Configuration > Configuration File Templates > Create Configuration Template** to open the **Create Configuration Template** window.
2. Type a name in the **Name** field.
3. In the **Template** field, enter or paste the template text.
   Text can be in any script. The amount of text is based on the database that HCL DevOps Deploy (Deploy) uses.
4. Save the configuration template.
5. To use the configuration template in a process, add the Install Template step to a component process:

    a. In a component process, add the Install Template step.
    This step creates a file that is based on the configuration template.

    b. In the step properties, specify the name of the configuration template.

    c. In the step properties, select the **Show Hidden Properties** check box.

    d. In the **Environment Property List** field, specify the properties to bring into scope.
    Example
    For example, to bring only the environment properties into scope, specify `${p:environment/allProperties}`. In this case, the configuration template can refer to only environment properties. To bring environment properties, agent properties, and resource properties into scope, specify the following value for the **Environment Property List** field:

    ```
    ${p:environment/allProperties}, ${agent/allProperties}, ${resource/allProperties}
    ```

    e. Save the step and the process

Results

When you run the component process, the Install Template step creates a file that is based on the configuration template. The step replaces the property references with the property values. The default name of the file is the same as the name of the configuration template.

Application processes

You can use application processes to deploy or to roll back components.

HCL DevOps Deploy (Deploy) provides several common process steps. Otherwise, application processes are assembled from processes that are defined for their associated components. Application processes, like component processes, are created with the process editor.

Application processes can run manually, automatically on some trigger condition, or on a user-defined schedule. When a component has several processes, the application determines which ones run and in which order. For instance, an **n**-tiered application might have a web tier, a middleware tier, and a database tier. And, continuing the example, the database tier must be updated before the other two, which are then deployed concurrently. An application can orchestrate the entire process, including putting target servers online and offline for load balancing as required.

An application process is always associated with a target environment. When an application process runs, it interacts with a specific environment. At least one environment must be associated with the application before the process can run. Application processes are independent of environment; processes can be designed independently of any particular environment. These application processes enable a single application to interact with separate environments, such as QA, or production. To use the same application process with multiple environments (a typical scenario), you associate each environment with the application and run the process separately for each one.

In addition to deployments, several other common processes are available, such as rolling-back deployments. Deploy tracks the history of each component version, which enables application processes to restore environments to any point.

Application processes and the steps that they comprise are configured with the process editor. For information about using the process editor, see Processes on page 2398. For information about individual process steps, see Process steps: Reference on page 2466.

Creating application processes

You can use application processes to deploy or to roll back components.

1. Display the **Create an Application Process** dialog box (**Applications > *select application* > Processes > Create Process**), and enter the following information:

Field	Description
Name and **Description**	Typically the name and description correspond to the application you plan on deploying. **Note:** You must specify a unique name. Your application process name cannot contain the same sequence of alphanumeric characters with different capitalization as an existing application process.
Inventory Management	If you want to handle inventory manually, select `Advanced`. To have inventory that is handled automatically, leave the default value, `Automatic`, selected. See Inventories on page 2394.

Field	Description
Offline Agent Handling	Specify how the process reacts if expected agents are offline: ◦ **Check Before Execution**: checks to see whether expected agents are online before you start the process. If agents are offline, the process does not run. ◦ **Use All Available**; **Report Failure**: process runs while at least one agent is online; reports any failed deployments because of offline agents. Useful for rollbacks or configuration deployments. ◦ **Always Report Success**: process runs while at least one agent is online; reports successful deployments.
Required Role	Use this list to select the role that a user must have to run the process. You will need to be in the required role for the team on the environment you are trying to run the process on. For more information, see Roles and permissions on page 2187. The default value is `None`.
Disable Deploying Snapshots	Allows you to create an application process that deploys component versions only. On enabling the option, you are forced to specify the component versions while deploying applications and alerts you that snapshot deployments are disabled.

2. Save your work.

What to do next

You can edit the process in the process editor. See Editing processes on page 2453.

Deploying components in an application process

You can deploy one or more components in an application process by calling component processes.

Before you begin

- Create an application and add one or more components to the application.
- Create an application process.
- Create a component process of the Deployment type for each component.

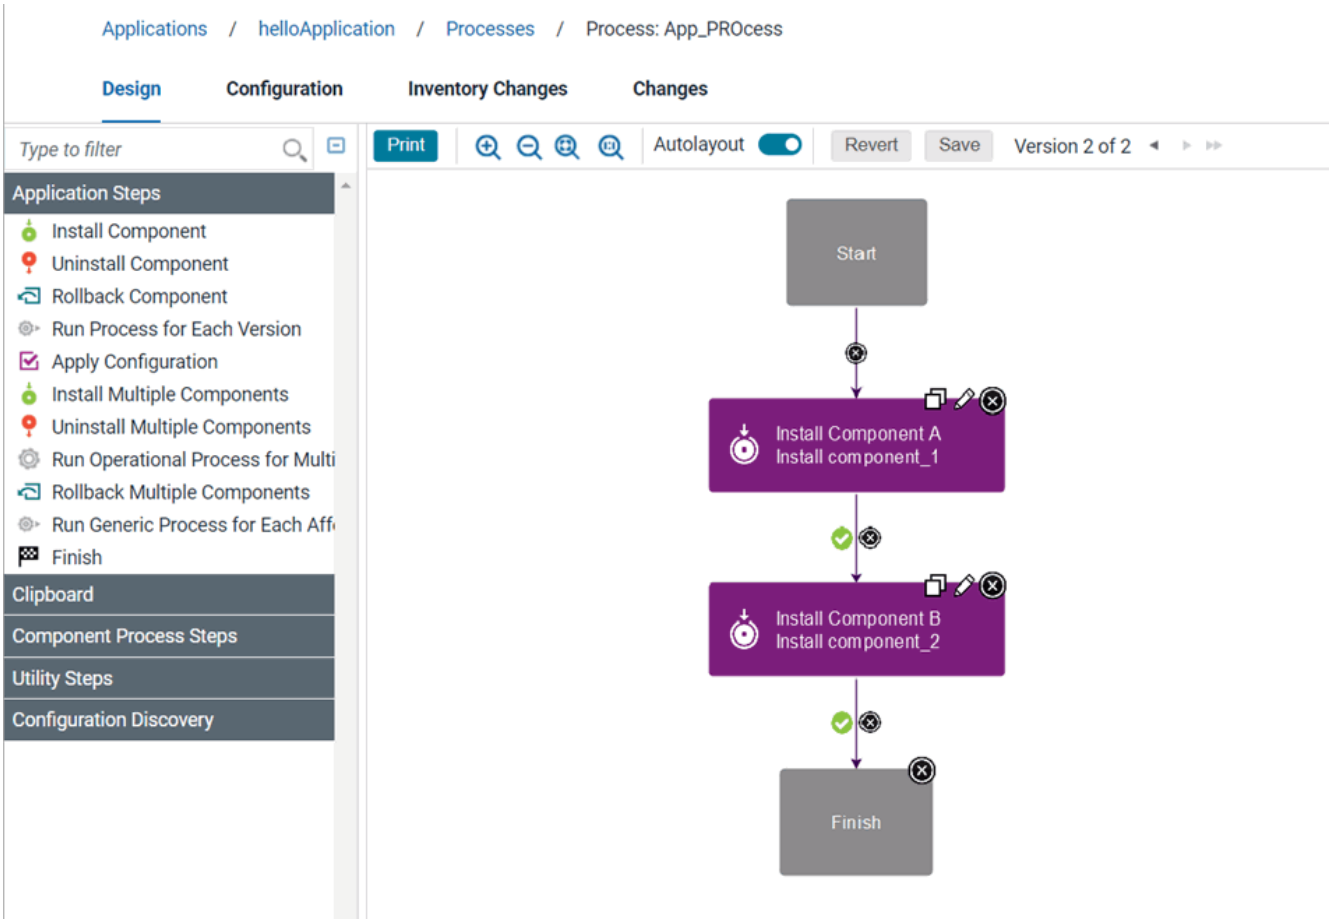
Important: If **Deployment** is not selected for **Type**, the deployment process will not succeed.

1. In an application process, add the Install Component step to the process, and click the edit icon . The **Edit Properties** window opens.
2. In the properties for this step, specify the component to deploy and the component process to run.
   For more information about this step, see Install Component on page 2476.
3. When you drag more steps to the process diagram, position the step so that the link between steps is highlighted, and then drop the step. The step is automatically linked to the earlier and subsequent steps.
4. Verify that all processes are connected in the correct order and that the flow is connected to the Start and Finish nodes; then, save the process.

5. Run the process on an environment.
   See Running application processes on page 2431.

Example

The following example application process deploys two components. The `Install Component A` and `Install Component B` steps call the deployment processes for each component.



Running application processes

To run an application process, specify the environment to use and the process to run. In many cases, you also specify the component versions to deploy.

Before you begin

You must have completed the following tasks:

- Created an environment.
- Created an application process.

About this task

Run an application process with a specific component version.

1. Click **Applications**, click the application, and then next to the environment, click **Request Process**.
   The **Create Deployment** wizard opens.
2. Set the process details.

   a. **Optional:** Re-select the application and environment names, if required.
   The **Application** and **Environment** fields are auto-filled based on the selection made in step 1.

   b. **Optional:** Enter the description for the process in the **Description** field.

   Note: You can also request a parameter. For example,

   ${**p:request.user.name**} (${**p:request.user.id**}) from ${**p:request.id**}

   c. To skip component versions that have not changed since the previous deployment, enable the **Only Changed Versions** option.
   If you do not select this option, all of the component versions that you select are deployed, even if they are already in the inventory.

   d. Select the application process from the **Process** list.

3. Choose the component versions or snapshot to deploy.
   If the process you selected deploys component versions, you must specify the component versions to deploy. You can use select a snapshot of component versions, or multiple component versions manually.
   Choose from:
   - To use the component versions in a snapshot, specify the snapshot from the **Select a Snapshot** list.
   - Specify component versions manually from the **Choose Component Version** window. You can add the component versions using any one of these actions:
     - To specify the versions for each component individually, click **Add** next to a component in the table, and select versions to deploy from **By Version Lookup**, and then choose any one of the following criteria:

Option	Description
Latest Available	Selects the most recent component version at the time that you make this selection regardless of when the process runs. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that is available then, click **Latest Available at Execution Time**.
Latest with Status	Selects the most recent component version at the time that you make this selection. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that has the specified status that is available at the later time, click **Latest with Status at Execution Time**.

Option	Description
Latest Available at Execution Time	Selects the latest component version that is available when the process starts. The version that is used might be generated after you make this selection.
Latest with Status at Execution Time	Selects component that have a status that you specify in the next dialog box. The version that is used might be generated after you make this selection.
Current Environment Inventory at Execution Time	Uses the environment inventory that is available when the process starts. The environment inventory might be different from the inventory that is available when you make this selection.

- To specify versions for all the components at one time, click **Select For All**, and then click one of the following options:

Option	Description
Latest Available	Select the most recent component version at the time that you make this selection regardless of when the process runs. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that is available then, click **Latest Available at Execution Time**.
Latest with Status	Select the most recent component version at the time that you make this selection. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that has the specified status that is available at the later time, click **Latest with Status at Execution Time**.
Versions With Name	Select the most recent component version whose name matches a string.
Current Environment Inventory	Uses the versions that are listed for that environment when you select it. This selection is typically related to the last version that was deployed to a certain environment of each component. For example, say that you deployed component A, version 1, to your environment. Then, in a separate deployment, you deployed an incremental version 1.1 to the same environment. If you look at the current environment inventory in the **Application** view, you see that the environment contains versions 1 and 1.1. Typically, you don't want to redeploy what is already there. However, this selection is useful when a deployment fails or is modified on the target computer itself, outside of Deploy. So if the deployment of version 1.1 succeeded on 10 agents but failed on two,

Option	Description
	you can schedule essentially a retry. Use of this selection is not common.
Latest Available at Execution Time	select the latest component version that is available when the process starts. The version that is used might be generated after you make this selection.
Latest with Status at Execution Time	Selects component that have a status that you specify in the next dialog box. The version might be generated after you make this selection.
Current Environment Inventory at Execution Time	Uses the environment inventory that is available when the process starts. The environment inventory might be different from the inventory that is available when you make this selection.
None (Clear All)	Clears your selection.

- To filter the list of components to the components with new versions, select the **Show only changed components** check box.

Notes:

- If you select multiple versions for one component, the versions are installed in the order you select.
- Make sure to select a version for each component. If you do not select a version for a component, that component is not included in the application process.

4. If the process has properties, specify values for those properties.
5. **Optional:** Schedule the deployment for a later date by disabling **Run Now** and then specify the date, time, and recurrence pattern of the deployment.
   You can choose the **Hourly**, **Daily**, **Weekly**, **Monthly**, and **Weekdays** recurrence pattern.
6. Review the deployment settings and click **Submit Deployment**.

Results

The server runs the application process with the specified component versions. You can view the process requests by going to the **History** tab for the environment or application. Typically, resources are mapped for each component version that is deployed by the application process. You can use the same application process for different environments, some of which do not have mappings for all components. If you run an application process on an environment where not all components are mapped, the resulting status for those components is `Not Mapped`.

What to do next

You can view the progress of the process by going to the **History** tab and opening the View Request. The application process request shows each step in the process. Within each process, the steps are not shown in the order that they run in. Instead, steps are shown in the order of appearance in the process editor, from the steps at the top of the canvas to the steps at the bottom of the canvas.

You can filter the **Application Process Request > Execution Log** based on the following **Status**:

- Any
- Not Executed
- Success
- Cancelled
- Failed

You can also search an application process by filtering any of the columns from the **History** tab:

- Environment
- Snapshot
- Scheduled For
- By
- Status

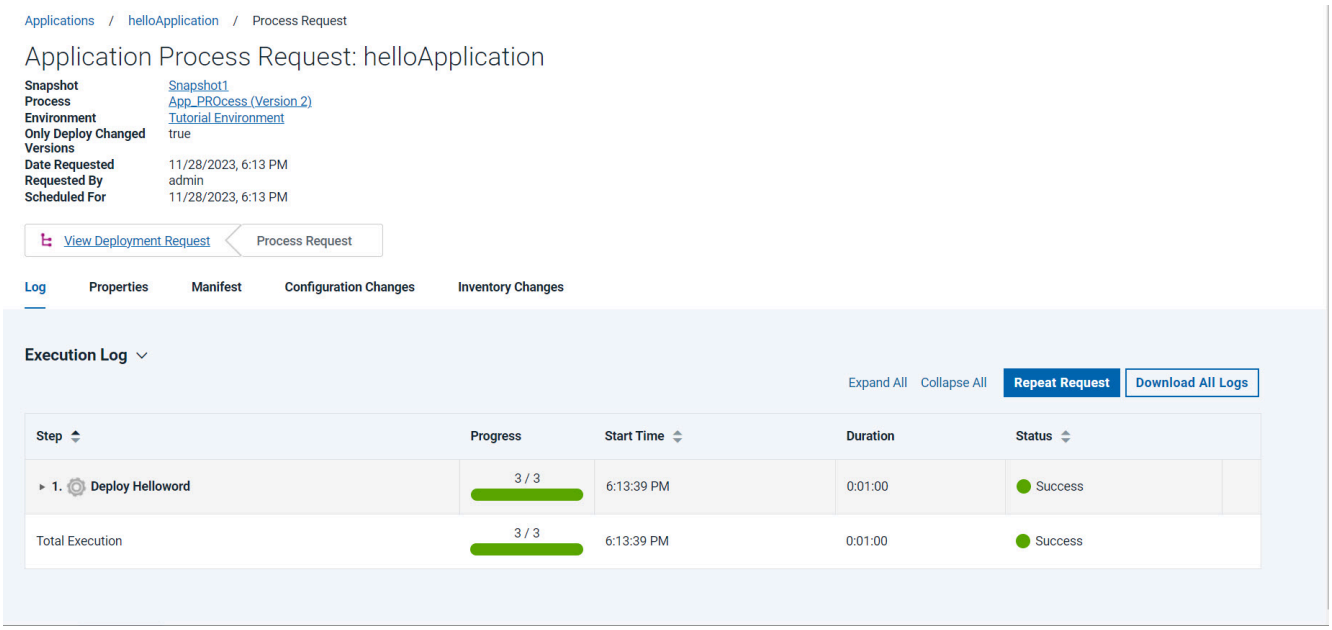
GitHub Action: Request Application process in Devops-Deploy

Running the same process again

The repeat request function is available after an application deployment completes. The **Repeat Request** feature is on the **Process Request** page for the application.

About this task



It repeats the same deployment that was previously requested, including the selected versions. Repeating a previous deployment might result in receiving an `Already Installed` message. When an application process step completes successfully, it is tagged with a version number. If a process does not complete successfully, it remains at the same version. Therefore, starting a repeat request function where some processes completed successfully and which some failed, a mixture of updated versions and remaining versions exist.

During the deployment process, the inventory of resources is verified. The resource version is compared to the requested deployment version. If the resource was successful in the previous build, the `Already Installed` message is displayed because the resource was successfully installed during the previous deployment process and it is not installed again.

Eliminating the `Already Installed` message, depends on how the request process is defined. For example, when a failed installation process results in mixed versions, you can manage environment inventory manually and remove artifacts for failed resources.

To start the deployment process without using the repeat request feature, start the request in the same manner as before and clear the **Only changed versions** options. Using this option causes the inventory check to be bypassed.

Uninstalling components with an application process

You can uninstall components by using an Uninstall Component step in an application process.

Before you begin

- Create an uninstall-type component process for each component version to remove. This process is run by the Uninstall Component step in an application process.
- If you intend to uninstall the component as part of a rollback process, create an application snapshot that contains the component versions to restore.

About this task

There are several ways to uninstall a component. To replace an existing component version, you can install another version over it by running an application process that contains a deployment process for the component. To remove a component version, you run an application process that includes the Uninstall Component step.

To uninstall a component version, complete these steps:

1. Create an application process that contains the Uninstall Component step.
2. In the Uninstall Component step, select the component to remove and the uninstall-type component process that is defined for it.
3. In the **Uninstall Type** field, specify **All Existing** to remove all versions of the component from the environment's inventory. Otherwise, specify **All Selected For Process** to remove only the versions that you select when you run the application process.
4. Run the application process.
   Result
   The selected component versions are no longer in the environment inventory.

Rolling back to a snapshot

You can roll back a component to the versions that are in a snapshot. In this case, you use a **Rollback Component** step with the **Remove Undesired Incremental Versions** option.

Before you begin

- Create a snapshot that includes the component versions to be restored. Snapshots are typically made for every completed deployment, especially for deployments in critical environments. See Creating snapshots on page 2383.
- Create an uninstall-type process for each component to be rolled back. For information about uninstalling component versions, see Uninstalling components with an application process on page 2436.

About this task

For a video demonstration of rolling back components, see Rollback Scenarios in Deploy.

When you roll back to a snapshot in this way, the server runs the uninstall process for each component version that is not in the snapshot. The server runs the uninstall processes in the reverse order in which it deployed the versions, starting with the most recently deployed version and ending with the version that was deployed first. Only the versions in the snapshot are left on the environment.

This method is intended to uninstall incremental versions, but you can also use it to uninstall full versions. However, for full versions, in many cases, it is simpler to install the new full version over the existing full and incremental versions.

This method works best for component versions that are already deployed, regardless of whether the deployments of those versions were completed. As an alternative, you can add a step that immediately rolls back deployments of versions that were not completed; for that method, see Rolling back components that fail to deploy on page 2439.

To roll back one or more components to the versions that are in a snapshot, complete these steps:

1. Create an application process with a name such as "Roll back to snapshot."
2. In the application process, add one or more **Rollback Component** steps, one for each component to roll back.
3. In the properties for each **Rollback Component** step, specify values for the fields that follow.

Tips:

- To specify these values, open the **Edit Properties** window by clicking the edit icon after you drag the steps to the process flow diagram.
- All steps in the process must be connected in a flow from the process Start node to the Finish node. When you drag the first step to the process, the step is automatically connected to the Start and Finish nodes. When you drag another steps to the process, position the step between two steps so

that the connection line is highlighted, and then drop the step. The step is automatically linked to the earlier and subsequent steps. If the connection line is not highlighted, you must manually make the connection from an earlier step to a subsequent step.

Component

Specify the component to roll back.

Component Process

Specify the uninstall process for the component.

Rollback Type

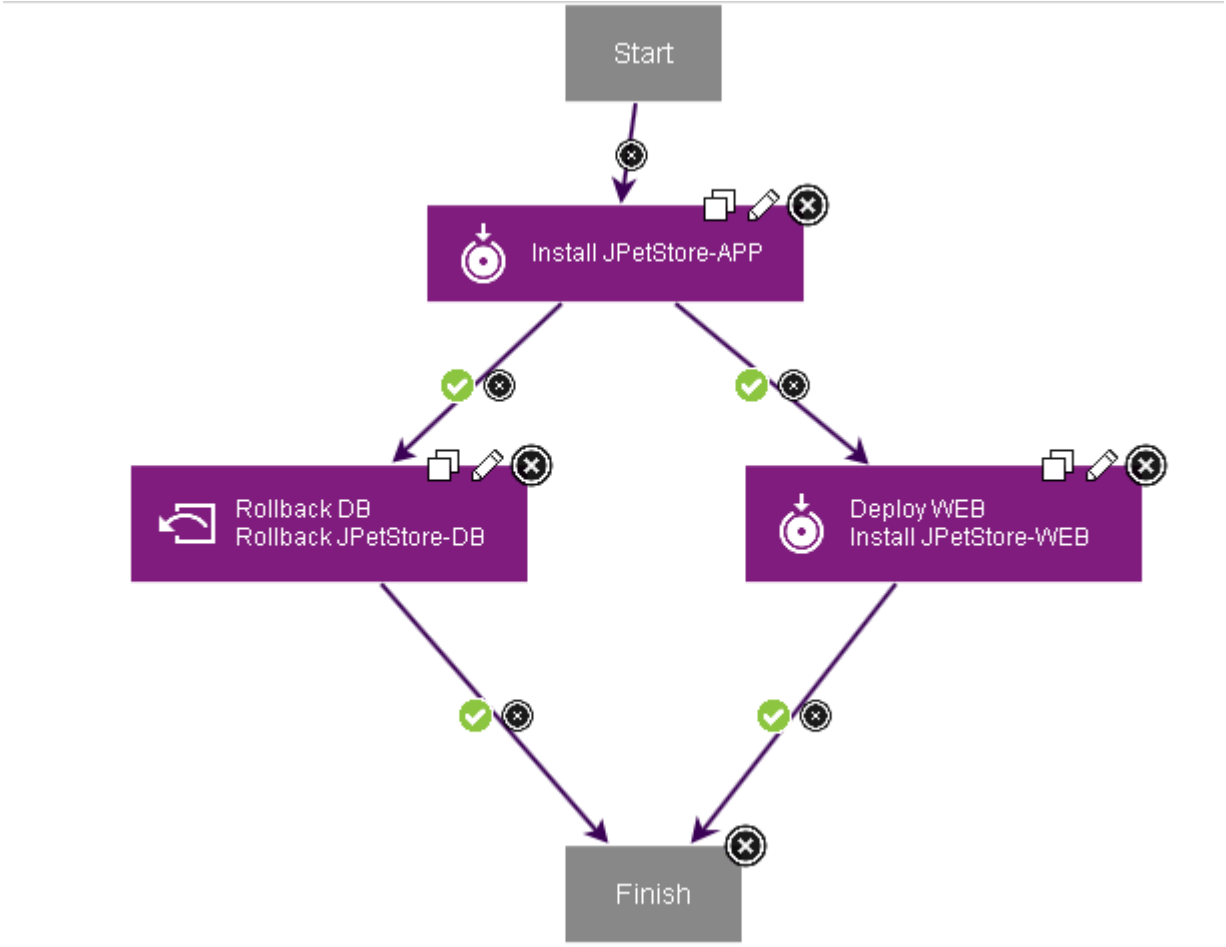
Select **Remove Undesired Incremental Versions**.

4. Verify that all steps in the process are connected in the order for them to run.

   To change the order of the steps, remove the links between steps by clicking the delete connection icon . Then, move the step into a new position and reconnect the steps in order.

   Example

   The following diagram shows a typical application process that includes a **Rollback Component** step. This application process is designed to roll back the three components in the application. Two components use an **Install Application** step that redeploys an earlier component version. The other component, the JPetStore-DB database component, uses a rollback step to roll back the incremental component version. This step uses the **Remove Undesired Incremental Versions** option and an uninstall-type component process.



5. Run the application process, and specify the snapshot to roll back to.
   If you are rolling back by redeploying an existing version, be sure to clear the **Only Changed Versions** check box. Otherwise, the process does not redeploy the version.

Results

The process uses the snapshot to determine which component versions to roll back. In each step that includes the **Remove Undesired Incremental Versions** option, versions that are not in the snapshot are removed.

Rolling back components that fail to deploy

If an application process fails to deploy a component, you can add a rollback step to the process to reverse the deployment. In this case, you use the **Replace with Last Deployed** option.

About this task

For a video demonstration of rolling back components, see Rollback Scenarios in Deploy.

To roll back a component in this way, you add a step in the application process that runs if the component is not deployed. This **Rollback Component** step with the **Replace with Last Deployed** option redeploys the previously installed component

version. The specified inventory still shows the new version and that the environment is noncompliant because the deployment of that version failed.

This method works best if you want to roll back a component within the same application process that attempted to deploy it. For example, you can install a component, run tests on it, and if the tests fail, roll back the component.

If the component is already installed and you want to switch to a different version, you can do one of these procedures:

- Install the new component version over the existing component version.
- Use the uninstall process for the component to remove the unwanted version.

  Create a rollback process that uses the **Remove Undesired Incremental Versions** option to roll back to a snapshot. See Rolling back to a snapshot on page 2437.

1. In an application process, add a step to deploy a component version as usual.
2. In the process, add a **Rollback Component** step.
3. In the **Rollback Component** step, specify the following information:

   Component

   Specify the component to roll back.

   Component process

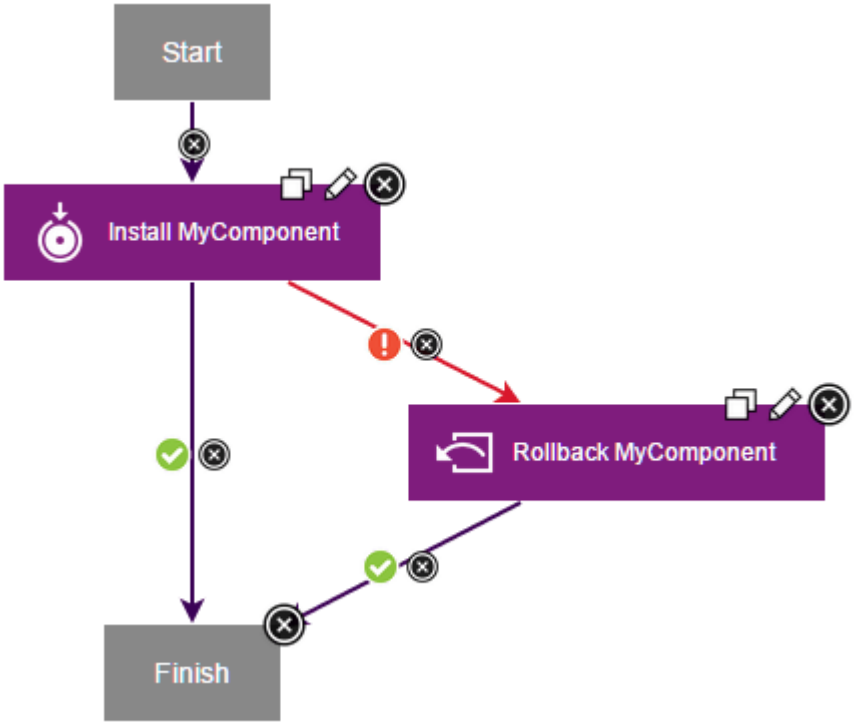
   Specify the process to run on the previously deployed version. In most cases, specify the deployment process for the component.

   Rolback Type

   Select **Replace with Last Deployed**.
4. Set a failure link from the deployment step to the rollback step so that the rollback step runs only if the deployment fails.

Example

Assume that version 1 of a component is deployed to an environment. You want to install version 2, but if that installation fails, you want to roll back to version 1. The application process looks like the following example. In this application process, the first step deploys the component version as usual. If that step fails, the rollback step runs with the **Replace with Last Deployed** option. In this case, the rollback step deploys version 1, which is the version that was in the inventory before the process started. However, the inventory is still noncompliant because you tried to deploy version 2 and failed.



Modeling blue-green, rolling, and canary deployments

The For Each Agent and For Each Tag steps provide ways to deploy to large environments in stages, allowing you to run flexible blue-green or rolling deployments, with or without updating canary nodes first.

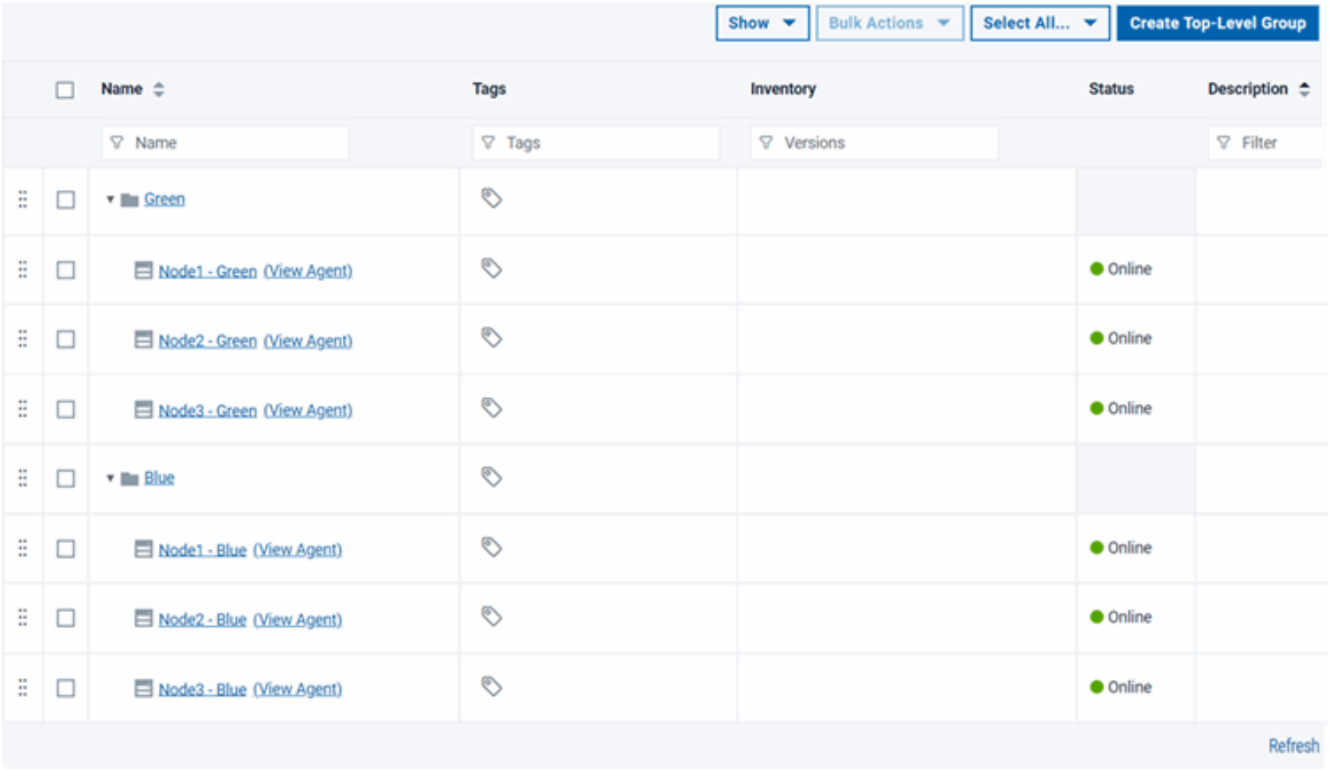
Two application process steps, the For Each Agent on page 2470 step and the For Each Tag on page 2472 step, provide flexible ways to deploy to multi-node environments in stages. You can use these steps to select subsets of agents and deploy to those subsets in specific orders. The following scenarios are just a few examples of how you can use these steps to control how deployments happen in multi-node environments.

Blue-green deployments

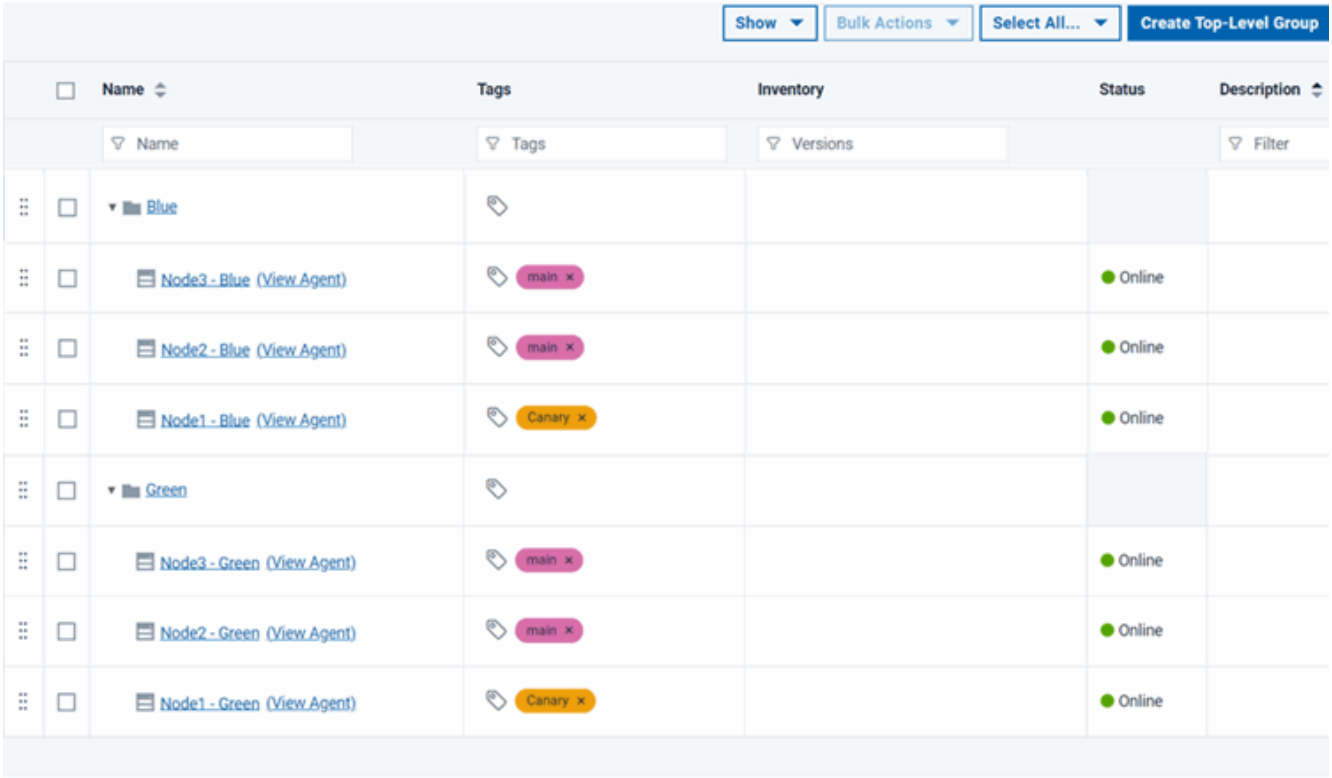
For a video demo of blue-green deployments, see Blue-green deployments with Deploy. For an article that covers a blue-green deployment scenario in detail, see Setting Up Blue-Green Deployments in Deploy.

Blue-green deployments use two identical environments. While clients are using one active environment, you can update the other environment without interrupting the active environment. Then, when the other environment is ready, you set a load balancer to send client traffic to the updated environment. Updating environments in this way allows for zero-downtime deployments and keeps a second working environment ready at all times in case anything goes wrong with the active environment.

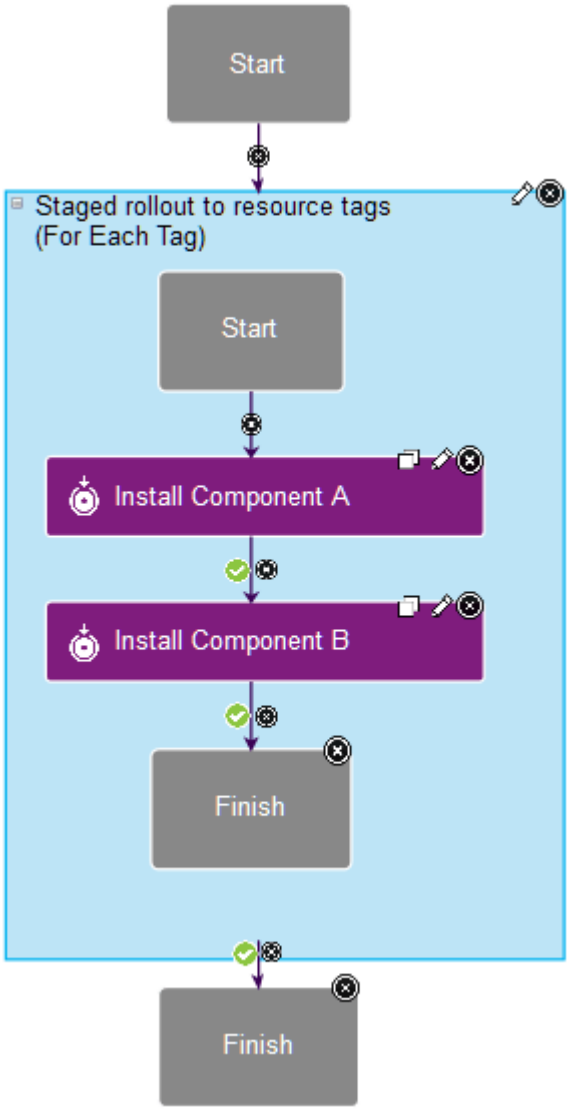
To set up a blue-green deployment, first set up matching environments on the server. These environments can point to the same physical environments as long as they have different agent resources. These different agent resources allow you to distinguish the two environments, as shown in the following figure.



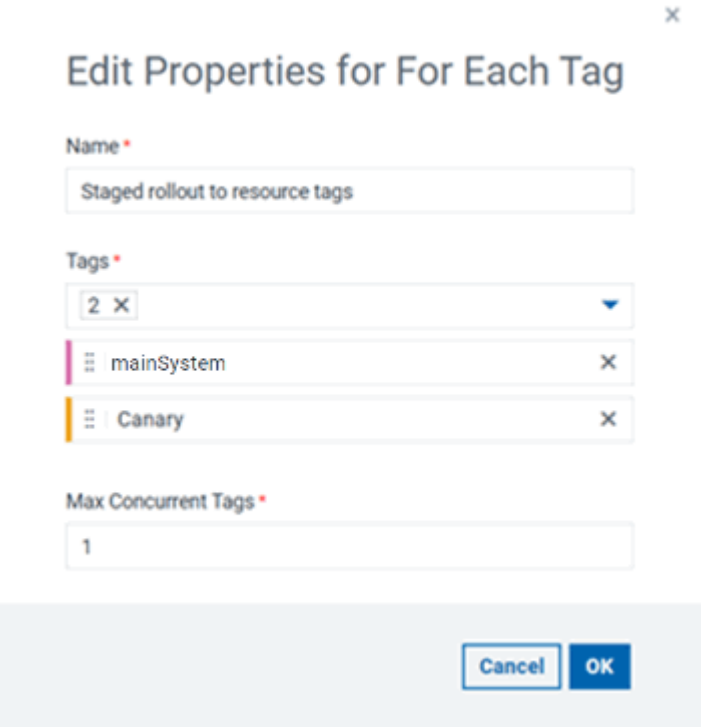
Then, apply resource tags to select subsets of the agent resources. For example, large deployments often update a few test nodes first, called *canary nodes*. You can apply a resource tag to your canary nodes to run deployments on those agent resources first. For example, the following figure shows the same resource tree with the addition of "canary" tags on the canary node and "main" tags on the other nodes:



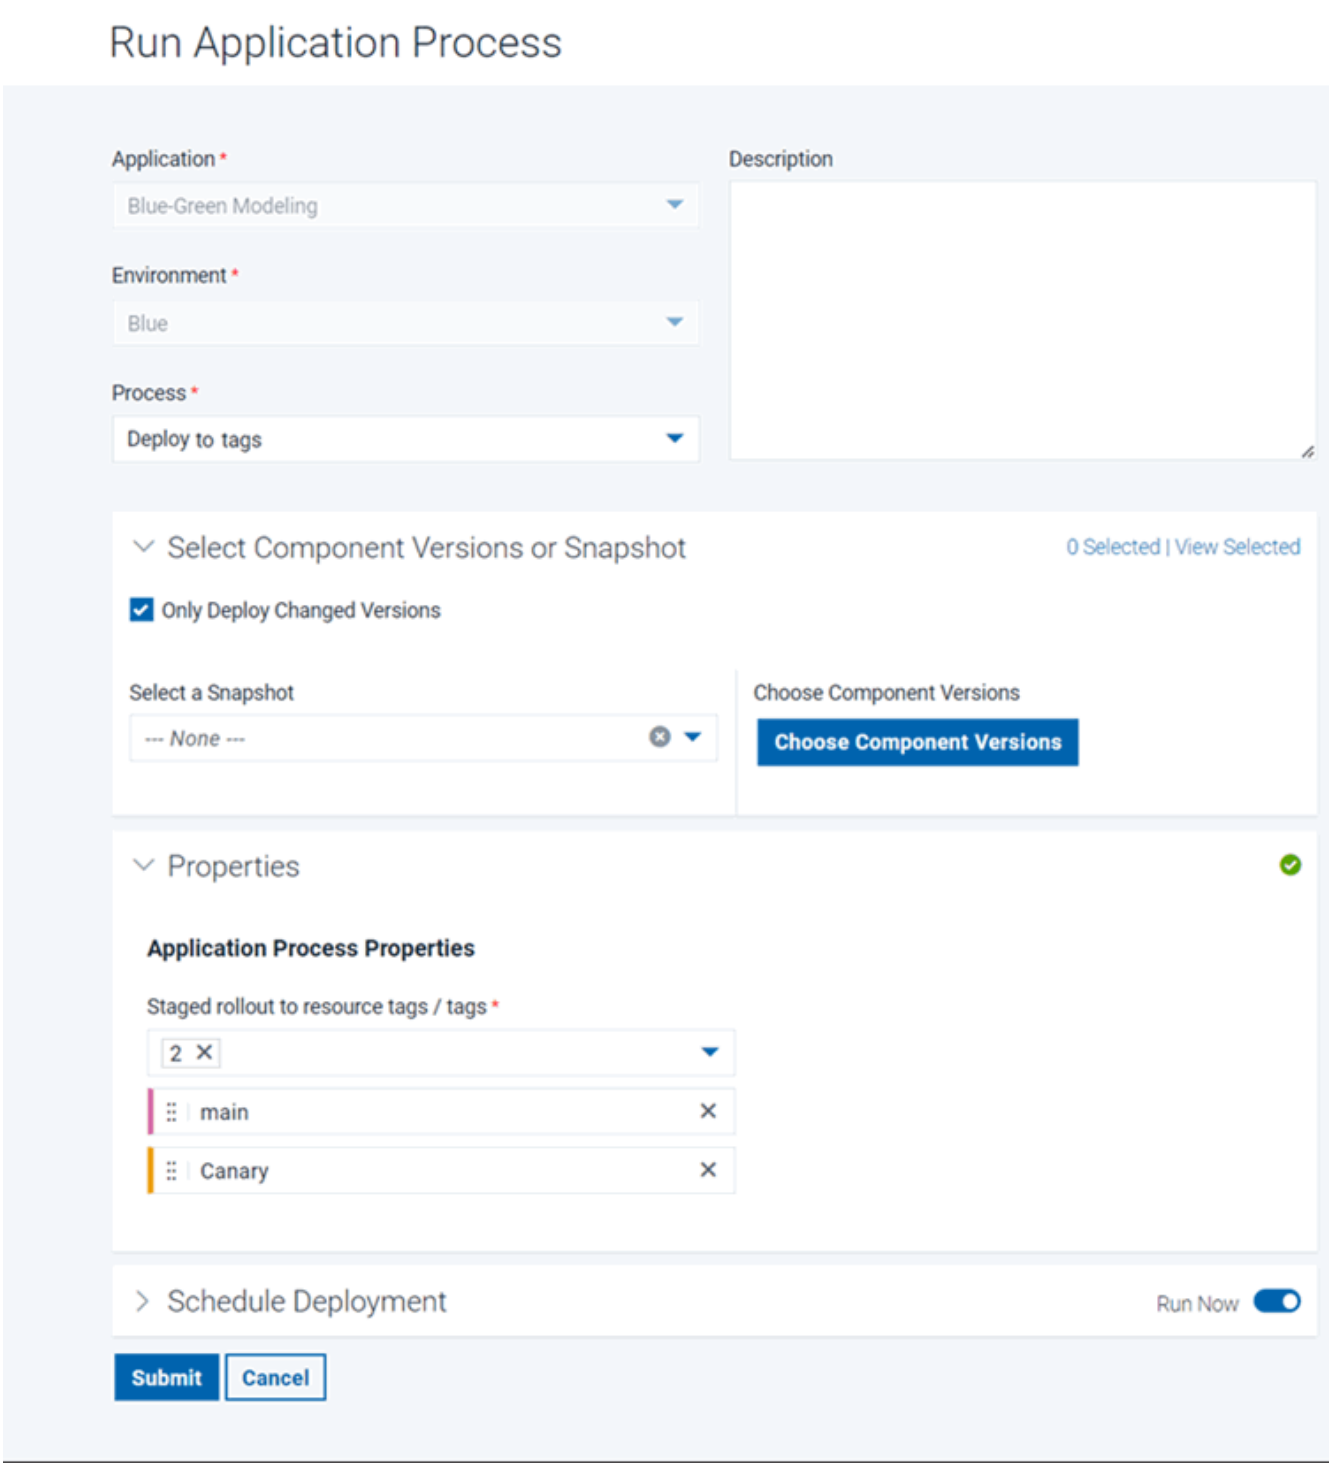
Then, in your application processes, run deployments based on the tags or agents. For example, to run a deployment on the canary agent resources first, and all of the other agent resources second, use a For Each Tag loop. In the loop, use the canary tag first and then a tag that represents the other resources. The following figure shows the For Each Tag step in use, and the next figure shows the properties for that step:



Start
Staged rollout to resource tags
(For Each Tag)
Start
Install Component A
Install Component B
Finish
Finish



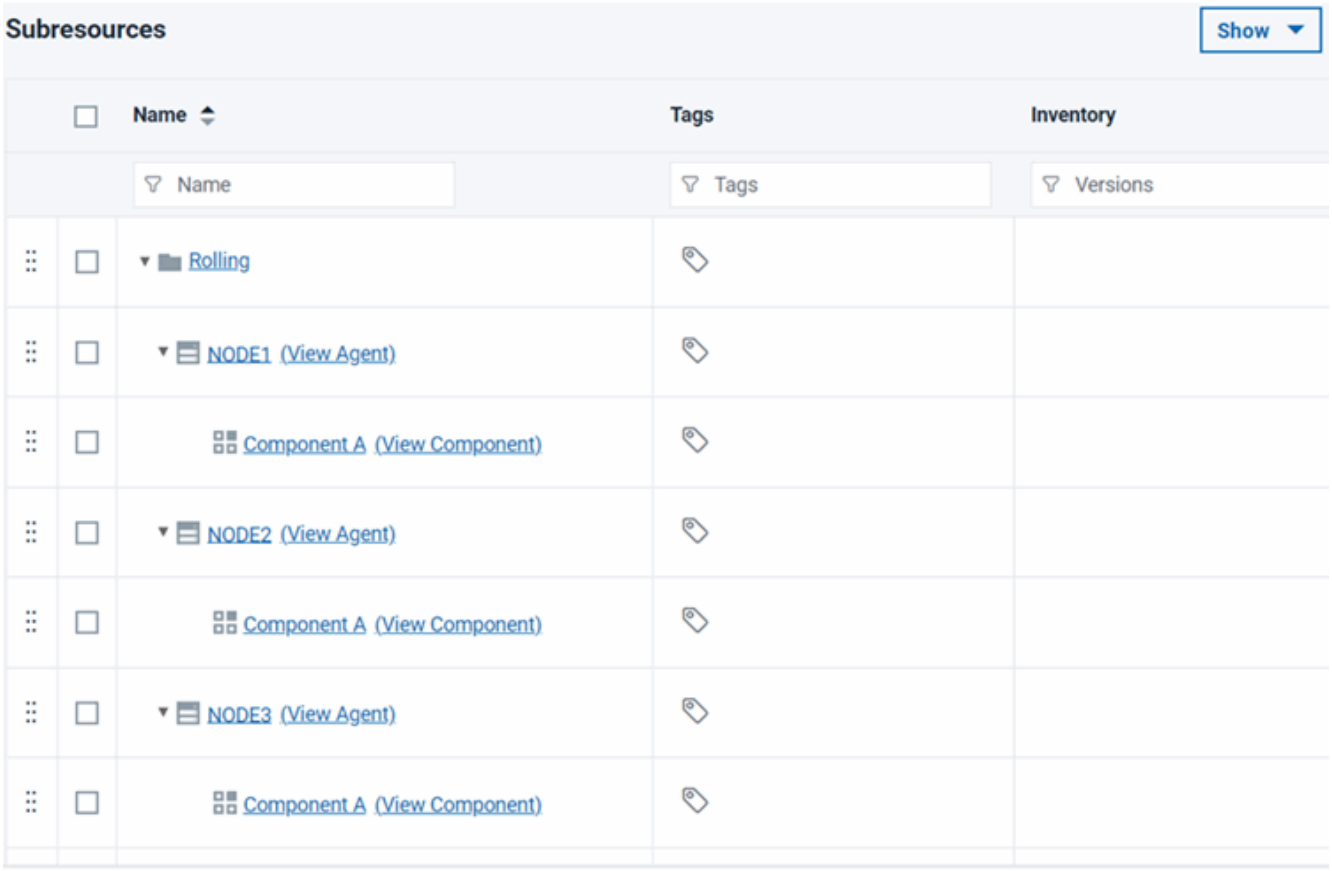
When you request the process, you can set the tags to use for that request, as shown in the following figure:



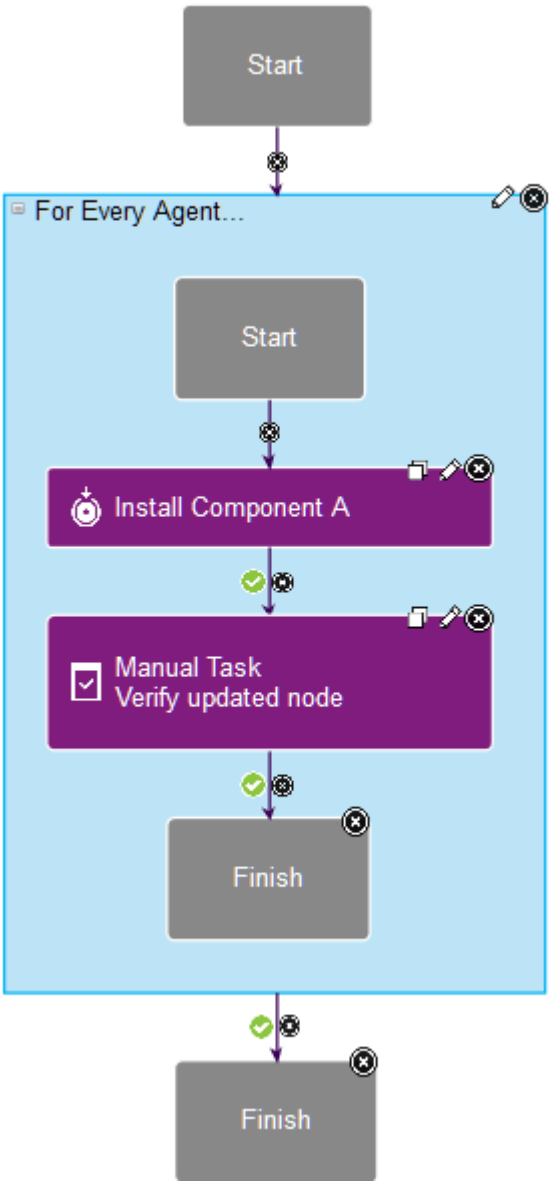
There are many other ways to organize this type of deployment. For example, instead of using separate environments, you could use a single environment and tag the nodes Blue and Green with resource tags. How you organize your environments and apply resource tags to them depends on the order in which you want to update your nodes.

Rolling deployments

Rolling deployments update large environments a few nodes at a time. The setup for rolling deployments can be similar to blue-green deployments, but this time with a single logical environment. The environment can have many nodes, as shown in the following figure:



To deploy to these nodes one at a time, use the For Each Agent step. For example, the following application process runs deployments on these nodes within the For Each Agent step. It pauses for a manual task after each deployment to ensure that the deployment ran correctly on that node. You could use any manual or automatic test in place of that manual task. In the properties for the loop, the **Max Concurrent Agents** property is set to 1 to run the deployment to a single agent at a time.



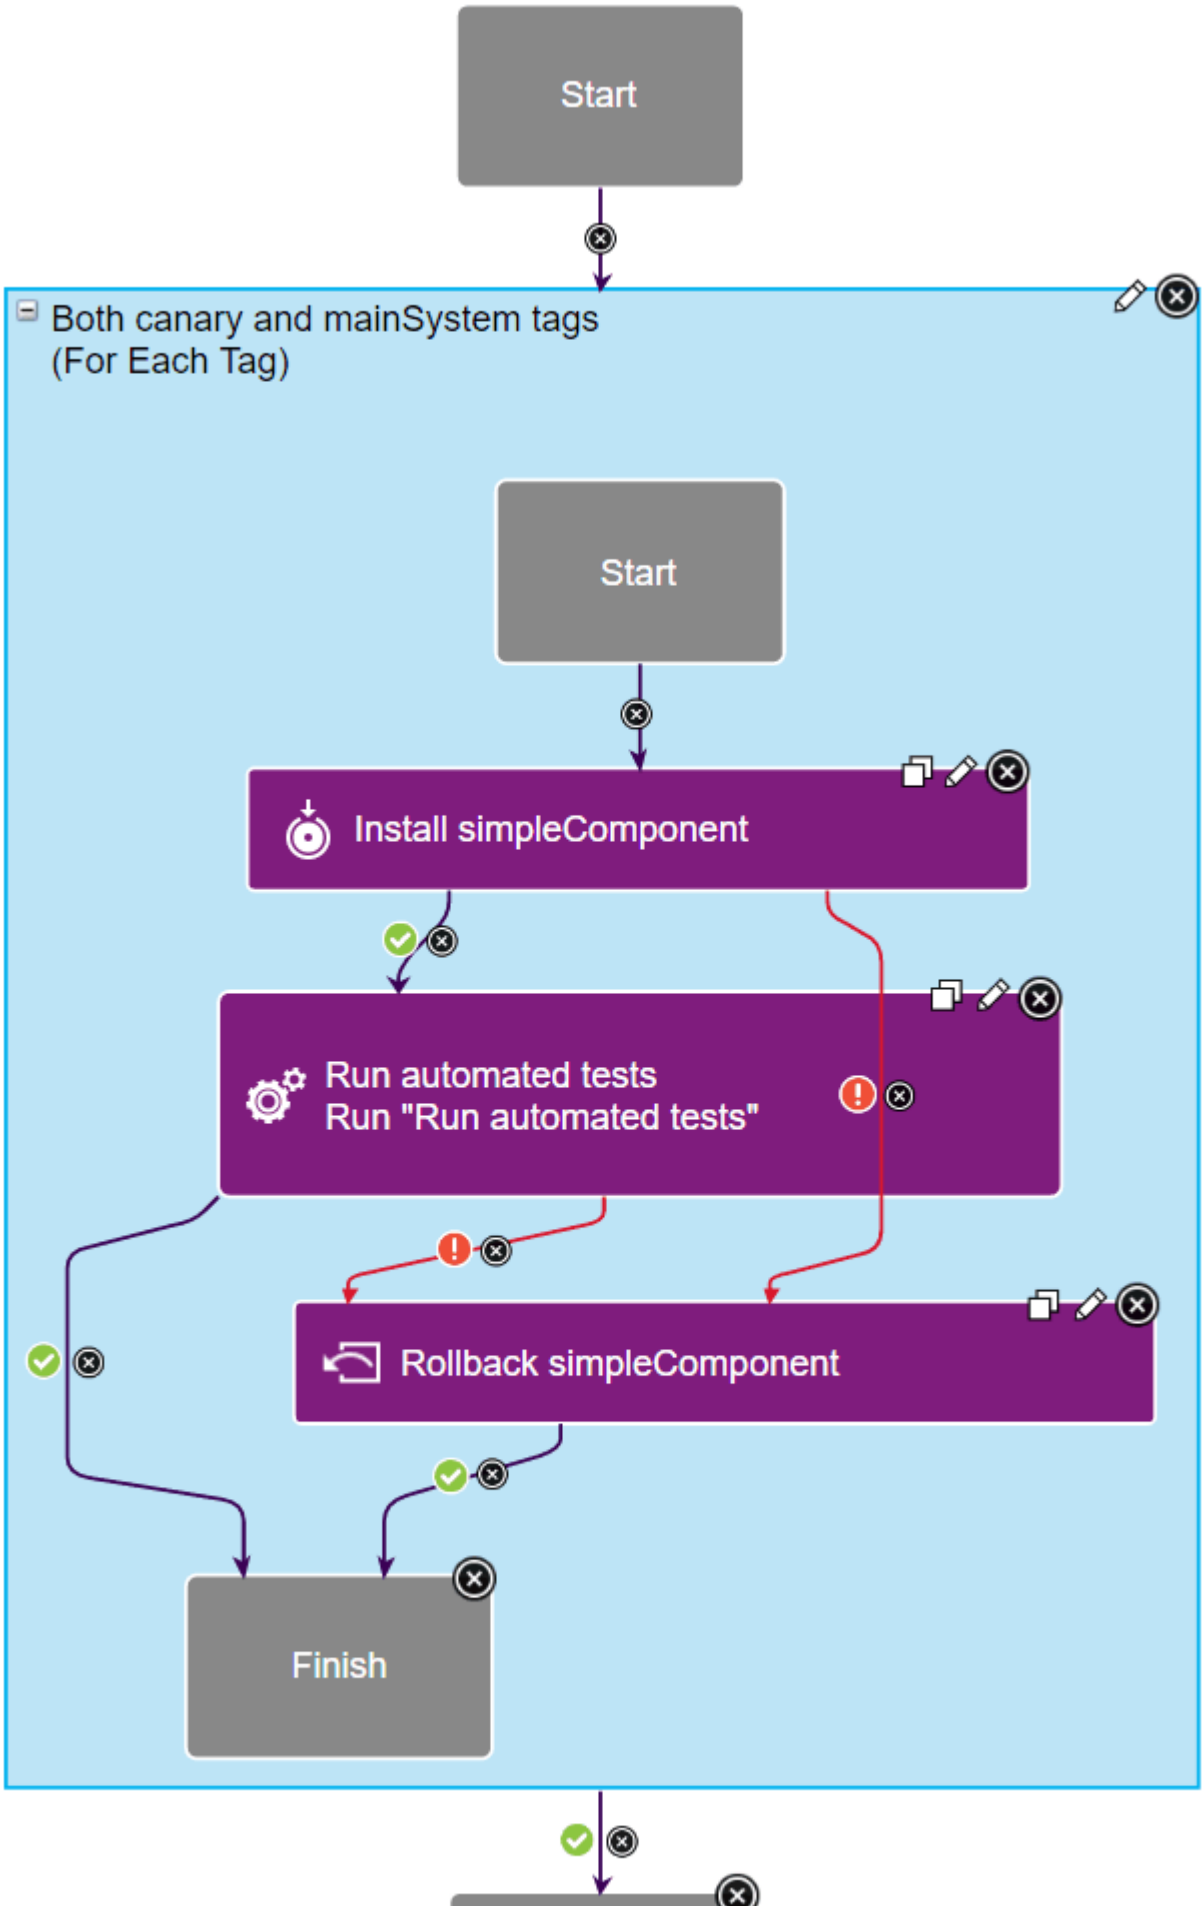
Canary deployments

Canary deployments are deployments that start by updating a single node or a subset of nodes. That way, you can test the update on a small subset of your system before you update every node. Canary deployments can be part of many other deployment scenarios. For example, the scenario in Setting Up Blue-Green Deployments in Deploy includes deployment to a canary node first.

All you need to do to use a canary node in your deployment is to pick one or a few nodes and make sure that you deploy to those nodes first. Then, you must run automated or manual tests to make sure that the canary node or nodes are working well with the new version.

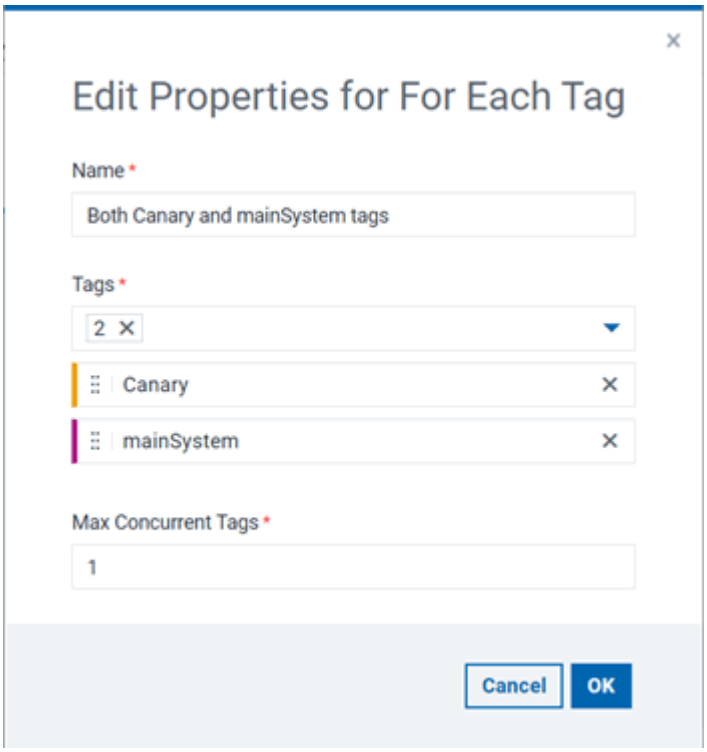
A straightforward way to deploy to canary nodes first is to apply a resource tag to them and to deploy to that resource tag first. For example, the scenario in the article Deploying applications with canary nodes applies the resource tag `canary` to one

node and the resource tag `mainSystem` to the other nodes. The article shows several ways to use those tags, but a simple way is to use a For Each Tag loop. This loop contains a simple sub-process that deploys the components and runs automated tests:



Start
Both canary and mainSystem tags
(For Each Tag)
Start
Install simpleComponent
Run automated tests
Run "Run automated tests"
Rollback simpleComponent
Finish

In the properties of the loop, you select the tags and then set the order for those tags. In this case, the `canary` tag runs first and the `mainSystem` tag runs second:



Generic processes

Generic processes are processes that are designed to run outside normal component or application processing. Generic processes are not specific to a particular component and can be used in any number of applications. They are like general purpose processes. You can use generic processes to download and install packages on the system or perform other configuration management related tasks such as configuring SSH or completing FTP tasks. With a generic process, for example, you can update Linux agents that were recently installed by using SSH to run as a service on a Linux computer. Linux agents cannot be updated in this way during a remote installation.

Generic processes can be used anywhere an application or component process might not be needed. Generic processes are run by agents on hosts that are managed by the agents. You can use generic processes in these instances, for example:

- In conjunction with a number of different component processes that do not fit well into a component template
- When you want to run processes that directly affect HCL DevOps Deploy (Deploy) agents that are unrelated to component, such as changing the agent configuration

Like component processes, generic processes consist of plug-in steps. Generic processes are created in the same way that component processes are created: steps are placed and configured in the process design editor. All plug-ins can be used, but some might be of little or no use outside a deployment. See Processes on page 2398.

To run a generic process, click **Processes**, and then click the generic process. On the **Dashboard** tab for the process, specify a resource (in most cases, an agent) in the **Resource** list, and then click **Submit**.

Generic processes can also be run from within component processes.

Starting in Deploy 7.0.3 generic processes can run against multiple resources at the same time. These resources can be selected at run time or in the process designer as part of the process flow.

Tip: You can set a default resource for generic processes:

1. Click the generic process to open it.
2. Open the **Configuration** tab.
3. Click **Basic Settings**.
4. In the **Default Resource** field, specify the default resource to run the process on. In most cases, specify an agent.
5. Click **Save**.

Importing and exporting generic processes

You can move generic processes between servers by exporting and importing them.

About this task

You can export a generic process from the **Processes** page to a JSON or YAML file containing the process, steps, and properties associated with the steps.

When you export components, applications, processes, or templates, and then import them on a different computer, the same versions of the same plug-ins must be installed on both computers.

You can export a generic process and import it into the another server.

1. On the first server, click **Processes** to open the **Processes** tab.
2. Export the process:
    a. Click the menu option of the process to be exported.
    b. Select **Export to JSON** or **Export to YAML**.

   You can load the file into a text editor or save it.

   Important: You must create the JSON file that contains the process definition from a server that uses the same version of HCL DevOps Deploy (Deploy) as the destination server.

   A file is created with the same name as the selected process.

   Example

   The file name takes the form of this example: `exampleprocess.json`.
3. Make the file available to the second server.
4. On the second server, click **Processes > Import Process** to open the **Import Process** window.
5. To upgrade an existing process, select **Upgrade Process**.

If the name of the process in the JSON file matches an existing process, the process parameters are updated with new values. If the process name is not found, the command has no effect.

Note: An existing process must match the name of the process in the JSON file, not the name of the file itself. The process name is the first parameter in the JSON file. The following text is the JSON representation of a process named `Post-process test`.

```
"name": "Post-process test",
```

6. Select an upgrade type from the dropdown list in the **Generic Process Upgrade Type for Linked Processes** field.
   - **Use Existing Process** type does not modify existing child processes that already exist on the system, but it still creates any child processes that are missing from the system but included in the import.
   - **Create Process** type generates a new process and appends a suffix to its name even if a process with the same name already exists during the import.
   - **Fail If Process Exists** type causes the import to fail if one of the processes being imported already exists on the system.
   - **Fail If Process Does Not Exist** type causes the import to fail if the process being imported does not already exist on the system.
   - **Upgrade Process if Exists** type updates any processes referenced by name to match the content of the import document and creates any processes that are missing.
7. Click **Choose File**, and then select the JSON file that contains the process definition.
8. Click **Submit**.

Results

You have exported and imported the generic processes between the servers.

Editing processes

In the process editor you organize the steps in a process, specify their properties, and connect them to each other.

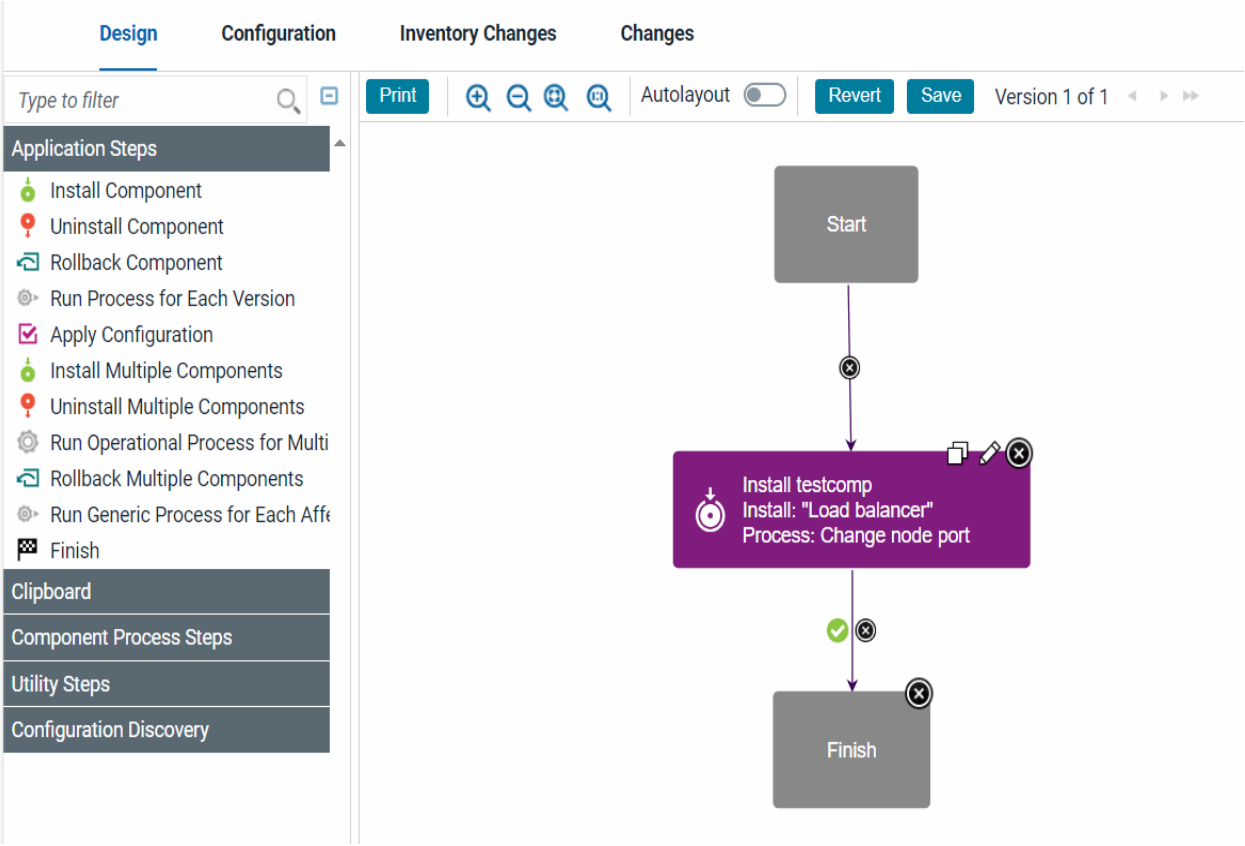
1. Open the component process in the process editor.

   Choose from:

   - To open a component process, click **Components**, click the component, click the **Processes** tab for the component, and click the process.
   - To open an application process, click **Applications**, click the **Processes** tab for the application, and click the process.
   - To open a generic process, click **Processes**, and click the process.

   Result

   The process editor opens. The editor is similar for each type of process, but the list of available steps is different for each type of process.



When the **Process Design** pane opens, the **Design** view is displayed. Processes are assembled with the **Design** view. Available steps are listed at the left of the window. Deploy provides several utility steps and plug-ins. More plug-ins and documentation for those plug-ins are available on: HCL plug-ins website.

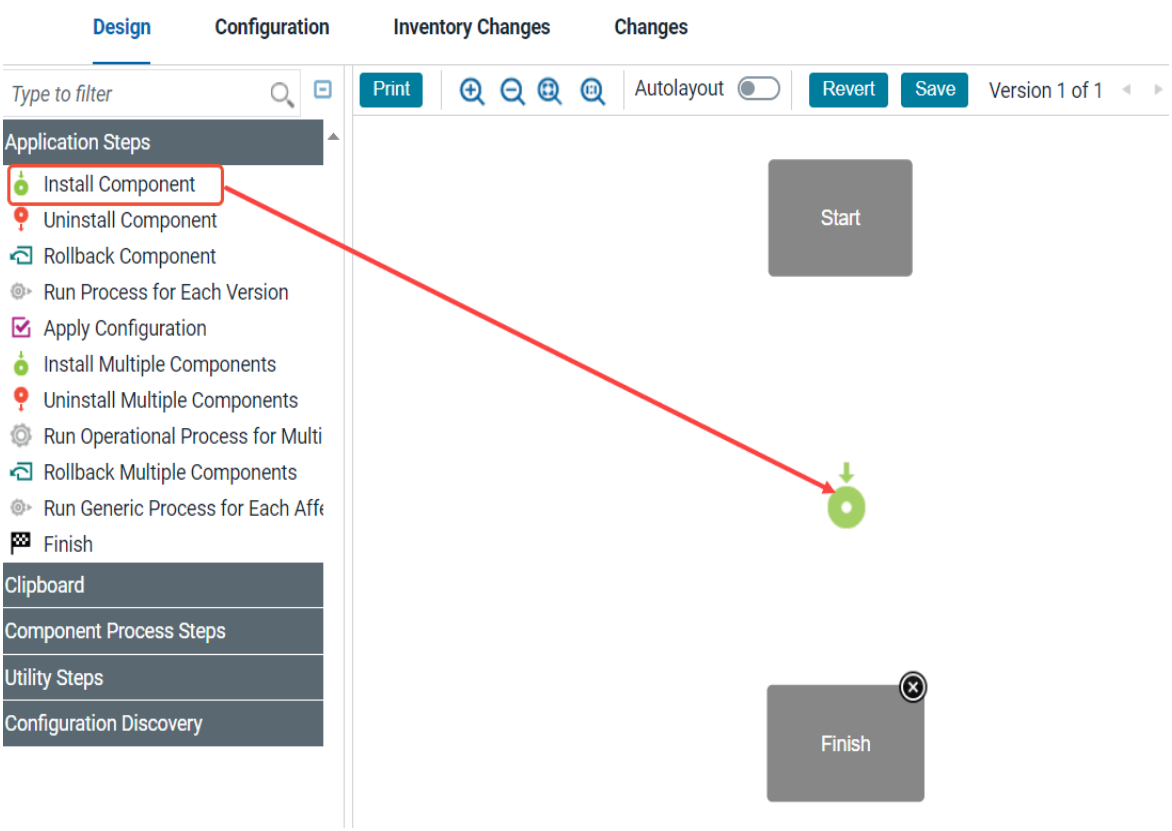
In addition to the process editor, the following two pages provide information about the process:

- The **Configuration** page shows the properties and settings for the process.
- The **Changes** page shows a record of every change to the process, addition or deletion of a property, and save or deletion of the process.

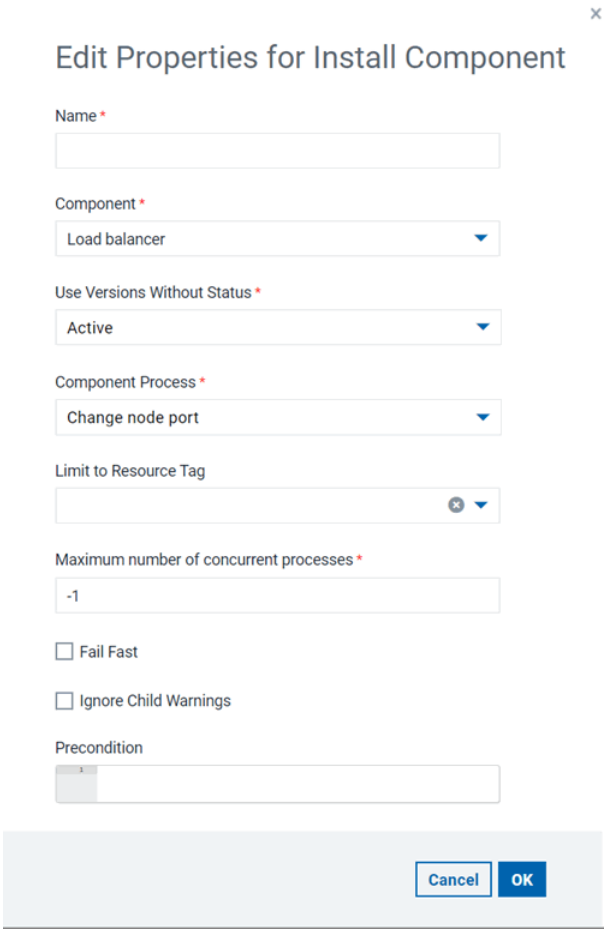
2. To add a step:

   a. From the list of steps at the left of the window, drag the step to use onto the design space.

   Result



To open the **Edit Properties** window, click the edit properties icon . When you drag the first property on the design pane, you can place the step anywhere on the design space. Connection links are automatically created from the Start node to the step and from the step to the Finish node. When you add more steps, drag them and position them so that they highlight the connection link between stesps so that the step is inserted and connection links are automatically created between the steps. Steps can be dragged and positioned at any time. However, you must delete the connection links from the step by clicking the delete connection icon , and then reconnect the moved steps.



Configuration dialogs boxes are tailored to the selected step. Only parameters that are associated with the step type are displayed.

b. Specify the properties for the step.
Each step has different properties. See Plug-ins on page 2556 for information about configuring specific steps.

c. **Optional:** To add or change the post-processing script, select a script in the **Post Processing Script** list. For more information, see Post-processing scripts on page 2415.

d. After you configure the step properties, save the step by clicking **Save**.

Result

The step is in the design space and is connected to other steps. If you change your mind, click **Cancel** to remove the step from the design space.

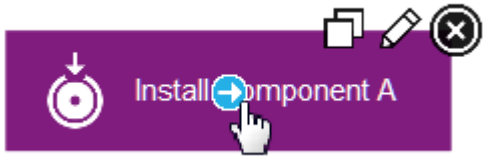
3. Verify that the step connections create the required process flow:
Connections control the process flow. The originating step runs before the target step. If you move steps or do not highlight a connection link when you place a step, creating a connection between steps is a simple process. You drag a connection from the originating step to the target step. Connections are typically formed automatically. However

when you create them manually, connections are formed one at a time between two steps, the originating step and the target step. To create connections manually:

a. Hover the cursor over the step to use as the origin of the connection.

Result

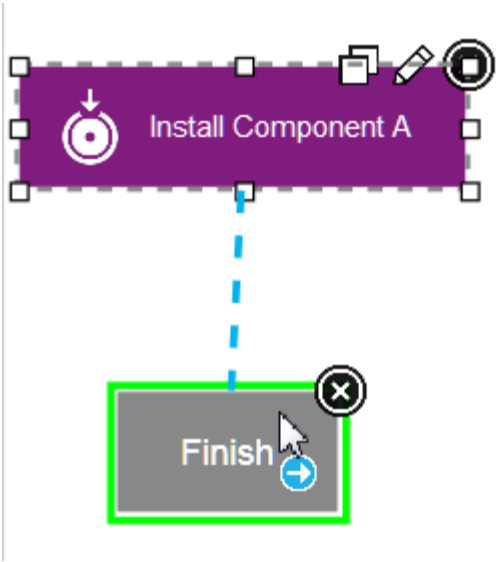
The connection tool is displayed.



b. Drag the connection tool over the target step.

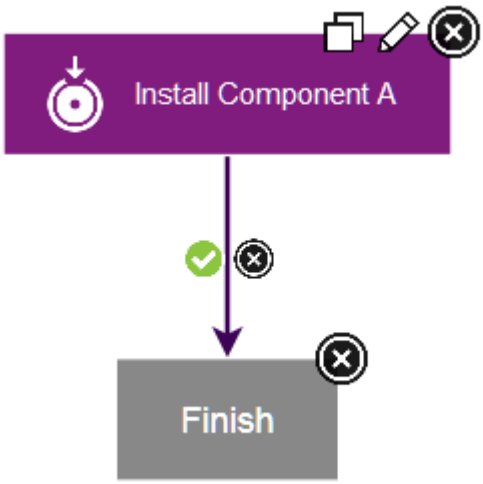
Result

The step beneath the connection tool is highlighted.



c. Release the connection tool over the target step to complete the connection.

Result



Each connection has a connection delete tool, *conditional flag*, and might have other tools depending on the originating step. Remove a connection by clicking the delete tool.

4. Add more steps to the process, connect them, and arrange them in the process editor.
   You can drag steps to move them around the process. In this way, you can arrange the steps in a meaningful arrangement on the process editor canvas.

   Tip: To move more than one step at a time, hold the Ctrl or Command key and click two or more steps to select them. Then, drag the steps to a different place in the editor.

5. Verify that the flow of steps is correct.
   Each process starts with the Start step and continues until it reaches the Finish step. Therefore, the Start step must connect to the first step or steps to run. Similarly, the last steps must connect to the Finish step, or else the process does not finish correctly.
6. When you are finished with your work on the process, click **Save**.
   If comments are required, the **Process Change Comment** window opens. Type a comment, and then click **Save**. The server settings control whether comments are required. To learn more about system settings, see Server settings and configuration on page 2069.

Working on processes in safe edit mode

Safe editing enables you to test component processes before making them available in normal environments. Make updates to your component process, test those updates safely, and then promote to a new version when you are ready.

Before you begin

Enable Safe Edit mode by completing the following steps:

1. Click **Settings > System Settings**. Select **Enable Safe Edit of Component Processes**, optionally select **Require Approval to Promote Component Process** and then click **Save** at the bottom of the System Settings page.
2. If **Require Approval to Promote Component Process** is enabled, after a draft is promoted you see **Promotion Pending** where the **Promote** push button was. The **Promotion Pending** button is inactive while an approval is pending. Approval requests go to anyone with manage processes permission on component. Under **Work Items**, there is a new Component Process promotion table with **Approve** and **Reject** actions. These actions link to latest promoted version and draft processes for which promotion was requested.
3. Two new parameters are displayed under the **Component Settings**.
    a. **Allow Process Locking**. When this option is enabled you will be able to lock component processes for editing.
    b. **Require Process Locking**. When this option is enabled you will not be able to edit component processes without locking the process first.

About this task

You can edit component processes and component template processes without affecting deployments to protected environments.

1. Under **Environments**, when you are editing the **Enable Drafts Processes** option, a new setting becomes available. After you select **Enable Draft Procees**, a new field, **Component using Process Drafts**, is displayed. Choose components for draft processes to run on.
2. On the **Components** tab, click the component name.
3. To **Edit** draft process, on the **Processes** tab, hover the cursor over the process to edit, and click the the pencil icon.
4. Design your draft process, and then click **Save**.
5. Test the process in the environment you set up in step one.
6. When process works as expected, go back to the process designer, and click **Promote**.
   This action makes the process available for use or creates a promotion approval.
7. **Optional:** Click **Lock** to lock draft.
   Result
   The name of the person who locked the draft is displayed under **Locked By** on the **Processes** page. Only the person who holds the lock can edit the process. Under **Actions** a **Force Unlock** option is available.
8. **Optional:** Click **Copy Latest Promoted Version To Draft** to create a copy of that version at the head of the draft stream. Click **Copy as Latest Draft** on a promoted process to create a copy of that version at the head of the draft stream.

Results

Environments that are set to allow draft processes can use draft process for deployments. Other environments must use the promoted processes.

Note: Snapshots can only lock to versions of component processes. They cannot lock to drafts. If a snapshot is deployed to an environment that allows drafts then one of these conditions apply:

- If the snapshot is using the latest version of a process, the draft will be used.
- If the snapshot is using a specific version of a process, then that specific version will be used.

Running processes

The way you run a process is different for each type of process.

About this task

To run a process, you must have permissions to access the processes and to run processes on the target agent resource.

Component processes

You cannot run a component process directly. Instead, you add one or more component processes to an application process and then run the application process.

Application processes

To run an application process, you must have an application environment. Click **Applications**, click the application, and then next to the environment, click **Request Process**. Then, specify the application process and the versions of the components to use. For more information, see Running application processes on page 2431.

Generic processes

To run a generic process, click **Processes**, and then click the generic process. On the **Dashboard** tab for the process, specify a resource (in most cases, an agent) in the **Resource** list, and then click **Submit**.

Tip: You can set a default resource for generic processes:

1. Click the generic process to open it.
2. Open the **Configuration** tab.
3. Click **Basic Settings**.
4. In the **Default Resource** field, specify the default resource to run the process on. In most cases, specify an agent.
5. Click **Save**.

Each time you request a process, the server keeps a log of information about the process and the individual logs from each step. To download these logs, open the process request and click **Download All Logs**.

Adding process properties

A *process property* provides a way to add user-supplied information to a process. A running process can prompt users for information and then incorporate it into the process. For example, if the process entails authenticating with another server, you can require that a user enter an ID and a password for the process to continue. Properties are defined in the **Edit Property** dialog box.

1. Open the process.
2. On the **Configuration** tab, click **Component Process Properties**, **Application Process Properties**, or **Process Properties**, depending on the type of process.
3. In the **Edit Properties** dialog box, enter a name in the **Name** field.
4. Optionally, enter a description in the **Description** field.
5. Enter a label in the **Label** field.
   The label is associated with the property in the user interface.

   Note: If two properties have the same label, they will not be grouped if the property names are not also the same.

6. In **Pattern**, enter a regular expression to require that user input values for this property match a specific pattern. Leave this field blank to accept any values.
7. If the property is required, check the **Required** check box.
   The default value is that the property is not required.
8. Specify the type of expected value with the **Type** list.
   Supported types are: `text`, `text area`, `check box`, `select`, `multi select`, and `secure`. Default type is `text`.
9. In the **Default Value** field, enter a default value (if any).
10. To save your work, click **Save**. To discard changes, click **Cancel**.

What to do next

To use a property in a process, reference it when you configure (see Component processes on page 2299) a step that uses it.

Copying process steps

You can copy and paste process steps in all process types: component, application, approval, and generic.

About this task

Steps that you copy are available until you delete them from the clipboard. Steps are saved to the clipboard on a per-user basis. Steps that you copy are not available in others' clipboards.

1. Open a process.
2. On the process step to copy, click the **copy** icon.
   The copy icon is to the left of the **edit** icon for the step: . Copying is not supported for the **For Each Agent** step in application processes.
   Result
   The process step is copied to the **Clipboard** folder in the **Step Palette**.
3. Expand the **Clipboard** folder in the **Step Palette**.
   Result

The steps that you copied are displayed. Only steps that apply to the current process are displayed in the **Clipboard** folder. For example, if you are editing an approval process, only the approval process steps that you copied to the clipboard are displayed.

4. To paste a step into a process, drag the step from the **Clipboard** folder to the design space.
   Click the **delete** icon on any step to remove the step from the **Clipboard** folder.

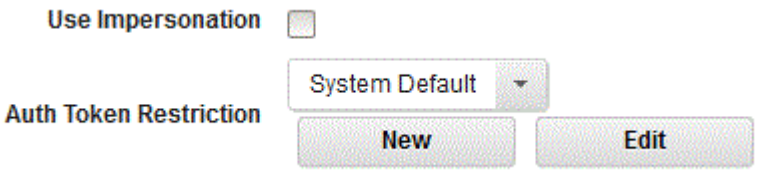
Manage process step authentication

Use token restrictions to manage process step authentication.

The HCL DevOps Deploy (Deploy) server generates an authentication token whenever it runs a plug-in process step. The token authenticates the user that is running the step and has the same permissions as that user. You can limit the actions available to tokens by applying token restrictions to them. A token restriction is a set of one or more REST API commands. When a token-restricted plug-in step runs, it uses the commands that are defined by the token restriction regardless of the user's permissions.

You apply token restrictions to plug-in steps in processes. You can apply a different token restriction to every plug-in step in a process. If you do not apply a restriction to a step, the default token restriction is used. The default token enables all the supported methods for all REST resources. You can modify the default token restriction but you cannot delete it.

You can apply token restrictions to component, application, and generic processes. To apply a token restriction to a process step, on the step configuration window, select the restriction from the **Auth Token Restriction** list.



You can edit the selected token restriction and also create a new token restriction from the plug-in step configuration window. For more information, see, Restricting authentication tokens on page 2223

User impersonation for process steps

HCL DevOps Deploy (Deploy) can use *user impersonation* when an agent must run a command for which it might not otherwise have permission, or when a specific user must be employed for a process.

On UNIX™ and Linux™ systems, the su and sudo commands are used to impersonate users; on Windows™ Deploy provides a utility program to handle impersonation. You implement impersonation when you configure a component's plug-in process step or resource.

Note:

When using impersonation, the user running the agent needs to have read, write, and execute access to the `<DEPLOY_AGENT_HOME>/var/work` directory.

The user starting the plugin as impersonating user needs to also have read, write, and execute access to the *<DEPLOY_AGENT_HOME>*`/var/work` directory.

Impersonation on Linux™ and UNIX™ systems

The su command (as used by HCL DevOps Deploy (Deploy)) enables a user to start a shell as another user (process steps can be considered individual shells).

When you configure a process step (see Processes on page 2398), you can tell Deploy to use impersonation for the step. By default, `su` is used but you can use sudo instead. To configure impersonation, you supply the user name that is required by the target host. When the impersonation-configured process step runs, the su or sudo command runs the step as the impersonated user. Each step that needs user impersonation must be configured independently.

Note: The user account must have root privileges in order to issue the su or sudo command when installing.

Before `sudo` can be used, impersonation privileges must be defined in the `/etc/sudoers` file. When you configure `sudoers`, ensure that the impersonating user does not need to supply a password. Typically, you would configure the `/etc/sudoers` file like the following example:

```
Defaults:X !requiretty
```

```
X ALL=(Y) NOPASSWD: ALL
```

where X and Y are user names. Configured this way, user X can run any command as user Y without supplying a password.

Also, Y can be a comma separated list, as shown here:

```
X ALL=(Y1, Y2, Y3) NOPASSWD: ALL
```

Note: The impersonated user must have read and execute access to the agent working directory.

As an alternative to configuring `sudoers`, in some cases you can configure the PAM via the module `pam_wheel.so` to allow certain users to log in without specifying a password. In this case, add users to a specific `wheel` group and edit the PAM configuration allow users in this group to run commands as though they were the root user.

su and sudo maintain a record in the system logs of all of their activity. su can be used without configuring the `sudoers` file. For information about su/sudo, see the UNIX™ or Linux™ documentation.

Note: For UNIX™ or Linux™ agents, the password option is ignored.

To customize the su and sudo commands, you can set the following properties on the agent, in the `installed.properties` file:

Table 732. Agent properties for the su and sudo commands

Property	Default value	Description
com.urbancode.shell.impersonation.unix.sudoFormat	`%s -n -u %u %c`	Syntax of the sudo command
com.urbancode.shell.impersonation.unix.sudoGroupFormat	`%s -n -u %u -g %g %c`	Syntax of the sudo command when a group is specified
com.urbancode.shell.impersonation.unix.suFormat	`%s - %u -c %c`	Syntax of the su command

Tip: To set these properties on new agents, create a generic process that updates the `installed.properties` file and run the process on new agents.

1. Create a generic process that appends the property to the file located at *<DEPLOY_AGENT_HOME>*`/conf/agent/installed.properties` (for example, use a Shell step to append the property to the file). Make sure you have the right file, the default working directory for a generic process is `\var\work`.
2. Once you've added the property, go to the **Resources -> Agents** tab, select the agents, and go to **Actions -> Restart** . This will restart the agent process and pick up the new property. It is recommended restarting no more than ~100 agents at a time to make sure they're all able to reconnect to the server quickly.

   If the agents are installed as services and you don't mind restarting the whole machine, you could alternatively use the Linux or Windows System tools plug-ins to restart the whole machine as part of the generic process, removing the need to restart all the agents from the UI.

   If the agents are started by a root user having system group, then the user running WAS plug-in should also be part of the system group or else the plug-in step fails with permission issue.
3. If later you need to run the generic process in bulk, you can create an application just for that purpose and add all the agents to an environment. You can then use the **For every agent** step to run a generic process on all the agents at once. It is recommended you should only do this process on a few agents so that you can test that everything is configured properly before moving to configuring the agents in bulk.

You can use the following variables in these properties:

Table 733. Variables for the su and sudo commands

Variable	Value
%s	The location of the su or sudo executable
%u	The user

Table 733. Variables for the su and sudo commands (continued)

Variable	Value
%g	The group
%c	The command to run

Impersonation on Windows™ systems

For agents that are running on Windows™, HCL DevOps Deploy (Deploy) provides a program that handles impersonation.

You implement impersonation for agents on Windows™ the same way you do for agents on UNIX™ or Linux™: when you configure a process step, you specify the user credentials that are used when the step is processed. These credentials are the user that the agent is impersonating. In this way, two user accounts are active: the user that the agent runs as normally and the user that the agent is impersonating while it runs the step.

To run steps on Windows™, the agent must be running as LocalSystem as a service or running in an administrator command prompt. Also, this user must have the following privileges, at a minimum:

- **SE_RESTORE_NAME** (Restore files and directories)
- **SE_BACKUP_NAME** (Back up files and directories)
- **SE_INCREASE_QUOTA_NAME** (Adjust memory quotas for a process)
- **SE_ASSIGNPRIMARYTOKEN_NAME** (Replace a process-level token)
- The user must also have access to the agent working directory, such as `<DEPLOY_AGENT_HOME>/var/work`.

Also, to impersonate an administrator, the agent user account must have the **SE_TCB_NAME** (Act as part of the operating system) permission.

The user that the agent is impersonating must have at least one of the following privileges:

- **SE_BATCH_LOGON_NAME** (Log on as a batch job)
- **SE_INTERACTIVE_LOGON_NAME** (Log on locally)
- **SE_SERVICE_LOGON_NAME** (Log on as a service)

In Windows™ Vista and later versions of Windows™, when the agent logs in as the impersonated user, the operating system returns a restricted token. If the impersonated user is a member of the Administrators group, the agent attempts to get an elevated token. However, if the agent user account does not have the **SE_TCB_NAME** permission, the agent does not receive an elevated token. In this case, the agent attempts to run the step with the restricted token, but it does not have administrator permissions.

You can also impersonate the Windows™ LocalSystem account. The LocalSystem account is installed on every Windows™ system and is the equivalent of the root user on UNIX™ and Linux™. It always has the privileges that are listed above.

Note: For agents on Windows™, the sudo option is ignored if selected.

Impersonation on z/OS® systems

The su command is used to impersonate users on agent computers that are running IBM® z/OS®.

The su command starts a shell as a different user. Process steps can be considered individual shells. When you configure a process step, you can specify that the step uses impersonation by selecting the **Use Impersonation** check box. To learn more, see Processes on page 2398. On z/OS® agent computers, the **Group**, **Password**, and **Use Sudo** fields that are displayed when you click **Use Impersonation** are ignored.

To configure impersonation, supply the user name that is required by the target computer. When the process step that is configured for impersonation runs, the su command runs the step as the impersonated user. You can configure user impersonation independently for each process step. You can also define user impersonation credentials for a resource. To learn more, see Defining default user impersonation credentials on page 2332.

You must configure a Resource Access Control Facility (RACF®) profile so that the su command can start a shell as a different user without specifying a password. The following RACF® profile grants authority to user X to impersonate user Y without entering a password:

```
RDEFINE SURROGAT BPX.SRV.Y UACC(NONE)
PERMIT BPX.SRV.Y CLASS(SURROGAT) ID(X) ACCESS(READ)
SETROPTS RACLIST(SURROGAT) REFRESH
```

For more information about the su command, see the *z/OS® UNIX™ Systems Services* help.

Process steps: Reference

Application processes, component processes, and generic processes are created with the process editor.

HCL DevOps Deploy (Deploy) provides several common process steps. Otherwise, application processes are assembled from processes that are defined for their associated components. Application processes, like component processes, are created with the process editor.

The following process steps are provided by the server. For information about steps that are provided by plug-ins, see the documentation for the individual plug-in in the HCL site: https://hcl-software.com/plugins/

Acquire Lock

This step acquires a lock on a specified string value. You can use locks to prevent concurrent modification of resources.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

Upon reaching this step, the process searches for the lock with the specified name and proceeds as follows:

- Evaluates the lock status: If the lock already exists and the **Fail if Lock Exists** option is selected, the step fails.
- Creates the lock: If the step does not fail and the lock does not already exist, the process creates the lock.
- Acquires the lock: If no other process is using the lock, the step continues. If the lock is currently in use, the process waits until the lock is released before proceeding.

To release the lock, use the Release Lock on page 2483 step. Also, locks are released automatically when the process finishes. If multiple processes are waiting for the same lock, when the lock is released, the server selects the process that made the earliest request to acquire the lock.

Note: You can see the active locks by clicking **Settings > Locks**.

Table 734. Acquire Lock properties

Field	Description
Lock Name	A string value that identifies the lock. **Note:** Lock Name character limit is 4000.
Fail if Lock Exists	Select this checkbox to fail the step immediately if a lock with the specified name has already been created.

Add Inventory Status

With this process step, the component resource that the process is running against will have an inventory entry created for it with the specified status.

Tip:

Applications and components share some process steps. This step applies only to component processes.

Table 735. Add Inventory Status properties

Field	Description
Status	The component resource that the process is running against will have an inventory entry created for it with the specified status. `Active` indicates that the component version is

Table 735. Add Inventory Status properties (continued)

Field	Description
	deployed to its target resource. You can create other statuses and have those statuses applied to component versions when processes are complete. The status is displayed on the Inventory panes for the component itself and environments that ran the process.

Apply Configuration

This step runs a component process of the type Operational (No Version Needed) or Configuration Deployment.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes.

This step runs the specified component process if there is a difference in the configuration inventory of the resource and the configuration in the component process.

Table 736. Apply Configuration properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Maximum number of concurrent jobs	The maximum number component instances to apply the new configuration to simultaneously. For example, if you set the maximum number of concurrent processes to 2, the server applies the configuration to only two instances of a component at a time, even if many instances of the component are installed. To apply the configuration to every component instance simultaneously, specify `-1`. To limit the number of components to change at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to

Table 736. Apply Configuration properties (continued)

Field	Description
	check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Apply to Live Configuration

This step is a wrapper step for applying configuration updates to an application server.

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step does not apply to application processes that are associated with application templates. This step runs on the server, gathers information about the specified resource, and then calls a specified plug-in step on an agent computer. To use this step, you must install a supported application server plug-in, such as the WebSphere® Application Server - Configure plug-in. For information about plug-ins, see HCL™ Plug-ins.

Table 737. Apply to Live Configuration properties

Property	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Resource	The resource that contains the configuration information to apply to the application server.
Plugin Step	The plug-in step to run to apply the configuration to the application server. If no plug-ins are installed that support the Apply to Live Configuration process step, this list is empty.

Compare with Live Configuration

This step is a wrapper step for comparing the configuration of an HCL DevOps Deploy (Deploy) resource to a live application server.

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step does not apply to application processes that are associated with application templates. This step runs on the server, gathers information about the specified resource, and then calls a specified plug-in step on an agent computer. To use this step, you must install a supported application server plug-in, such as the WebSphere® Application Server - Configure plug-in. For information about plug-ins, see HCL™ Plug-ins.

Table 738. Compare with Live Configuration properties

Property	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Resource	The resource that contains the configuration information to compare with the application server.
Plugin Step	The plug-in step to run to compare the configuration to the application server. If no plug-ins are installed that support the Compare with Live Configuration process step, this list is empty.

Finish

Ends processing. A process can have more than one Finish step. All processes must reach a Finish step to complete successfully.

For Each Agent

This step creates a loop that iterates over the agents in the environment.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

This step provides vertical iterations, or iteration containers, for application processes. If, for example, you have numerous application servers, you can use this step to employ all agents in the environment to simultaneously deploy components to the servers. In this case, using this step means that overall deployment is not impacted even if one application server is slow.

This step runs the process that is defined within the container for each agent in the application environment. The workflow in the container has its own context, and its own start and finish steps, as shown in the following figure. You can use any application process step in the subprocess. An iteration container can connect to any step, even other iteration containers, but you cannot include other iteration containers within an iteration container.

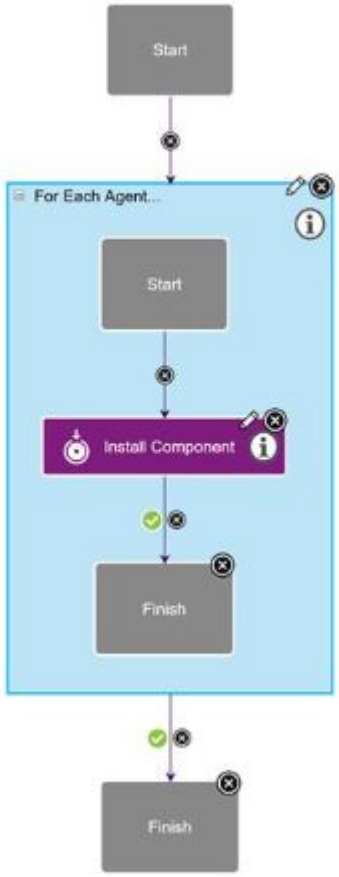


Table 739. For Each Agent properties

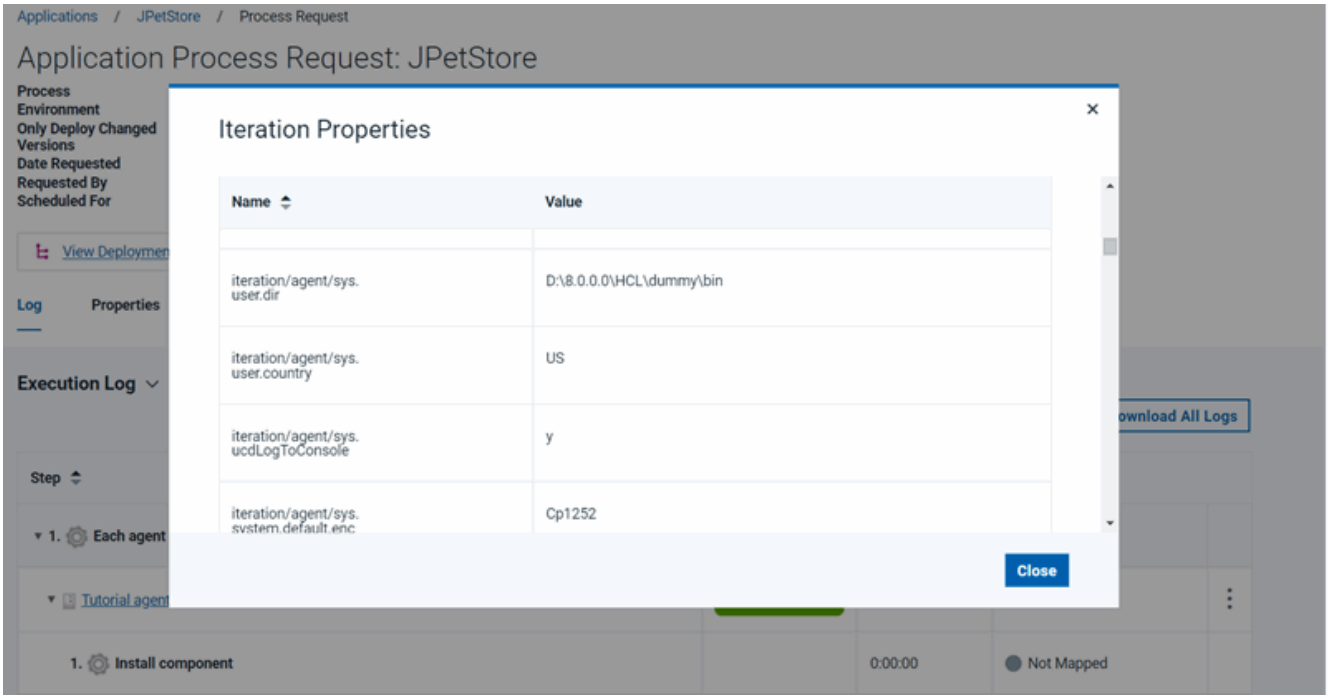
Field	Description
Name	A name for the iteration container.
Limit to Resource Tags	A list of resource tags that limit the container. The subprocess runs only on the agent resources that have one or more of the specified resource tags.
Maximum number of concurrent processes	The maximum number of agents that run the subprocess at a time. To run the subprocess on every agent at once, specify `-1`. To limit the number of agents to deploy to at once, as in blue/green deployments or rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Iteration properties

The For Each Agent step has properties, called iteration properties, that can be used to reference steps within the iteration context. By using these properties, for example, you can identify the current agent within the context. To reference iteration properties, use the following format: `${p:iteration/<name>}`.



To view the iteration properties for the step, follow these steps:

1. Open the log for the application process request by clicking **Applications > application_name > History > View Request**.
2. Expand the container step and, next to one of the iterations, click **Iteration Properties**.

For Each Tag

This step iterates over resource tags in application processes.

Tip:

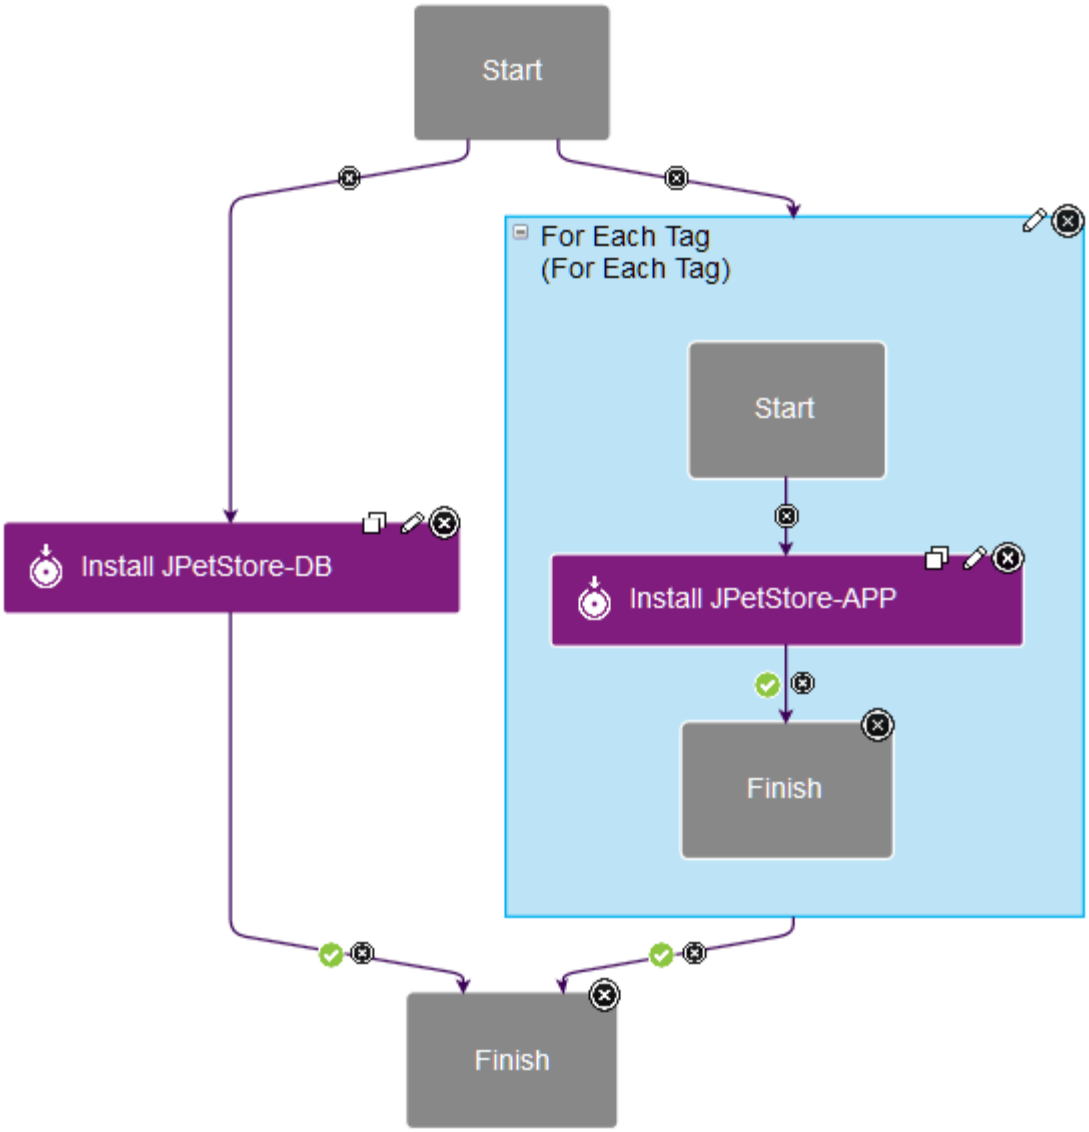
Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

This step iterates over one or more resource tags. If you have many agent resources mapped to an environment, you can use this step to choose which resources to run steps on. For example, if you are running a rolling deployment, you can use this step to deploy to a few resources first, and then run automated tests on those resources before deploying on the other resources. Also, if you are running a blue/green deployment, you can use this step to limit the deployment to the blue nodes

or green nodes. Finally, you can select the order of the tags to iterate over, such as if you want to update specific canary nodes before all other nodes. For a tutorial of Blue/Green deployments, see Blue/Green deployments.

Note: If the process fails in a For each tag step for any agent or agent pool, no new agents will have the process run for them and the step will fail.

Like the For Each Agent step, this step creates an iteration container for subprocesses. You specify one or more resource tags, and the order of those resource tags, and the step runs the subprocess once for each resource tag. The workflow in the container has its own context, and its own start and finish steps, as shown in the following figure. You can use any application process step in the subprocess. An iteration container can connect to any step, even other iteration containers, but you cannot include other iteration containers within an iteration container.



To make it easier to control which resources you deploy to, such as in a staged, rolling, or blue/green deployment scenario, you can set the tags on the fly when you request the process. In the **Request Process** window, the list of tags for the container is shown. You can add or remove tags here, or change the order of the tags. This way, you can use one process to deploy in different scenarios. For example, if you want to deploy to a canary node first, put that resource tag first, and then follow with the other tags. The following figure shows a process request to a canary node first, and to the rest of the resources next.

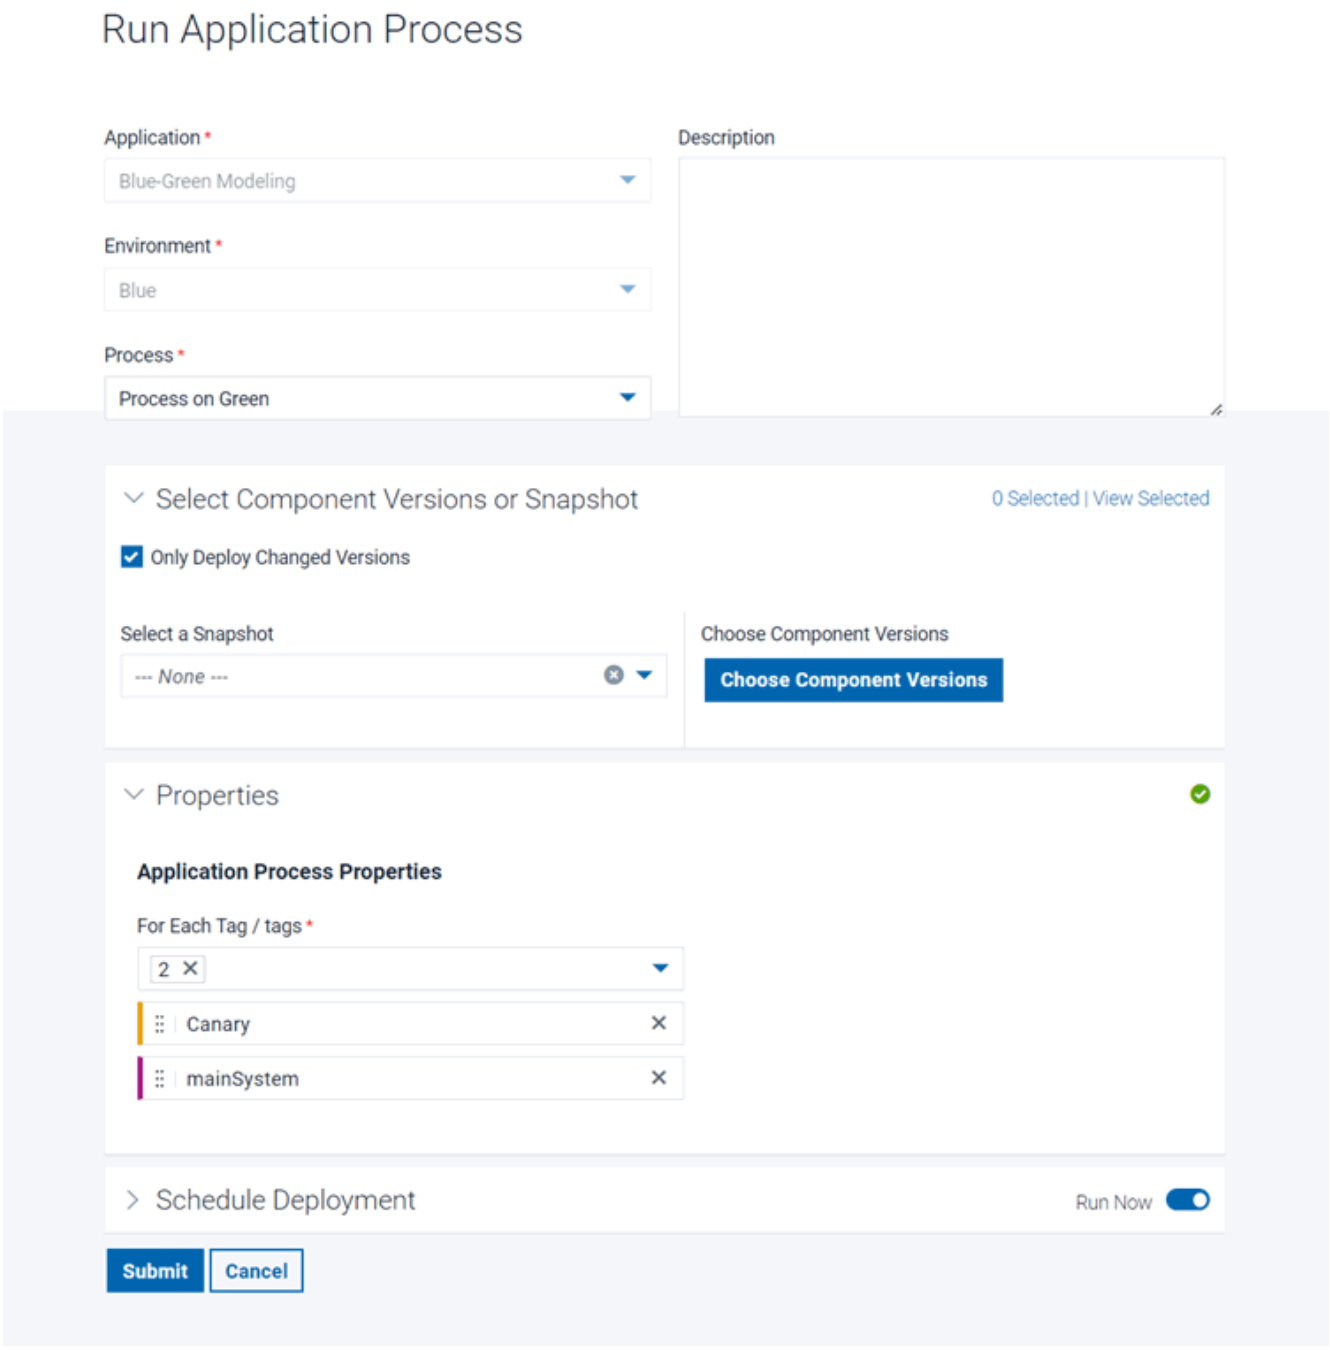


Table 740. For Each Tag properties

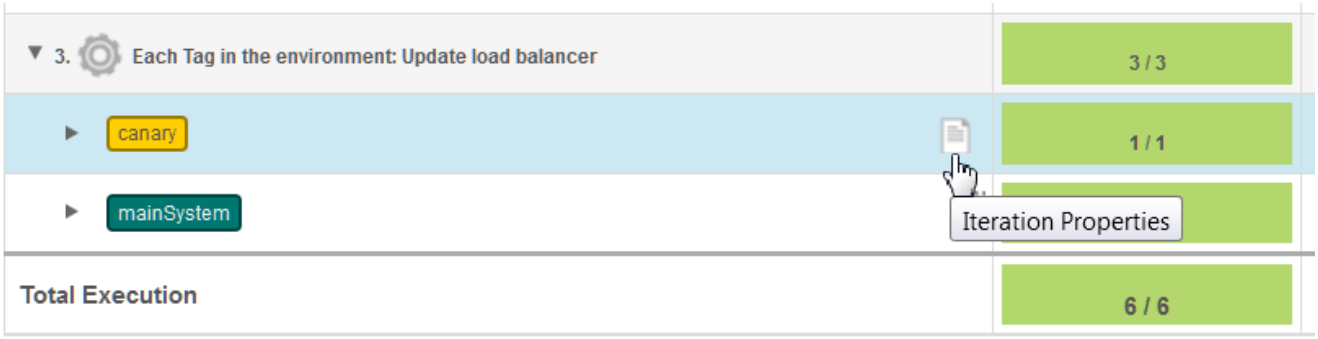
Field	Description
Name	A name for the iteration container.
Tags	A list of resource tags to use in the container. The subprocess runs once for each resource tag. You can order the resource tags by dragging and dropping them.
Max Concurrent Tags	The maximum number of tags for which to run the subprocess at a time. To run the subprocess on all of the tags at the same time, specify `-1`. To run the subprocess on only a few of the tags at a time, as in blue/green deployments or rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Iteration properties

The For Each Tag step has properties, called iteration properties, that can be used to reference steps within the iteration context. By using these properties, for example, you can identify the current agent within the context. To reference iteration properties, use the following format: `${p:iteration/<name>}`. For example, the current tag name is in the property `${p:iteration/tag.name}`.

When you run the application process, the log shows each iteration of the container as a separate entry. For example, the following log shows a For Each Tag step that ran over two tags:



To view the iteration properties for the step, follow these steps:

1. Open the log for the application process request by clicking **Applications > application_name > History > View Request**.
2. Expand the container step and, next to one of the iterations, click **Iteration Properties**.

Note: If the process fails in a For Each Tag step for any agent or agent pool, no new agents will have the process run for them and the step will fail.

Related information

Blue-green deployments on page 1984

Install Component

This step installs the selected component with one of the processes that are defined for the component.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes.

This step runs the specified component process for all selected component versions, except the component versions that are already in the inventory. By contrast, the Run Process for Each Version on page 2492 step runs the process for each component version, whether or not each component version is in the inventory.

It is up to you to select an appropriate component process to run. In most cases, select a component process of the Deployment type. If you select a different type of component process, you might get results that you do not expect. The server runs whatever component process you select, even if that process does not install the component. For example, if you select a component process of the Uninstall type, the Install Component step runs that component process as usual. Then, the component process uninstalls the component and removes the component from the inventory.

This step can install multiple incremental versions of the same component. To do this, use a single Install Component step in the application process. Then, when you run the application process, select multiple incremental versions to deploy. The incremental versions are deployed in the order that you select them in the **Run Process** window. To deploy the incremental versions in a specific order, you can also create a snapshot, add the component versions to the snapshot in the order that you want to deploy them, and run the application process with the snapshot.

Table 741. Install Component properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. To install another component, add another install step to the process.
Use Versions Without Status	Restricts the components that can be used by the step. Components with the selected status are ignored. Available statuses: `Active` means ignore components that are currently deployed.
Component Process	The component process to run.
Limit to Tag	User-defined roles can be used in processes; see Adding tags to objects on page 2521.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously to deploy the component. For example, if you set the maximum number of concurrent processes to 2, only two instances of the component are installed at a time, even if many instances of the component are mapped to agents. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Install Multiple Components

Install multiple components that are based on component tags or resource tags.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

It is up to you to select an appropriate component process to run. In most cases, select a component process of the Deployment type. If you select a different type of component process, you might get results that you do not expect. The server runs whatever component process you select, even if that process does not install the component. For example, if you select a component process of the Uninstall type, the Install Component step runs that component process as usual. Then, the component process uninstalls the component and removes the component from the inventory.

Table 742. Install Multiple Components properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	A process for the components that contain the selected tag. The process name must be the same for each tagged component. Only components that contain the specified process run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Use Versions Without Status	Restricts the components that can be used by the step. Components with the selected status are ignored. Available statuses: `Active` means ignore components that are currently deployed.
Maximum number of concurrent	The maximum number of components to deploy at one time. For example, if you specify 5, this step deploys five components at a time to all agents to which the components are mapped. To run this step on all components at the same time, specify `-1`. To limit the number of components to access at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Table 742. Install Multiple Components properties (continued)

Field	Description
components	**Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously to deploy each component. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are installed at a time, even if many instances of the component are mapped to agents. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Inventory Update

This step updates the inventory and compliance for the environment.

Restriction: The Component Inventory Update and Snapshot Inventory Update steps are available only in application processes that have **Inventory Management** set to **Advanced**. See Managing environment inventory and compliance on page 2396. This step is available only to processes that have the **Inventory Management** check box set to **Advanced**.

Table 743. Inventory Update properties

Field	Description
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available.
Limit to Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.

Table 743. Inventory Update properties (continued)

Field	Description
Action	Select **Add Desired Inventory** to add component versions to the inventory. Select **Remove Desired Inventory** to remove component versions from the inventory.

Join

The Join step merges a process so that only one step runs at a time. If any of the steps that connect to a Join step fail or do not run, the Join step causes the process to fail.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

For information about this step, see Branching and joining steps on page 2402.

This step has no properties.

Lock Snapshot

This step locks an application snapshot version to prevent its component configurations from being modified or overwritten.

When a snapshot is locked, its component versions become immutable. If the specified snapshot is already locked, the step completes successfully without making changes.

This step is available for use in application processes, component processes, and generic processes.

Table 744. Lock Snapshot properties

Field	Description
Snapshot Name or ID	The name or unique ID of the snapshot to lock. You can specify a name or use a property reference defined in the process, such as `${p:snapshot.name}`.
Application Name or ID	The name or unique ID of the application associated with the snapshot. You can specify a name or use a property reference defined in the process, such as `${p:application.id}`.

Manual Application Task (Utility)

A manual task interrupts an application process until manual intervention is done. A task-interrupted process remains suspended until the targeted user or users respond. Typically, manual tasks are removed after the process is tested or automated.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates. However, the generic process step includes the **Comment Prompt** field.

Similar to approvals, triggered tasks alert targeted users. Alerts are associated with environment- or application-defined user roles. Affected users can respond (approve) by using the **Work Items** pane (see Responding to approval requests on page 2394). Unlike approvals, manual tasks can be incorporated within an application process.

For information on using manual tasks in application processes, see Manual application tasks on page 2387.

Table 745. Manual Application Task properties

Field	Description
Name	The name for the manual task.
Only Allow Deploying User To Complete	Restrict approval to the user who started the deployment.
Notification Template	Specify a notification template. The individual tasks map to the notification scheme used by the application (see Creating Notifications in a Notification Scheme on page 2081). If you do not want notifications created for the task, select **None**.
Properties	Optionally, add one or more properties to the task.
Require Comment	Select to require that users must add a comment about this manual task.
Comment Prompt	**Note:** This field applies only to generic process steps. Enter the text that requests users to add a comment about this manual task.

Note

The Note step adds a note to a process diagram.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

This step has a single property, which is the text of the note.

Operational component processes

Runs the specified operational (no version needed) component process.

You can add operational component processes to application processes if the operational component processes do not require a component version. Operational component processes that do not require versions are listed in the step palette under **Component Process Steps**. To add an operational (no version needed) component process to an application process, drag the folder that represents the component to the application process and then select the operation process to run. To run an operational (with version) component process, use the Run Process for Each Version on page 2492 step.

To learn about the different types of component processes, see Component process types on page 2423.

Table 746. Operational component process properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Limit to Tag	Run the process only on the versions with the specified tag.
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously. For example, if you set the maximum number of concurrent processes to 2, the process runs on only two instances of a component at a time, even if many instances of the component are installed. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Run on First Onl	Instead of being run by all agents that are mapped to the environment, the step runs only on the first online agent that the server identifies. The mechanism that is used to identify the "first" agent is database-dependent, and thus indeterminate. If no agents are online, the server skips the step and marks its status as "Not Mapped." This setting

Table 746. Operational component process properties (continued)

Field	Description
ine Reso urce Only	may cause the environment to become noncompliant or to provide unexpected results, because only one agent runs the process, even if many agents are mapped to the environment.
Preco ndit ion	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.
Run If Comp one nts Cha nge	When this check box is selected, this step runs only if an agent resource that is mapped to this component has other component resource mappings whose inventories are changed by the process. When you select this check box, you can select components and specify whether the step runs on all resources for the component that contains this process, or only on resources that include both the component for this process and one of the selected components that was changed by this process. **Resource Selection Mode** options: • To run the operational process only on resources that have had their inventory updated for one of the selected components, select **Only resources where selected components are changed**. For example, when you have a component that contains some operational processes, for example, "Restart HTTP Server", you can add the operational process to the application process and you can select this option to run only on machines where you have deployed changes to web sites being hosted. • To run the operational process wherever the component defining the process is added to any agents in the environment, select **All resources mapped to this process's component**. For example, if after you deploy changes to a web site you want to restart a load balancer that is on a different machine than the web site, you can select this option to run the operational process wherever the "Load Balancer" component that contains the "Restart Load Balancer" operational process is mapped.

Release Lock

This step releases a lock on a specified string value.

Tip: Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

To create a lock, use the Acquire Lock on page 2466 step. If multiple processes are waiting for the same lock, when the lock is released, the server selects the process that made the earliest request to acquire the lock.

Table 747. Release Lock properties

Field	Description
Lock Name	A string value that identifies the lock.

Remove Inventory Status

With this process step, the component resource that the process is running against will have an inventory entry removed from it.

Tip:

Applications and components share some process steps. This step applies only to component processes.

Table 748. Remove Inventory Status properties

Property	Description
Status	The component resource that the process is running against will have the specified inventory entry removed from it.

Rollback Component

Use this process step to roll back a component version to the version in a snapshot or to the version that was deployed when the process began.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes.

For a video demonstration of rolling back components, see Rollback Scenarios in Deploy.

In most cases, to switch to a different version of a component, you deploy the new version over the existing version. If necessary, you can run the uninstall process for the component first.

However, you can also use the **Rollback Component** step to automate the process of switching to a previous component version. This step has two options:

- **Remove Undesired Incremental Versions**: This option removes versions that are not in a specified snapshot. See Rolling back to a snapshot on page 2437.
- **Replace with Last Deployed**: This option rolls back components that fail to deploy. See Uninstalling components with an application process on page 2436.

Table 749. Rollback Component properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. If you want to roll back another component, add another rollback step to the process or use the Rollback Multiple Components on page 2486 step.
Remove Versions with Status	Restricts the component versions that are affected by the step. Only versions with the selected status are affected. By default, the status `Active` refers to versions that are currently deployed.
Component Process	The component process to run. In most cases, select a component process that uninstalls the component.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Rollback type	Determines the type of rollback. If you specify `Remove Undesired Incremental Versions`, the server runs the uninstall process for each version that is not in the specified snapshot. See Rolling back to a snapshot on page 2437. If you specify `Replace with Last Deployed`, the server runs the specified process on the version that was installed when the process began. See Uninstalling components with an application process on page 2436.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are rolled back at a time, even if there are many instances of the component. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Rollback Multiple Components

Use this step to roll back multiple component versions to versions in a snapshot or to versions that were deployed when the process began. The multiple components are based on component tags or resource tags.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

In most cases, to switch to different component versions, you deploy the new versions over the existing versions. If necessary, you can run the uninstall process for the components first.

However, you can also use the Rollback Component step to automate the process of switching to a previous component version. This step has two options:

- **Remove Undesired Incremental Versions**: This option removes versions that are not in a specified snapshot. See Rolling back to a snapshot on page 2437.
- **Replace with Last Deployed**: This option rolls back components that fail to deploy. See Uninstalling components with an application process on page 2436.

Table 750. Rollback Multiple Components properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	The component process to run. In most cases, select a component process that uninstalls the component.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Remove Versions With Status	Restricts the components that are affected by the step. Only components with the selected status are affected. Available statuses: `Active` refers to components that are currently deployed.
Rollback Type	Determines the type of rollback. If you specify `Remove Undesired Incremental Versions`, the server runs the uninstall process for each version that is not in the specified snapshot. See Rolling back to a snapshot on page 2437. If you specify `Replace with Last Deployed`, the server runs the specified process on the version that was installed when the process began. See Uninstalling components with an application process on page 2436.

Table 750. Rollback Multiple Components properties (continued)

Field	Description
Maximum number of concurrent components	The maximum number of components to roll back at one time. For example, if you specify 5, this step rolls back five components at a time on all agents to which the components are installed. To run this step on all components at the same time, specify `-1`. To limit the number of components to access at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously to roll back each component. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are rolled back at a time, even if there are many instances of the component. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Run Component Process

You can run a component process as a part of a step.

Tip: Applications and components share some process steps. This step applies only to component processes.

Important: If you have not created another component process before you attempt to place this step into the current process you receive this message: `This will call the current process and risk the creation of an infinite loop. Are you sure you want this process to run itself?` You can close the message window and work with the properties. However, the only process that you can select in **Component Process** is the current process.

Table 751.

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Process	The component process to run.

Run Generic Process

This step runs a generic process as a step in an application process.

Tip: Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

Table 752. Run Generic Process properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Process	The generic process to run.
Resource Path	The resource on which to run the generic process.
Other properties	After you select a generic process, the properties for that process are listed. You can set values here to pass to the process.

Run Generic Process for Each Affected Resource

Runs the specified generic process on each resource that is affected by the application process.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

Table 753. Install Component properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Process	The generic process to run.
Maximum number of concurrent processes	The maximum number of concurrent processes to run at the same time. For example, if you set the maximum number of concurrent processes to 2, the generic process runs on only two resources at a time. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.
Other properties	After you select a generic process, the properties for that process are listed. You can set values here to pass to the process.

Run Operational Process for Multiple Components

Runs the operational (no version needed) process for multiple components.

You can add multiple operational component processes to application processes if the operational component processes do not require a component version. To learn about the different types of component processes, see Component process types on page 2423. To run a single operational process, see Operational component processes on page 2482.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

Table 754. Operational component process properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	A process for the components that contain the selected tag. Only components that contain the process will run. Only one process can be selected per step.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Maximum number of concurrent comp	The maximum number of components on which to run processes at one time. For example, if you specify 5, this step runs processes on five components at a time. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Table 754. Operational component process properties (continued)

Field	Description
onents	
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously. For example, if you set the maximum number of concurrent processes to 2, the process runs on only two instances of a component at a time, even if many instances of the component are installed. To run an unlimited number of concurrent processes, specify `-1` . To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Run on First Online Resource Only	Instead of being run by all agents that are mapped to the environment, the step runs only on the first online agent that the server identifies. The mechanism that is used to identify the "first" agent is database-dependent, and thus indeterminate. If no agents are online, the server skips the step and marks its status as "Not Mapped." This setting may cause the environment to become noncompliant or to provide unexpected results, because only one agent runs the process, even if many agents are mapped to the environment.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.
Run If Comp	To run this step only if another step in the application process changes the inventory of a component, select this option. If you select a component tag, for this step to run, a component that contains that tag must have an inventory change. If you do not select a component tag, any inventory change that is caused by the application process causes this step to run. **Note:** Do not select the same component tag that you selected in the **Component Tag** list. Select

Table 754. Operational component process properties (continued)

Field	Description
on ent with Tag Cha n ges	an option in the **Resource Selection Mode** list to control the agent resources that this step runs on. To run the step on only resources where the inventory of other components changes, select **Only resources where component with selected tag is changed**. For example, you might have a component that contains some operational processes, such as "Restart HTTP Server." If you add the operational process to the application process, you can select this option to run only on machines where you are deploying changes to websites that are hosted. To run the operational process on all possible resources, select **All resources mapped to this process's component**. For example, if you deploy changes to a website, you might want to restart a load balancer that is on a different machine than the website. You can select this option to run the operational process wherever the "Load Balancer" component that contains the "Restart Load Balancer" operational process is mapped.

Run Process for Each Version

Use this step to run the specified process once for each version of the specified component.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes.

This step runs the specified component process for all selected versions, whether or not each component version is in the inventory. By contrast, the Install Component on page 2476 step runs the component process only for component versions that are not already in the inventory.

Table 755. Run Process for Each Version properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Compon ent	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available.
Compon ent Process	The component process to run.
Limit to Resou rce Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Maxi mum number	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously on each component. For example, if you set the maximum number of concurrent processes to 2, the server accesses only two instances of a component at a time, even if many

Table 755. Run Process for Each Version properties (continued)

Field	Description
of concurrent processes	instances of the component are installed. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Run on First Online Resource Only	Instead of being run by all agents that are mapped to the environment, the step runs only on the first online agent that the server identifies. The mechanism that is used to identify the "first" agent is database-dependent, and thus indeterminate. If no agents are online, the server skips the step and marks its status as "Not Mapped." This setting may cause the environment to become noncompliant or to provide unexpected results, because only one agent runs the process, even if many agents are mapped to the environment.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Set Status

This step sets the ending status of the process. The step can specify that the process is completed or failed.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

Table 756. Set Status property

Field	Description
Status	`Failure` or `Success`.

Switch

Use this step to create branches in the process that are based on the value of a property.

Tip:

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step applies to application processes that are associated with application templates.

For information about this step, see Switch steps on page 2400.

Table 757. Switch properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Property Name	The property to use for the branching. You can specify the property name by itself or in the same form as you would use in other steps, such as `${p:propertyName}`. You cannot use a secure property in this field.

Uninstall Component

Use this step to uninstall the selected component.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes.

It is up to you to select an appropriate component process to run. In most cases, select a component process of the Uninstall type. If you select a different type of component process, you might get results that you do not expect. The server runs whatever component process you select, even if that process does not uninstall the component. For example, if you select a component process of the Deployment type, the Uninstall Component step runs that component process as usual. Then, the component process deploys the component and adds the component to the inventory.

Table 758. Uninstall Component Properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. To uninstall more than one component, add another uninstall step to the process.
Remove Vers	Restricts the component versions that are affected by the step. Only versions with the selected status are affected. By default, the status `Active` refers to versions that are currently deployed.

Table 758. Uninstall Component Properties (continued)

Field	Description
ions with Status	
Component Process	The component process to run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Uninstall Type	The **All Existing** option removes all the versions of this component that are in the inventory. The **All Selected For Process** option removes only the versions that you specify when you start the application process.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously to uninstall component instances. For example, if you set the maximum number of concurrent processes to 2, only two instances of the component are uninstalled at a time, even if many instances of the component are currently installed. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Uninstall Multiple Components

Use this step to uninstall multiple components that are based on component tags or resource tags.

Tip:

Applications, components, and generic processes share some process steps. This step applies only to application processes, including application processes that are associated with application templates.

It is up to you to select an appropriate component process to run. In most cases, select a component process of the Uninstall type. If you select a different type of component process, you might get results that you do not expect. The server runs whatever component process you select, even if that process does not uninstall the component. For example, if you select a component process of the Deployment type, the Uninstall Component step runs that component process as usual. Then, the component process deploys the component and adds the component to the inventory.

Table 759. Uninstall Multiple Components properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	The component process to run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Remove Vers	Restricts the components that are affected by the step. Only components with the selected status are affected. Available statuses: `Active` refers to components that are currently deployed.

Table 759. Uninstall Multiple Components properties (continued)

Field	Description
ions With Status	
Maximum number of concurrent components	The maximum number of components to uninstall at one time. For example, if you specify 5, this step runs the uninstall component processes for five components at a time. To run this step on all components at the same time, specify `-1`. To limit the number of components to access at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously to uninstall each component. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are uninstalled at a time, even if many instances of the component are currently installed. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.
Uninstall	The **All Existing** option removes all the versions of this component that are in the inventory. The **All Selected For Process** option removes only the versions that you specify when you start the application process.

Table 759. Uninstall Multiple Components properties (continued)

Field	Description
Type	

Update from Live Configuration

This step is a wrapper step for updating a resource with the configuration information from an application server.

Applications, components, and generic processes share some process steps. This step applies to application processes, component processes, and generic processes. This step does not apply to application processes that are associated with application templates. This step runs on the server, gathers information about the specified resource, and then calls a specified plug-in step on an agent computer. To use this step, you must install a supported application server plug-in, such as the WebSphere® Application Server - Configure plug-in or the WebSphere® Application Server - Deploy plug-in. For information about plug-ins, see HCL™ Plug-ins.

Table 760. Update from Live Configuration properties

Property	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Resource	The resource to use to store the configuration information that is retrieved from the application server.
Plugin Step	The plug-in step to run to retrieve the configuration information from the application server. If no plug-ins are installed that support the Update from Live Configuration process step, this list is empty.

Statuses

Create and apply statuses to track component inventory states or to track component versions in environments and resources.

Statuses can be used to track component version and component inventory states. Version statuses are used with application gates (see Environment gates on page 2360) to ensure that only component versions that meet certain criteria are deployed. Inventory statuses can track component versions in environments and resources. You can create inventory statuses for any requirement.

You apply a version status to a component that you created. You apply an inventory status when you configure a component process. See Creating component processes on page 2425.

Creating statuses

Define component version, snapshot, and inventory statuses on the **Statuses** tab.

1. Click **Settings > Statuses**.
2. For the status type to create, click **Add Status**.
3. Configure the status in the **Add Status** window:

Parameter	Description
Name	Identifies the status and is included in many UI elements.
Description	Conveys more information about the process.
Color	Defines the status color that is displayed in the UI.
Unique	When checked, specifies that only a single instance of the status describes a component. For inventory or snapshot statuses, an application removes the status from existing versions in the environment or resource inventory. For version or snapshot statuses, the status can be used by only one version or snapshot at a time.
Required Role	Specifies the user role that is necessary for a user to assign the status.

4. Save your work when finished.
   Statuses are stored in the HCL DevOps Deploy (Deploy) database.

Tip: Default statuses are defined in an XML file, which you can edit to add your own values.

Adding version statuses

Manage component version statuses through the version options interface.

About this task

You add or remove statuses from individual component versions to provide information about the version. If you copy files to an agent without deploying them, you might apply a `Staged` status to them. When you install the version, you might set the status to `Active`.

1. To select the component, click **Components > *selected component***.
2. To select the version, click **Versions > *selected version***.
3. Click **Add a Status**.
4. Select the status from the list, and click **Save**.

What to do next

Add a status by using the Add Status to Version plug-in step, which is available from the Version plug-in.

Adding snapshot statuses

Manage snapshot statuses through the snapshot options interface.

About this task

You add a status to a snapshot to provide information about the snapshot deployment status. If a snapshot deployment fails, you might apply a `Failed` status to them. When a snapshot is deployed, you might set the status to `Active`.

1. Click **Applications > *selected application***.
2. To select the snapshot, click **Snapshots > *selected snapshot***.
3. Click **Add Status**.
   The **Add a status** window is displayed.
4. Select a status from the list, and click **Save**.

What to do next

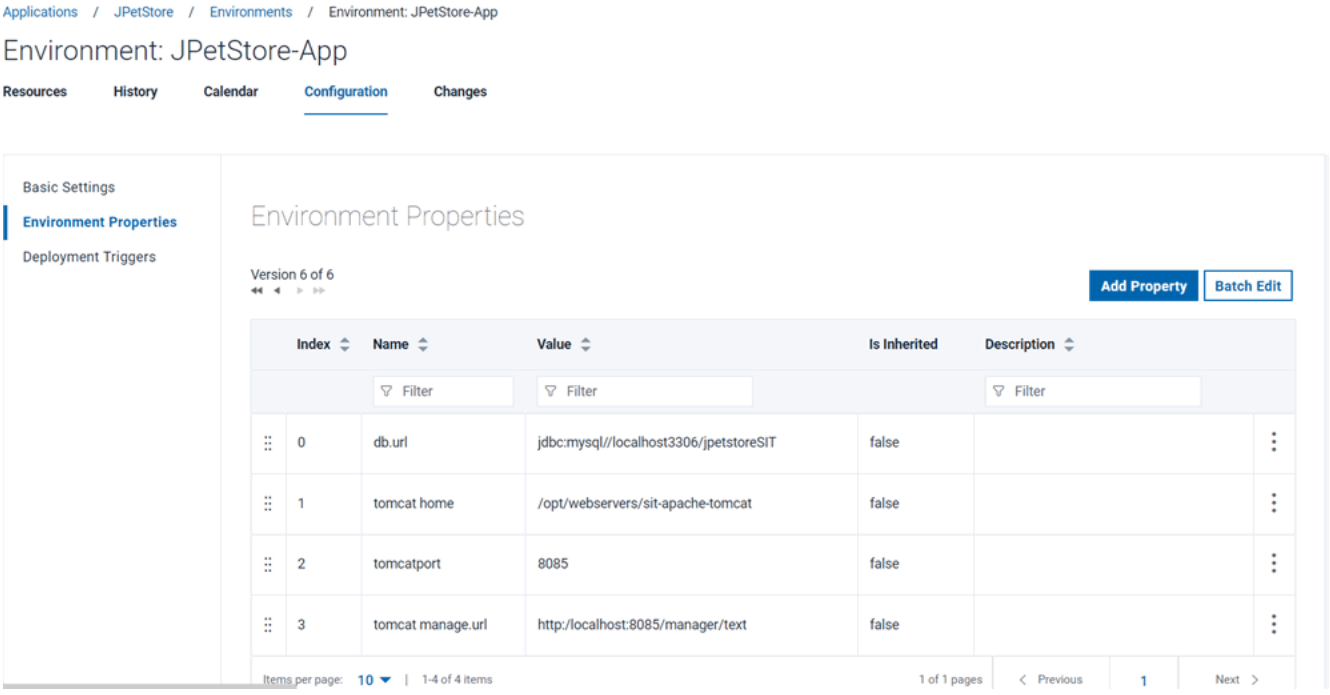
You can now create snapshot gates using the snapshot statuses.

Properties

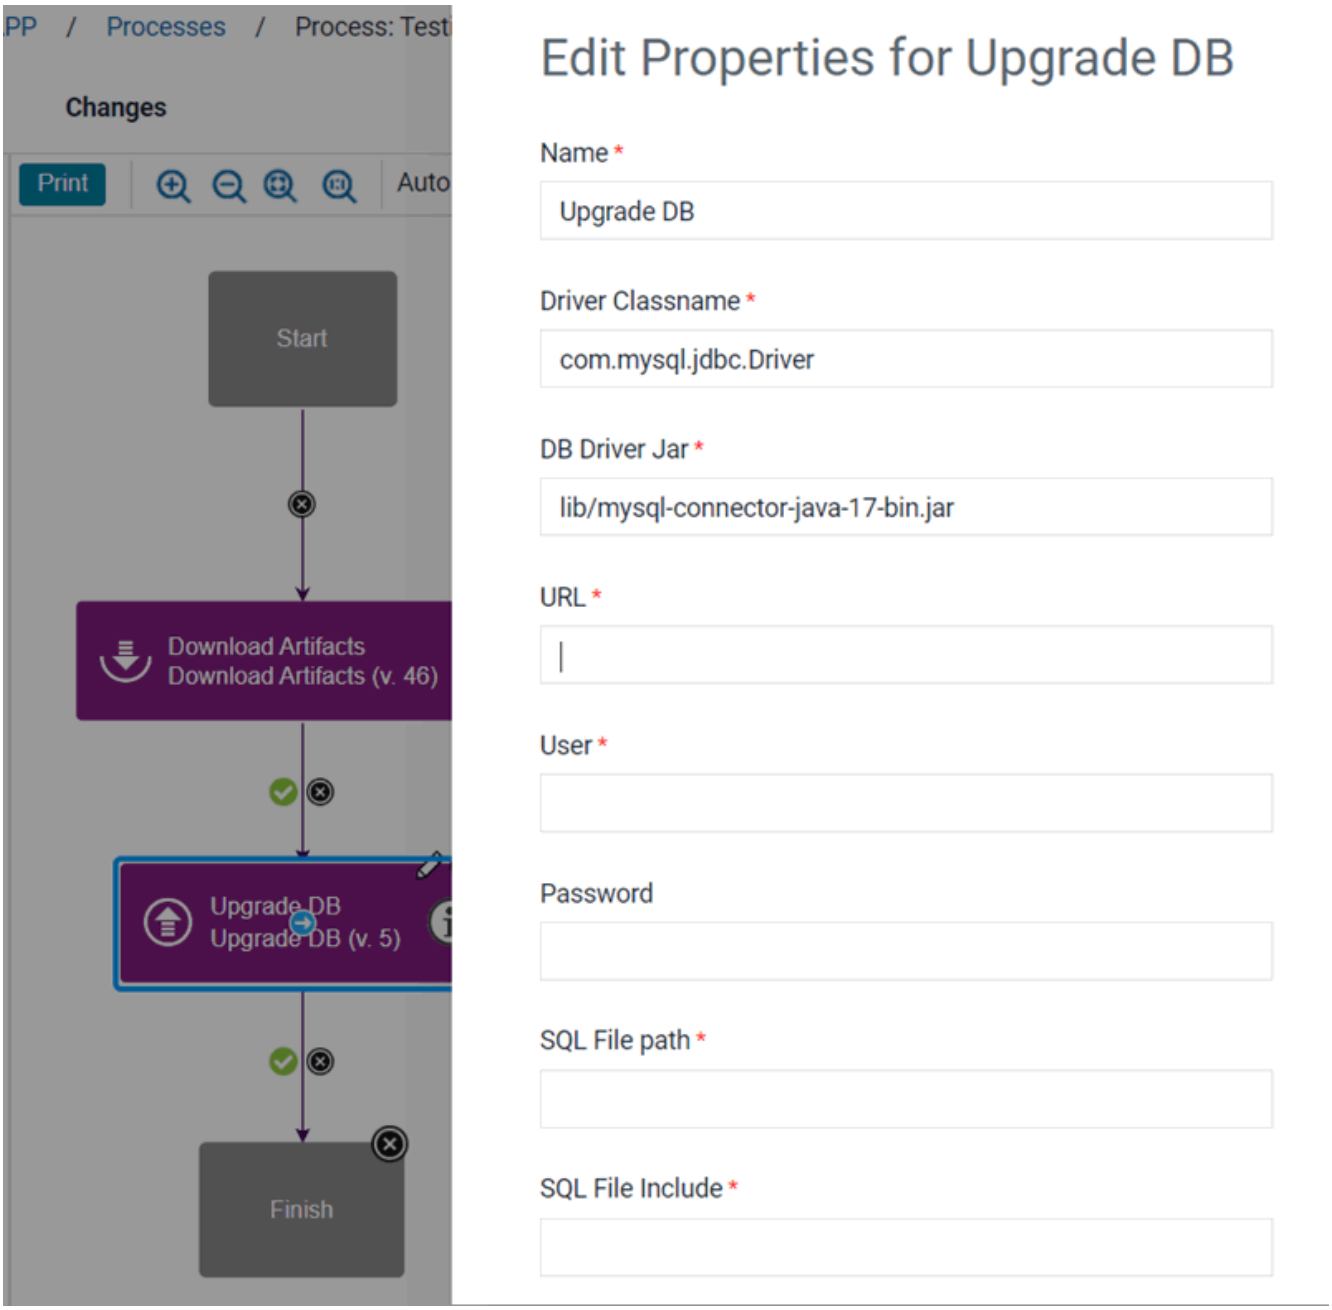
Properties are variables that store information about many different elements, including components, environments, processes, and applications. You can also set global properties for the system.

Common uses of properties are to store the locations of files, folders, servers, tools, or other resources that might change. For example, the application in the tutorial Deploying a simple web application on page 1934 uses properties to store the location of a web server and a database. In the tutorial, you set the location of a database in an environment property that is named `db.url`. Then, any time that you want to refer to the location of the database, such as when you configure an application to store data in that database, you can use the property value `${p:environment/db.url}`. If you need to change the location of the database, you only need to change the property value, and all references of the property now point to the new location.

In this case, you set the property by opening the environment, clicking its **Configuration** tab, and then clicking **Environment Properties**, as shown in the following figure. Components, applications, and processes have equivalent properties tabs.

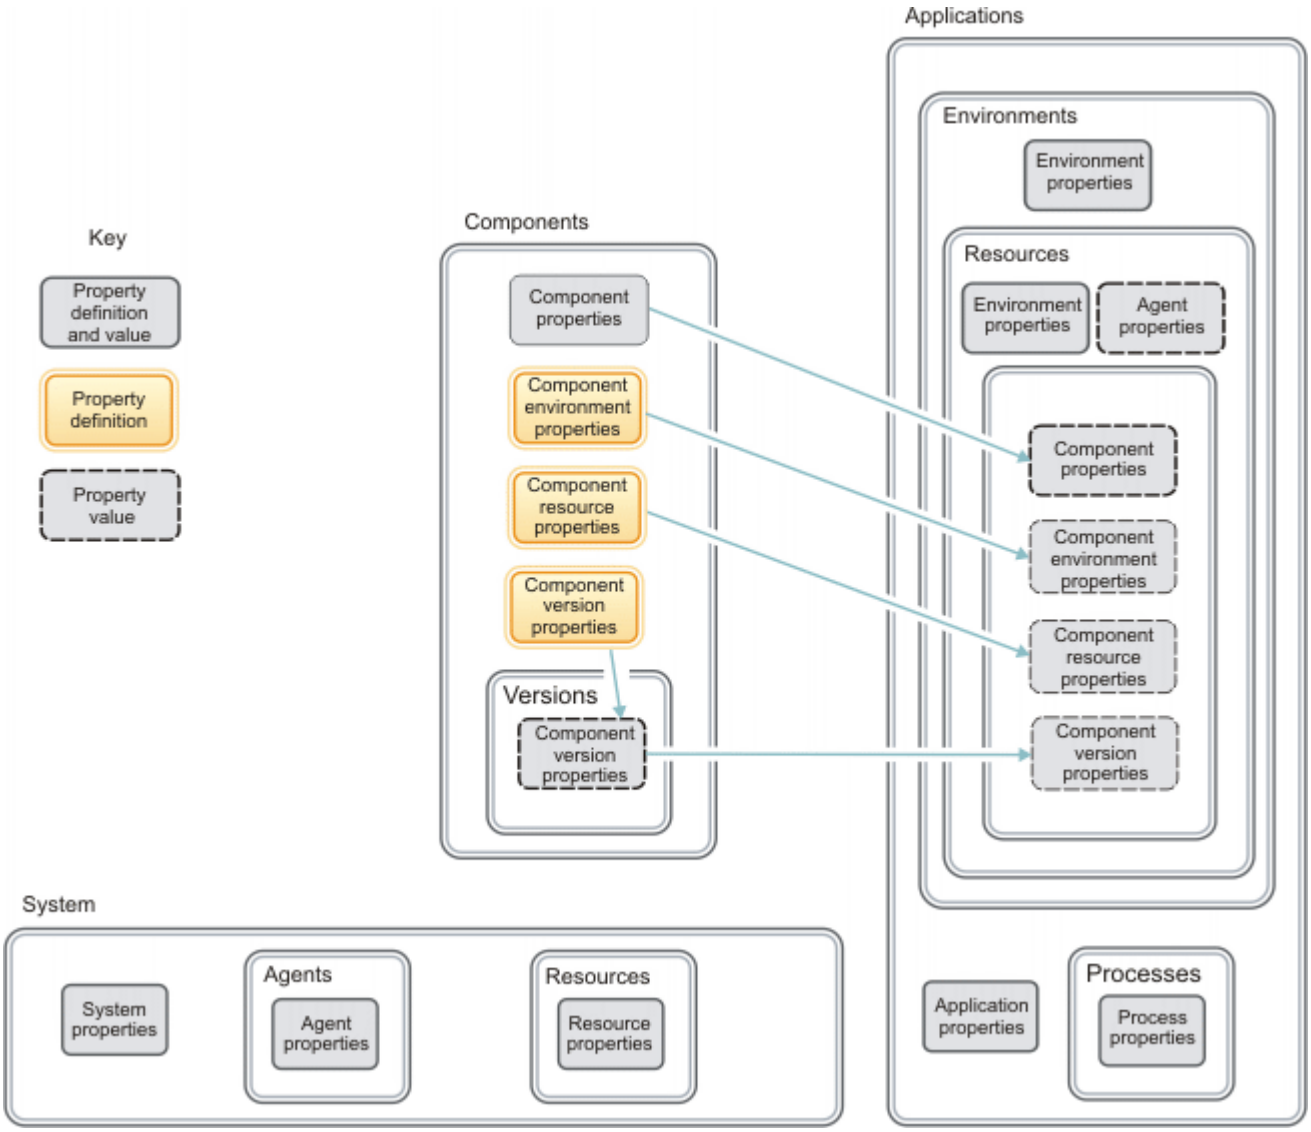


You can then refer to the properties in processes. For example, the following step is in a component process that accesses the database. In one of the step parameters, the value `${p:environment/db.url}` represents the database location.



Properties have scope, which limits where they can be accessed and which properties take precedence over others with the same name. For example, environment properties can be accessed from within the environment, including from components and applications that are deployed to that environment. For more information on property scope, see Property contexts on page 2508.

The following diagram shows some of the major properties that are available and where they can be set and accessed.



- The box at the bottom of the diagram represents the properties that you can set at the system level or the resource tree level. These properties include system properties, which are available in all contexts. The server also stores properties on agents and resources, and these properties are available in all contexts in which these agents and resources are used.
- The box at the center of the diagram represents the properties that you can set on components. Components have component properties, but components also have several types of properties that are specified in a way that is different from other properties. These properties are defined on the component, but their values are set in other places:

  Component environment properties

  Component environment properties are defined on components, but they are not given a value until the component is deployed to an environment. Then, the property behaves much like an environment property; it is available within the scope of the environment.

Component resource properties

Component resource properties are defined on components, but they are not given a value until the component is added to an environment as a resource. Then, the property behaves much like a resource property. Because a component can be added to an environment multiple times, each instance of the component can have a different value for the component resource property.

Component version properties

Component version properties are defined on components, but they are not given a value until you import a component version. Thus, each component version has a different value for the component version property. When you deploy the component to an environment, the component version property behaves much like an ordinary component property.

The boxes at right show which properties are defined in applications and environments, and which properties are accessible in applications and environments. Applications, environments, and the processes and resources in those applications and environments can all have properties. Also, with environments, you can access the properties of components that are deployed to those environments.

You set properties on these HCL DevOps Deploy (Deploy) elements to achieve four primary goals:

- Providing information that varies in different contexts on page 2503
- Storing secure information on page 2503
- Providing property values to other processes, resources, and steps on page 2504
- Setting system variables on page 2504

Providing information that varies in different contexts

Environments are configured differently, which can make automating deployments difficult. With properties, however, you can provide the correct information to each set of components in each environment.

An application might be deployed to several target environments. Each of these environments might be configured differently; for example, tools and resources might be in different directories, or the application must use different ports depending on the environment. Environment properties provide information about those different environments. For example, an environment property can map to different ports as required by the target computers for applications that run on different ports and that communicate with different databases.

As described in Property contexts on page 2508, you can also use properties to override defaults in certain areas.

Storing secure information

To deploy applications, installing components on a target computer might require IDs and passwords that must remain secure. The user interface might display this information, and testing and debugging might require log reviews. In this case, use secure properties to store the passwords. These properties can contain the ID and password information, but they display in the user interface and in logs as asterisks (*).

Providing property values to other processes, resources, and steps

In complex processes and deployment scenarios, you want to automate as much as possible. Passing property values among processes, resources, and steps helps to limit the requirement to provide input manually and to maintain accuracy and reliability. For example, you can refer to output properties from one step in another step. See Output properties on page 2516.

Setting system variables

Properties are flexible, and you can apply them to processes, environments, components, and even the system. However, keeping track of what properties are set where and on what element can present a challenge. One way to meet that challenge is to set system properties that apply to all situations. Of course, you must be judicious in setting system properties so that you can be flexible in applying properties to other elements. When you want to define a property one time and have it apply to all situations, the system property reduces set up time.

Assume that you have one Maven repository for all your code. You might refer to the address for this repository many times in many different applications. You don't need to set the address for this repository more than once. You set a system property, for example: `maven.repository.url=/theURL/`. In most places in a deployment process, use this property in place of the actual address. If the address of the Maven repository changes, you can universally change all references by changing the system property.

Creating, setting, and editing properties

Properties can be created for most elements, including components, resources, applications, and agents. You can set and change properties in many different ways.

About this task

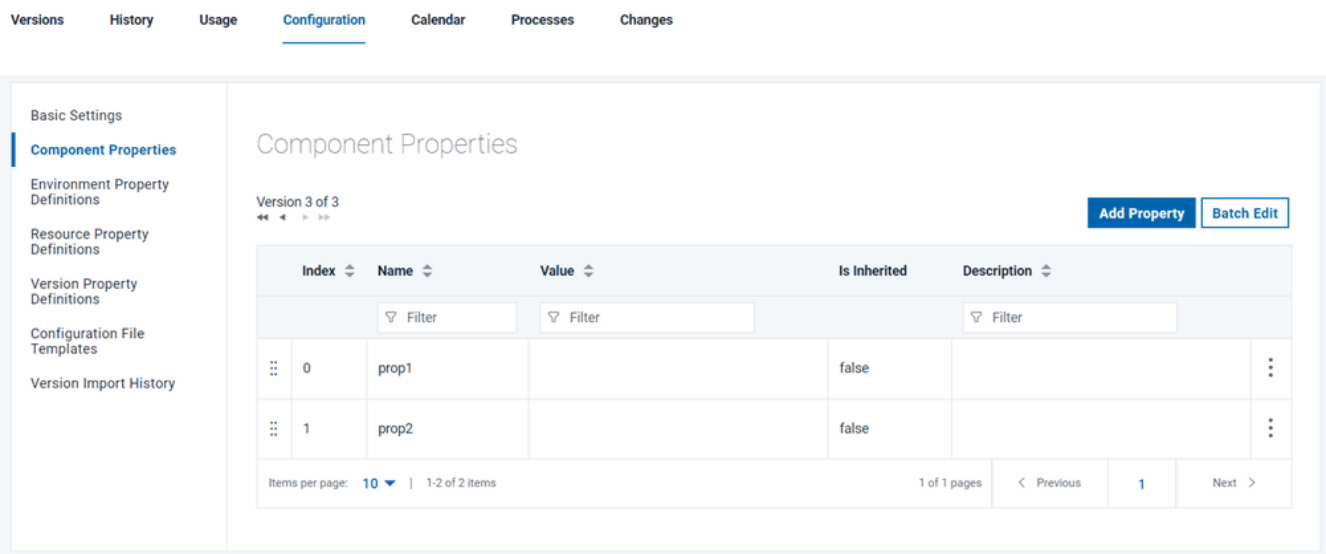
A property represents a user-defined parameter. Properties are typically accessed in processes. For information about using properties, see Referring to properties on page 2509.

Setting properties manually

You can create and edit properties on many elements by opening the element and going to its **Configuration** tab.

About this task

To edit most of the properties for an element, open the element, go to its **Configuration** tab (not the **Configuration** tab at the top of the page), and then click ***element_type* Properties**. For example, to edit component properties, click the component, click **Configuration**, and then click **Component Properties**, as shown in the figure.



However, if you created an application from a template, any environment or application properties that you specified are not available on the **Configuration** tabs. You can view and edit, but not delete, these properties by clicking the element's **Configuration** tab (not the **Configuration** tab at the top of the page), and then clicking **Basic Settings**.

To add a property, click **Add Property**, and provide the information about the property, including its name, value, and description. You can also edit multiple properties at once by clicking **Batch Edit**. Then, in batch mode, specify the properties in name-value pairs that are separated by line breaks, as in the following example:

```
Property1=Value1
Property2=Value2
Property3=Value3
```

Escape backslash, equals, and colon characters (`\`, `=`, `:`) with a backslash, for example:

```
WindowsPath=C\:\\myfolder\\myfile.txt
PropertyWithColons=This string\: has a colon
```

To create a property, put the new property and its value on a new line. To include a line break in a property value, use "`\n`". Be sure to click **Save** to save your changes when you are finished editing multiple properties. To close batch edit mode, use the **Use Table** command. Secured values are encrypted when they are displayed in batch mode. If you modify an encrypted value, the modifications are encrypted when you exit edit mode.

Note: You can reorder the properties by moving them up or down using the row handler ⁘. Property order can only be changed while sorting by index.

Auto-completing properties

Starting in v7.0.5, auto-completing properties were added to the script editor fields. The auto-complete functionality works in application, component, and generic processes.

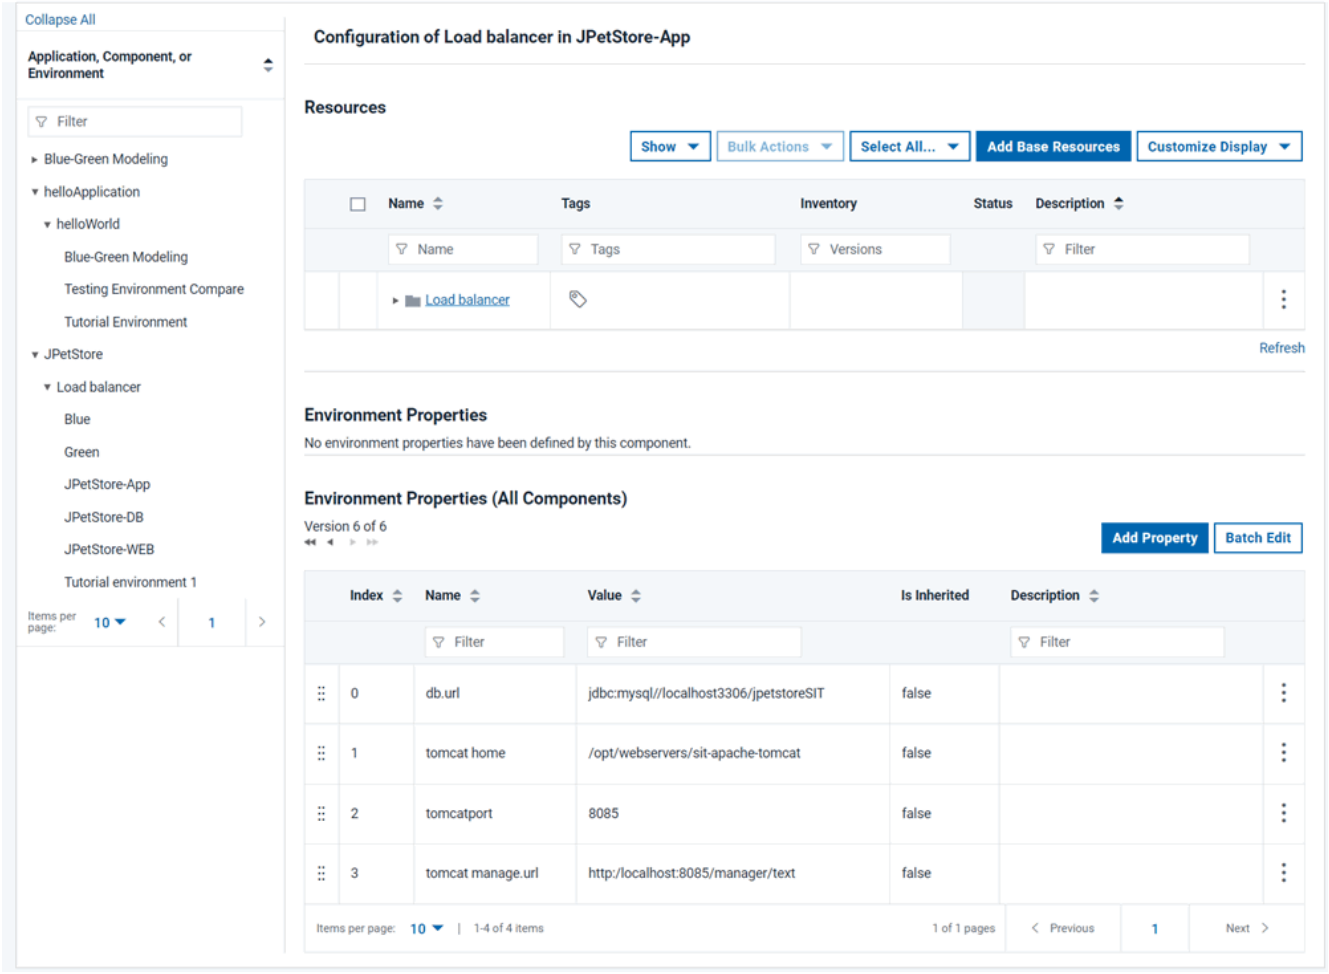
Setting properties with the **Configuration** tab

On the top-level **Configuration** page you can directly manage properties for applications, components, and environments.

About this task

Access the **Configuration** page by clicking the **Configuration** tab. From this page, you can add properties to applications, components, and environments.

Configuration

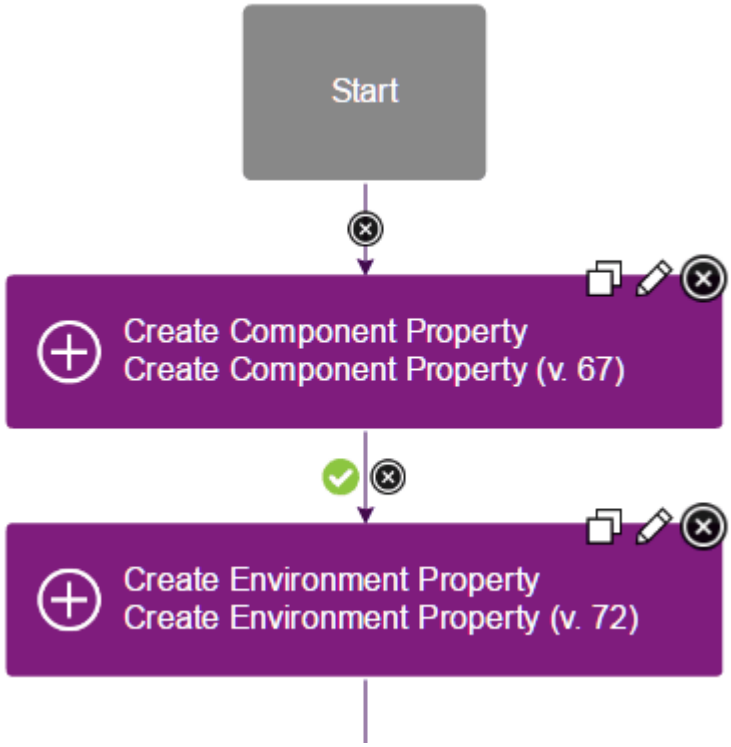


Setting properties in processes

Several different steps are available to create and set properties in processes.

About this task

For example, the Deploy component plug-in contains the Create Component Property step. This step creates a component property or changes the value of an existing component property.



Note: If you use these steps to change the value of a property, the new property value is not available until the next process runs. Later steps in the same process use the same value that the property had when the process started.

Setting properties with the REST API and command-line client

About this task

Several commands in the REST API and in the command-line client can set properties. See REST API reference and Command-line client (CLI) reference on page 2591.

Setting output properties

About this task

To pass properties from one step to another within a process, you can use output properties. See Output properties on page 2516.

Renaming properties

About this task

Properties can be renamed if the new name is not already in use. Renamed property references are not updated automatically.

Setting properties from external files

About this task

You can retrieve property values from an external file. See Retrieving property values from external files.

Property contexts

Properties are available in various contexts. Not all properties are available for all contexts. To plan and set properties, you must know where to access properties and how that setting behaves in context.

The following table shows the contexts in which properties are available and how you can use the properties.

Tip: The context that you set a property in can have narrow or widespread influence. For example, if you set a system property, that property persists in all areas. The key to setting properties effectively is to find a balance to setting narrowly as possible without setting them so narrow that you create extra work for yourself.

Example: Overriding server locations Consider this example: Initially you have one Tomcat server. To store the location of that server, you create an application property with the name `Tomcat.server.url` and the location of that server. Your environments refer to that property to know where the Tomcat server is. Then, suppose that you add a second Tomcat server. This Tomcat server is intended for use only by specific environments. So on those specific environments, you create an environment property with the same name `Tomcat.server.url` and the location of the second server. Now the environment has two properties with the same name: one system property and one environment property. The order of precedence determines which property value is used. Environment properties come before system properties in the order of precedence. Therefore, the environment uses the value of the environment property instead of the system property. In this way, you can use system properties to set defaults and then you can override those properties in specific contexts.

The following table shows the order of precedence of properties.

Context	Description
Process	Available on the **Configuration** tab of the process, whether it is a generic process, application process, or component process. Reference syntax: `${p:propertyName}`.
Component version	Available on the component **Configuration** tab. Click **Component > *selected component* > Configuration > Version Property Definitions**. Then, specify values on individual component versions. Referenced: `${p:version/propertyName}`.
Resource	Available on the resource **Configuration** tab. Click **Resources > *selected resource* > Configuration > Resource Properties**. Referenced: `${p:resource/propertyName}`. You can also use the following syntax to get a comma-separated list of all properties: `${p:resource/allProperties}`.

Context	Description
Agent	Available on the agent **Configuration** tab. Click **Resources > Agents > *selected agent* > Configuration > Agent properties**. Referenced: `${p:agent/propertyName}`. In a For Each Agent context, you can use the following syntax to get a comma-separated list of all properties: `${p:iteration/allProperties}`.
Environment	Environment properties are available on the **Configuration** tab for environments. Also, components can have component environment properties; these properties transfer to the environment when the component is deployed. An environment property overrides the value that is set on a component environment property that has the same name. Reference syntax: `${p:environment/propertyName}`. You can also use the following syntax to get a comma-separated list of all properties: `${p:environment/allProperties}`. Both the component and environment properties use the same syntax. For example, assume that you are deploying a web application to three environments. Each environment might have the application server in a different location. You can specify this location in an environment property on each environment.
Component	Available on the component **Configuration** tab. Click **Component > *selected component* > Configuration > Component Properties**. Referenced: `${p:component/propertyName}`. You can also use the following syntax to get a comma-separated list of all properties: `${p:component/allProperties}`.
Application	Available on the application **Properties** tab. Click **Applications > *selected application* > Configuration > Application Properties**. Reference syntax: `${p:application/propertyName}`.
System	System (global) properties are available on the **Settings** tab. Click **Settings > Properties**. Reference syntax: `${p:system/propertyName}`. The system property is broadest. If you plan to deploy an application, use application properties because it's more specific. If you have an `xyz` system property and an `xyz` application property, and you want to use the value of the system property, you must provide the entire context. Otherwise, the value resolves to the application property. You can also use the following syntax to get a comma-separated list of all properties: `${p:system/allProperties}`.

Note: The system properties are only available during the process executions. Do not use them in your System Setting configurations.

Referring to properties

HCL DevOps Deploy (Deploy) provides several ways to refer to properties.

Referring to properties

Normally, properties can be referred to without scope; but some properties, such as stepoutput properties, are referred to by scope. The scope is the type of artifact that contains the property, such as the environment or component. You refer to a property by scope this way:

```
${p:scope/propertyName}
```

You refer to a property without scope this way:

```
${p:propertyName}
```

For example, if you create an environment variable that is named UAT, you can refer to it this way:

```
${p:environment/UAT}
```

You can refer to the same environment variable without scope this way:

```
${p:UAT}
```

In the same way, you can refer to many types of properties, such as application properties, system properties, and resource properties.

Warning: In some cases, you can refer to a property without the `p:` prefix, such as in the code `${myProperty}`. This method for referring to properties is deprecated and should not be used. Referring to properties in this way can conflict with shell script variables or other values.

Use the `?` syntax if you are not sure about a property name:

```
${p?:propertyName}
```

This syntax returns a blank if the property is not found, and avoids the undefined property error.

Properties in application processes and component processes

When you create or edit process steps for applications and components, you can use the autocomplete feature to determine which properties are available in a particular context. When you are editing an input field for a process step, if you type `${p:`, a list of the available property scopes is displayed. Select a scope from the list. The list of all available properties in that scope is then displayed. Select the property to use from the list.

Secure properties

When you create a property, you can specify whether it is secure. Secure properties are stored in encrypted form. Secure properties are encrypted with an Advanced Encryption Standard (AES) algorithm and a 128-bit key. Secure properties are displayed in obscured form in the user interface.

If you create a custom plug-in that uses secure properties, the property value is displayed in obscured form in the user interface. For example, if your plug-in prints the property value to standard output and you examine the standard output in the user interface, the property value is displayed in obscured form.

If your custom plug-in writes the property value to a file, then the property value is not obscured.

Note: Use strong and complex values for secure properties. Because the secure property value is obscured in the output log, any other text that matches the secure property value is also obscured.

Property order of precedence

If a property is defined in multiple places, its value is determined by the *property order of precedence*. The following list defines the order of precedence from highest to lowest:

Process
Component version
Resource
Agent
Environment
Component
Application
System

If you have an environment property that is named `${p:environment/db.hostname}` and a resource property with the same name, you can refer to the resource property by using `${p:db.hostname}` or `${p:resource/db.hostname}`. Because the resource property is higher on the order of precedence than the environment property, in this case you must refer to the environment property by using the scoped format: `${p:environment/db.hostname}`.

Example: Overriding server locations Consider this example: Initially you have one Tomcat server. To store the location of that server, you create an application property with the name `Tomcat.server.url` and the location of that server. Your environments refer to that property to know where the Tomcat server is. Then, suppose that you add a second Tomcat server. This Tomcat server is intended for use only by specific environments. So on those specific environments, you create an environment property with the same name `Tomcat.server.url` and the location of the second server. Now the environment has two properties with the same name: one system property and one environment property. The order of precedence determines which property value is used. Environment properties come before system properties in the order of precedence. Therefore, the environment uses the value of the environment property instead of the system property. In this way, you can use system properties to set defaults and then you can override those properties in specific contexts.

Example: Defining properties in a step

Consider a process that defines properties in a step.

In this example, create a component process with a **Replace Tokens** step. Edit the step to reference a property list, using the **Property List** field. When the process runs, the normal order of precedence is not used. Instead, the order of properties in the property list is used to replace the tokens.

Example: Component Environment Properties Override Environment Properties

In current precedence model, the environment properties overrides component environment properties with the same name. If there are a large number of components, larger environments, or a combination of the both, this precedence model will require several edits on multiple resources. To reduce this effort, you can make component environment property override environment properties.

In this example, name the component environment property `${p:propName}` as opposed to `${p:environment/propName}`. Enable the **Component Environment Properties Override Environment Properties** settings from the Legacy Configuration Options in the System Settings page. When the process runs, the order of precedence takes place as: Component > Component Environment Properties > Environment.

Setting multiple component properties by environment

When components share a property, you can save time by setting the property value on the environment instead of setting it on every component. To use this feature:

1. Click **Components > *selected component* > Configuration > Environment Property Definitions**.
2. On the **Environment Property Definitions** page, define the property.
3. Repeat the process for each effected component.
4. On the environment that uses the components, click **Configuration > Environment Properties > Set a Single Value**.
5. Set the property value.

Component version properties

Properties can be defined for component versions. Each version can have a unique property value. To use this feature:

1. Click **Components > *selected component* > Configuration > Version Property Definitions**.
2. On the **Version Property Definitions** page, define the property. By default, this value is applied to every version that is created for this component.
3. To override a component version property with a unique value, click **Configuration > Version Properties** for the version.
4. Set the property value.

Using the ? wildcard in property references

The question mark character, `?`, can be used to reference properties. The syntax is:

```
${p?:propertyName}
```

For example:

```
${p?:agent/wsadmin.path}
```

returns the value of the property if it exists, otherwise it returns an empty string.

Escaped characters

Deploy escapes the following characters:

```
\
=
,
```

You must replace the character `\` with `\\`, character `=` with `\=`, and character `,` with `\,`.

Default properties

Many default properties are available for use while a process runs. These properties provide information about the process and the elements that are involved in the process, such as applications, components, and resources.

To see the properties that are available to a process, run the process. When the process is finished, go to the **Properties** tab of the process request. This tab lists all the properties that are available to the process.

The following table lists properties that are automatically available to processes and the types of processes that can access each property.

Property	Description	Process types
agent.id	The unique ID of the agent.	Generic processes and component processes
agent.name	The name of the agent.	Generic processes and component processes
application.id	The unique ID of the application.	Application processes, component processes
application.name	The name of the application.	Application processes, component processes
applicationProcess.id	The unique ID of the application process.	Application processes
applicationProcess.name	The name of the application process.	Application processes
component.id	The unique ID of the component.	Application processes, component processes
component.name	The name of the component.	Application processes, component processes
componentProcess.defaultWorkDir	The default working directory for the component. The value of this property is equivalent to `${p:resource/work.dir}/${p:component.name}`, where `${p:resource/work.dir}` is the	Component processes

Property	Description	Process types
	default working directory for the agent and `${p:component.name}` is the component name.	
componentProcess.id	The ID of the component process.	Component processes
componentProcess.name	The name of the component process.	Component processes
currentVersion.id	The ID of the component version that is used in the process.	Component processes
currentVersion.name	The name of the component version that is currently in inventory.	Component processes
currentVersion.type	Whether the component version is a full version or incremental version.	Component processes
environment.id	The unique ID of the environment.	Application processes, component processes
environment.name	The name of the environment.	Application processes, component processes
finalStatus	Whether the process succeeded (`Success`) or failed (`Failure`).	Application processes, generic processes, component processes
parentRequest.id	The ID of the parent process.	Application processes, component processes
previousVersion.description	The description of the version that was previously in inventory.	Component processes that take versions
previousVersion.id	The unique ID of the component version that was previously in inventory.	Component processes that take versions
previousVersion.name	The name of the component version that was previously in inventory.	Component processes that take versions
previousVersion.type	Type of the version as specified on creation that was previously in inventory.	Component processes that take versions
request.id	The unique ID of the process request.	Application processes, generic processes, component processes
request.user.displayName	The name of the user that requested the process.	Application processes, generic processes, component processes
request.user.email	The email ID of the user that requested the process.	Application processes, generic processes, component processes

Property	Description	Process types
request.user.id	The unique ID of the user that requested the process.	Application processes, generic processes, component processes
request.user.name	The user name of the user that requested the process.	Application processes, generic processes, component processes
resource	The unique ID of the resource that the process runs on.	Generic processes
resource.id	The unique ID of the resource that the process runs on.	Generic processes, component processes
resource.name	The name of the resource that the process runs on.	Generic processes, component processes
resource.parent.path	The parent of the resource that the process runs on	Generic processes, component processes
resource.path	The location of the resource in the resource tree.	Generic processes, component processes
resource/system/work.dir	The working directory on the agent resource.	Generic processes
resource/work.dir	The working directory on the agent resource.	Generic processes
server.url	The URL of the HCL DevOps Deploy (Deploy) server.	Application processes, component processes, generic processes
snapshot.id	The unique ID of the snapshot that was used to specify the component versions. This snapshot is sent only when a snapshot is being deployed.	Application processes
snapshot.name	The name of the snapshot that was used to specify the component versions. This snapshot is sent only when a snapshot is being deployed.	Application processes
version.description	The description of the version.	Component processes that take versions
version.id	The unique ID of the component version.	The built-in version of this property is available only to component processes that are not of the Operation(no version required) type.
version.type	Type of the version as specified on creation. FULL or INCREMENTAL	Component processes that take versions.

Property	Description	Process types
version.name	The name of the component version.	The built-in version of this property is available only to component processes that are not of the Operation(no version required) type.
working.dir	The working directory for the process.	Generic processes

Steps in component processes also have access to the output properties of previous steps, as in this table:

Property	Description
stepName/exitCode	The exit code of the component process step. 0 indicates success; any other value indicates failure.
stepName/LOI	The lines of interest (LOIs) are lines of code that the postprocessing script finds in the step's output log. See The post-processing element on page 2576.
stepName/Status	Whether the step succeeded (`Success`) or failed (`Failure`).
stepName/*outputProperty*	An output property from a previous step. See Examples of post-processing scripts on page 2417.

For example, if a prior step in the process is named `step1`, later steps can access properties such as `step1/exitCode`. If the step `step1` creates an output property that is named `output1`, later steps can access that property with the code `step1/output1`.

Output properties

Output properties are specialized properties that process steps generate. You use output properties to pass parameters to subsequent steps in a process.

You can use output properties in component processes and generic processes.

In the JavaScript™ code for your postprocessing steps, you can establish output properties. See Examples of post-processing scripts on page 2417. You set an output property for a step by assigning it a name and a value in the postprocessing script. For example, the following code from the Check If BLA Exists step in the IBM® WebSphere® Application Server Deployment plug-in establishes three possible values for the `blaExists` output property:

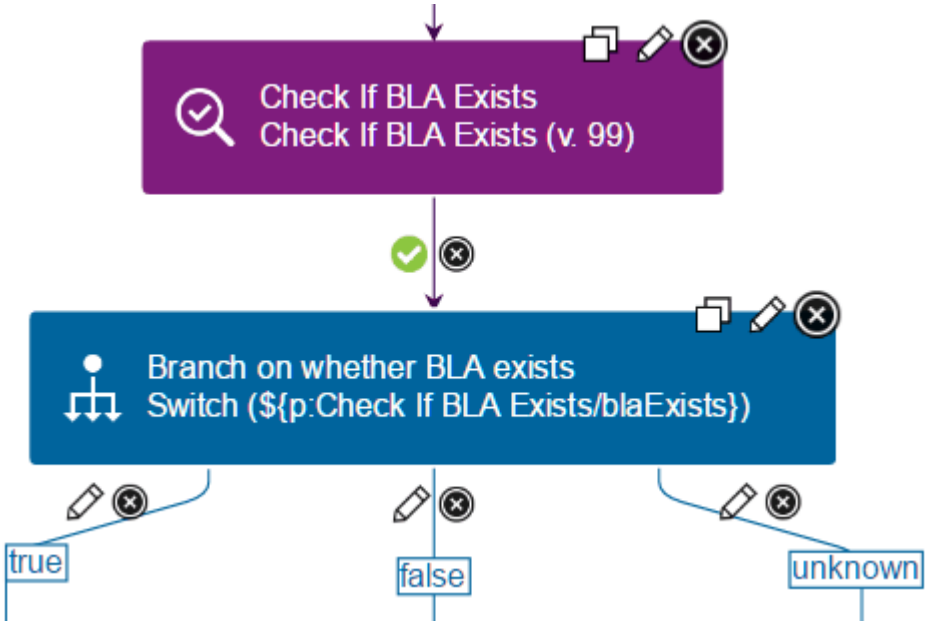
```
def exitCodeChecker = { exitCode ->
    if (exitCode == 0) {
        properties.setProperty("blaExists", "true");
        exitValue = 0;
    }
    else if (exitCode == 30) {
        properties.setProperty("blaExists", "false");
```

```
        exitValue = 0;
    }
    else {
        properties.setProperty("blaExists", "unknown");
        exitValue = 1;
    }
```

In the same way, you can create your own output properties by adding them in post-processing scripts. Use the format `properties.setProperty("propName",propValue);`, where `propName` is the name of the property and `propValue` is the value of the property. For example:

```
properties.setProperty("url", "http://example.com");
```

Then, you can refer to these output properties in other steps in a process. To do so, you must know the name of the step that contains the output property that you use. For example, your process might require different actions if a BLA exists. In this case, you could use a Switch step to branch the process for each case. In the following figure, the Switch step checks the value o f the `blaExists` output property by using the code `${p:Check If BLA Exists/blaExists}`:



You can use output properties in other postprocessing scripts, step preconditions, step properties, or the code of steps themselves. Passing property values among processes, resources, and steps helps limit the requirement to provide input manually and to maintain accuracy and reliability.

Secure output properties

You can set an output property as secure property for a process running on a Web agent. As an example, you can obsecure the value of a password field in the output log and Web UI. Define the secure output property by adding `.$secure` at the end of the property.

For example, set the property in JavaScript™ as:

```
outProps.setProperty("Password.$secure", "xyz");
```

or set the same property in Groovy as:

```
outProps.setProperty("Password.\$secure", "xyz");
```

Note that the agent must have support for the special handling of the indicated output property naming convention. The environment variable `UCD_USE_ENCRYPTED_PROPERTIES` with a value of `true` indicates the support of this functionality in a plug-in step and is handled by the agent.

If the environment variable is not available with the agent, then upgrade the agent to a newer version that has the functionality. Manually adding the environment variable does not enable the desired functionality in an older agent. It rather sets the propery as a regular output property when it is intended to be set as secure.

Manual task output properties

The output properties when added to a process containing a manual task gives you information about the approver and aprroval date. You can view the following information in the output log for a manual task:

- Name of the approver.
- Display name of the approver.
- Date and time of approval in the Epoch format.

  Epoch time is a standard machine-readable format. The `ApprovalTime` property is used to display the time in Epoch format. This format is used internally by another plug-in step.
- Date and time of approval in the UTC format.

  The `FormattedApprovalTime` property is used to get the approval time in UTC format and in a human-readable format.

As an example, you have two steps in a process. The first step is a manual task, named `manualTask` and the second step is a Shell step. You can add the following manual task output properties to the Shell step:

```
echo "${p:manualTask/ApproverName}"
echo "${p:manualTask/ApproverDisplayName}"
echo "${p:manualTask/ApprovalTime}"
echo "${p:manualTask/FormattedApprovalTime}"
```

After the completion of the process, you can view the following information in the output log:

```
=======================
command output:
John P. Doe
John
1123489611901
2024-08-12T19:06:51.901Z
=======================
```

System properties

System properties are global variables for the server.

System properties are available on the **Settings** tab: click **Settings > Properties**.

References to system properties are similar to the following example:

```
${p:system/propertyName}
```

If you create a `SUCCESS` system variable , for example, you would refer to it as in the following example:

```
echo ${p:system/SUCCESS}
```

Output in this case:

```
SUCCESS
```

Property availability

The properties that are available to you depends on the context. For example, in a component process, you can access the component properties of the current component. In an application process, you can access the application properties and environment properties, but not any component properties. The following table shows the processes in which each type of property is available.

To see the properties that are available to a process, run the process. When the process is finished, go to the **Properties** tab of the process request. This tab lists all the properties that are available to the process. The following table lists types of properties that are available to processes and which processes have access to each type of property.

Property type	Processes that can access the property	Sample syntax
Generic process properties	Generic processes	`${p:ProcessProp1}`
Application process properties	Application processes and component processes	`${p:ProcessProp1}`
Component process properties	Component processes	`${p:ProcessProp1}`
Component version properties	Component processes types that include versions, such as Deployment and Operational (with version)	`${p:version/VersionProp1}`
Resource properties	Component processes and generic processes	`${p:resource/ResourceProp1}`
Environment properties	Component processes and application processes	`${p:environment/EnvProp1}`
Application properties	Application processes and component processes	`${p:application/AppProp1}`

Property type	Processes that can access the property	Sample syntax
Component properties	Component processes	`${p:component/CompProp1}`
System properties	All processes	`${p:system/SystemProp1}`
Request properties	All processes	`${p:request.user.id}`, `${p:request.user.displayName}`, `${p:request.user.name}`, `${p:request.user.email}`
Iteration properties	Processes in the For Each Agent step context	`${p:iteration/agent.name}`, `${p:iteration/agent/AGENT_HOME}`
Agent properties	Generic processes and component processes	`${p:agent/PropName}`
External approval properties	Application processes	`${p:ext/PropName}`
Property Definition		
Environment Property Definitions	Component processes	`${p:environment/`*`propertyName`*`}`
Resource Property Definitions	Component processes	`${p:resource/`*`propertyName`*`}`
Version Property Definitions	Component processes	`${p:version/`*`propertyName`*`}`

Tags

A tag is a user-defined, shared, short label that you use to classify, view, and conduct operations on objects such as applications, components, agents, and resources.

If you manage many objects, you can use tags to organize objects so that the user interface is easier to navigate. You can also use tags to simplify deployment operations. If you use application templates, assign tags to components so that you can easily add components to applications that you create from templates.

Creating tags

You can create the agent, application, component, and resource tags from the **Tags** tab.

Before you begin

Ensure that your role has the **Create Tags** permission enabled.

1. Click **Settings > Tags**.
2. Select a tag type such as **Agent Tags**, **Application Tags**, **Component Tags**, or **Resource Tags** and click **Create Tag**.
3. Configure the tag in the **Create Tag** window:

Parameter	Description
Name	Identifies the tag name and is included in the Tags column when added.
Description	Conveys more information about the tag.
Color	Defines the tag color that is displayed in the UI.

4. Save your changes.
   The tag lists in the Agent Tags page.

   Note: Tags once created can only be edited and not deleted.

5. Alternatively, you can create a tag by navigating to the respective agent, application, component, or resource.
   a. Click **Add Tag** icon, select **Add New Tag**.
   b. Provide the tag details as described in the table above.

   Note: To create a tag on an object, you must have the Edit Basic Settings permission enabled on the object.

Adding tags to objects

Add tags to objects to simplify object management, to improve object sorting, and to facilitate task execution by tag.

Before you begin

Ensure that your role has the **Edit Tags** permission and the **Edit Basic Settings** permission on the object type is enabled.

1. Navigate to the object.
   You can apply tags to applications, components, and resources. You can apply tags to resources in your current resource tree or to resources in a resource template. See Creating resource templates on page 2333.
2. Hover the mouse pointer over the object, and click the **Add Tag** icon that is displayed.
   Result
   A window opens where you can select or create a tag.
3. Expand the list, and select a tag.

What to do next

- To organize a list of objects by tag, click **Flat list**. Select **By Tag** to organize the objects into a hierarchical list that is sorted by tag.
- To tag multiple objects at a time or to remove tags from multiple objects at a time, first select the check boxes to left of the objects. Then, click **Actions**, and select **Add Tag** or **Remove Tag**.
- To view all objects that have the same tag, in the tags field at the top of any list of objects, type the name of a tag, and then press Enter. Only the objects that are tagged with the exact text that you type in the **Tags** field are displayed. If a tag name contains spaces, surround the name with double quotation marks when you type it in the **Tags** field.
- To select all objects that have the same tag, first filter the objects as explained in the previous section. Then, click **Select All**, and select **Matching Filter**.
- To quickly assign a process to a specific agent, first tag the agent. Then, click the top-level **Processes** tab, click a process, and then click **Set** . Filter the agents as explained in the previous section, select the agent, and then click **OK**.
- To limit the installation of multiple components in application process to certain components or resources, first tag the components or resources. In the application process, click and drag the **Install multiple components** step to the process editor. In that step, use the **Component Tag** field to deploy the components that have a specific tag and the **Limit to Tag** field to use resources with a specified tag.
- To automatically import versions of a component by using any one of several agents, tag the agents. From the **Components** tab, click **Create Component**. Click **Import new component versions using any agent with the specified tag.**, and in the **Agent Tag for Version Imports** list, select the tag.

Grouping servers by using tags

You can use tagging to group target servers for organized deployments.

About this task

By using tags and filtering, you can separate resources that represent production servers into two logical groups. If you tag half the resources with a blue tag and half with a green tag, then you can run deployments in a fashion that is sometimes called blue-green deployment. When you plan to deploy a new version of an application to a production environment, deploy it to the blue group first. Meanwhile, the green group of servers still provides the older version of the application. After the new version of the application is deployed to the blue group, repeat the process with the green group. In this way, you can deploy a new version of software while still providing uninterrupted service in your production environment.

1. Tag resources, which represent target servers, in two groups.
   To learn more about tagging, see Adding tags to objects on page 2521. If you have resources that are organized in groups, you can apply a tag to a top-level group.
   Example
   For example, create top-level groups for the Blue servers and the Green servers. If you tag the two top-level groups as `Blue` and `Green`, then all resources that a particular group contains are included in deployment steps when you limit deployment to a specific tag.
2. Create two application deployment processes that correspond to the two tags.
   When you add an `Install Component` step to an application process, you can use the **Limit to Tag** field to restrict the deployment to resources that have a specific tag.
3. Deploy the new version of an application by using the first application deployment process.
   Example

For example, deploy the application to a group of servers that are tagged as `Blue` servers.

4. Check that the new version of the application is running as expected.
5. Deploy the new version of an application by using the other application deployment process.

   Example

   For example, deploy the application to a group of servers that are tagged as `Green` servers.

Component tags and component resource tags

You can tag components while you work on the **Components** tab, or you can tag components while you work in the **Resources** tab. However, the tags that you associate with components in these two contexts behave differently. Furthermore, you can also include components in a resource by using the tags that are associated with components in the **Component** tab.

In the **Components** tab, you can tag components according to your requirements. See Adding tags to objects on page 2521. You can organize and associate components by using tags.

In the **Resources** tab, you can tag components and other objects just as in other tabs. When you tag a component in the **Resources** tab, that tag is not applied to the component throughout all tabs. The component resource tag applies to the component only when the component is related to a resource.

As you develop processes, you can use the component resource tag for a few things. You can specify a set of components to be used for an Install Multiple Components or Rollback Multiple Components step in an application process. Specifying a set of components this way runs a process for each component with the specified component tag in the environment. Alternatively, you can also add a component resource tag to an agent resource in the resource tree. Adding the tag is a way of directing that this is a component slot that can be fulfilled with any component that is tagged with the corresponding component tag.

Tip: In the **Resources** tab, you can click the **Actions** menu, click **Component Tag**, and select the tag of components you want to add to the resource. By adding components this way, you automate the components that are included in resources. Otherwise, you have to add components manually and individually to resources.

Webhooks

Using a webhook, you can send text-based responses to users in messaging platform such as MS Teams and Slack when a specific event occurs during deployment process.

The webhooks allows the processes to submit a web-based notification to other applications such as MS Teams and Slack whenever a specific event occurs. Webhooks are transmitted via HTTPS, usually as a POST request over a specific URL. The POST data is interpreted by the receiving application's API, which triggers the requested action and sends a message to the original application to confirm the event has happened.

Managing webhook template

You can create and manage a webhook template to allow Deploy to send notifications to your messaging platform for a specific event.

Before you begin

Make sure that you have configured the template body for your event. See How-tos on page 1998 for example JSON body for Slack and Teams applications.

1. Click **Settings > Automation > Webhook Template**.
2. Click **Create Webhook Template**.
3. Configure the template in the **Create Webhook Template** window as follows:

Parameter	Description
Name	Specify the webhook template name.
Description	Add additional information about the webhook.
Body	Define the template body in JSON format. To get started with a template format,
Type	Indicate the event type that triggers the notification. Webhooks support events such as Process Success, Process Failure, Process Started, Scheduled Process Not Started, Approval Completed, Approval Failed, Approval created, External Approval Completed, External Approval Failed, and Task Created.
Teams	Allow access of a template type to specific teams.

4. Save your changes.

Results

The Webhook template is created and lists in the **Webhook Templates** page.

Adding webhooks to process

You can add a webhook template to applications and generic processes for the process notifications to appear in your configured Teams or Slack messaging applications.

Before you begin

Before you add a webhook to application, make sure that you have created an environment for the application and have resources added to it.

1. Open the webhook configuration UI using any of the following methods:
   - To add webhook to an application, go to **Applications > *application name* > Configuration > Webhooks > Add Webhook**.
   - To add webhook to a process, go to **Processes > *process name* > Configuration > Webhooks > Add Webhook**.

   The **Add Webhook** window is displayed.
2. Copy the generated webhook URL and paste it in the **URL** field.
   Refer to the Slack or Teams documentation for information about how you can get this URL.
3. If you are using a proxy server for Teams, you must specify the following details: **Proxy Host**, **Proxy Port**, **Proxy Username**, and **Proxy Password**.

These fields can also be automatically populated by setting the corresponding system properties: `proxyHost`, `proxyPort`, `proxyUsername`, and `proxyPassword`.

4. Specify an **Event Type**.
5. Select a template name from the **Webhook Template** field.
   See Managing webhook template on page 2523 for more information.
6. If you are adding the webhook to an application, specify the environment name from the **Environments** field.
7. Submit your changes.

Results

The webhook template is added to the application. When a process runs, the notifications appear in your configured messaging platform app.

Notes:

- Notifications can be out-of-order in any of the following cases:
  - Message A is sent and fails to complete for a reason. For example, the remote server has an error.
  - Message B is sent and completes.
  - The remote server error is now resolved.
  - The message A is resent, and completes.
- When you export or import an application or a generic process, the webhooks are also imported/exported with them.

Deploying

Learn how to deploy applications in HCL DevOps Deploy (Deploy).

Getting started with running deployments

You run a deployment by running an application process in a target environment.

You run a deployment in a specific application environment. When you start a deployment, you identify the application process and the component versions (or snapshot) to deploy. Any process that is defined for the parent application can be selected. All components that are associated with the application can be used. When you select component versions, you can filter the list to identify components of interest to you.

When an application process starts, the **Application Process Request** pane displays information about the application's status and provides links to logs and the application manifest. If the process requires an approval or manual task, you respond on this pane also.

HCL DevOps Deploy (Deploy) provides two different Web UI for starting an application deployment process. One is single-page form (default) and the other is deployment wizard. To use deployment wizard UI, go to application configuration, and enable **Use Deployment Wizard**.

Related topics:

- How to run a deployment; see Deploying applications on page 2526.
- How to create notification schemes; see Creating Notifications in a Notification Scheme on page 2081.
- How to setup authorizations; see Creating an approval process on page 2388.
- How to create application gates; see Environment gates on page 2360.

Deploying applications

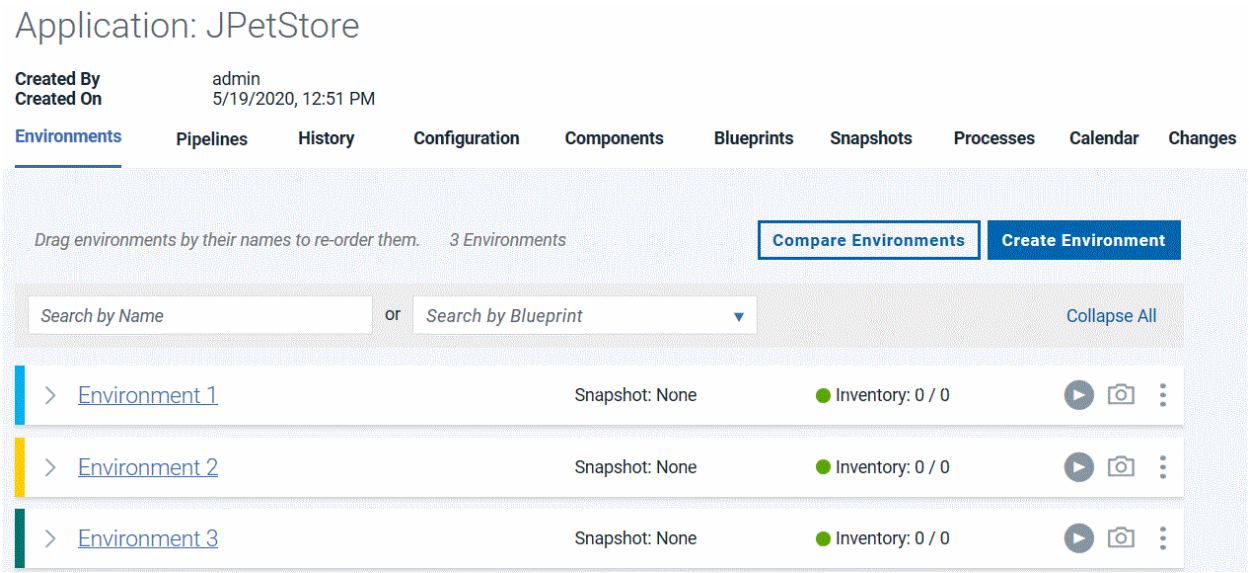
To deploy application components, run an application process on an environment.

Before you begin

Create an application, add components to it, and create an application process that deploys the components.

1. In the web UI, click the **Application** tab.
2. Click the name of the application.

   The application environments are displayed.



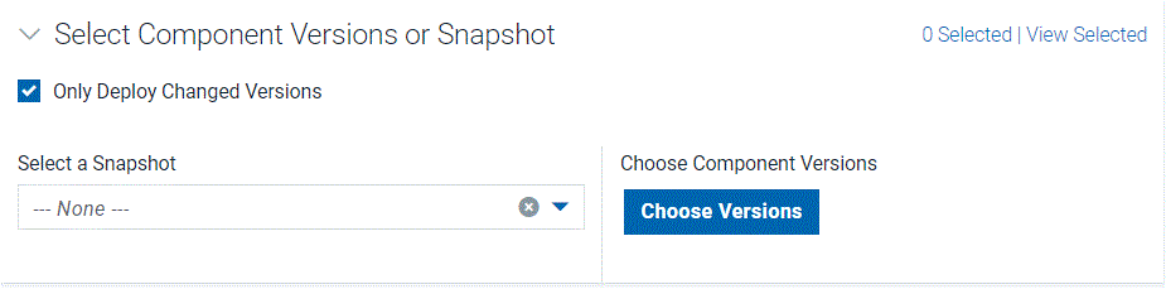
3. For the environment to run the deployment in, click **Request Process** .

   Result

   The **Run Application Process** window is displayed.
4. Select the process to run from the **Process** list.

   All processes for the application are listed.
5. Specify component versions or snapshot to deploy.

a. Expand the **Select Component Versions or Snapshot** area.



b. Enable the **Only Changed Versions** option, if not already, to specify whether to deploy only versions that have changed or to deploy all versions.
This option is enabled by default. If it is enabled, no previously deployed versions are deployed again. Disable the **Only Changed Versions** option to deploy a version regardless of whether it is already deployed. For example, if the inventory is out of date, disable the option.

c. To use a snapshot, select it from the **Select a Snapshot** list.
If you select a snapshot, the deployment automatically uses the component versions that are defined for the snapshot.

d. If you are not using a snapshot, specify the component versions to deploy by clicking **Choose Versions** and specify the versions of each component to deploy.
   - To specify the versions for each component individually, click **Add** next to a component in the table, and select versions to deploy from **By Version Lookup**, and then choose any one of the following criteria:

Option	Description
Latest Available	Selects the most recent component version at the time that you make this selection regardless of when the process runs. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that is available then, click **Latest Available at Execution Time**.
Latest with Status	Selects the most recent component version at the time that you make this selection. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that has the specified status that is available at the later time, click **Latest with Status at Execution Time**.
Latest Available at Execution Time	Selects the latest component version that is available when the process starts. The version that is used might be generated after you make this selection.

Option	Description
Latest with Status at Execution Time	Selects component that have a status that you specify in the next dialog box. The version that is used might be generated after you make this selection.
Current Environment Inventory at Execution Time	Uses the environment inventory that is available when the process starts. The environment inventory might be different from the inventory that is available when you make this selection.

- To select versions for all components at once, click **Select For All**, and then select an option from the list. Version options are described in the following table:

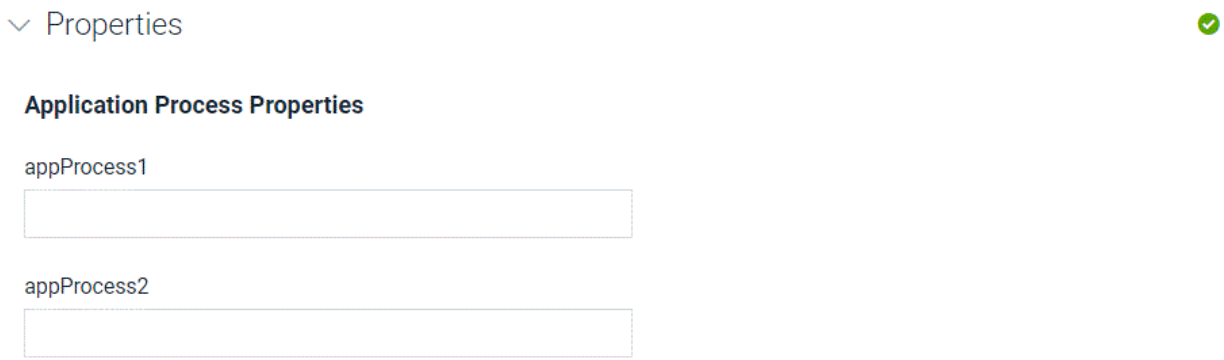
Version option	Description
Latest Available	Select the most recent component version at the time that you make this selection regardless of when the process runs. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that is available then, click **Latest Available at Execution Time**.
Latest with Status	Select the most recent component version at the time that you make this selection. If you schedule a process to run, for example, a week after you make this selection and you want to use the most recent version that has the specified status that is available at the later time, click **Latest with Status at Execution Time**.
Versions With Name	Select the most recent component version whose name matches a string.
Current Environment Inventory	Uses the versions that are listed for that environment when you select it. This selection is typically related to the last version that was deployed to a certain environment of each component. For example, say that you deployed component A, version 1, to your environment. Then, in a separate deployment, you deployed an incremental version 1.1 to the same environment. If you look at the current environment inventory in the **Application** view, you see that the environment contains versions 1 and 1.1. Typically, you don't want to redeploy what is already there. However, this selection is useful when a deployment fails or is modified on the target computer itself, outside of Deploy. So if the deployment of version 1.1 succeeded on 10 agents but failed on two, you can schedule essentially a retry. Use of this selection is not common.

Version option	Description
Latest Available at Execution Time	select the latest component version that is available when the process starts. The version that is used might be generated after you make this selection.
Latest with Status at Execution Time	Selects component that have a status that you specify in the next dialog box. The version might be generated after you make this selection.
Current Environment Inventory at Execution Time	Uses the environment inventory that is available when the process starts. The environment inventory might be different from the inventory that is available when you make this selection.
None (Clear All)	Clears your selection.

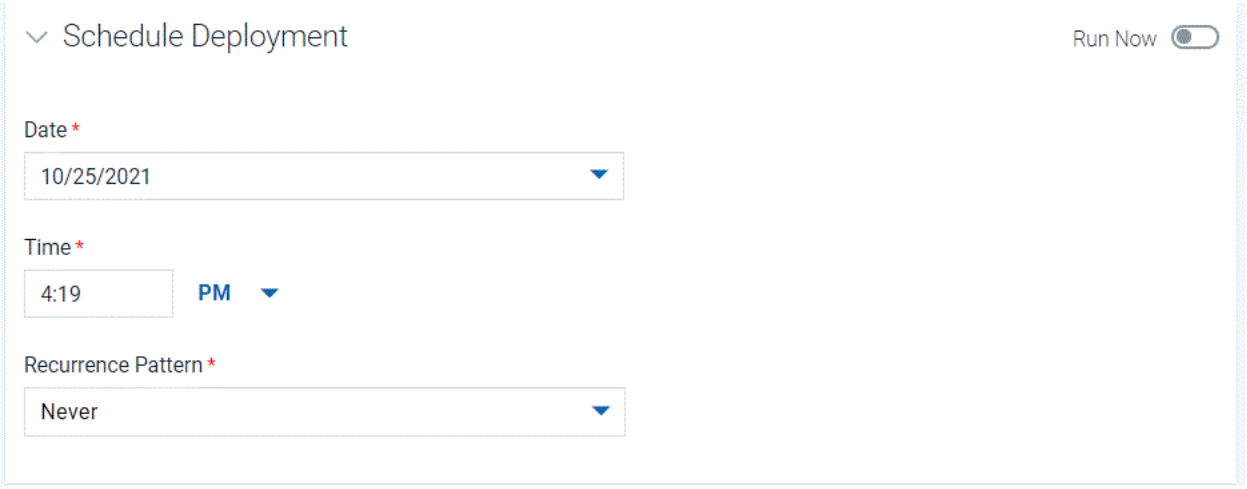
Note: If you select multiple versions for one component, the versions are installed in the order you select.

Note: Make sure to select a version for each component. If you do not select a version for a component, that component is not included in the application process.

6. Expand the Properties area and specify application properties for the deployment, if any.



7. Schedule the deployment for a later date by disabling **Run Now** and then specify the date, time, and recurrence pattern of the deployment.



8. Click **Submit**.

   Result

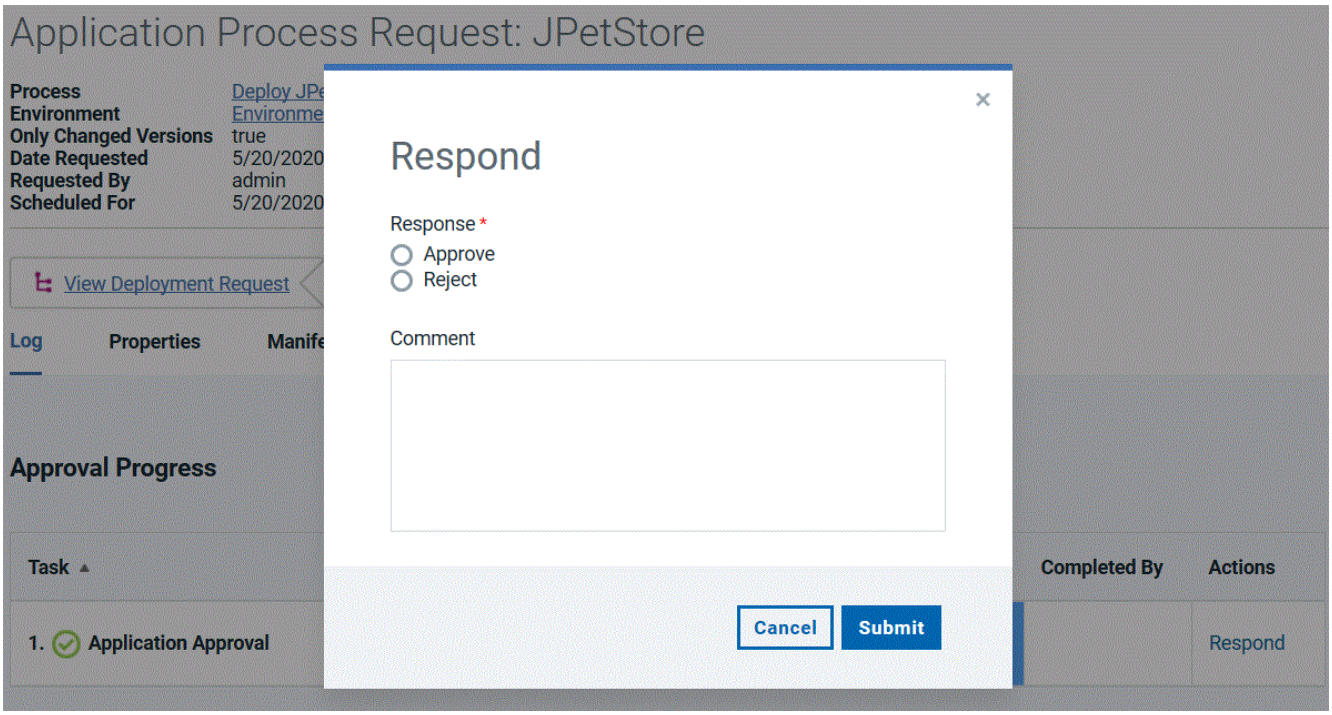
   The application process starts immediately unless it is scheduled for a later time.

Example

For an example, see Deploying a simple web application on page 1934.

What to do next

When a process starts, use the **Application Process Request** pane to review the deployment status. This pane is also used if the process requires approvals, as shown in the following figure.



The application process request shows each step in the process. Within each process, the steps are not shown in the order that they run in. Instead, steps are shown in the order of appearance in the process editor, from the steps at the top of the canvas to the steps at the bottom of the canvas.

The deployment is considered successful when the application process finishes. An application process might skip component processes and still finish. This means that a technically successful application process might not deploy all of the expected components. To ensure that all components deploy successfully, review the deployment details. Expand a process step and click **View Child Execution** to open the **Deployment of Component** pane, which can be used to review the deployment details.

In the **Deployment of Component** pane, you can review the deployment output log, error log, and input and output parameters.

Deploying components to the z/OS® platform

Use the toolkit to deploy to the IBM® z/OS® platform.

Before you begin

Deploying components to the IBM® z/OS® platform is similar to deploying to other platforms. Create an application, components, environments, and resources. Import versions of artifacts to the components, and then create an application process that deploys the components to a target environment.

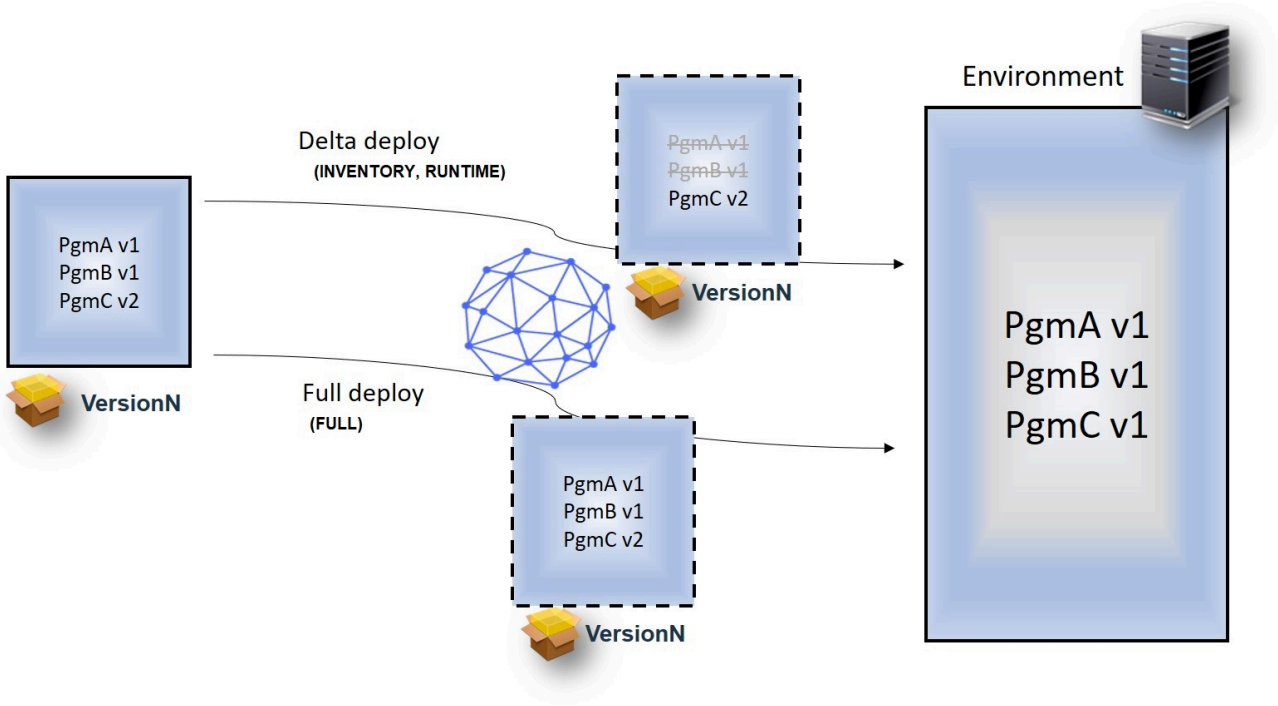
About this task

When you create a component for z/OS artifacts, select **z/OS®** as the component type.

Versions can be imported to a z/OS component by using the z/OS File source configuration plug-in or by using the buztool command line from an z/OS agent.

Two or more z/OS component versions can also be merged from a snapshot into one to simplify the deployment to the next environment. Refer to Merging z/OS component versions on page 2292.

In your application process with the components to deploy, configure the **Deploy Data Set** process step as either a **FULL**, **INVENTORY**, or **RUNTIME** deployment for z/OS data sets and HFS



files.

A **FULL** deployment type replaces all artifacts with artifacts in the current component version.

An **INVENTORY** deployment type, or delta deployment, reduces deployment time significantly by deploying only the changes between artifacts.

A **RUNTIME** deployment type is a delta deployment that uses checksum logic to compare artifacts to be deployed with the same artifacts in the target environment. This check is done for every artifact. Only artifacts with checksums that don't match are considered as changed and used for deployment.

Note: Two artifacts are considered the same when at least one attribute can be used for comparison and all attributes that are used for comparison match exactly.

For each artifact in a delta deployment, the following attributes are compared to the latest inventory version of the same artifact.

Parameter	Where Used
Last Modified Timestamp	**INTENTORYRUNTIME**

Parameter	Where Used
Custom properties starting with **SYS.id** (aka identification properties)	**INVENTORYRUNTIME**
checksum	**RUNTIME**

1. Install the z/OS® agent. See Installing the z/OS agent.
2. Create a ship list file.
   See Ship list files on page 2533.
3. Create a deployable component version.
   See Creating z/OS component versions on page 2279.
4. Create component processes and application processes as you would for any other deployment, by using the z/OS® Utility plug-in for process steps that retrieve and deploy z/OS® artifacts.
   Example
   For example, use Download Artifacts for z/OS process steps to retrieve z/OS® artifacts. Configure the Deploy Data Set process step for either a **FULL**, **INVENTORY** or **RUNTIME** deployment of the z/OS® data sets and HFS files.
   The z/OS® Utility plug-in also includes process steps for rolling back data sets, for running commands from the time sharing option (TSO) command line, and for running ISPF commands. For best results, create components by using the MVSCOMPONENT template which has built-in deploy processes.

What to do next

To learn more about the z/OS® Utility plug-in, see the HCL plug-in site.

Ship list files

The ship list file describes the files from the build to include in the new component version to deploy. Ship list files can also use generic artifacts to describe changes that are not physical files, such as configuration changes.

You must create a ship list file before you run the IBM® z/OS® deployment tools. Typically, you write a script that works with your build engine to create a ship list file from the build output. Ship list files are XML files that contain a list of file specifiers.

Partitioned data sets

Partitioned data set (PDS) members are identified by the **PDS** container type and the **PDSmember** resource type. You can use an asterisk (*) as a wildcard for the resource name, if you want all members in a partitioned data set to be included in a package.

For example, to package the BLZCPBTK member from the BLD.JCL PDS and all of the members in the BLD.LOAD1 PDS and the ORDRSET and RDBKC01 members from the BLD.LOAD2 PDS, the ship list file might contain the following lines:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.JCL" type="PDS">
        <resource name="BLZCPBTK" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD1" type="PDS">
        <resource name="*" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD2" type="PDS">
        <resource name="ORDRSET" type="PDSMember"/>
        <resource name="RDBKC01" type="PDSMember"/>
    </container>
</manifest>
```

Sequential data sets

Sequential data sets are identified by the **sequential** container type.

For example, to package the BLD.DATA1 sequential data set, the ship list file might contain the following lines:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name=" BLD.DATA1" type="sequential">
    </container>
</manifest>
```

HFS files

Hierarchical file system (HFS) files used in z/OS UNIX are identified by the directory container type and the file resource type. Both container name and resource name support the Ant file include pattern. (For more information about Ant, see https://ant.apache.org/.) Each directory container must use the **rootDir** attribute to identify the root directory to resolve files from. Only files in that root directory are considered.

For example, to package `*.wsbind` files and `*.wsdl` files from the `wsbind` directory and the `wsdl` directory within the root directory `/u/dave/cicsfiles`, the ship list file might contain the following lines:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="wsbind" rootDir="/u/dave/cicsfiles" type="directory">
        <resource name="*.wsbind" type="file"/>
    </container>
    <container name="wsdl" rootDir="/u/dave/cicsfiles" type="directory">
        <resource name="*.wsdl" type="file"/>
    </container>
</manifest>
```

To package everything from the root directory `/u/dave/cicsfiles`, the ship list file might contain the following lines:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="." rootDir="/u/dave/cicsfiles" type="directory">
        <resource name="**/*" type="file"/>
    </container>
 </manifest>
```

To deploy HFS files, use the same plug-in steps as you use to deploy data sets. HFS files and data sets can be put into the same version and deployed or rolled back together.

Deployment types

You can set the **deployType** attribute on containers and resources. The **deployType** attribute is used to identify different types of artifacts so that they can be processed differently during a deployment. The following ship list file shows **deployType** attributes that are added to the previous PDS example:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.JCL" type="PDS" deployType="JCL">
        <resource name="BLZCPBTK" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD1" type="PDS" deployType="CICS LOAD">
        <resource name="*" type="PDSMember"/>
    </container>
    <container name="BLD.LOAD2" type="PDS">
        <resource name="ORDRSET" type="PDSMember" deployType="CICS LOAD"/>
        <resource name="RDBKC01" type="PDSMember" deployType="CICS LOAD"/>
    </container>
</manifest>
```

Custom properties

You can add custom properties to containers and resources. The properties are displayed in the **Version Artifacts** view and can be used by plug-in steps. For example, properties can be used by the Generate Artifact Information step in the IBM® z/OS® Utility plug-in. The following ship list file shows an example of custom properties.

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.DBRM" type="PDS">
        <property name="COLLID" value="C001"/>
        <resource name="MOD01" type="PDSMember">
            <property name="devowner" value="Martin"/>
        </resource>
    </container>
</manifest>
```

You can add custom properties to the manifest element. When a property is the child of the manifest element, it is created as a component version property. If the value of the property is a URL, a link is added to the version.

To learn more about using custom properties, see "Using custom properties in deployments" in the z/OS Utility Plug-in.

Deletions

You can mark PDS members, sequential data sets, or HFS files for deletion by specifying the containers inside a **deleted** element. Data sets or HFS files that are marked for deletion are deleted from the target environment when the deployment process runs. The deleted artifacts can be rolled back if the backup option is enabled in the deployment step. If you use the ship list file to delete data sets, you can roll back the deletions as needed.

For example, the following ship list deploys PGM1 and PGM2 and deletes PGM3 from the target environment:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.LOAD1" type="PDS">
        <resource name="PGM1" type="PDSMember"/>
        <resource name="PGM2" type="PDSMember"/>
    </container>
<deleted>
     <container name="BLD.LOAD1" type="PDS">
         <resource name="PGM3" type="PDSMember"/>
 </container>
</deleted>
</manifest>
```

Notes:

- Wildcard (*) is not supported in the resource names for a deleted container.
- Wildcards must not be used for directory or file names.

Generic artifacts

Use generic artifacts to describe changes to deploy that are not physical files. For example, use generic artifacts to deploy system configuration changes or middleware configuration changes that are not associated with standard artifacts. Generic artifacts have the `GENERIC` container type.

For example, the following ship list describes two message queues to deploy to the target environment:

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
<container name="QLOCAL" type="GENERIC" deployType="">
  <resource name="LCQ1">
    <property name="maxdepth" value="5000"/>
  </resource>
  <resource name="LCQ2">
    <property name="maxdepth" value="200000"/>
  </resource>
</container>
</manifest>
```

To deploy generic artifacts, use the Generate Artifact Information step from the z/OS® Utility plug-in to generate commands for deploying the artifacts. Then, use an appropriate command step to run the commands. Steps that you can use to run commands include the Submit Job step, the Shell step, and the TSO/ISPF Command step. Other plug-ins can also use the output of the Generate Artifact Information step to deploy changes.

Source information

You can add source information to PDS members and sequential data sets to build traceability from deployable artifacts to the source code version. The source information is displayed in appropriate views in the HCL DevOps Deploy (Deploy) server.

In following example, the source information in the `<inputs>` and `<input>` elements indicate `BLD.LOAD(ORDRSET)` is compiled from two source code files, a main program ORDERSET and a copybook ORDRDATA. The version of the source code is identified by the version attribute.

```
<?xml version="1.0" encoding="CP037"?>
<manifest type="MANIFEST_SHIPLIST">
    <container name="BLD.LOAD" type="PDS">
        <resource name="ORDRSET" type="PDSMember">
<inputs url="">
<input name="ORDRSET" version="3" compileType="Main" url = ""/>
               <input name="ORDRDATA" version="1" compileType="Copybook" url = ""/>
            </inputs>
 </resource>
    </container>
</manifest>
```

Notes:

- The ship list file must be encoded in CP037 format.
- If a data set member name contains invalid characters, the characters are replaced by % to match any characters. Valid data set member name characters are `0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ@#$`.

Generating Ship list for Endevor and Changeman packages

You can generate shiplist.xml using Endevor SCL and Changeman configurations. Generated shiplist.xml can later be used to create component version using buztool.sh.

Generating Ship list from Endevor SCL

Run shiplistgen.sh to generate ship list from an Endevor SCL.

Parameters	Required	Description
-d, -dataset	Yes	MVS Dataset that contains Endevor SCL (or) use '-f' option
-f, -file		HFS File that contains Endevor SCL (or) use '-d' option
-o, -output	No	Ship list file name to be written to. By default, a file 'shiplist.xml' is created in current working directory
-m, -mapping	Yes	Mapping file for Endevor
-verb, -verbose	No	Set to true to display trace log

This tool requires Endevor Package SCL containing only MOVE statements in a Data set or file. Refer to the following sample Endevor SCL:

```
MOVE ELEMENT 'CARP001'
     FROM ENVIRONMENT 'PROD'
          SYSTEM 'PAYROLL'
          SUBSYSTEM 'REPORTS'
          TYPE 'COBOL'
          STAGE NUMBER 1
     OPTIONS CCID REQ#43034
          COMMENT 'MOVE INTO PRODUCTION'
          WITH HISTORY.

     MOVE ELEMENT 'CARPBACH'
     FROM ENVIRONMENT 'PROD'
          SYSTEM 'PAYROLL'
          SUBSYSTEM 'REPORTS'
          TYPE 'DBRM'
          STAGE NUMBER 1
     OPTIONS CCID REQ#43034
          COMMENT 'MOVE INTO PRODUCTION'
          WITH HISTORY.

     MOVE ELEMENT 'SCRN001'
     FROM ENVIRONMENT 'PROD'
          SYSTEM 'PAYMENTS'
          SUBSYSTEM 'FINANCE'
          TYPE 'COPYBOOK'
          STAGE NUMBER 1
     OPTIONS CCID REQ#43034
          COMMENT 'MOVE INTO PRODUCTION'
          WITH HISTORY.
```

This tool also requires a mapping file in JSON format. Assign Data set names DSNAME for each TYPE available in Endevor. For example, A SCL type **COBOL** is assigned to Data set name **TEST.ENDEVOR.COBOL** as shown in below sample mapping JSON:

```
[
    {
        "TYPE": "COBOL",
        "DSNAME": "TEST.ENDEVOR.COBOL"
    },
    {
        "TYPE": "COPYBOOK",
        "DSNAME": "TEST.ENDEVOR.COPYBOOK"
    },
    {
        "TYPE": "DBRM",
        "DSNAME": "TEST.ENDEVOR.DBRM"
    }
]
```

For example, the following command creates a ship list using Endevor package SCL stored in file `/u/user/Sample_SCL.txt` and mapping in `/u/user/Endevor_mappings.json`.

```
/opt/devops-deploy/agent/bin/shiplistgen.sh -f /u/user/Sample_SCL.txt -m /u/user/Endevor_mappings.json
```

The shiplistgen.sh creates a **shiplist.xml** file in the working directory.

Generating shiplist for Changeman packages

HCL DevOps Deploy (Deploy) can create its own versions for equivalent packages in Changeman. This is done using the help of shiplist4changeman.sh shell script that is shipped in the z/OS agent.

The shiplist4changeman.sh accepts the following parameters:

Parameters	Required	Description
-m, -mapping	Yes	A file in USS that can map one of (TEXT, BINARY, EXEC) types to COBOL, JCL and other types in Changeman SCM in key value pairs like below: EXEC=LOAD TEXT=COBOL, COPYBOOK, JCL, PROCLIB BINARY=DBRM Multiple values must be separated by commas.
-p, -package	Yes	Name of the package.
-hlq	Yes	High-level qualifier of datasets for Changeman packages. The HLQ can be like: HLQ.*. PKGNAME.*. LOADLIB HLQ.*. PKGNAME.*. LOAD* HLQ.PKGNAME. LOAD* HLQ.*. PKGNAME.*. JCLLIB HLQ. **. PKGNAME.*. COBOL
-o, -output	No	The output xml file to which the shiplist.xml is generated to. The file need not be present in the system.
-verb, -verbose	No	Set to true to display the trace log.

The shell script is found in `<AGENT_HOME>/bin` and hence must be executed from this directory.

For a package "PKG" containing only JCL members, a high-level qualifier "HLQ ", and mapping file "mappingfile.txt" containing TEXT=JCL and output "shiplist.xml", the command displays as below:

```
/opt/devops-deploy/agent/bin/shiplist4changeman.sh -m /u/user/mappingfile.txt -p PKG -hlq HLQ. **.PKG
 -o /u/user/shiplist.xml
```

The output shiplist.xml will look like below:

```
<?xml version="1.0" encoding="IBM-1047"?><manifest type="MANIFEST_LIST"> <container deployType="TEXT"
name="HLQ.PKG.JCL" type="PDS"> <resource name="*" type="PDSMember"/> </container> </manifest>
```

Deploying by using the Job Monitor

You use the Job Monitor to submit jobs and to monitor the job status in your deployment. You must ensure that you have a Job Monitor task running and that you run the HCL DevOps Deploy (Deploy) process to submit or to monitor the job. Then, you must set up Job Monitor connection properties in your HCL DevOps Deploy (Deploy) environment.

About this task

Install the following agent or product and use the Job Monitor that is bundled with it:

- z/OS agent
- IBM Developer for IBM Z
- IBM Rational Team Concert

Note: For the z/OS agent, the Job Monitor is installed automatically in the `hlq.SBUZAUTH` data set. Also, the **LOOPBACK_ONLY** property must be set to OFF in the `Job Monitor` configuration file.

`The hlq.SBUZSAMP(BUZJJCL)` member has the sample PROC for starting JMON. The `hlq.SBUZSAMP(BUZJCNFG)` member is the JMON configuration file that is referred to in the PROC. JMON installed for another product (for example, IDz or IBM RTC) can be used, but the **LOOPBACK_ONLY** property must be OFF

Submitting and monitoring jobs in deployment processes

1. Start the Job Monitor task and check that a task that is called **JMON** is running.
2. To submit or to monitor jobs, run the process that uses the **Submit Job** or **Wait For Job** steps.
3. Set the following Job Monitor connection properties in the Deploy environment or resource:

```
jes.host=localhost
jes.user=z/OS user ID
jes.password=Password of the user. Set blank to use PassTicket authentication.
jes.monitor.port=The port number for Job Monitor host server.
The default port is 6715.
```

Authenticating with a user ID and Password

To use a password to authenticate, store the password in the *jes.password* property.

Note: As you complete the **Submit Job** or **Wait For Job** step, do not store the password directly in the **Password** field. The **Password** field contains plain text only and this field must be used to reference a property.

Authenticating with PassTickets

If you do not provide a password, the plug-in uses PassTickets authentication. You can use PassTickets authentication to eliminate the requirement to store user passwords in Deploy.

To configure your system to use PassTickets, complete the following steps:

1. Activate the RACF PTKTDATA class if it is not already active. The following code shows sample RACF commands:

```
SETROPTS GENERIC(PTKTDATA) SETROPTS CLASSACT(PTKTDATA) RACLIST(PTKTDATA)
RDEFINE PTKTDATA IRRPTAUTH.FEKAPPL.USER1 UACC(NONE)
```

2. To create a PTKTDATA profile that defines the secret key and the application name to which it applies for the Job Monitor, complete the following steps:
    a. Define the application name as FEKAPPL.
    b. Define the key as a 64-bit number (16 hex characters).

c. Replace the key16 placeholder with a user-supplied 16 character hex string (characters 0-9 and A-F) as shown in the following sample RACF commands:

```
RDEFINE PTKTDATA FEKAPPL UACC(NONE) SSIGNON(KEYMASKED(key16)) APPLDATA('NO REPLAY PROTECTION - DO
 NOT CHANGE') DATA('URBANCODE DEPLOY')
```

The following example shows the command with the key16 value replaced:

```
RDEFINE PTKTDATA FEKAPPL UACC(NONE) - DATA('URBANCODE DEPLOY') - APPLDATA('NO REPLAY PROTECTION -
 DO NOT CHANGE') - SSIGNON(KEYMASKED(0123456789ABCDEF))
```

d. Read the following scenarios:

i. If the PTKTDATA class is already defined, verify that it is defined as a generic class before you create the profile that was shown previously. The support for generic characters in the PTKTDATA class is new in the z/OS V1.7 release, with the introduction of a Java interface to PassTickets.

ii. If a cryptographic product is installed and available on the system, you can encrypt the secured sign-on application key for added protection. Use the KEYENCRYPTED keyword instead of the KEYMASKED keyword. For more information, see the Security Server RACF Security Administrator's Guide (SA22-7683).

iii. If the Rational Developer for System z or the Rational Team Concert server components are already installed on the system, the PTKTDATA profile might be defined already.

3. To define a profile to generate a PassTicket, you must define the IRRPTAUTH profile in the PTKTDATA class. Then, this profile controls for which user ID a PassTicket is generated, as shown here:

Operation	Profile name	Required access
Generate PassTicket	`IRRPTAUTH.application.target-userid`	Update

4. To set permissions for the Deploy agent to generate a PassTicket so that the agent generates a PassTicket, the user ID of the agent or the impersonated ID must have UPDATE access in the PTKTDATA profile that you created in the previous step. For more information, see the following RACF commands:

```
PERMIT IRRPTAUTH.FEKAPPL.USER1 CLASS(PTKTDATA) ID(AGNTUSR) ACCESS(UPDATE)
```

5. To refresh the PTKTDATA class for the new profiles and permissions to take effect, see the following commands:

```
SETROPTS RACLIST (PTKTDATA) REFRESH
```

Example

See the following PassTicket examples:

Example 1. Agent is started by user AGNTUSR. In a deployment process, a Job needs to be submitted on behalf of user USER1.

```
RDEFINE PTKTDATA IRRPTAUTH.FEKAPPL.USER1 UACC(NONE)
PERMIT IRRPTAUTH.FEKAPPL.USER1 CLASS(PTKTDATA) ID(AGNTUSR) ACCESS(UPDATE)
SETROPTS RACLIST (PTKTDATA) REFRESH
```

Example 2. Agent is started by user AGNTUSR. Allow this agent to submit jobs on behalf of any user.

```
RDEFINE PTKTDATA IRRPTAUTH.FEKAPPL.* UACC(NONE)
PERMIT IRRPTAUTH.FEKAPPL.* CLASS(PTKTDATA) ID(AGNTUSR) ACCESS(UPDATE)
SETROPTS RACLIST (PTKTDATA) REFRESH
```

Example 3. Agent is started by user AGNTUSR. Allow this agent to submit job on behalf of user AGNTUSR:

```
RDEFINE PTKTDATA IRRPTAUTH.FEKAPPL.AGNTUSR UACC(NONE)
PERMIT IRRPTAUTH.FEKAPPL.AGNTUSR CLASS(PTKTDATA) ID(AGNTUSR) ACCESS(UPDATE)
SETROPTS RACLIST (PTKTDATA) REFRESH
```

What to do next

More JES security considerations are described in the IBM Developer for IBM Z documentation. For more information, see JES Security.

Authenticating with Trusted IP

Starting with v2.9.17 or higher, JMON can authenticate client IP as a trusted source and process client requests. This allows the `Wait for Job` and `Submit Job` plug-in steps to run with Agent User Id or Impersonation Id. The User Id and password/ pass-ticket that are usually needed for these steps are ignored and hence can be left empty. If the client (z/OS UCD Agent in this case) is on the same system as JMON then no changes are required. But if JMON is active on another system in the SYSPLEX, TCPIP RACF profiles are required.

While it is recommended to execute JMON as a started task, it is also possible to execute it as a user job. When not active as a started task, JMON will query your security product for explicit permission to start.

Security profile	Required access
BUZ.START.BATCH.*jobName.port*	READ

The security class where this profile resides can be specified with *SAF_CLASS* variable in the BUZJCNFG configuration file and is FACILITY by default. When the profile is not defined, or the class is not active, permission is denied, and batch startup will fail.

Use the following RACF commands to allow USER ID (IBMUSER in this case) to start JMON in batch with job name JMONJCL and port 6715:

```
RDEFINE FACILITY BUZ.START.BATCH.JMONJCL.6715 UACC(NONE)
DATA('Start JMON in Batch')
PERMIT BUZ.START.BATCH.JMONJCL.6715 CLASS(FACILITY) ACCESS(READ)
ID(IBMUSER)
SETROPTS RACLIST(FACILITY) REFRESH
```

Job Monitor customization

The Job Monitor binary is installed with the IBM® z/OS® deployment tools in the hlq.SBUZAUTH data set. You need the assistance of a security administrator and a TCP/IP administrator to complete this customization task.

Before you begin

1. Create a JCL file in a partitioned data set and base the file on the sample in the *high_level_qualifier*.SBUZSAMP(BUZRJCL) file.
2. Use the buztool createzosversion command to create the component version.

Table 761. Arguments for the buztool createzosversion command

Parameter	Required	Description
-c	true	The name of the component in HCL DevOps Deploy (Deploy). The component name can contain only letters, numbers, and spaces.
-v	false	The name of the version to create. If a version is not specified, a version name is generated from the current time stamp. The version name can contain only letters, numbers, and spaces. **Note:** The version name must not end in a space.
-s	true	The location of the ship list file.
-verb	false	To display a trace log, set this parameter to `true`.

Example

For example, the following command creates a new version in the CICSModules component:

```
buztool "createzosversion" "-c" "CICSModules" "-v" "fixbug100" "-s" "/u/ucduser/build/shiplist.xml"
```

As shown, you must enclose all arguments in double quotation marks.

3. Modify the sample file to reflect your system configuration.
4. Submit the JCL.

Results

The content that the ship list file specifies is available in a component in Deploy.

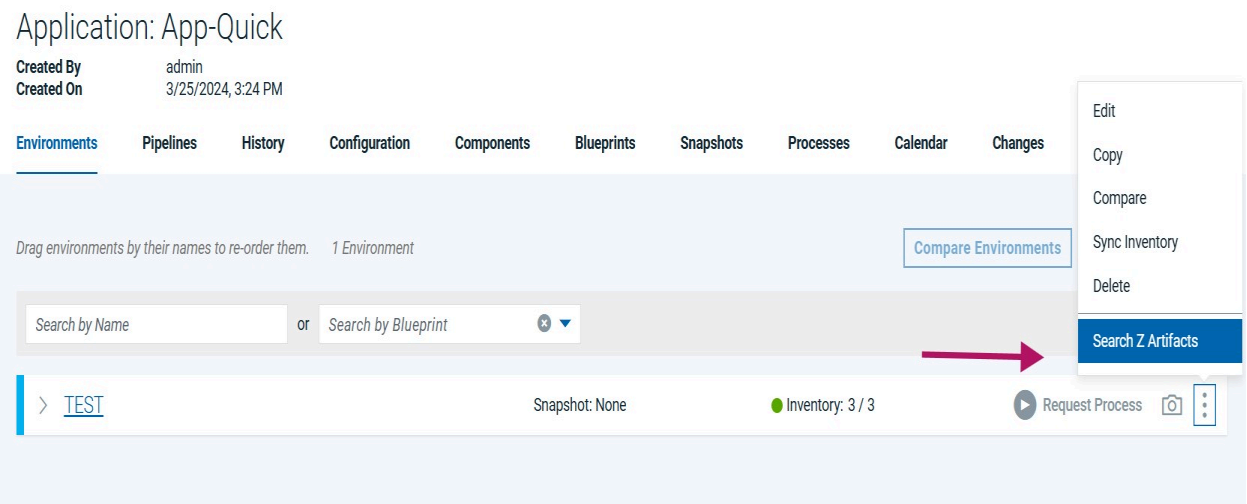
Searching the z/OS environment inventory

You can search z/OS environment inventory for any application that contains a z/OS type component. Search is performed for a specific file in the artifacts belonging to the z/OS components deployed to that environment.

About this task

Files in the z/OS environment can be identified with the **Search Z Artifacts** option available in the z/OS application environment.

1. Navigate to the environment of interest (**Applications > *application name* > Environments > Environment: *environment name***.
2. From the menu options for the environment, select **Search Z Artifacts**.



3. Enter the name of the file to search in the **Search Z Artifacts** dialog, then click **Search.**

   You can refine your search result by using the following approaches:
   - Use wildcard syntax (*) after you enter a partial file or version name.
   - Limit the search scope by selecting any one of the applications, environments or components. The component filter is exclusive to an application or environment filter.

Notes:
- The search report displays the deployments done in z/OS agent v7.3.1 and later, and plug-in z/OS-Utility v80 and later.
- By default, the search result shows active records that match the searched criteria. You can include inactive records by selecting the **Show Inactive Records** checkbox.

Tips:
- File name search is case-insensitive and version name search is case-sensitive.
- The **File name** or **Version name** are required fields for searches.

The z/OS search report shows information in the columns below:

Table 762. z/OS Search report columns

Column	Description
Filename, **Inputs**, **Version Name**, and **Deploy Type**	Uses values from the version `shiplist.xml` file.
Component, **Version**, **Deployment Time**, **Application**, **Environment**, **Status**	Provides you deployment information based on the deployment target.

Column	Description
Target	Indicates the target PDS/PS or USS directory where the artifact is copied.
Target Type	Specifies the type of artifacts.
Operation Type	Shows the nature of action performed on the artifact in the target. For example, DEPLOY for created and updated artifacts, and DELETE for deleted artifacts.
(Download icon)	Downloads search results in the CSV format upon clicking this icon

Results

You have searched the files in z/OS environment inventory.

Related information

z/OS search on page 2548

Scheduling deployments

HCL DevOps Deploy (Deploy) has a built-in deployment scheduling system for setting regular deployments, or even black-out dates, for your Deployments.

Deployments for an individual application are scheduled on a per-environment basis, set when you run a deployment of a snapshot or deployment process. Black-out dates are set within the individual environments.

Deploy stores all times relative to Coordinated Universal Time and displays them based on your time zone. A process that you schedule during Daylight Saving Time moves back an hour after Daylight Saving Time ends.

To set up a scheduled deployment, click **Applications**, click your application, and next to the environment, click **Request Process**, and in the **Create Deployment** window, go to **Schedule Deployment**, and disable the **Run Now** option.

When you disable the **Run Now** option, the **Date** and **Time** fields appear for you to specify the date and time for the deployment to run. The **Recurrence Pattern** setting deploys the application on a regular schedule. For example, if you are practicing continuous delivery, the **Daily** option deploys the application to the target environment every day. You can choose the **Hourly**, **Daily**, **Weekly**, **Monthly**, and **Weekdays** recurrence pattern.

Note: When scheduling deployments for week days, if the deployment start date falls on a weekend, the deployment date gets scheduled for the following Monday at the defined start time.

After you schedule the deployment, it is added to the calendar. There, if you click the scheduled deployment, you can edit, delete, or investigate the deployment. Alternatively, click **Schedule Process** on the **Calendar** page to add scheduled deployments.

Notes:

- Do not change the starting time of a scheduled deployment. Instead, delete the recurring deployment and recreate it.
- Click **List**, on the **Calendar** page, to view the list of scheduled deployments for the chosen period. Click the enabled **List** to display the deployments in default view.

A *blackout* is a set per-environment, per-application. After the blackout is set, no deployments or snapshots can be scheduled to occur in that environment. Any previously scheduled deployments to the environment fail if they fall within the blackout date you set. To set up a blackout, go to (**Application > Environments > Calendar > Add Blackout**). If you must set blackouts for more than one environment, you must set a separate blackout for each environment. Deploy prompts you to give the dates and times for the blackout.

Calendar hotkey shortcuts

Table 763. Calendar hotkey shortcuts

Keyboard shortcut	Function
Double Click or Shift + Click	Brings up Schedule Deployment for the clicked date cell.
Ctrl + Click or Alt + Click inside an environment calendar	Enables you to set blackout date by dragging the mouse and releasing.

Canceling stalled deployments

There might be cases when the deployment processes fail to progress as expected. These stalled processes are listed in the deployment process log. You can cancel these stalled deployment processes.

Before you begin

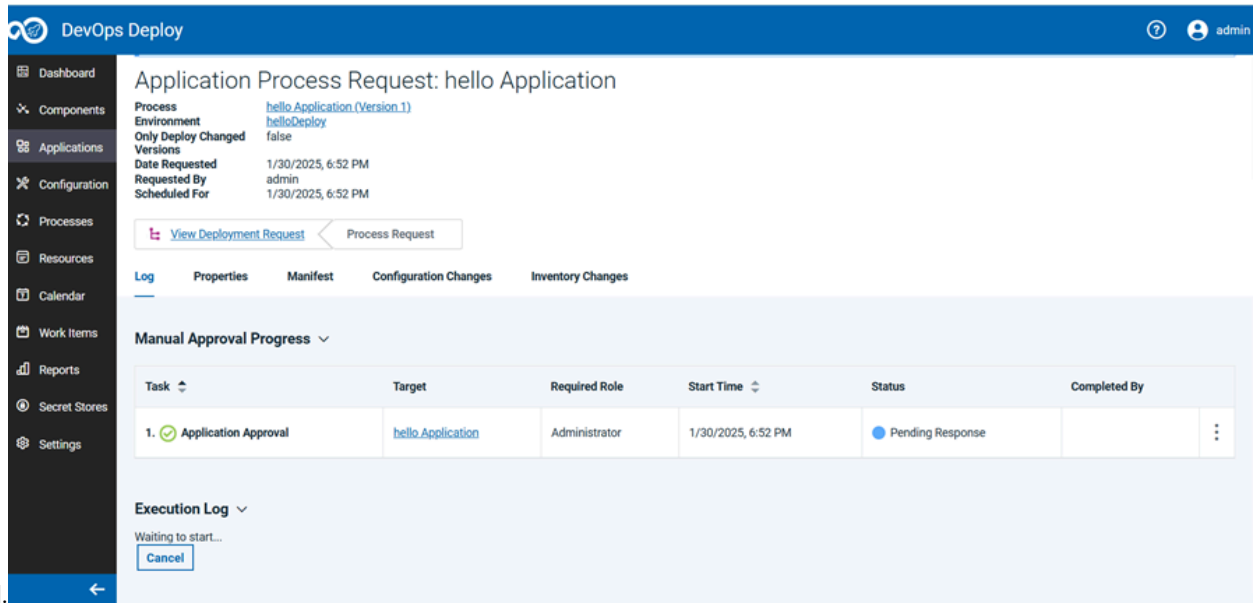
You must have permission to cancel stalled deployments.

About this task

You can cancel all the stalled deployment processes in the **Waiting to start** state.

1. Log in to Deploy.
2. Navigate to **Applications**.
   The list of applications is displayed.
3. Click the application for which you want to delete the stalled deployment processes.
4. Go to the **History** tab.
5. Click (**View Request**) for the process.

The **Log** tab is displayed.



6. Click **Cancel** in the **Execution Log** panel.

Results

The stalled deployment processes are canceled.

Reporting

HCL DevOps Deploy (Deploy)

Provides several different deployment and security reports.

Deployment reports contain historical information about deployments. Data can be filtered in various ways and reports can be printed and saved. In addition, you can save search criteria for later use. See Deployment reports on page 2547.

Security reports provide information about user roles and privileges. See Security reports on page 2549.

Deployment reports

Deployment reports contain historical information about deployments, such as the total number of deployment runs and the average duration of those runs.

To run a deployment report, select the filters at the top of the report, including the date range and application, and then click **Run**.

Deployment average duration

This report provides average deployment times for applications that ran during a specified reporting period. The report provides both a tabular presentation and line graph of the data.

Deployment total duration

This report provides total deployment times for applications that ran during a specified reporting period. The report provides both a tabular presentation and line graph of the data.

Deployment count

This report provides information about the number of deployments that ran during a specified reporting period. The report provides both a tabular presentation and a line graph of the data.

Deployment detail

This report provides a detailed, historical view of deployment data across applications, environments, and components. Each row in the report represents a deployment that ran during the reporting period and matches the filter conditions. Use this report to track application statuses, execution durations, utilized snapshots, request descriptions, scheduling timelines, and process approvers.

Note: To filter the deployment history, select one or more items from the **Application** list. If you select a single application, the **Environment** list becomes a multi-select drop-down menu of mapped environments. If you select multiple applications, or leave the **Application** list blank, the **Environment** list changes to a text search filter.

z/OS search

This search feature helps you search for a file name or version name in z/OS components in all environments and applications. Use this to search for a deployed artifact and find historical deployment information about the artifact. You can also search artifacts in rolled back versions using **Deploy-datasets**/ **rollback** step in the z/OS utility plug-in, which in its process updates the database inventory of the affected artifacts.

You can refine your search result by using the following approaches:

- Use wildcard syntax (*) after you enter a partial file or version name.
- Limit the search scope by selecting any one of the applications, environments or components. The component filter is exclusive to an application or environment filter.

Notes:

- The search report displays the deployments done in z/OS agent v7.3.1 and later, and plug-in z/OS-Utility v80 and later.
- By default, the search result shows active records that match the searched criteria. You can include inactive records by selecting the **Show Inactive Records** checkbox.

Tips:

- File name search is case-insensitive and version name search is case-sensitive.
- The **File name** or **Version name** are required fields for searches.

The z/OS search report shows information in the columns below:

Table 764. z/OS Search report columns

Column	Description
Filename, **Inputs**, **Version Name**, and **Deploy Type**	Uses values from the version `shiplist.xml` file.
Component, **Version**, **Deployment Time**, **Application**, **Environment**, **Status**	Provides you deployment information based on the deployment target.
Target	Indicates the target PDS/PS or USS directory where the artifact is copied.
Target Type	Specifies the type of artifacts.
Operation Type	Shows the nature of action performed on the artifact in the target. For example, DEPLOY for created and updated artifacts, and DELETE for deleted artifacts.
(Download icon)	Downloads search results in the CSV format upon clicking this icon

For information about saving and printing reports, see Saving and printing reports on page 2550.

Security reports

Security reports provide information about the user roles and privileges that are defined with the HCL DevOps Deploy (Deploy) security system.

You can sort each report by clicking on the column headers for things like the components and environments. Not all columns can be sorted.

Application security report

This report provides information about the user roles and privileges that are defined for applications in Deploy. Each report row represents an individual application.

Component security report

This report provides information about the user roles and privileges that are defined for components. Each report row represents an individual component.

Environment security report

This report provides information about the user roles and privileges that are defined for environments. Each report row represents an individual environment.

Resource security report

This report provides information about the user roles and privileges that are defined for resources. Each report row represents an individual resource.

User security report

This report provides information about the authentication realms and groups that are defined for users. Each report row represents an individual user. By default, the report runs automatically for all users. You can also filter the report based on authentication realms and groups.

For information about saving and printing reports, see Saving and printing reports on page 2550.

Setting up recurring reports

Recurring reports run on a schedule and e-mail the results to you.

Before you begin

- In the server system settings, in the **Mail Server Settings** section, configure an e-mail server.
- Make sure that your e-mail address in your account information is correct. Recurring reports are sent to that address.

About this task

Recurring reports can run monthly, weekly, or daily.

1. Create a report as usual.
2. Open the report.
3. Click **Schedule Recurring Report** .
4. Set the date on which to start the report, the time to run it, and the frequency for the report, and click **Submit**.
   You can choose the **Hourly**, **Daily**, **Weekly**, **Monthly**, and **Weekdays** recurrence pattern.

Results

The server runs the report on the schedule you set and e-mails a CSV file to your e-mail address.

What to do next

To cancel the recurring report, open the report, click **Schedule Recurring Report**, and select the **Stop scheduling this report?** check box.

Saving and printing reports

You can print and save report data for all report types. In addition, you can save filter and sort order information for deployment-type reports.

About this task

To save report data in a CSV (comma-separated value) file, follow these steps:

1. Set filters, if any, and run the report.
2. Click **Download CSV**.
3. From the browser dialog box, save the data to a file, or open the data by using an application that is associated with CSV files.

Note: The sort order and hidden or visible column information is not preserved in the CSV file.

To print a report, follow these steps:

1. Set the filter conditions.
2. Define the reporting period.
3. Run the report.
4. Optional: Set the sort order. Your changes are reflected in the printed report.
5. Optional: Change the column visibility. By default, all columns are selected to be shown in the printed report. Hidden columns are not shown in the output.
6. Click **Print** to print the report.

Saving report filters

You can save filter and sort-order settings for deployment reports. Saved reports can be retrieved with the **My Reports** menu on the **Reports** pane.

1. Set the filter conditions.
2. Define the reporting period.
3. Run the report.
4. **Optional:** Set the sort order.
   You can change the sort order for any column by clicking the column header.
5. **Optional:** Change column visibility. Click **Edit** to display the **Select Columns** dialog box. By default, all columns are selected to be shown in a report. To hide a column, select the corresponding check box.
6. Click **Save**.
7. Enter a name for the file, and save your work.

What to do next

To run your report, click the report name in the **My Reports** menu.

To delete your report, click **Delete**.

Monitor operating details with MBeans

With an external monitoring tool, such as IBM® Performance Management on Cloud 8.1.3 or New Relic, you can use Managed Beans (MBeans) to review numerous details about HCL DevOps Deploy (Deploy). For example, you can view statistics that specify how many components are available or see how long it takes for an application process to run to completion. You can use these statistics and details to assess the health of your deployments and deployment processes.

You can request and specify metrics by using four MBeans. Two MBeans provide summary information for all the targeted elements. For example, the agent summary information MBean provides aggregate information about all agents. The other two MBeans provide specific information about elements. The individual component information MBean provides details about a particular component, which you specify by name. The following list shows the four areas and the structure of the data that each MBean provides. Access the data according to the requirements of your monitoring tool. Refer to the documentation for the tool as required.

By default, the metrics monitoring is turned off. To enable the metrics monitoring, you must add a property to the `installed.properties` file. By default, this file is in the `/opt/install-dir/server/conf/server` folder. To enable monitoring, add this line to the file:

```
jmx.monitoring.enabled=true
```

If your servers are working in high availability, you can specify how frequently the servers synchronize data to ensure that the servers maintain a consistent list of components and applications. In the `installed.properties` file, add the following line:

```
jmx.monitoring.ha.update.interval.minutes=measurement_update_time
```

where *measurement_update_time* is a whole number is greater than or equal to 30. You cannot get updates more frequently than every 30 minutes. This limit reduces the processing requirements on the servers.

You can monitor four areas of operational details.

Agent summary information

JMX: com.urbancode.ds.agents:type=monitor

- `AllAgentCount` (The total number of agents)
- `ConnectingAgentCount` (The number of agents that are currently attempting to connect to the server)
- `UpgradeRecommendAgentCount` (The number of agents to upgrade to achieve best results)
- `UpgradeRequiredAgentCount` (The number of agents that must be upgraded)
- `ErrorAgentCount` (The number of agents that are in an error state)
- `OfflineAgentCount` (The number of agents that are offline)
- `InstallableAgentCount` (The number of agents that can be installed)
- `OnlineAgentCount` (The number of agents that are online)
- `LicensedAgentCount` (The number of the agents that have licenses)
- `UnlicensedAgentCount` (The number of unlicensed agents)

Individual component information

JMX: com.urbancode.ds.components.individual.monitor:type=

COMPONENT_NAME

`LatestVersionSizeInBytes` (The size in bytes of the most recent version of the specified component)

`PreviousVersionSizeInBytes` (The size in bytes of the previous version of the specified component)

`AverageVersionSizeInBytes` (The average in bytes size of all the versions of the specified components)

You can specify multiple components individually in three ways:

- Name the component specifically, for example:

```
com.urbancode.ds.components.individual.monitor:type=
     ComponentA

com.urbancode.ds.components.individual.monitor:type=
     ComponentB
```

- Use wildcards to report components with names that match the sample, for example:

```
com.urbancode.ds.components.individual.monitor:type=
     Component*
```

- Use a wildcard to report all components, for example:

```
com.urbancode.ds.components.individual.monitor:type=*
```

Component summary information

JMX: com.urbancode.ds.components.summary:type=monitor

`TotalComponentCount` (The total number of components)

`FailedImportComponentCount` (The number of components whose latest version was not imported after an import request)

`ImportingComponentCount` (The number of components that are currently being imported)

`NoVersionComponentCount` (The number of components that do not have versions)

`OKComponentCount` (The number of components whose latest versions were not imported successfully)

Individual application information

JMX:com.urbancode.ds.applications.individual.monitor:type=

APPLICATION_NAME

`LatestDeploymentDurationInMS` (The amount of time that the most recently completed deployment process lasted for the specified component)

`PreviousDeploymentDurationInMS` (The amount of time that the previously completed deployment process lasted for the specified component)

`AverageDeploymentDurationInMS` (The average amount of time that completed deployment processes lasted for the specified component)

- Name the component specifically, for example:

```
com.urbancode.ds.components.individual.monitor:type=
      ApplicationA

com.urbancode.ds.components.individual.monitor:type=
      ApplicationB
```

- Use wildcards to report components with names that match the sample, for example:

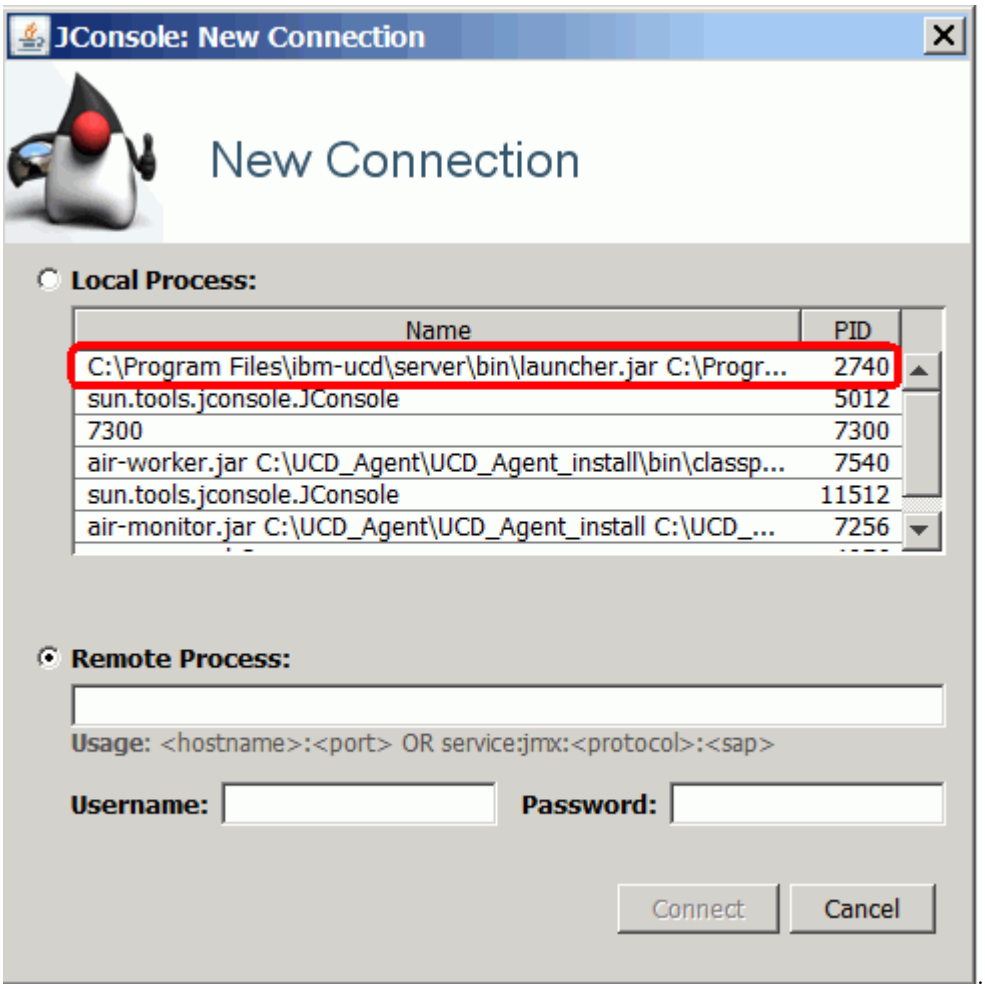
```
com.urbancode.ds.components.individual.monitor:type=
      Application*
```

- Use a wildcard to report all components, for example:

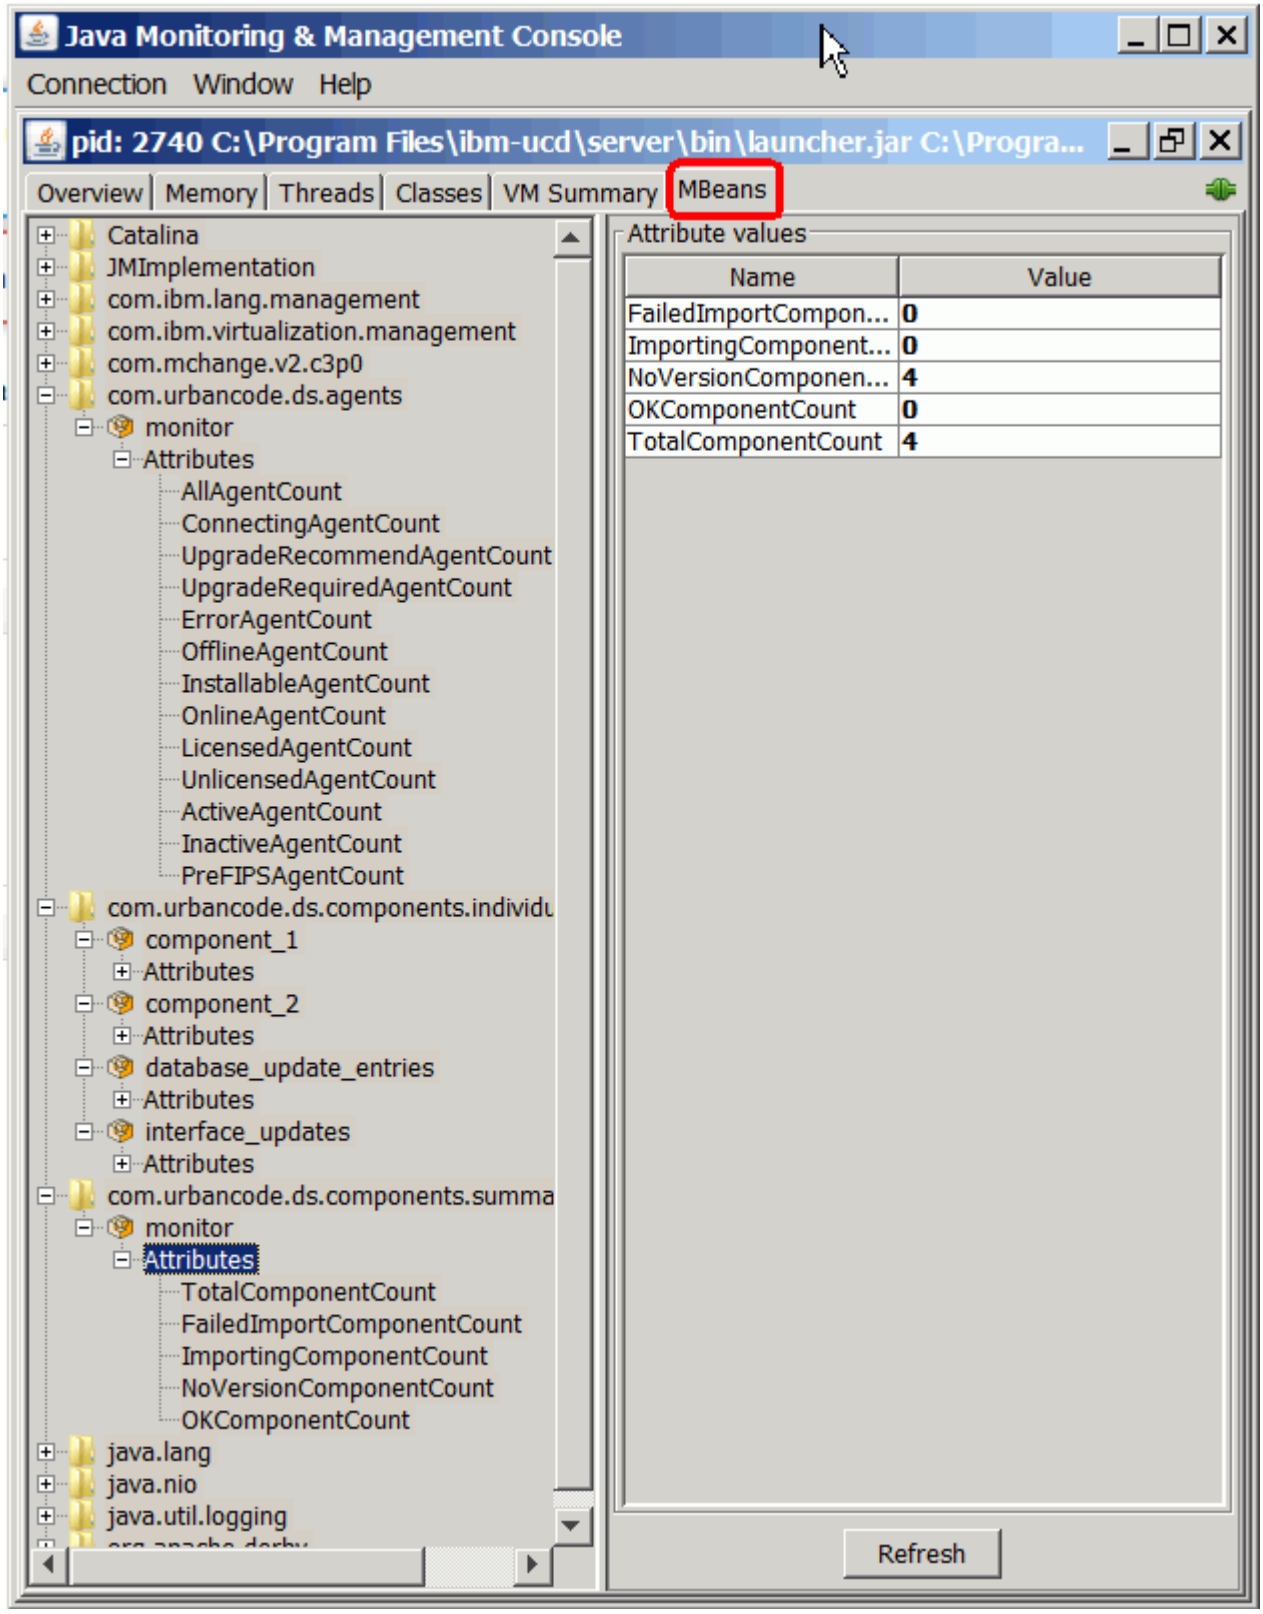
```
com.urbancode.ds.components.individual.monitor:type=*
```

Viewing metrics with JConsole

JConsole is one external monitoring tool that is immediately available to you. For information about JConsole and starting the tool, see Using JConsole. After you turn on monitoring as described earlier and start JConsole, select a new connection as shown in this illustration:



Then, click the **Mbeans** tab. In the left navigation, select the metrics to view.



Elasticsearch and Kibana reports

Use your project data to create Elasticsearch reports and Kibana charts.

If you use Elasticsearch and Kibana for data analytics, you can use HCL DevOps Deploy (Deploy) data with your ELK stack environment. The following reports are currently available

API requests

This report provides data about API requests made to the Deploy server.

Application process requests

This report contains application process requests such as average duration, and average warning count.

Codestation

This report contains data about Codestation usage including total size and cleanup counts.

Information about configuring your ELK stack for Deploy is found in this post.

Extending Product Function

Learn how to extend the function of HCL DevOps Deploy (Deploy).

Plug-ins

The Deploy plug-ins provide tools for creating component processes and integrations. HCL provides plug-ins for several common deployment processes, and others are available to integrate with a wide variety of tools, such as middleware tools, databases, and servers.

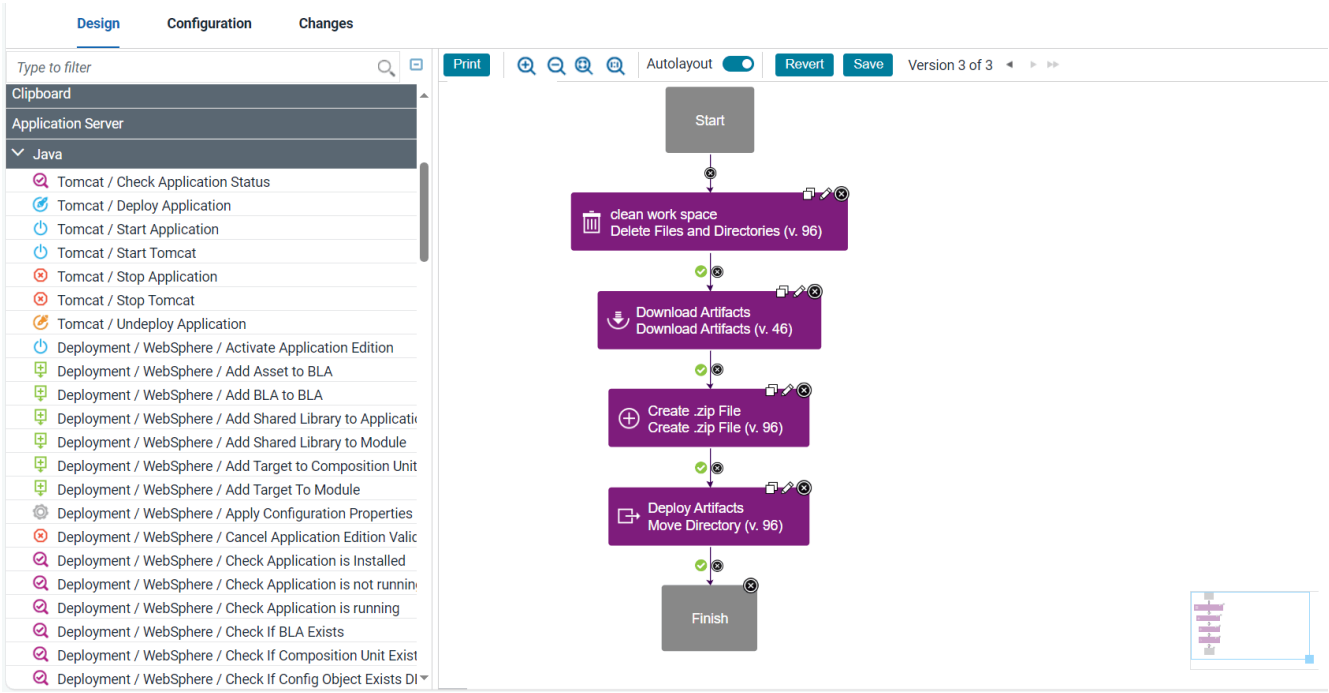
Plug-ins provide processing and integration functions. There are two types of plug-ins:

- *Source-type* plug-ins integrate with external systems to import artifacts and create component versions.
- *Automation-type* plug-ins provide process steps that manipulate components, typically by deploying them.

Both types of plug-ins consist of distinct processes called *steps*. Each step consists of a number of properties, a command that runs the step, and post-processing instructions. (Post-processing typically ensures that expected results occur.) Step properties can serve various purposes, from providing input to the command to supplying some, or all, the actual command itself. Automation-type plug-in properties can be set at design time in the process editor, or at run time in the user interface. Source-type plug-in properties are typically defined when a component is created.

Automation-type plug-ins

You use automation plug-ins to deploy components or otherwise manage them. Each step is a self-contained unit with inputs, outputs, and properties. By combining automation plug-in steps in the process editor, you can create fully automated deployment processes. When you create a process, you drag steps onto the design area and define the properties as you go. Property values can be specified when you define the process or at run time. The process flow is defined by drawing connections between steps. The following illustration, shows a series of automation-type plug-in steps and the connections between them.



For information about creating component processes, see Component processes on page 2299.

At deployment time, component processes are run by agents that are installed in the target environment. For a process to run, the agent must have access to all resources, tools, and files that are required by the plug-in steps in the process. When you install an agent, ensure that these conditions are met:

- The agent that runs the process has the necessary user permissions to run commands and can access required resources. Assigning these permissions typically entails granting permissions if an external tool is installed as a different user; installing the agent as a service; or impersonating the appropriate user. See User impersonation for process steps on page 2462.
- External tools that plug-in steps require are installed in the target environment.
- The required minimum version of an external tool is installed.

For information about installing agents, see Installing agents from the command line.

Source-type plug-ins

You use source plug-ins to import artifacts and create component versions. A source plug-in defines the type of artifacts that can be imported and identifies where the artifacts are located. Source-type plug-ins are configured when components are created, you do not use the process editor to configure source-type plug-ins. Unlike automation plug-ins, source plug-ins always have a single step, the Import Version step.

Artifacts are imported into component versions by agents that are running in the environment where the artifacts are located. For a component version to be created, the agent must have the required permissions and access to all required resources and files. For information about installing agents that run source plug-ins, see System settings on page 2086.

For information on how to use the source config plug-ins that are provided with Deploy, see Creating components on page 2248.

Related information

Installing plug-ins from the Web UI on page 2560

Installing plug-ins from the plug-in site on page 2559

Installation of plug-ins

You can install plug-ins from the Deploy Web UI and the plug-ins site.

Deploy plug-ins are categorized into two types; core plug-ins and external plug-ins.

Core plug-ins

Plug-ins that are shipped and pre-installed in Deploy are called the core plug-ins. In an initial installation, the core plug-ins are listed on the **Settings > Automation > Installed Plugins** page. Alternatively, these plug-ins are available to download and their documentation is also available from the HCL plug-ins site.

The following table lists the core plug-ins:

Plug-in	Plug-in Type	Description
ClearCase	Source Configuration	Automates importing version artifacts from ClearCase (Base and UCM).
DevOps Build	Source Configuration	Automates uploading artifacts from a DevOps Build server.
File System	Source Configuration	Automates uploading artifacts from a normal file system.
File System (Versioned)	Source Configuration	Automates uploading artifacts from a versioned file system.
Git	Source Configuration	Automates importing artifacts from Git.
Maven	Source Configuration	Automates downloading artifacts from Maven projects.
Subversion	Source Configuration	Automates importing artifacts from a Subversion repository.
TFS_SCM	Source Configuration	Automates importing version artifacts from a TFS server.
zOS File	Source Configuration	Automates uploading data sets, UNIX files, and generic artifacts from a z/OS system.
File Utils	Automation	Includes steps, such as deleting or creating directories and replacing tokens in a file, that perform folder-level and file-level tasks as part of a deployment process.
General Utilities	Automation	Provides utilities for basic tasks that don't fit in a specific plug-in.
Groovy	Automation	Provides steps for executing user-defined Groovy scripts.

Plug-in	Plug-in Type	Description
Kubernetes	Automation	Includes steps to work with resources and images in Kubernetes.
OpenShift	Automation	Includes steps to work with resources and images in Red Hat OpenShift.
Shell	Automation	Allows users to run custom shell scripts during the deployment process.
System Information	Automation	Includes a variety of checks to perform against the operating system. These steps can be used to verify that a deployment can succeed or has succeeded.
Launch Applications	Automation	Creates and manages Deploy applications.
Launch Component	Automation	Creates and manages Deploy components.
Launch Configuration Management	Automation	Downloads and uploads configuration templates from/to Deploy.
Launch Environments	Automation	Creates and manages Deploy environments.
Launch Processes	Automation	Supports interaction with processes and process requests.
Launch Resources	Automation	Manages Deploy resources.
Launch Versioned File Storage	Automation	Allows Deploy to upload artifacts to CodeStation.
Launch Versions	Automation	Allows editing Component Versions in Deploy.
zOS Multi Generate Artifact Information	Automation	Generates one or more informational texts based on defined templates.
zOS Utility	Automation	Includes steps related to deployment activities for z/OS.

External plug-ins

External plug-ins are the plug-ins that you must install to be able to use them. Deploy supports integration with many external applications. You can install the external plug-ins by using the following methods:

- Installing plug-ins from the plug-in site on page 2559
- Installing plug-ins from the Web UI on page 2560

Note: The plug-ins are developed and updated independently of the Deploy release cycles.

Installing plug-ins from the plug-in site

You can install plug-ins by downloading them from the plug-ins site and loading them into the Deploy product.

About this task

You can browse, download, and get documentation for external plug-ins from the HCL Plug-ins site. The site contains many plug-ins that are available in the Deploy product.

The site includes plug-ins that are developed by the following sources:

- **HCL Software** — Your Deploy license entitles you to download and install the plug-ins that are developed by HCLSoftware.
- **Partners** — Plug-ins that are provided by partners can be purchased from the partner website. Search for `partner` to find the partner plug-ins in the plug-ins site.

  Note: Support for each partner plug-in is provided exclusively by the partner who provided the plug-in.

- **Community** — Plug-ins are provided by members of the Deploy community on the HCLSoftware Deploy Community website. Search for `community` to find the community plug-ins in the plug-ins site. You can contribute to code in the community or use code posted there to incorporate into your own.

  Note: Support is provided exclusively through the community.

1. On the Web UI, go to **Settings > Automation > Installed Plugins**.
2. Load the plug-in by clicking **Load Plugin**.
3. Enter the path to the compressed plug-in file, and then click **Submit**.

Results

The plug-in is installed and listed on the **Installed Plugins** page. After the plug-in is installed, it is available immediately.

Notes:

- You do not need to restart the server after you install a plug-in.
- You can upgrade a plug-in by installing the new version over the old version.
- You cannot roll back a plug-in version to a previous version from the Web UI. To move to a previous version of a plug-in, see Rolling back a plug-in version to a previous version.

Installing plug-ins from the Web UI

To avoid navigating to the plug-ins site, you can seamlessly install the latest plug-in versions directly from the Web UI.

Before you begin

You must have ensured that the server has network access and can reach the plug-ins site.

Note: If the server cannot access the site because the site location has changed since your product version was released, then you must set the `com.urbancode.ds.web.cli.rest.plugin.PluginsManifest.url` property in the

`appdata/conf/server/getting-started-custom-urls.properties` file to a reachable URL for the plug-ins. For example, you must set the property as:

```
com.urbancode.ds.web.cli.rest.plugin.PluginsManifest.url=https://
ucd-plugins.example.com/path/to/manifest.json
```

1. Go to the **Settings > Automation > Available Plugins**.

   Note: To view information about a plugin, click **View Documentation** from the **Actions** menu. This option opens the documentation site for that specific plugin.

2. Search for the plug-in you want to install.
3. Click the menu option on the right of the plug-in for which you want to install.
4. Click **Install**.

Results

The plug-in is installed and listed on the **Installed Plugins** page. After the plug-in is installed, it is available immediately.

Notes:

- You do not need to restart the server after you install a plug-in.
- You can upgrade a plug-in by installing the new version over the old version.
- You cannot roll back a plug-in version to a previous version from the Web UI. To move to a previous version of a plug-in, see Rolling back a plug-in version to a previous version.

Creating plug-ins

You can create your own plug-ins for use with HCL DevOps Deploy (Deploy). A plug-in consists of XML files and supporting script files that the plug-in requires.

- The `plugin.xml` file defines the steps that constitute the plug-in; plug-in steps define a plug-in's functions. Each step is an independently configurable entity in the Deploy editor.
- The `info.xml` file contains a version ID and other information that describes the plug-in.

Note: The plug-in files must use UTF-8 encoding.

A plug-in step is defined by a `<step-type>` element that contains these elements:

- One `<properties>` element
- One `<command>` element
- One `<post-processing>` element

The `<properties>` element is a container for `<property>` child elements, and can contain any number of `<property>` elements. Property values can be specified at design time or run time. The `<post-processing>` element provides error-handling capabilities and sets property values that other steps can use. The `<command>` element runs the step's function. The function can be defined completely by the element or be constructed in part or entirely from the step's properties at design time or run time.

A command can access these properties:

- The step's own properties
- Properties that were set earlier by other steps in the process
- Properties that were set by the application that started the process
- Properties on the target environment and resource

Step property values become unavailable after the component process ends.

Plug-in steps are run by an agent that is installed in the target environment. Thus, plug-ins can be written in any scripting language, and the agent can access the required scripting tools on the host. After a plug-in is created, upload it into Deploy to make it available to users. To upload a plug-in, create an archive file that contains the XML files (`plugin.xml` and `info.xml`) and scripts that the plug-in requires. Then, import the archive file with the **Automation Plugins** pane for automation-type plug-ins or the **Source Config Plugins** pane for source plug-ins.

To troubleshoot plug-ins, you can retrieve the information from each step that ran in a process request. To download these logs, open the process request and click **Download All Logs**.

The `plugin.xml` file for automation plug-ins

An automation plug-in is defined with the `plugin.xml` file.

The structure of this file consists of a `header` element and one or more `step-type` elements. The `header` element identifies the plug-in. Each `step-type` element defines a step. Steps are available to users in the process editor and are used to construct component processes.

After the document type declaration, the `plugin` root element identifies the XML schema type, PluginXMLSchema_v1.xsd, which all plug-ins use. The following code sample presents the basic structure of the `plugin.xml` file for automation plug-ins:

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin xmlns="http://www.urbancode.com/PluginXMLSchema_v1"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <header>
    <identifier id="plugin_id" version="version_number" name="Plug-in Name"/>
    <description/>
    <tag>Plugin type/Plugin subtype/Plugin name</tag>
  </header>
  <step-type name="Step_Name">
    <description/>
    <properties>
      <property name="property_name" required="true">
         <property-ui type="textBox" label="Driver Jar"
```

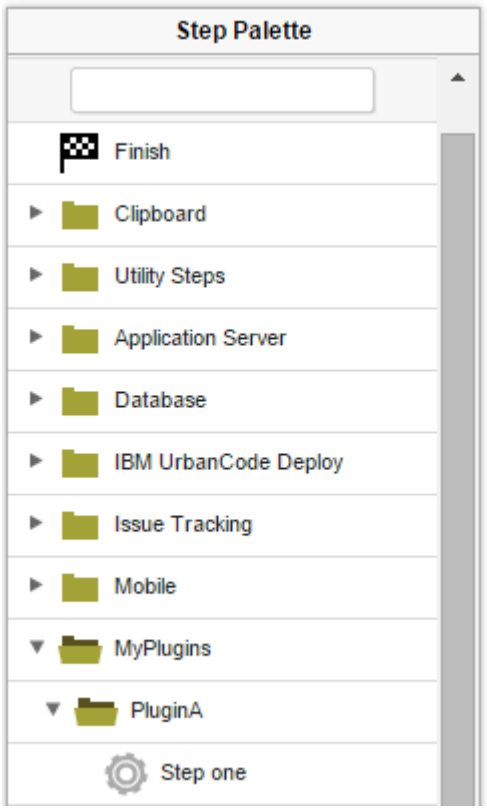
```
            description="The full path to the jdbc driver jar to use."
            default-value="${p:resource/sqlJdbc/jdbcJar}"/>
      </property>
    </properties>
    <post-processing>
      <![CDATA[
        if (properties.get("exitCode") != 0) {
            properties.put("Status", "Failure");
        }
        else {
            properties.put("Status", "Success");
        }
     ]]>
    </post-processing>

    <command program="${path_to_tool">
      <arg value="parameters_passed_to_tool"/>
      <arg path="${p:jdbcJar}"/>
      <arg file="command_to_run"/>
      <arg file="${PLUGIN_INPUT_PROPS}"/>
      <arg file="${PLUGIN_OUTPUT_PROPS}"/>
    </command>
  </step-type>
</plugin>
```

The `<tag>` tag specifies the location of the steps in the process editor palette. This is a required tag and the tag value cannot be null. For example, the following code specifies that the steps are in the `MyPlugins/PluginA` folder.

```
<tag>MyPlugins/PluginA</tag>
```

When the plug-in is installed, the steps appear in the specified folder in the palette, as shown in the following figure.



You can further organize specific steps into sub-folders. For example, assume that the `plugin.xml` file puts steps in the `MyPlugins/PluginA` folder, as in the previous example. The following code puts a step in the `MyPlugins/PluginA/Subgroup1` sub-folder:

```
<step-type name="Step one">
  <server:sub-tag>Subgroup1</server:sub-tag>
```

To organize steps into sub-folders in this way, you must add the namespace `xmlns:server="http://www.urbancode.com/PluginServerXMLSchema_v1"` to the `<plugin>` tag that is at the root of the `plugin.xml` file, as in the following example:

```
<plugin xmlns="http://www.urbancode.com/PluginXMLSchema_v1"
  xmlns:server="http://www.urbancode.com/PluginServerXMLSchema_v1"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
```

For information about the structure of `plugin.xml` for source plug-ins, see Creating source plug-ins on page 2566.

The `header` element

The mandatory `header` element identifies the plug-in and contains three mandatory child elements and one optional child element:

Table 765. Contents of the `header` element

`<header>` Child Elements	Description
`<identifier>`	This element's three attributes identify the plug-in:

Table 765. Contents of the `header` element (continued)

`<header>` Child Elements	Description
	• `version` API version (the version number for upgrading plug-ins is defined in the `info.xml` file). • `id` Identifies the plug-in. • `name` The plug-in name is shown on the **Automation Plugins** pane, and on informational pages for the plug-in. All values must be enclosed within single quotation marks.
`<description>`	Describes the plug-in; is shown on the **Automation Plugins** pane, and on informational pages for the plug-in.
`<tag>`	Defines where the plug-in is listed within the process editor's hierarchy of available plug-ins. The location is defined by a string that is separated by slashes. For example, the Tomcat definition is the following string: `Application Server/Java/Tomcat`. The Tomcat steps are listed beneath the Tomcat item, which in turn is nested within the other two. **Note:** Do not include underscores in this element.
`<server:required-server-version>`	This optional element defines the minimum version of HCL DevOps Deploy (Deploy) required for use with the plug-in. The version is defined by 4 digits. For example, a plug-in that requires Deploy Version 7.1.0 or later would include the following element in the header: `<server:required-server-version>7.1.0.0</server:required-server-version>`
`<server:dependencies>`	This optional element specifies other plug-ins that must be loaded before this plug-in. The `<server:dependencies>` element contains a `<server:dependency>` element that specifies the identifier and minimum version for each dependency. For example, a plug-in that requires version 76 or later of the WebSphere® Application Server - Deploy plug-in would include the following elements in the header:

Table 765. Contents of the `header` element (continued)

`<header>` Child Elements	Description

	`<server:dependencies>`
	`  <server:dependency plugin-id="com.urbancode.air.plugin.WebSphere"`
	` min-version="76"/>`
	`</server:dependencies>`

The following text is a sample header definition:

```
<header>
  <identifier version="3" id="com.&company;.air.plugin.Tomcat" name="Tomcat"/>
  <description>
  The Tomcat plugin is used during deployments to run Tomcat run-book
  automations and deploy or undeploy Tomcat applications.
  </description>
  <tag>Application Server/Java/Tomcat</tag>
</header>
```

The `plugin-javaopts.conf` file

The `plugin-javaopts.conf` file can be used to set the *JAVA_OPTS* environment variable for automation plug-ins that use Groovy.

By default, the `plugin-javaopts.conf` file is stored on the agent computer in the *`agent_installation_directory`*`/conf/` folder. You can use the `plugin-javaopts.conf` file to set the *JAVA_OPTS* environment variable for a plug-in that is different from the *JAVA_OPTS* variable for the agent process itself. The plug-in must use Groovy, and not Java™.

Note: If there are syntax errors in the `plugin-javaopts.conf` file, errors and unpredictable behavior can result. Also, any custom modifications that you make to the `plugin-javaopts.conf` file might be overwritten if you upgrade the agent to a newer version.

JVM options for optimizing performance

When you run a plug-in step, the agent automatically adds the appropriate Java optimization options to the `plugin-javaopts.conf` file, if it's not available. For example, if you use the IBM Java Runtime Environment (JRE), the agent adds the `-Xquickstart` parameter automatically to the `plugin-javaopts.conf` file.

If you use Oracle JDK or Open JDK distributions, the agent adds the `-XX:TieredStopAtLevel=1` parameter to the `plugin-javaopts.conf` file to optimize the plug-in step run time.

Creating source plug-ins

Source-type plug-ins are defined the same way that automation-type plug-ins are defined except for some modifications to the `plugin.xml` file.

Like automation plug-ins, source plug-ins are defined with two files, an `info.xml` file and a `plugin.xml` file. The structure of the first file is identical for both plug-in types. The structure of the `plugin.xml` file varies depending on the type of plug-

in. For information about the `plugin.xml` file for automation plug-ins, see The plugin.xml file for automation plug-ins on page 2562.

The following code fragment is an example of a source plug-in file. The `<server:plugin-type>Source</server:plugin-type>` tag identifies the type of plug-in. For source plug-ins, the type must be `Source`:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- the xmlns:server argument is necessary to parse the tags with the server prefix -->
<plugin xmlns="http://www.urbancode.com/PluginXMLSchema_v1"
    xmlns:server="http://www.urbancode.com/PluginServerXMLSchema_v1"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <header>
    <identifier id="com.urbancode.air.plugin.source.Name" name="Plugin Name" version="1"/>
    <description>Short description</description>
    <tag>SCM/Name</tag>

    <server:plugin-type>Source</server:plugin-type>
  </header>
```

A source plug-in has one step, which must be named `Import Version`:

```
    <step-type name="Import Version">
     <description>Creates a new component version and imports artifacts</description>
     <properties>
     </properties>
     <post-processing><![CDATA[
       if (properties.get("exitCode") != 0) {
           properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
       }
       else {
           properties.put("Status", "Success");
       }
    ]]></post-processing>

     <command program="${JAVA_HOME}/bin/java">
       <arg value="${JAVA_OPTS}"/>
       <arg value="-jar"/>
       <arg file="FileSystemSourceConfig.jar"/>
       <arg value="ImportVersion"/>
       <arg file="${PLUGIN_INPUT_PROPS}"/>
       <arg file="${PLUGIN_OUTPUT_PROPS}"/>
     </command>

   </step-type>
```

As shown in the following code fragment, source plug-ins have two property groups. `Component` type properties are configured with the **Create Component** window. `Import` type properties are configured with the **Import Component** window.

```
    <!-- ==================================== -->
    <!--   Properties                         -->
    <!-- ==================================== -->

    <server:property-group type="Component" name="FileSystemComponentProperties">
      <server:property name="property-name" required="true">
        <server:property-ui type="textBox"
                            label="property-label"
                            description="property-description" />
      </server:property>
    </server:property-group>

       <!-- If left empty or omitted then no dialog will appear -->
    <server:property-group type="Import" name="FileSystemImportProperties">
      <server:property name="property-name" required="true">
        <server:property-ui type="textBox"
                            label="property-label"
                            description="property-description" />
      </server:property>
    </server:property-group>
</plugin>
```

Plug-in steps: The `step-type` element

You define plug-in steps with the `step-type` element; each `step-type` element represents a single step in the HCL DevOps Deploy (Deploy) process editor.

A `step-type` element has a name attribute and up to four child elements:

- `description`
- `properties`
- `command`
- `post-processing`

The mandatory name attribute identifies the step. The description and name are shown in the web application and on informational pages for the plug-in. The contents of the description determine which icon is displayed with the step.

```
<step-type name="Start">
<description>Start Apache HTTP server</description>
```

Note: A step name cannot contain the forward slash (/) character.

Step properties: the `properties` element

The `properties` element is a container for properties, which are defined with the `property` tag.

Each step has a single `properties` element; a `properties` element can contain any number of `property` child elements.

A `property` tag has a mandatory `name` attribute, optional `required` attribute, and two child elements, `property-ui` and `value`, which are defined in the following table.

Table 766. The `<property>` element

`<property>` Child Elements	Description
`<property-ui>`	Defines how the property is presented to users in the HCL DevOps Deploy (Deploy) editor. This element has several attributes: • `label` Identifies the property in the editor's **Edit Properties** dialog box. • `description` Text that is displayed to users in the associated roll-over help box. • `default-value` Property value that is displayed when the **Edit Properties** dialog box is displayed; used if unchanged. • `type` Identifies the type of widget that is displayed to users. Possible values are: ◦ `textBox` Enables users to enter an arbitrary amount of text, limited to 4064 characters. ◦ `textAreaBox` Enables users to enter an arbitrary amount of text (larger input area than textBox), limited to limited to 4064 characters. ◦ `secureBox` Used for passwords. Similar to textBox except values are redacted. ◦ `checkBox` Displays a check box. If checked, a value of true is used; otherwise the property is not set. ◦ `selectBox` Requires a list of one or more values, which are displayed in a list. Configuring a value is described below.

Table 766. The `<property>` element (continued)

`<property>` Child Elements	Description
`<value>`	Used to specify values for a selectBox. Each value has a mandatory `label` attribute, which is displayed to users, and a value that is used by the property when selected. Values are displayed in the order they are defined.

Here is a sample `<property>` definition:

```
<property name="onerror" required="true">
  <property-ui type="selectBox"
    default-value="abort"
    description="Action to perform when statement fails: continue, stop, abort."
    label="Error Handling"/>
  <value label="Abort">abort</value>
  <value label="Continue">continue</value>
  <value label="Stop">stop</value>
</property>
```

Plug-in step icons

A keyword in the description determines which icon is displayed in the plug-in step.

In most cases, the first word in the description of the plug-in step determines the icon that is displayed. The following table shows the available icons, the keywords that are associated with the icons, and whether the keyword must be the first word in the description.

Table 767. Plug-in step icons

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Activate	Yes	start	
Add	Yes	add	
Allocate	Yes	allocate	
AppCmd	Yes	shellArgs	
Approval	No	setStatus	

Table 767. Plug-in step icons (continued)

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Assign	Yes	set	
Associate	Yes	link	
Batch Import	Yes	import	
Cancel	Yes	stop	
Change	Yes	modify	
Check	Yes	check	
Configure	Yes	configure	
Copy	Yes	copy	
Delete	Yes	delete	
Deploy	No	deploy	
Define	No	modify	
DesiredInventoryAction	No	process	
Disable	Yes	stop	
Download	No	download	

Table 767. Plug-in step icons (continued)

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Each	No	runProcess	
Enable	Yes	start	
Execute	Yes	start	
Export	Yes	export	
Flip	Yes	flip	
FTP	Yes	ftp	
Get	Yes	read	
Import	Yes	import	
Install	No	install	
Launch	Yes	deploy	
Link	Yes	link	
Modify	Yes	modify	
Monitor	Yes	monitor	
Move	Yes	move	

Table 767. Plug-in step icons (continued)

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Manual Task	No	manualTask	
Process	Yes	runProcess	
Publish	Yes	publish	
Read	Yes	read	
Reboot	Yes	restart	
Recycle	Yes	recycle	
Register	Yes	create	
Receive	Yes	receive	
Retrieve	Yes	receive	
Restart	Yes	restart	
Revert	Yes	revert	
Rollback	No	revert	
Run	No	runProcess	
Run Groovy Script	Yes	runScript	

Table 767. Plug-in step icons (continued)

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Send	No	send	
Shell	Yes	shell	
Shell (with xargs)	Yes	shellArgs	
Start	Yes	start	
Stop	Yes	stop	
Set	Yes	set	
Submit	Yes	setStatus	
Sync	Yes	sync	
Terminate	Yes	stop	
Unzip	Yes	unzip	
Untar Tarball	Yes	unzip	
Update	Yes	sync	
Upload	Yes	upload	
Upgrade	Yes	upgrade	

Table 767. Plug-in step icons (continued)

Step keyword	Keyword must be the first word in the description	Image name	Displayed image
Undeploy	Yes	undeploy	
Uninstall	No	uninstall	
Untar	No	unzip	
Validate	Yes	setStatus	
Verify	Yes	check	
View	Yes	monitor	
Wait	Yes	wait	
WebSphere®	No	websphere	

The `command` element

Steps are run by starting the scripting tool or interpreter that is specified by the `<command>` element. The `<command>` element's `program` attribute defines the location of the tool that runs the command.

It bears repeating that the tool must be on the host and the agent that starts the tool must have access to it. In the following example, the location of the tool that runs the command (the Java™ scripting tool Groovy in this instance) is defined.

```
<command program='${GROOVY_HOME}/bin/groovy'>
```

The actual command and any parameters it requires are passed to the tool by the `<command>` element's `<arg>` child element. Any number of `<arg>` elements can be used. The `<arg>` element has several attributes:

Table 768. `<arg>` element attributes

Attribute	Description
`<value>`	Specifies a parameter that is passed to the tool. Format is tool-specific; must be enclosed by quotation marks.
`<path>`	Path to files or classes that are required by the tool. Must be enclosed by quotation marks.
`<file>`	Specifies the path to any files or classes that are required by the tool. Format is tool-specific; must be enclosed by quotation marks.

Because `<arg>` elements are processed in the order they are defined, ensured the order conforms to the order that is expected by the tool.

```
<command program='${GROOVY_HOME}/bin/groovy'>
  <arg value='-cp' />
  <arg path='classes:${sdkJar}:lib/commons-codec.jar:
    lib/activation-1.1.1.jar:
    lib/commons-logging.jar:lib/httpclient-cache.jar:
    lib/httpclient.jar:lib/httpcore.jar:
    lib/httpmime.jar:lib/javamail-1.4.1.jar' />
  <arg file='registerInstancesWithLB.groovy' />
  <arg file='${PLUGIN_INPUT_PROPS}' />
  <arg file='${PLUGIN_OUTPUT_PROPS}' />
</command>
```

The `<arg file='${PLUGIN_INPUT_PROPS}'/>` specifies the location of the tool-supplied properties file. The `<arg file='${PLUGIN_OUTPUT_PROPS}'/>` specifies the location of the output file for the step-generated properties.

Note: new lines are not supported by the `<arg>` element and are shown in this example only for presentation.

The `post-processing` element

When a plug-in step's `<command>` element finishes processing, the step's mandatory `<post-processing>` element runs.

The `<post-processing>` element sets the step's output properties (step name/property name, see Output properties on page 2516) and provides error handling. The `<post-processing>` element can contain any valid JavaScript™ 1.7 script (unlike the `<command>` element, `<post-processing>` scripts must be written in JavaScript™ 1.7). Users can also provide their own scripts when they define the step in the editor; see Post-processing scripts on page 2415.

Post-processing scripts have access to the following objects:

- The **properties** object is an instance of the class java.util.Properties. This variable has several special properties: `exitCode` contains the process exit code and `Status` contains the step's status. A `Status` value of `Success` means that the step completed successfully.

  This object is the same Java™ properties object that the step returns. Therefore, you can use the **properties** object in the post-processing script to change the output properties of the step. For example, to add an output property that is named `OutputProp1` with the value `value1`, add the following code to the post-processing script:

  ```
  properties.put("OutputProp1","value1");
  ```

  Then, the precondition scripts of other steps can access this property. See Process step preconditions on page 2411.

  For more information about this object, see the Java reference for java.util.Properties.

- The **scanner** object can scan the step's output log (scanning occurs on the agent) and run commands based on the results. **scanner** has several public methods:
  - `register(String regex, Function script)` registers a function to be called when the regular expression is matched. The function accepts two parameters: the first parameter is the line number that matched the regular expression, and the second parameter is the line of text that matched that expression.
  - `addLOI(Integer lineNumber)` adds a line to the lines of interest list, which are highlighted in the Log Viewer. The scanner adds all matching lines to this list automatically, but you can add other lines by calling this method.
  - `getLinesOfInterest()` returns a java.util.List of lines of interest; can be used to remove lines.
  - `scan()` scans the log. Call this method after you have registered all regular expressions with register(). If you do not call this method, the registered matchers do not run.
- The **commandOut** object is an instance of the class java.io.PrintStream. You can use this object to write to the log, as in the following example:

  ```
  commandOut.println("Log message.");
  ```

  For more information about this object, see the Java reference for java.io.PrintStream.

Post-processing scripts must set the **Status** property to specify the status of the script. The script can specify any value for the **Status** property. For example, to specify that the script was a success, run the following command in the post-processing script:

```
properties.put("Status","Success");
```

You can use a post-processing script to set output properties that can be used in other steps in the same process, which enables complex workflows. In a post-processing (or precondition) script, refer to prior step output properties this way:

```
properties.get("stepName/propName")
```

For example, to set a property named `myProp` whose value is included in the output log, enter this script:

```
var exit = properties.get('exitCode');

scanner.register("regex", function(lineNumber, line) {
     var thing = 'do stuff';
});
```

```
scanner.scan();

if (exit == 0) {
    properties.put('Status', 'Success');
}
else {
     properties.put('Status', 'Failure');
}
```

In instances other than post-processing and precondition scripts, refer to prior step output properties this way:

```
${p:stepName/propName}
```

The script that is defined in the `<post-processing>` element is the step's default behavior. Users can also provide their own script, overriding the default behavior, when they define the step in the process editor. See Editing processes on page 2453.

Upgrading plug-ins

This example shows how to upgrade a plug-in.

To create an upgrade, first, increment the number of the `version` attribute of the `<identifier>` element in the `plugin.xml` file. Next, update the property and step-type elements in the `plugin.xml` file.

If you change the names of a step or property, you must create an `upgrade.xml` file that contains the changes. Add a `<migrate>` element in the `upgrade.xml` file with a `to-version` attribute that contains the new number. Finally, place the names of changed property and step-type elements that match the updated `plugin.xml` file in this element, as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin-upgrade
        xmlns="http://www.&company;.com/UpgradeXMLSchema_v1"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <migrate to-version="3">
    <migrate-command name="Run SQLPlus script">
      <migrate-properties>
        <migrate-property name="sqlFiles" old="sqlFile"/>
      </migrate-properties>
    </migrate-command>
  </migrate>
</plugin-upgrade>
```

You can also make a script-only upgrade, which is an upgrade that contains changes to the step's associated scripts and files but does not change the `plugin.xml` file. This mechanism can be useful for plug-in development and for minor bug-fixes and updates.

If an update to a plug-in removes functionality, such as removing a step property, you must upgrade the plug-in and then open and re-save any processes that use the step. Until you open and re-save the processes, they use the pre-upgrade steps.

When creating a new version of a plugin, you many change the value of server:sub-tag in `plugin.xml`, and you do not need to add an entry to `upgrade.xml` for the change to take effect.

The `info.xml` file

Use the `info.xml` file is required for each plug-in. It describes the plug-in and provides release notes to users for each version.

The following code is an example of a simple `info.xml` file.

```
<?xml version="1.0" encoding="UTF-8"?>
<pluginInfo>
  <author name="Deploy User">
    <organization>IBM</organization>

  </release-notes>
</pluginInfo>
```

This file contains the following sections:

`<author>` (required)

This section provides information about the author of the plug-in.

`<integration>` (required)

This tag specifies the general type of plug-in. For source configuration plug-ins, specify `Source`. For plug-ins that retrieve artifacts from a repository during a deployment, specify `Artifact`. For plug-ins that deploy code to a middleware server, specify `Deploy`. For other automation tasks, specify `Automation`.

<source>

This tag specifies the location of the source code for the plug-in, if that source code is available.

<licenses>

This tag provides a description of the license for the plug-in.

<tool-description>

This tag provides information about the software or system that the plug-in integrates with.

<related-info>

This tag provides related links.

<meta-html>

This tag provides information about the description of the plug-in on web pages.

<release-version>

The build version of the plug-in, which is not necessarily the same as the version in the `plugin.xml` file.

<release-notes> (required)

This section includes release notes for the current and previous versions of the plug-in. These versions must match the version in the `plugin.xml` file.

Automatically importing objects from plug-ins

You can add objects to plug-ins so that they are automatically imported when the plug-in is installed or upgraded. Objects include applications, components, component templates, and processes. For example, you can add a component template that implements a standard process to a plug-in, so that the plug-in user does not have to create the component template.

To automatically import objects from plug-ins, place the JSON representation of the object in the plug-in archive file, in the appropriate directory. The JSON files must have the `.json` extension. For example, if you have an application in a JSON file, the file must be in the `imports/applications` folder of the archive file.

The following table lists the locations for each object type.

Object type	Location
Applications	`imports/applications/`
Components	`imports/components/`
Component templates	`imports/componenttemplates/`
Processes	`imports/processes/`

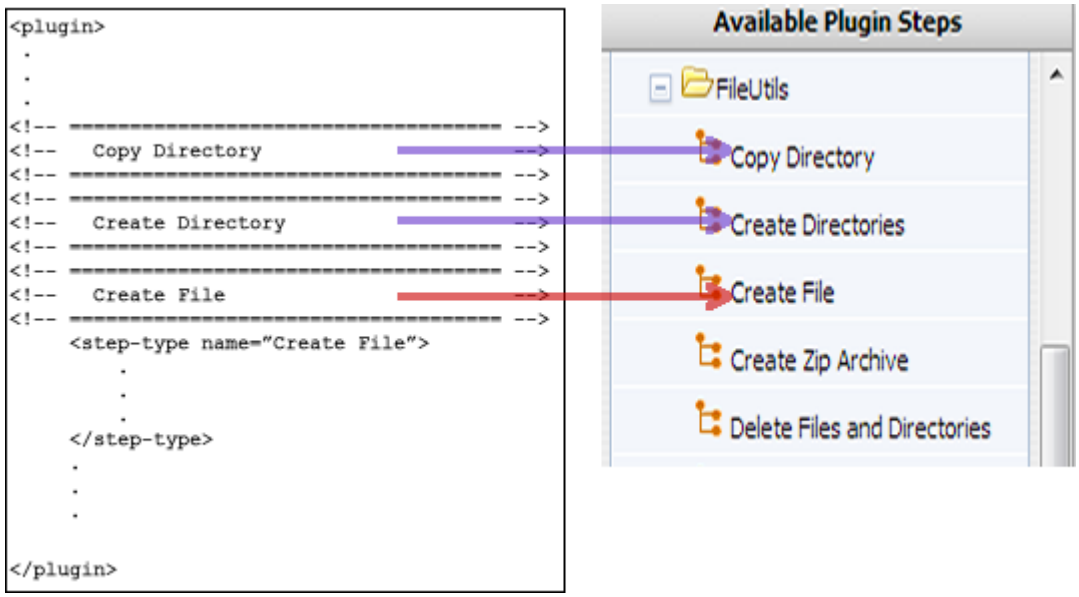
Example plug-in

A plug-in consists of one or more steps. A step represents a unit of functionality that can be user-configured and combined with other steps into a process. Creating a plug-in consists in defining its individual steps and then grouping them together for presentation in HCL DevOps Deploy (Deploy).

Plug-in steps are run by an agent that is installed in the target environment. This means that plug-ins can be written in any scripting language as long as the agent can access the required scripting tools on the host.

In this section, we examine the mechanics of plug-ins by examining a plug-in step in detail. The example plug-in that we use is FileUtils, which contains several steps that are related to file manipulation. The FileUtils plug-in is shipped with Deploy.

Each plug-in step is an individually configurable object in the editor. In the following illustration, you can see some of FileUtils' individual steps in the process editor.



We examine the `Create File` step in this example. Create File is straightforward and (as the name implies) creates a file.

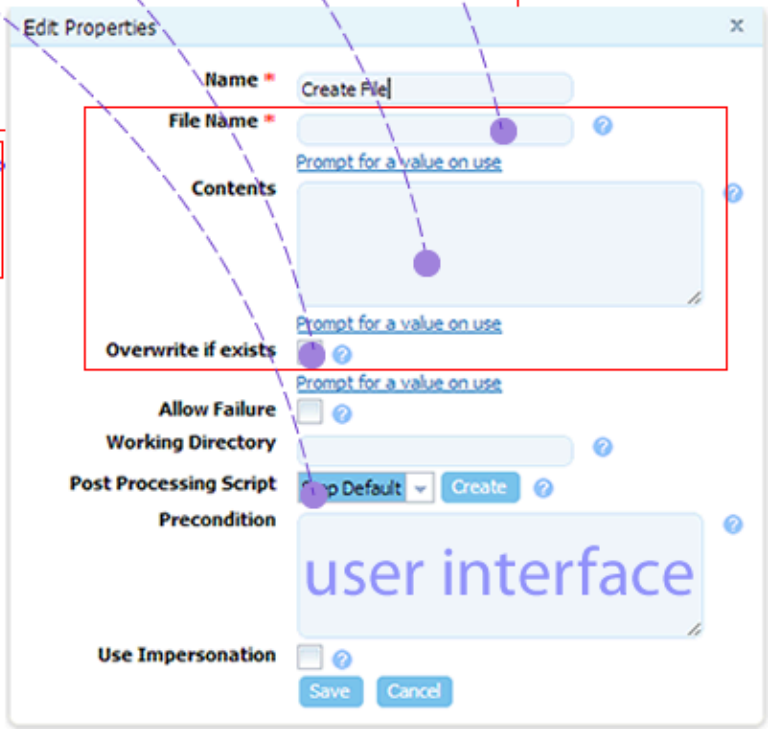
Each step (`step-type` element) has the same structure:

- `properties` element can contain any number of `<property>` child elements; property values can be supplied at design time or runtime
- `post-processing` element provides error-handling and sets property values that can be used by other steps
- `command` element performs the step's function. The function can be defined completely by the element, or be constructed in part or entirely from the step's properties at design time or runtime

The following figure illustrates the structure of the Create File step.

```
<step-type name="Create File">
     <description>Create a new file.</description>
     <properties>
       <property name="file" required="true">
         <property-ui type="textBox"
                      label="File Name"
                      description="The name of the new file."/>
       </property>
       <property name="contents">
         <property-ui type="textAreaBox"
                      label="Contents"
                      description="The contents of the new file."/>
       </property>
       <property name="overwrite">
         <property-ui type="checkBox"
                      label="Overwrite if exists"
                      description="Check here to overwrite an existing file."/>
       </property>
     </properties>
     <post-processing>
       <![CDATA[
         if (properties.get("exitCode") != 0) {
             properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
         }
         else {
             properties.put("Status", "Success");
         }
       ]]>
     </post-processing>

     <command program="${GROOVY_HOME}/bin/groovy">
       <arg file="create_file.groovy" />
       <arg file="${PLUGIN_INPUT_PROPS}"/>
       <arg file="${PLUGIN_OUTPUT_PROPS}"/>
     </command>
</step-type>
```



Step properties

In the context of our discussion, properties are values that are used by the step's command. Step properties are defined with the `property` element.

As you can see in Example plug-in on page 2580, the Create File step has three properties:

- `file` contains the name of the file the command creates; it is represented as a text box in the process designer
- `contents` contains the content of the file; it is represented by a text-area box, which can contain a large amount of data
- `overwrite` is used to specify whether the file can overwrite an existing file; it is represented by a check box in the process designer

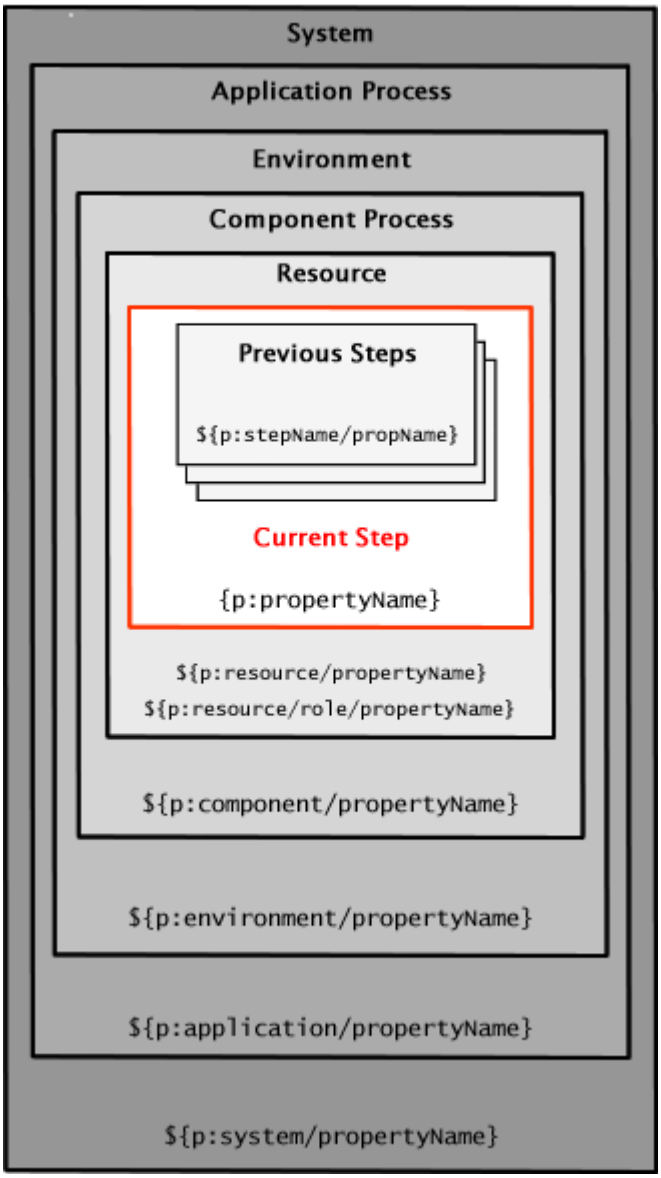
These properties are displayed in the dialog box that appears when the step is added to a component process. The other properties in the dialog are displayed for every step (post-processing is discussed below). Property values can be entered into the dialog box by the process designer at design-time, or left to be furnished at runtime by the user that runs the application.

You can configure most properties with the `property-ui` child element (the `selectBox` type requires the `value` child element as well). See Creating plug-ins on page 2561 for information about the options available for presentation in the UI. Default values can be defined when you create the step.

In addition to a step's own properties, a command has access to properties set earlier by other steps within the process, to properties set by the application that started the component process, to properties on the target environment and resource.

The following illustration shows the properties that are available to an individual step. Step property values become unavailable after the component process ends.

Properties Available to Component Steps



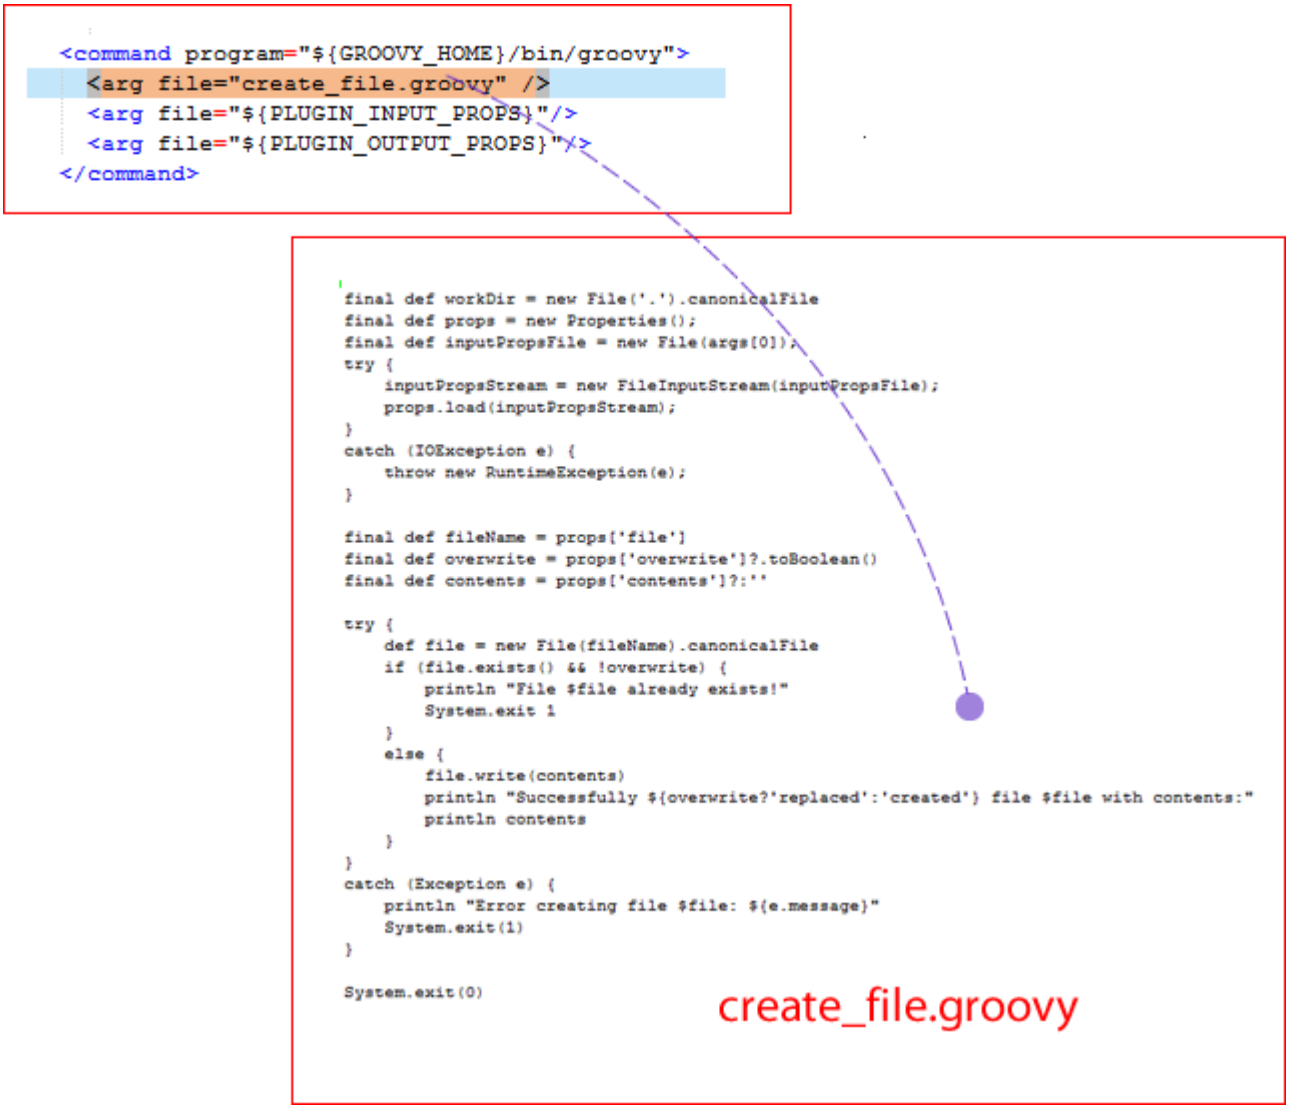
Runtime defined properties are combined with the properties that were defined earlier and together sent to the agent. Earlier properties (those properties that were defined outside the current process) are retrieved from the database. How properties are processed and consumed is discussed further in the next section.

Step commands

The step's `command` element specifies the scripting tool that runs the step and identifies the file that contains the actual script.

The agent that runs the step downloads the plug-in and expects to find the script among the downloaded files. The agent must also have access to the scripting tool. Any other arguments that are required by the script or tool can also be specified with the `arg file` attribute. The `arg file` attributes should be defined in the order compatible with the scripting tool.

The Create File command script is written in Groovy. Groovy is scripting language similar to Java™. The following illustration shows a command that runs an external Groovy file that is named `create_file.groovy`.



This command instructs the Groovy interpreter to run `create_file.groovy` (more about Groovy and the particulars of this file in the following section).

This line (which is part of every command):

```
<arg file="${PLUGIN_INPUT_PROPS}"/>
```

sends a file that contains the properties that are required by the step to the agent. The properties in the file are those properties that are furnished at runtime and others that are defined earlier that are required by the step. See Example plug-in on page 2580. The `${PLUGIN_INPUT_PROPS}` variable resolves to the location of this properties file.

And this line (which is also part of every command):

```
<arg file="${PLUGIN_OUTPUT_PROPS}"/>
```

refers to the file returned by the agent after finishing the step. The properties in this file are available to later steps in the process. The `${PLUGIN_OUTPUT_PROPS}` variable resolves to the location of this properties file.

create_file.groovy

The `create_file.groovy` file contains the Groovy script that runs the step's command.

Groovy is a dynamic scripting language (similar to Python, Ruby, and Perl) for the Java™ platform. Most Java™ code is also syntactically valid Groovy, which makes Groovy popular with Java™ programmers. Groovy provides native support for regular expressions.

The first lines of the script create a properties object, `props`. Then it attempts to load the properties from the file that is sent from the server (specified by the `${PLUGIN_OUTPUT_PROPS}` variable). If it can load the file, it populates `props`; otherwise, it throws an exception.

```
final def workDir = new File('.').canonicalFile
final def props = new Properties();
final def inputPropsFile = new File(args[0]);
try {
inputPropsStream = new FileInputStream(inputPropsFile);
props.load(inputPropsStream);
}
catch (IOException e) {
throw new RuntimeException(e);
}
```

To run the command (create a file), the script uses the properties that are defined by the step itself. The script retrieves the three properties from `props` and creates corresponding local variables.

Next, the script creates a file with a name specified by `fileName`, and tests the `overwrite` Boolean variable. If a file with the same name exists and `overwrite` is false, the script ends (fails) with an exit code of 1. Exit codes can be examined during post-processing.

Otherwise, the file is written with the content of `contents`. A message is written to the output log, and the exit code is set to 0 (success).

```
final def fileName = props['file']
final def overwrite = props['overwrite']?.toBoolean()
final def contents = props['contents']?:''

try {
def file = new File(fileName).canonicalFile
if (file.exists() && !overwrite) {
println "File $file already exists!"
System.exit 1
}
else {
file.write(contents)
println "Successfully ${overwrite?'replaced':'created'} file
$file with contents:"
println contents
}
}
```

```
catch (Exception e) {
println "Error creating file $file: ${e.message}"
System.exit(1)
}

System.exit(0)
```

Creating notification templates

Notification templates are the basis for emails that the server sends to users after an event occurs on the server. You can create customized notification templates by modifying the default templates provided, or by creating new templates of your own.

About this task

Notification templates are in Apache Velocity format. You can use this format to put together a message template with scripts and parameters that are specified when the notification happens. For example, the template can include information about a process that started, succeeded, or failed. For more information about creating templates with Velocity, see https://velocity.apache.org/.

Notifications templates are in XML format. The XML references application-specific parameters that are used by Java code to produce the notification email sent to the user. The application-specific parameters that can be used to customize the XML templates are provided in the topic Parameters for notification templates on page 2588.

1. Duplicate an existing template.
   The application templates are in the folder *application_data*`/conf/server/notification-templates`, where *application_data* is the application data folder. The default location is `/opt/install-dir/server/appdata/conf/server/notification-templates` on Linux™ and `C:\Program Files\devops-deploy\server\appdata\conf\server\notification-templates` on Windows™.
2. Open the new template in a text editor.
3. In the `<name>` tag, give the new template a unique name.
   Each template must have a unique name.
4. In the template, add parameters and other information.

   To use information from the event that created the notification, use the parameters in Parameters for notification templates on page 2588.

   Example
   For example, if you are creating a notification for an application process, you can use the parameter **$applicationProcess.getName()** to get the name of the process.
   Example

   You can also refer to properties just like you can in process steps. For example, to refer to the property **environment.name**, use the following code:

   ```
   $properties.get("environment.name")
   ```

Similarly, if the step `myStep` creates the output property `outputProperty1`, you can refer to the property in the notification template with the following code:

```
$properties.get("myStep/outputProperty1")
```

You use the same syntax to refer to other properties, too. For example, if an application has an application property that is named `myApplicationProp`, you can refer to that property with the following code:

```
$properties.get("application/myApplicationProp")
```

Similarly, you can refer to environment properties with code that is similar to the following example:

```
$properties.get("environment/myEnvironmentProp")
```

5. Restart the server.
   The server loads notification templates at start time, so when you change a template, you must restart the server before you can use it.

What to do next

Now you can use this template as part of a notification scheme. See Creating Notifications in a Notification Scheme on page 2081.

Parameters for notification templates

Depending on the context of the notification, you can insert parameters into the notification template. When the notification is sent, these parameters are replaced with values such as the names and information about applications, components, and processes.

Note: Not all parameters are available in all contexts. For example, when you run a generic process, parameters that are related to applications are not available.

Table 769. General parameters

Parameter	Description	Example
$externalUrl()	The URL of the server	`http://myserver.example.com:8443`
$request	The request that caused the notification, such as an application process request	`ApplicationProcessRequest#74ae3853-3444-4d7d-a0f3-68107f47b29f`

Table 770. Application parameters

Parameter	Description	Example
$application.getName()	The name of the application	`My application`

Table 770. Application parameters

(continued)

Parameter	Description	Example
$application.getId()	The ID of the application	`b37054b7-7b20-49b6-973d-fd0ee0b1b62b`
$application.getDescription()	The description of the application	`This is my application`
$application.getPath()	The URL path of the application	`applications/b37054b7-7b20-49b6-973d-fd0ee0b1b62b`

Table 771. Application process parameters

Parameter	Description	Example
$applicationProcess.getId()	The ID of the application process	`50d5bca2-d8d9-47f2-a0ce-5b75b3f24d3b`
$applicationProcess.getName()	The name of the application process	`Deploy application`
$appRequest.getPropSheet().getPropValue()	The name of the application process property.	`property_name`

Table 772. Environment parameters

Parameter	Description	Example
$environment.getId()	The ID of the application	`072a54df-8c3a-4b23-a660-323cf205c86c`
$environment.getName()	The name of the environment	`Environment 1`
$environment.getDescription()	The description of the environment	
$environment.getColor()	The color that is assigned to the environment in the table of environments	`#00B2EF`
$environment.isRequireApprovals()	True if the environment requires approvals	

You can retrieve an array of application process versions with the parameter **$versions**. For the size of the array, use the parameter **$versions.size()**. To access individual versions within this array, access them with a loop as in the following example:

```
<div class="data-table-container">
#if ($versions.size() > 0)
```

```
  <h3>Versions Included:</h3>
  <table class="data-table" cellpadding="4" cellspacing="1" width="100%">
   <thead class="data-table-head">
      <th style="text-align:left;" scope="col" valign="middle">Component</th>
      <th style="text-align:left;" scope="col" valign="middle">Version</th>
      <th style="text-align:left;" scope="col" valign="middle">Description</th>
   </thead>
   <tbody>
    #foreach ($version in $versions)
      #if ($velocityCount % 2 == 1)
          #set ($rowClass = "odd")
      #else
          #set ($rowClass = "even")
      #end
      <tr class="$rowClass">
       <td>$version.getComponent().getName()</td>
       <td>$version.getName()</td>
       <td>
         #if ($version.getDescription())
           $version.getDescription()
         #end
       </td>
     </tr>
    #end
   </tbody>
  </table>
#else
  <h3>No Versions Included</h3>
#end
</div>
```

Within the loop, you can access information about the individual versions with the parameters in the following table:

Table 773. Version parameters

Parameter	Description	Example
$version.getName()	The name of the component version	
$version.getComponent()	The component	

Table 774. Snapshot parameters

Parameter	Description	Example
$snapshot.getId()	The ID of the snapshot	`5d95883f-be45-4abe-8664-3ca6a7635a12`
$snapshot.getName()	The name of the snapshot	`My snapshot`
$snapshot.getDescription()	The description of the snapshot	
$snapshot.getCreatedDate()	The creation date of the snapshot	`Fri Mar 20 09:56:42 EDT 2015`

Table 774. Snapshot parameters

(continued)

Parameter	Description	Example
$snapshot.getCreatedTime()	The creation time of the snapshot in UNIX™ format	`1418136059500`

Table 775. User parameters

Parameter	Description	Example
$user.getId()	The ID of the user	`20000000000000000000000001000000`
$user.getName()	The user name	`jsmith`
$user.getActualName()	The full name of the user	`Joe Smith`
$user.getEmail()	The email address of the user	`jsmith@example.com`

Table 776. Approval parameters

Parameter	Description	Example
$processname	The name of the requested process	
$scheduledDate	The date for which the process is scheduled	`Fri Apr 10 13:16:53 EDT 2015`
$appRequest.getDescription()	The description of the application process request	
$requestType	The type of request	`applicationProcessRequest`
$roles	The roles that a user must have to approve the request	`[Role: Administrator]`
$appRequest	For application process requests, the application process request ID	`ApplicationProcessRequest#81701a8b-332c-47dd-8efe-87aab8fa2dfd`

Command-line client (CLI) reference

CLI is a command-line interface that provides access to the HCL DevOps Deploy (Deploy) server. It can be used to find or set properties and to run numerous functions.

The command-line client contains commands that match the REST commands for the Deploy server.

Installing the command-line client

The command-line client is available in an archive file that you can download from the server.

Before you begin

Make sure that the **JAVA_HOME** system variable is set to the location of a JRE or JVM.

About this task

Beginning with Deploy version 6.1, the command-line client is installed on agents automatically. The client is in the folder *agent_install*`/opt/udclient`.

1. To install the tool, download the `udclient.zip` file to the system on which you want to use the tool.
   You can download the file from the Deploy server by clicking **Help > Tools** and then clicking Deploy **Client**. You can also find the file in the folder *server_install*`/opt/tomcat/webapps/ROOT/tools/`, where *server_install* is the installation folder for the server.
2. Extract the file.
3. **Optional:** Set system variables such as **DS_WEB_URL** so you do not have to specify credentials each time you run a command.
   See Command format on page 2592.

What to do next

For information about specific commands, see CLI Commands on page 2595.

Command format

To run a command, open a command-line window and specify the command and its parameters. In some cases, you must pass a JSON string with information for a command.

Commands have the following format:

```
udclient [global-args...] [global-flags...] <command> [args...]
```

Notes:

- You must enter CLI commands on one line.
- CLI commands and parameters are case-sensitive.
- Using CLI commands requires the same permissions as using the web interface. For information about permissions, see Roles and permissions on page 2187.

Authenticating

You can authenticate to the server in any of the following ways:

- You can specify a user name and password in the **username** and **password** parameters, and the location of the server in the **weburl** parameter, as shown in the following examples.
- You can specify a user name and password in the **DS_USERNAME** and **DS_PASSWORD** system variables, and the location of the server in the **DS_WEB_URL** system variable.
- You can specify a token in the **authtoken** parameter or in the **DS_AUTH_TOKEN** system variable.
- You can use the login on page 2842 command to create a temporary authentication to the server.

Passing parameters

Most commands require one or more parameters. Parameters can change how the server interprets the command.

For example, if you do not pass any parameters to the getResources command (except the required global parameters), the server lists the top-level resources:

```
udclient -weburl http://ucdserver.example.com:8080
  -username admin
  -password admin
  getResources
```

However, if you pass the path or ID of a resource in the **parent** parameter, the command returns the resources that are under that resource, as in the following example:

```
udclient -weburl http://ucdserver.example.com:8080
  -username admin
  -password admin
  getResources
  -parent "/My Agents"
```

Passing JSON strings

Some commands require a JSON string or file instead of or in addition to the parameters.

For example, the createApplication command creates an application. To use this command, you must pass a valid JSON string that specifies the name, description, and some properties of the new application. The JSON string for this command must follow this template:

```
{
  "description": "Description",
  "enforceCompleteSnapshots": "Specify true to require
     an explicit version for each component",
  "name": "Application name or ID",
  "notificationScheme": "Notification scheme"
}
```

Note: To see the JSON template that a command requires, run the command with the `-t` switch, as in the following example:

```
udclient -weburl http://ucdserver.example.com:8080
  -username admin
  -password admin
```

```
createApplication
-t
```

This template is also listed in the reference information for the command; see createApplication on page 2636.

For example, the following JSON string represents an application that is named `My Application`:

```
{
  "description": "My new application",
  "enforceCompleteSnapshots": "false",
  "name": "My Application",
  "notificationScheme": "Default Notification Scheme"
}
```

To pass this JSON string, save the string to a file and pass the file to the command. For example, if you save the string to a file that is named `newApplication.json`, the command looks like the following example:

```
udclient -weburl http://ucdserver.example.com:8080
  -username admin
  -password admin
  createApplication
  newApplication.json
```

Note: The string that you pass to the command must be a valid JSON string.

Global parameters and flags

The following table lists the global parameters for the commands. These global parameters are listed as `[global-args...]` in code examples.

Table 777. Global parameters

Argument	Description
-authtoken, **--authtoken**	Optional. Can be set with the **DS_AUTH_TOKEN** environment variable. An authentication token (authtoken) that is generated by the server. Either an authtoken or a user name and password are required.
-password, **--password**	Optional. Can be set with the **DS_PASSWORD** environment variable. A password to authenticate with the server. Either an authtoken or a user name and password are required.
-proxyHost, **--proxyHost**	Optional. Can be set with the **proxyHost** environment variable. The host name of a proxy (for example, an agent relay) to use instead of a direct connection to the server.
-proxyPassword, **--proxyPassword**	Optional. Can be set with the **proxyPassword** environment variable. A password to use to authenticate with the proxy.
-proxyPort, **--proxyPort**	Optional. Can be set with the **proxyPort** environment variable. The proxy port to use if a proxy host name is specified.

Table 777. Global parameters (continued)

Argument	Description
-proxyUser, **--proxyUser**	Optional. Can be set with the **proxyUser** environment variable. A user name to use to authenticate with the proxy.
-username, **--username**	Optional. Can be set with the **DS_USERNAME** environment variable. A user name to authenticate with the server. Either an authtoken or a user name and password are required.
-weburl, **--weburl**	Required. Can be set with the **DS_WEB_URL** environment variable. The base URL of the Deploy server. For example, http://ds.example.com:8585.

The following table shows the global flags. These global flags are listed as `[global-flags...]` in code examples.

Table 778. Global flags

Flag	Description
-t, **--getTemplate**	Shows the JSON template for the command instead of running the command. If a file argument is provided, the template is output to the specified file.
-h, **--help**	Prints the full description and help of the command instead of running the command. You can get the information, such as: • The name of the command and its usage. • The synopsis of the command. • The required and optional parameters you can use with the command. • For some commands, the possible HTTP response status codes.
-v, **--verbose**	Prints extra information.

When you specify objects such as applications, components, agents, and resources on the command line, you can use the name of the object or the object ID. The ID of an object is part of the URL that is displayed when you inspect the object in Deploy. For example, if you browse to a specific component and the URL is `https://ucdeploy.example.com:8443/#component/2f153e93-00c3-44ef-a7fd-87e544e698d4`, then the ID of the component is `2f153e93-00c3-44ef-a7fd-87e544e698d4`.

This example shows the getResources command:

```
udclient -weburl http://localhost:8080 -username admin -password admin getResources
```

CLI Commands

The following list shows the commands that are available.

Note:

- CLI commands do not support new lines. Entries are broken for display purposes only.
- While you create standard-type objects such as components, applications, environments, or resources, you must not specify a type. For example, you can omit the resourceRoleLabel attribute.

Most of these commands have equivalent commands in the REST API. See REST commands for the DevOps Deploy server.

addAgentPoolToTeam

Add an agent pool to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addAgentPoolToTeam [parameters]
```

Parameters

Table 779. Parameters

Parameter	Type	Required	Description
agentPool	string	true	Name or ID of the agent pool
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard agent pool".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addAgentPoolToTeam
  -agentPool MyAgentPool
  -team MyTeam
```

Related REST command: Add an agent pool to a team.

addAgentServerPin

Add public key pin for a server host to an agent

This command requests the agent add a public key pin for a server host, but does not wait for or report the result. The returned maintenance task can be used to query the result.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addAgentServerPin [parameters]
```

Parameters

Table 780. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
host	string	true	The host name, as it is known by the agent, that will receive the public key pin
alias	string	true	A keypair alias in the server keystore file that holds the target public key
allowUnknownHost	boolean	false	If true, allow setting a pin for a host not currently known to the agent (optional)

Related REST command: Add public key pin for a server host to an agent.

addAgentToPool

Add an agent to an agent pool

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addAgentToPool [parameters]
```

Parameters

Table 781. Parameters

Parameter	Type	Required	Description
pool	string	true	Name or ID of the agent pool
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addAgentToPool
  -agent Agent1
  -pool Pool1
```

Related REST command: Add an agent to an agent pool.

addAgentToTeam

Add an agent to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addAgentToTeam [parameters]
```

Parameters

Table 782. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Application".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addAgentToTeam
  -agent MyAgent
  -team MyTeam
```

Related REST command: Add an agent to a team.

addApplicationToTeam

Add an application to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addApplicationToTeam [parameters]
```

Parameters

Table 783. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
team	string	true	Name or ID of the team

Table 783. Parameters (continued)

Parameter	Type	Required	Description
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Application".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addApplicationToTeam
  -application JPetStore
  -team MyTeam
```

Related REST command: Add an application to a team.

addComponentResourcePropDef

Create a component resource property definition

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addComponentResourcePropDef [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "allowedValues": "Comma separated list of allowed values
  in SELECT or MULTI_SELECT properties (Optional)",
  "component": "Name or ID of the component",
  "description": "Description for the property (Optional)",
  "label": "Label of the property (Optional)",
  "name": "Name of the property to set",
  "pattern": "A regular expression that specifies valid
  values for the property. Follows java.util.regex.Pattern
  (Optional)",
  "required": "Whether the property is required (Optional,
  Boolean)",
  "type": "the type of property definition; valid values
  are TEXT (the default), , TEXTAREA, CHECKBOX, SELECT,
  MULTI_SELECT, DATETIME, and SECURE)",
  "value": "Default value of the property definition
  (Optional)"
}
```

Related REST command: Create a component resource property definition.

addComponentTemplateToTeam

Add a component template to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addComponentTemplateToTeam [parameters]
```

Parameters

Table 784. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Component Template".

Related REST command: Add a component template to a team.

addComponentToApplication

Add a component to an application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addComponentToApplication [parameters]
```

Parameters

Table 785. Parameters

Parameter	Type	Required	Description
component	string	true	Name of the component
application	string	true	Name of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addComponentToApplication
  -application JPetStore
  -component JPetStore-WEB
```

Related REST command: Add a component to an application..

addComponentToTeam

Add a component to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addComponentToTeam [parameters]
```

Parameters

Table 786. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Component".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addComponentToTeam
  -component JPetStore-APP
  -team MyTeam
```

Related REST command: Add a component to a team.

addEnvironmentBaseResource

Add a base resource to an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addEnvironmentBaseResource [parameters]
```

Parameters

Table 787. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name of the application; this value is required if you specify the environment name instead of ID
resource	string	true	Path or ID of the resource to add

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addEnvironmentBaseResource
  -application MyApplication
  -environment Environment1
  -resource /agents/agent1
```

Related REST command: Add a base resource to an environment.

addEnvironmentProperty

Create a component environment property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addEnvironmentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Name or ID of the component",
  "default": "Default value (Optional)",
  "description": "Description for the property (Optional)",
  "label": "Label of the property (Optional)",
  "name": "Name of the property",
  "pattern": "A regular expression that specifies valid
  values for the property. Follows java.util.regex.Pattern
  (Optional)",
```

```
  "required": "Whether the property is required (Optional,
  Boolean)",
  "secure": "Specify true to create a secure property
  (Optional, Boolean)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addEnvironmentProperty
  -name MyProperty
  -component d2e59ca4-a2f5-4851-9c85-629c1019ba20
  -required true
```

Related REST command: Create a component environment property.

addEnvironmentToTeam

Add an environment to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addEnvironmentToTeam [parameters]
```

Parameters

Table 788. Parameters

Parameter	Type	Required	Description
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
environment	string	true	Name or ID of the environment
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Environment".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addEnvironmentToTeam
```

```
  -application MyApplication
  -environment MyEnvironment
  -team MyTeam
```

Related REST command: Add an environment to a team.

addGroupToTeam

Add a group to a role on a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addGroupToTeam [parameters]
```

Parameters

Table 789. Parameters

Parameter	Type	Required	Description
group	string	true	Name or ID of the group
team	string	true	Name or ID of the team
role	string	true	Name or ID of the role to give to the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addGroupToTeam
  -group group1
  -team MyTeam
  -role MyRole
```

Related REST command: Add a group to a role on a team.

addJavaPackage

Upload a Java package.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addJavaPackage [parameters]
```

Parameters

Table 790. Parameters

Parameter	Type	Required	Description
name	string	false	Custom package name (typically, the file name of the package). Limited to 100 characters from [-_.0-9a-zA-Z]. Certain names that have special meaning as file names such as ".." or "COM1" are rejected.

Related REST command: Upload a Java package..

addPostProcessingScriptToTeam

Add a post processing script to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addPostProcessingScriptToTeam [parameters]
```

Parameters

Table 791. Parameters

Parameter	Type	Required	Description
script	string	true	Name/ID of the post processing script
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Post Processing Script"

Related REST command: Add a post processing script to a team.

addProcessToTeam

Add a process to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addProcessToTeam [parameters]
```

Parameters

Table 792. Parameters

Parameter	Type	Required	Description
process	string	true	Name or ID of the process
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Process".

Related REST command: Add a process to a team.

addResourceToTeam

Add a resource to a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addResourceToTeam [parameters]
```

Parameters

Table 793. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Resource".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addResourceToTeam
  -resource /Resource1/Subresource1
  -team MyTeam
```

Related REST command: Add a resource to a team.

addStatusToSnapshot

Add a status to a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addStatusToSnapshot [parameters]
```

Parameters

Table 794. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot.
application	string	false	Name or ID of the application; this value is required if you specify the snapshot name instead of the ID.
statusName	string	true	Name or ID of the status. This value cannot be longer than 36 characters.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addStatusToSnapshot
  -application MyApplication
  -snapshot MySnapshot
  -statusName NewStatus
```

Example

Example response

```
{
  "id": "d3dfd0c8-90f5-427b-8432-3c71c086cc93",
  "name": "MySnapshot",
  "description": "",
  "created": 1450130946382,
  "active": true,
  "versionsLocked": false,
  "configLocked": false,
  "applicationId": "99822240-cc96-4e4e-91e9-bcc483521cec",
  "user": "jsmith"
}
```

Related REST command: Add a status to a snapshot.

addTagToAgent

Add a tag to an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addTagToAgent [parameters]
```

Parameters

Table 795. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
tag	string	true	Name of the tag
color	string	false	Hex representation of the color for the tag, such as FF0000. This parameter is used only if the tag is being created.
description	string	false	Description of the tag. This parameter is used only if the tag is being created.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addTagToAgent
  -agent myAgent
  -tag Tag1
```

Related REST command: Add a tag to an agent.

addTagToApplication

Add a tag to an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addTagToApplication [parameters]
```

Parameters

Table 796. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
tag	string	true	Name of the tag
color	string	false	Hex representation of the color for the tag, such as FF0000. This parameter is used only if the tag is being created.
description	string	false	Description of the tag. This parameter is used only if the tag is being created.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addTagToApplication
  -application JPetStore
  -tag Tag1
```

Related REST command: Add a tag to an application.

addTagToComponent

Add a tag to a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addTagToComponent [parameters]
```

Parameters

Table 797. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
tag	string	true	Name of the tag

Table 797. Parameters (continued)

Parameter	Type	Required	Description
color	string	false	Hex representation of the color for the tag, such as FF0000. This parameter is used only if the tag is being created.
description	string	false	Description of the tag. This parameter is used only if the tag is being created.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addTagToComponent
  -component JPetStore-APP
  -tag Tag1
```

Related REST command: Add a tag to a component.

addTagToResource

Add a tag to a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addTagToResource [parameters]
```

Parameters

Table 798. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
tag	string	true	Name of the tag

Table 798. Parameters (continued)

Parameter	Type	Required	Description
color	string	false	Hex representation of the color for the tag, such as FF0000. This parameter is used only if the tag is being created.
description	string	false	Description of the tag. This parameter is used only if the tag is being created.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addTagToResource
  -resource /Resource1/Subresource1
  -tag Tag1
```

Related REST command: Add a tag to a resource.

addUserToGroup

Add a user to a group

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addUserToGroup [parameters]
```

Parameters

Table 799. Parameters

Parameter	Type	Required	Description
user	string	true	Name of the user
group	string	true	Name of the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addUserToGroup
  -user jsmith
  -group group1
```

Related REST command: Add a user to a group.

addUserToTeam

Add a user to a role on a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addUserToTeam [parameters]
```

Parameters

Table 800. Parameters

Parameter	Type	Required	Description
user	string	true	Name or ID of the user
team	string	true	Name or ID of the team
role	string	true	Name or ID of the role to give to the user

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addUserToTeam
  -user jdoe
  -team MyTeam
  -role MyRole
```

Related REST command: Add a user to a role on a team.

addVersionFiles

Upload files to a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addVersionFiles [parameters]
```

Parameters

Table 801. Parameters

Parameter	Type	Required	Description
component	string	false	Name/ID of the component (Only required if not using version ID)
version	string	true	Name/ID of the version
base	string	true	Local base directory for upload. All files inside this will be sent.
offset	string	false	Target path offset (the directory in the version files to which these files should be added)
include	string	false	An include file pattern for selecting files to add (may be repeated)
exclude	string	false	An exclude file pattern for excluding files (may be repeated). Overrides includes.
saveExecuteBits	boolean	false	Saves execute bits for files.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addVersionFiles
  -component JPetStore-WEB
  -version 1.1
  -base newImageFolder
  -exclude */subDirName/*
```

addVersionLink

Add a link on a version

This command adds an external link on the specified component version.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addVersionLink [parameters]
```

Parameters

Table 802. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component. This value is required if you specify a version name instead of an ID
version	string	true	Name or ID of the version
linkName	string	true	Name of the link to add
link	string	true	Value of the link to add
isPriority	boolean	false	Optional. If true, prioritize the link by placing it in the version page header for quicker access

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addVersionLink
  -component JPetStore-APP
  -version 1.0
  -linkName "Link to IBM web site"
  -link http://www.ibm.com
```

Related REST command: Add a link on a version.

addVersionLinkWithName

Add a link on a version

This command adds an external link on the specified component version.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addVersionLinkWithName [parameters] [JSON file]
```

Parameters

Table 803. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component. This value is required if you specify a version name instead of an ID

Table 803. Parameters (continued)

Parameter	Type	Required	Description
version	string	true	Name or ID of the version

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "isPriority": "Optional. If true, prioritize the link by
  placing it in the version page header for quicker access",
  "link": "Link url",
  "name": "Link name"
}
```

Related REST command: Add a link on a version.

addVersionStatus

Add a status to a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addVersionStatus [parameters]
```

Parameters

Table 804. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version
status	string	true	Name of the status to apply

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addVersionStatus
  -component JPetStore-APP
```

```
  -version 1.0
  -status Approved
```

Related REST command: Add a status to a version.

addVersionToSnapshot

Add a component version to a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addVersionToSnapshot [parameters]
```

Parameters

Table 805. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID
version	string	true	Name or ID of the component version
component	string	false	Name of the component; this value is required if you specify the component name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  addVersionToSnapshot
  -application MyApplication
  -component MyComponent
  -snapshot MySnapshot
  -version 1.2
```

Related REST command: Add a component version to a snapshot.

addWebhookToApplication

Add a webhook to an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addWebhookToApplication [parameters]
```

Parameters

Table 806. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	ID or name of webhook template
url	string	true	Url for the webhook
environment	string	true	ID of environment to add the webhook to. This can be repeated for multiple environments.
webhookProxyHost	string	false	Host name of http proxy. Default ${p?:system/proxyHost}.
webhookProxyPort	string	false	Port of http proxy. Default ${p?:system/proxyPort}.
webhookProxyUsername	string	false	Username for authentication with http proxy. Default ${p?:system/proxyUsername}.
webhookProxyPassword	string	false	Password for authentication with http proxy. Default ${p?:system/proxyPassword}.
application	string	true	ID or name of application

Related REST command: Add a webhook to an application.

addWebhookToApplicationWithCredentials

Add a webhook to an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addWebhookToApplicationWithCredentials [JSON file]
```

Parameters

Table 807. Parameters

Parameter	Type	Required	Description
application	string	true	ID or name of application

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "environments": ["Name or ID of environments"],
  "proxyHost": "Proxy Host. Updating proxy host will unset
  proxy username and password if those are not provided",
  "proxyPassword": "Password to use for basic
  authentication with the proxy",
  "proxyPort": "Proxy Port. Updating proxy port will unset
  proxy username and password if those are not provided",
  "proxyUsername": "Username to use for basic
  authentication with the proxy",
  "url": "Url for the webhook",
  "webhookTemplate": "Name or ID of the webhook template"
}
```

Related REST command: Add a webhook to an application.

addWebhookToProcess

Add a webhook to a process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addWebhookToProcess [parameters]
```

Parameters

Table 808. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	Id or name of webhook template.
url	string	true	Url for the webhook
webhookProxyHost	string	false	Host name of http proxy. Default ${p?:system/proxyHost}.

Table 808. Parameters (continued)

Parameter	Type	Required	Description
webhookProxyPort	string	false	Port of http proxy. Default ${p?:system/proxyPort}.
webhookProxyUsername	string	false	Username for authentication with http proxy. Default ${p?:system/proxyUsername}.
webhookProxyPassword	string	false	Password for authentication with http proxy. Default ${p?:system/proxyPassword}.
process	string	true	Id or name of process

Related REST command: Add a webhook to a process.

addWebhookToProcessWithCredentials

Add a webhook to a process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addWebhookToProcessWithCredentials [JSON file]
```

Parameters

Table 809. Parameters

Parameter	Type	Required	Description
process	string	true	Id or name of process

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "proxyHost": "Proxy Host. Updating proxy host will unset
  proxy username and password if those are not provided",
  "proxyPassword": "Password to use for basic
  authentication with the proxy",
  "proxyPort": "Proxy Port. Updating proxy port will unset
  proxy username and password if those are not provided",
  "proxyUsername": "Username to use for basic
  authentication with the proxy",
  "url": "Url for the webhook",
  "webhookTemplate": "Name or ID of the webhook template"
```

```
}
```

Related REST command: Add a webhook to a process.

addZInventoryEntries

Add entries to Z inventory.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  addZInventoryEntries [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or Id of the application.",
  "component": "Name or Id of the component.",
  "deploy-time": "Time in milliseconds.",
  "environment": "Name or Id of the environment.",
  "resources": [{
    "deploy-type": "Type of deployment for this resource.",
    "inputs": "Inputs",
    "name": "Filename of the entry.",
    "operation-type": "Type of operation for this entry. e.
  g. 'Deploy' or 'Delete'.",
    "target": "Target",
    "target-type": "Type of the target for this resource."
  }],
  "version": "Name or Id of the version."
}
```

Related REST command: Add entries to Z inventory..

archiveVersion

Archive the given versions of a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  archiveVersion [parameters]
```

Parameters

Table 810. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
version	string	true	Name or ID of the version(s) to be archived. This option can be repeated to archive multiple versions.
path	string	false	Deprecated. Archive path. An absolute path which overrides the System's archive path. Must be enabled on the server.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  archiveVersion
  -component MyComponent
  -version 1.0
  -version 1.2
  -version 1.3
```

Related REST command: Archive the given versions of a component.

autoDiscoverResource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  autoDiscoverResource [parameters]
```

Parameters

Table 811. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1

Related REST command: Autodiscover resource.

bulkAddAgentServerPin

Add public key pins for server hosts to an agents in bulk

This command requests a set of agent add a public key pin for a server host, but does not wait for or report the results. The returned maintenance tasks can be used to query the result. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkAddAgentServerPin [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "alias": "A keypair alias in the server keystore file
  that holds the target public key",
    "allowUnknownHost": "If true, allow setting a pin for
  a host not currently known to the agent (optional)",
    "host": "The host name, as it is known by the agent,
  that will receive the public key pin"
  }]
}
```

Related REST command: Add public key pins for server hosts to an agents in bulk.

bulkGetAgentJavaHomes

Get list of managed Java installations in bulk

This command returns a list of managed Java installations for a set of agents. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkGetAgentJavaHomes [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
```

```
  "entity": [{"agent": "Name or ID of an agent"}]
}
```

Related REST command: Get list of managed Java installations in bulk.

bulkGetPreferredJavaPackageForAgent

Get the preferred Java packages compatible with agents in bulk.

This command gets the preferred Java packages compatible with the platforms of a set of agents. If no such package is currently defined for an agent, then no content is returned for the respective sub-request. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkGetPreferredJavaPackageForAgent [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{"agent": "Name or ID of the agent"}]
}
```

Related REST command: Get the preferred Java packages compatible with agents in bulk..

bulkInstallAgentJava

Install Java packages as a new managed Java installations in bulk

This command request a set of agents install Java, but does not wait for or report the results. The returned maintenance tasks can be used to query the result. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkInstallAgentJava [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "package": "Name or ID of the Java package"
  }]
}
```

Related REST command: Install Java packages as a new managed Java installations in bulk.

bulkRemoveAgentServerPin

Remove public key pins for server hosts from agents in bulk

This command requests a set of agent remove a public key pin for a server host, but does not wait for or report the results. The returned maintenance tasks can be used to query the result. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkRemoveAgentServerPin [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "host": "The host name, as it is known by the agent,
  from which the public key pin is removed",
    "publicKeyFingerprint": "The ingerprint for the public
  key pin to remove"
  }]
}
```

Related REST command: Remove public key pins for server hosts from agents in bulk.

bulkSetAgentJavaHome

Set the configured JAVA_HOME of agents in bulk

This command requests a set of agents set JAVA_HOME, but does not wait for or report the results. Each new JAVA_HOME will not take effect until the respective agent is restarted. The returned maintenance tasks can be used to query the results.Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkSetAgentJavaHome [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "javahome": "Name of managed Java install or absolute
  path of a valid JAVA_HOME directory"
  }]
}
```

Related REST command: Set the configured JAVA_HOME of agents in bulk.

bulkSetAgentKeypairPolicy

Add public key pins for server hosts to an agents in bulk

This command requests a set of agents set or modify their keypair policy, but does not wait for or report the results. The returned maintenance tasks can be used to query the result. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests. If the maximum age of a keypair is changed to be less than its current age, keypair rotation may begin immediately, but the outcome of the returned maintenance tasks do not depend on that.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkSetAgentKeypairPolicy [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "maxAgeDays": "The maximum age in days of the agent's
  keypair, or zero to disable rotation"
  }]
}
```

Related REST command: Add public key pins for server hosts to an agents in bulk.

bulkUninstallAgentJava

Uninstall a managed Java installations in bulk

This command requests a set of agents uninstall Java, but does not wait for or report the result. If an installation is the active JAVA_HOME or configured as JAVA_HOME, that installation is not removed. The returned maintenance tasks can be used to query the result. Individual sub-requests may succeed or fail independently. A single request may contain up to 250 sub-requests.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  bulkUninstallAgentJava [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "agent": "Name or ID of an agent",
    "package": "Name of a managed Java package"
  }]
}
```

Related REST command: Uninstall a managed Java installations in bulk.

cancelApplicationPipelineExecution

Cancel an application pipeline execution

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelApplicationPipelineExecution [parameters]
```

Parameters

Table 812. Parameters

Parameter	Type	Required	Description
executionId	string	true	Id of the pipeline execution.

Related REST command: Cancel an application pipeline execution.

cancelApplicationProcessRequest

Cancel an application process request

Cancel an outstanding application process request

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelApplicationProcessRequest [parameters]
```

Parameters

Table 813. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the application process request.

Related REST command: Cancel an application process request.

cancelComponentProcessRequest

Cancel an component process request

Cancel an outstanding component process request

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelComponentProcessRequest [parameters]
```

Parameters

Table 814. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the component process request.

Related REST command: Cancel an component process request.

cancelMaintenanceBlackoutSeries

Cancels the entire series for a recurring maintenance blackout.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelMaintenanceBlackoutSeries [parameters]
```

Parameters

Table 815. Parameters

Parameter	Type	Required	Description
series	string	true	ID of the series

Related REST command: Cancel the entire series for a recurring maintenance blackout.

cancelMaintenanceBlackoutSeriesEvent

Cancels a single event in the series for a recurring maintenance blackout.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelMaintenanceBlackoutSeriesEvent [parameters]
```

Parameters

Table 816. Parameters

Parameter	Type	Required	Description
series	string	true	ID of the series
event	string	true	ID of the event
scheduled	string	true	Scheduled date of the event (its start date)

Related REST command: Cancel a single event in the series for a recurring maintenance blackout.

cancelProcessRequest

Cancel an process request

Cancel an outstanding process request

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelProcessRequest [parameters]
```

Parameters

Table 817. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the process request.

Related REST command: Cancel a process request.

cancelScheduledDeploymentSeries

Cancels the entire series for a recurring scheduled deployment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelScheduledDeploymentSeries [parameters]
```

Parameters

Table 818. Parameters

Parameter	Type	Required	Description
series	string	true	ID of the series

Related REST command: Cancel the entire series for a recurring scheduled deployment.

cancelScheduledDeploymentSeriesEvent

Cancels a single event in the series for a recurring scheduled deployment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelScheduledDeploymentSeriesEvent [parameters]
```

Parameters

Table 819. Parameters

Parameter	Type	Required	Description
series	string	true	ID of the series
event	string	true	ID of the event

Table 819. Parameters (continued)

Parameter	Type	Required	Description
scheduled	string	true	Scheduled date of the event

Related REST command: Cancel a single event in the series for a recurring scheduled deployment.

cancelServerKeystoreImportTask

Cancels an incomplete keystore import task. Incomplete tasks can be cancelled by any user with the required permission.

Cancel an incomplete keystore import task

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelServerKeystoreImportTask [parameters]
```

Parameters

Table 820. Parameters

Parameter	Type	Required	Description
task	string	true	ID of an import task.

Related REST command: Cancel an incomplete keystore import task..

cancelWorkflow

Cancel a workflow in progress

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  cancelWorkflow [parameters]
```

Parameters

Table 821. Parameters

Parameter	Type	Required	Description
workflow	string	true	ID of the workflow to cancel.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  cancelWorkflow
  -workflow 193e892f-677d-4534-9763-ff8d005a5829
```

Related REST command: Cancel a workflow in progress.

closeTask

Approve or reject an approval task

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  closeTask [JSON file]
```

Parameters

Table 822. Parameters

Parameter	Type	Required	Description
taskId	string	true	The ID of the task.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "comment": "Comment to close the task with",
  "p:Property name": "Property value (Optional,
  Repeatable)",
  "passFail": "Submit passed to approve, fail to fail"
}
```

Related REST command: Approve or reject an approval task.

completeServerKeystoreImportTask

Complete a server keystore import task

Complete a server keystore import task by uploading a keystore containing new key pairs. This will modify keystore file at path appdata/conf/server.keystore. The uploaded keystore must be in a format consumable by your Java virtual machine; currently, JKS and PKCS12 are the supported formats. Your Java virtual machine may impose additional restrictions such that keystores from other virtual machines or generated by other tools may not be readable. Imports can only be completed by the same user that created the import task.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  completeServerKeystoreImportTask [parameters]
```

Parameters

Table 823. Parameters

Parameter	Type	Required	Description
task	string	true	ID of a prepared import task to complete

Related REST command: Complete a server keystore import task.

copyResource

Copy a resource into a new parent

To update a resource's parent with this command, you must specify, at a minimum, the resource path or id, and optionally provide info for the resource template, blueprint, and application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  copyResource [parameters] [JSON file]
```

Parameters

Table 824. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
parent	string	true	The path or id of the new parent
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agent": "Name or ID of an agent to use for automation
  (Optional)",
  "agentPool": "Name or ID of an agent pool to use for
```

```
  automation (Optional)",
  "component": "Name or ID of a component to associate
  with the resource (Optional)",
  "componentTag": "Name or ID of a component tag to
  associate with the resource; any components with that tag
  can be deployed to this resource (Optional)",
  "description": "Description",
  "impersonationForce": "Specify true to prevent children
  or steps from specifying their own impersonation settings
  (Optional)",
  "impersonationGroup": "Group for default impersonation
  (Optional)",
  "impersonationPassword": "Password for default
  impersonation. Agents running on Linux and Unix machines
  will ignore this value (Optional)",
  "impersonationUseSudo": "Specify true to use the sudo
  command for impersonation. Agents running on Windows
  machines will ignore this value (Optional)",
  "impersonationUser": "User name for default
  impersonation (Optional)",
  "inheritTeam": "Whether or not to set inherit teams for
  resource. teamMappings will be ingored if true. Defaults
  to true (Optional)",
  "name": "Name for the new resource; leave blank to
  inherit the name from an agent, pool, or role",
  "parent": "ID or path to parent resource; leave blank to
  create a root resource (Optional)",
  "role": "Name or ID of a resource role to associate with
  the agent; if this resource is for a component, specify
  the component name instead (Optional)",
  "roleProperties": {"Property name": "Property value
  (Optional)"},
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }]
}
```

Related REST command: Copy a resource into a new parent.

copyVersion

Copy a component version with all of its properties

Do not use the keywords latest, latestVersion, or newest as the version name. Artifacts are not copied to the created component version.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  copyVersion [parameters]
```

Parameters

Table 825. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the new version
from	string	true	Name of the version to copy
description	string	false	Description of the new version
type	string	false	Type to use for the new version (incremental or full); the default is the default version type for the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  copyVersion
  -component MyComponent
  -name NewCopiedVersion
  -from ExistingVersion
  -type full
```

Example

Example response

```
{
  "properties": [],
  "propSheets": [{
    "properties": [],
    "id": "62ee0d83-97aa-4006-b4a7-933a803abdc3",
    "path": "components\/5ad2f8a2-88d3-4f55-94e0-499bdbc5f0a9\/versions\/2d9e369b-8ac9-45c0-a192-017c201820e6\/
    propSheetGroup\/propSheets\/62ee0d83-97aa-4006-b4a7-933a803abdc3",
    "version": 1,
    "versionCount": 1,
    "commit": 0,
    "versioned": true,
    "propSheetDef": {
```

```
      "id": "bce76bb6-b660-4f62-b23a-859cd3ac61c2",
      "path": "components\/5ad2f8a2-88d3-4f55-94e0-499bdbc5f0a9\/versionPropSheetDef",
      "version": 1,
      "versionCount": 1,
      "commit": 9,
      "resolveHttpValuesUrl": "property\/propSheetDef\/
      components%265ad2f8a2-88d3-4f55-94e0-499bdbc5f0a9%26versionPropSheetDef.-1\/resolveHttpValues",
      "versioned": true
    }
  }],
  "totalSize": 0,
  "totalCount": 0,
  "id": "2d9e369b-8ac9-45c0-a192-017c201820e6",
  "name": "NewCopiedVersion",
  "type": "FULL",
  "created": 1443806239480,
  "active": true,
  "archived": false,
  "sizeOnDisk": 0
}
```

Related REST command: Copy a component version with all of its properties.

createAgentPool

Create an agent pool

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createAgentPool [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agents": [
    "Agent ID or name",
    "Agent ID or name (repeat as necessary)"
  ],
  "description": "Description",
  "name": "Name of the agent pool"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createAgentPool newPool.json
```

Example

Example JSON request

```
{
  "name": "New pool",
  "description": "My new agent pool",
  "agents": [
    "Agent1",
    "Agent2"
  ]
}
```

Example

Example response

```
{
  "id": "62eb25dd-edc0-4900-a4c7-25b440abb1a3",
  "name": "New pool",
  "active": true,
  "description": "My new agent pool",
  "status": "ONLINE"
}
```

Related REST command: Create an agent pool.

createApplication

Create an application from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createApplication [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Description",
  "enforceCompleteSnapshots": "Specify true to require an
  explicit version for each component",
  "name": "Application name or ID",
  "notificationScheme": "Notification scheme",
  "onlyChangedVersions": "If true, the 'Only Deploy
  Changed Versions' deployment option will be checked by
  default (default: true)",
  "teamMappings": [{
    "resourceRoleId": "ID of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
```

```
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "useWizard": "Specify true to use the Deployment Wizard
  when submitting application process request (default:
  false)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createApplication newApplication.json
```

Example

Example JSON request

```
{
  "name": "My new application",
  "description": "New application for command example",
  "notificationScheme": "Default Notification Scheme",
  "enforceCompleteSnapshots": "false"
}
```

Example

Example response

```
{
  "id": "5064e2b5-08aa-4e79-b0d5-9b63ba218d48",
  "name": "My new application",
  "description": "New application for command example",
  "created": 1390504790883,
  "enforceCompleteSnapshots": false,
  "active": true,
  "tags": [
  ],
  "user": "admin"
}
```

Related REST command: Create an application from a JSON file.

createApplicationFromTemplate

Create an application with components from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createApplicationFromTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Description",
  "enforceCompleteSnapshots": "Specify true to require an
  explicit version for each component",
  "existingComponentIds": "The list of existing Component
  IDs to attach the application.",
  "name": "Application name or ID",
  "notificationScheme": "Notification scheme",
  "teamMappings": [{
    "resourceRoleId": "ID of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "templateId": "The ID of the template to use. If you are
  using an application template, either this field or
  templateName are required.",
  "templateName": "The name of the template to use. If you
  are using an application template, either this field or
  templateId are required.",
  "templateProperties": [{
    "name": "The name of the property defined on the
  template. Required properties must be included here",
    "value": "Value of the property to set on the new
  application"
  }],
  "templateVersion": "The version of the template to use.
  This field is required if you are using an application
  template."
}
```

Related REST command: Create an application with components from a JSON file.

createApplicationPipeline

Create a new application pipeline

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createApplicationPipeline [parameters] [JSON file]
```

Parameters

Table 826. Parameters

Parameter	Type	Required	Description
application	string	true	Application name or id.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "name of the application pipeline",
  "stages": [{
    "blocks": [{
      "environment": "name of the environment for this
  block",
      "processes": ["process-name"]
    }],
    "name": "name of the stage"
  }]
}
```

Related REST command: Create a new application pipeline.

createApplicationProcess

Create an application process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createApplicationProcess [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Application ID",
  "description": "Description. This template includes one
  step, which deploys a component.",
  "disableSnapshots": "When true, prevent deployments
  using any snapshot and this application process",
  "inventoryManagementType": "The inventory management for
```

```
the process request, such as AUTOMATIC",
"name": "Application process name",
"offlineAgentHandling": "PRE_EXECUTION_CHECK",
"propDefs": [{
  "label": "Property label",
  "name": "Property name",
  "type": "TEXT"
}],
"properties": [{
  "description": "Description",
  "name": "Property name",
  "secure": true,
  "value": "Property value"
}],
"requiredRoleId": "Required Role Name or ID",
"rootActivity": {
  "children": [
    {
      "children": [{
        "children": [{
          "allowFailure": false,
          "children": [],
          "componentName": "Component name",
          "componentProcessName": "Component process
name",
          "name": "First step name",
          "properties": {},
          "type": "componentProcess"
        }],
        "componentName": "Component name",
        "name": "inventoryVersionCheck",
        "status": "Active",
        "type": "inventoryVersionDiff"
      }],
      "componentName": "Component name",

      },
      {
        "name": "FINISH",
        "x": "0",
        "y": "420"
      }
    ],
    "propDefs": [],
    "type": "graph",
    "versionPresets": []
  }
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createApplication newApplicationProcess.json
```

Example

Example JSON request

To use an existing application process as a template, follow these steps:

1. Open the application process in the editor.
2. In your web browser, open the developer tools or install an extension that shows the network traffic from your browser to the server.
3. In the process editor, make a change to the application process. This change can be a trivial change, such as moving a step slightly. The process must need to be saved.
4. Save the application process.
5. In the web browser developer tools, find the REST PUT call to the endpoint `https://hostName:port/rest/deploy/applicationProcess/applicationProcessID/saveActivities`, where *`hostname`* and *`port`* are the host name and port of your server, and *`applicationProcessID`* is the ID of the application process. This PUT call is the call that sends the new version of the application process to the server.
6. Find the JSON payload of the REST PUT call. This code describes the steps in the process and the location of the steps on the editor. This payload starts with the code `{"type":"graph","layoutMode":`.
7. Copy the content of the JSON payload into the **rootActivity** property of your JSON request.
8. Update the other properties of the JSON request, such as **name** and **description**.

The following example request creates an application process that deploys a component.

```
{
  "name": "My new application process",
  "application": "79f33ffb-9d72-4967-9146-dc252eaea706",
  "description": "New application process for command example",
  "inventoryManagementType": "AUTOMATIC",
  "offlineAgentHandling": "PRE_EXECUTION_CHECK",
  "rootActivity": {
    "type": "graph",
    "name": "GRAPH",
    "edges": [
      {
        "to": "Deploy component",
        "type": "ALWAYS",
        "value": ""
      },
      {
        "to": "FINISH",
        "from": "Deploy component",
        "type": "ALWAYS",
        "value": ""
      }
    ],
    "offsets": [
      {
        "name": "Deploy component",
        "x": "-35",
        "y": "210"
      },
      {
        "name": "FINISH",
        "x": "0",
        "y": "420"
      }
    ],
    "children": [
      {
        "componentName": "Component Y",
        "failFast": "false",
        "runOnlyOnFirst": "false",
        "maxIteration": "-1",
        "type": "componentEnvironmentIterator",
        "name": "Deploy component",
        "children": [
          {
            "componentName": "Component Y",
            "status": "Active",
            "type": "inventoryVersionDiff",
            "name": "inventoryVersionCheck",
            "children": [
              {
                "componentName": "Component Y",
                "componentProcessName": "Deploy Component Y",
                "allowFailure": false,
                "properties": {
                },
                "type": "componentProcess",
                "name": "Deploy component",
                "children": [
```

```
                ]
              }
            ]
          }
        ]
      },
      {
        "type": "finish",
        "name": "FINISH",
        "children": [
        ]
      }
    ],
    "propDefs": [
    ]
  }
}
```

createApplicationTemplate

Create an application template from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createApplicationTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Application template description
  (Optional)",
```

```
  "enforceCompleteSnapshots": "Specify true to require an
  explicit version for each component",
  "name": "Application template name",
  "notificationScheme": "Notification scheme (Optional)",
  "onlyChangedVersions": "If true, the 'Only Deploy
  Changed Versions' deployment option will be checked by
  default (default: true)",
  "tagRequirements": [
    {
      "name": "Name of the Component tag",
      "number": "Number of components for the tag",
      "type": "GREATER_THAN, LESS_THAN, or EQUALS"
    },
    " (Optional)"
  ],
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    " (Optional)"
  ],
  "useWizard": "Specify true to use the Deployment Wizard
  when submitting application process request (default:
  false)"
}
```

Related REST command: Create an application template from a JSON file.

createAuthToken

Create an authentication token

Tokens provide authentication for agents, users, and external systems or applications.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createAuthToken [parameters]
```

Parameters

Table 827. Parameters

Parameter	Type	Required	Description
user	string	true	The user this token is associated with
expireDate	string	true	Expiration date and time of the token, in the format MM-DD-YYYY-HH:mm
description	string	false	Description of the authorization token
allowedIps	string	false	Allowed IP addresses in CIDR notation, such as 192.169.1.0/24
restriction	string	false	Name or ID of auth token restrictions to apply to created auth token. Required if set by administrator.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createAuthToken
  -user admin
  -expireDate 12-31-2020-12:00
```

Example

Example response

```
{"token":"42ece458-b197-4c2e-92a0-c63e10fd9b4f"}
```

Related REST command: Create an authentication token.

createAuthenticationRealm

Create an AuthenticationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createAuthenticationRealm [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "authorizationRealmIds": ["AuthorizationRealms"],
  "description": "A descrption (optional)",
  "name": "AuthenticationRealm name",
  "properties": {
    "auth-endpoint": "OIDC: The URI for authorization with
  the OpenID Provider",
    "authentication-mech": "LDAP: Simple or DIGEST-MD5",
    "client-id": "OIDC: The Client ID which is registered
  with the OpenID Provider",
    "client-secret": "OIDC: The Client Secret which is
  provided by the OpenID Provider upon registration",
    "connection-name": "LDAP: The username to use for
  Simple binding to LDAP for searches. If not specified, an
  anonymous connection is made.",
    "connection-password": "LDAP: The password to use for
  Simple binding to LDAP for searches.",
    "email-claim": "OIDC: The claim containing the user's
  email.",
    "end-session-endpoint": "OIDC: Optional: The URI for
  RP-initiated logout",
    "end-session-id-token-hint": "OIDC: If an ID token
  hint parameter (id_token_hint) is appended to the End
  Session Endpoint URL.",
    "groups-delim": "SSO: A string that acts as the
  delimiter between groups that are passed in the headers.
  For example, if the user should be added to groups GROUP1
  and GROUP2, and the header value was \"GROUP=GROUP1;
  GROUP=GROUP2\" the delimiter would be ';'. Note: special
  regex characters such as '+' must be escaped with one
  backslash ''.",
    "groups-header": "SSO: The header name that denotes
  the user groups to which user will be added.",
    "groups-regex": "SSO: The regular expression to find
  the groups in the header value. If a capturing group is
  specified, only the first will be caught (per delimited
  string). If no capturing group is specified with
  parentheses, then the whole delimited string will be
  captured.",
    "issuer": "OIDC: The issuer identifier for the issuer
  of the token response.",
    "jwks-uri": "OIDC: The JSON Web Key Sets URI endpoint",
    "name-claim": "OIDC: The claim containing user's name.",
    "sasl-realm": "LDAP: The sasl Realm for DIGEST-MD5
  authentication",
    "token-endpoint": "OIDC: 'The URI for token requests
  with the OpenID Provider",
    "url": "LDAP: The URL of the LDAP server. It should
  begin with 'ldap://' or 'ldaps://'. Failover servers can
  be added by separating the URLs with a space. Example:
  ldap://ldap.mydomain.com:389 ldap://ldap.mydomain2.com",
    "user-base": "LDAP: When you search multiple
  directories, specify the starting directory that is used
  for searches, such as ou=employees,dc=mydomain,dc=com.",
```

```
    "user-pattern": "LDAP: LDAP users exist in a single
  directory; use a pattern to create the DN for users.",
    "user-search": "LDAP: The LDAP filter expression to
  use when searching for user directory entries. The
  username is put in place of {0} in the search pattern. If
  this is an attribute and not part of the user DN, wrap in
  parentheses. E.g. uid={0} or (sAMAccountName={0})",
    "user-search-subtree": "LDAP: Search the full subtree
  for the user, as opposed to a single-level search only
  covering users directly inside the specified search base.
  \"true\" or \"false\"",
    "userinfo-endpoint": "OIDC: The URI for userinfo
  requests with the OpenID Provider"
  },
  "type": [
    "Any one of:",
    "INTERNAL",
    "LDAP",
    "SSO",
    "OIDC"
  ]
}
```

Related REST command: Create an AuthenticationRealm.

createAuthorizationRealm

Create an AuthorizationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createAuthorizationRealm [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "A descrption (optional)",
  "name": "AuthorizationRealm name",
  "properties": {
    "authentication-mech": "LDAP: Simple or DIGEST-MD5",
    "connection-name": "LDAP: The username to use for
  Simple binding to LDAP for searches. If not specified, an
  anonymous connection is made.",
    "connection-password": "LDAP: The password to use for
  Simple binding to LDAP for searches.",
    "group-attribute": "LDAP: The name of the attribute
  that contains group names in the user directory entry.",
    "group-base": "LDAP: The base directory to execute
  group searches in.",
    "group-name": "LDAP: The name of the entry that
  contains the user's group names in the directory entries
```

```
  returned by the group search. If this is not specified, no
  group search will take place.",
    "group-search": "LDAP: The LDAP filter expression to
  use when searching for group entries. The username will be
  put in place of {1} in the search pattern and the full
  user DN will be put in place of {0}.",
    "group-search-iterative": "LDAP: Perform additional
  lookups to find indirectly assigned groups. This option
  may significantly increase the amount of time required to
  authenticate users. Consult your LDAP administrators
  before enabling this option.",
    "group-search-subtree": "LDAP: Search the full subtree
  for the groups, as opposed to a single-level search only
  covering groups directly inside the specified search
  base.",
    "groups-delim": "SSO: A string that acts as the
  delimiter between groups that are passed in the headers.
  For example, if the user should be added to groups GROUP1
  and GROUP2, and the header value was \"GROUP=GROUP1;

  covering users directly inside the specified search base.
  \"true\" or \"false\""
  },
  "type": [
    "Any one of:",
    "INTERNAL",
    "LDAP",
    "SSO"
  ]
}
```

Related REST command: Create an AuthorizationRealm.

createBlueprintDesignerIntegration

Create a blueprint designer integration from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createBlueprintDesignerIntegration [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Description",
  "name": "Blueprint Designer name or ID",
  "properties": {
    "landscaperPassword": "Landscaper password if
  useAdminCredentials is true",
    "landscaperUrl": "URL of Landscaper server",
    "landscaperUser": "Landscaper username if
  useAdminCredentials is true",
    "useAdminCredentials": "Boolean value true/false"
  }
}
```

Related REST command: Create a blueprint designer integration from a JSON file.

createComponent

Create a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createComponent [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "cleanupCountToKeep": "Number of most recent versions to
  keep; omit this parameter to inherit the system settings
  (Optional)",
  "cleanupDaysToKeep": "Number of days to keep versions;
  omit this parameter to inherit the system settings
```

```
  (Optional)",
  "defaultVersionType": "The default type to create
  versions with; valid values are FULL and INCREMENTAL",
  "description": "Description",
  "importAutomatically": "Specify true to import new
  versions automatically",
  "inheritSystemCleanup": "Inherit the system cleanup
  settings. If set to true, this overrides the other cleanup
  attributes. (Optional, Boolean)",
  "integrationAgent": "ID of the Agent to use for
  importing new component versions (Optional)",
  "integrationTag": "Tag name of the Agent to use for
  importing new component versions (Optional)",
  "name": "Component name or ID",
  "properties": {"Source configuration plugin property
  name": "Property value"},
  "sourceConfigPlugin": "The name of the source
  configuration plug-in to use (Optional)",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "templateId": "ID of the template to use (Optional)",
  "templateName": "Name of a template to use; this
  parameter is ignored if  templateId is specified
  (Optional)",
  "templateVersion": "Version number of the specified
  template (Optional)",
  "useVfs": "Boolean"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createComponent newComponent.json
```

Example

Example JSON requests

```
{
  "name": "My new component",
  "description": "New component for command example",
  "importAutomatically": false,
  "useVfs": true,
  "sourceConfigPlugin": "File System (Versioned)",
```

```
  "defaultVersionType": "FULL",
  "properties": {
    "FileSystemVersionedComponentProperties\/basePath":
    "/opt/newcomponent"
  }
}
```

The **properties** attribute in the JSON template refers to properties for the source configuration plug-in, not custom properties. For example, the following code creates a component from a Maven repository. It includes properties that are prefixed with `MavenComponentProperties` to refer to the properties for that plug-in.

```
{
  "name": "Component from Maven",
  "description": "New component for command example for Maven",
  "importAutomatically": false,
  "useVfs": false,
  "sourceConfigPlugin": "Maven",
  "defaultVersionType": "FULL",
  "properties": {
    "MavenComponentProperties\/artifactId":"MyArtifact",
    "MavenComponentProperties\/groupId":"MyGroup",
    "MavenComponentProperties\/extension":"ext",
    "MavenComponentProperties\/repoUrl":"http:\/\/myserver.com"
  }
}
```

To see the properties for a source configuration plug-in, create a component in the web interface and use the source configuration plug-in. Then, then export its information with the getComponent on page 2751 command. The JSON that this command returns includes the properties for the source configuration plug-in. You can also look in the `plugin.xml` file in the plug-in.

To create a component from a template, specify either the **templateId** attribute or the **templateName** attribute. Then, specify the **templateVersion** attribute; to use the most recent version of the template, specify an empty string. If the template contains property definitions, you can specify values for those properties with the attribute **`template/`***`propertyName`*, where *`propertyName`* is the name of the property. For example, the following JSON code creates a component from the most recent version of the **Template1** template. This code specifies the value `MyValue` for the parameter **template/MyProperty**.

```
{
  "name":"NewComponent1",
  "description":"",
  "templateName":"Template1",
  "templateVersion":"",
  "template/MyProperty":"MyValue",
  "componentType":"STANDARD",
  "sourceConfigPlugin":"",
  "importAutomatically":"false",
  "useVfs":"true",
  "defaultVersionType":"FULL",
  "importAgentType":"inherit",
  "inheritSystemCleanup":"true",
  "runVersionCreationProcess":"false",
  "properties":{},
  "teamMappings":[]
}
```

Example

Example response

```
{
  "id": "e84c7947-fad1-4399-8eb8-0d0d354b9e2b",
  "name": "My new component",
  "description": "New component for command example",
  "created": 1391456765556,
  "importAutomatically": false,
  "useVfs": true,
  "active": true,
  "deleted": false,
  "defaultVersionType": "FULL",
  "cleanupDaysToKeep": 0,
  "cleanupCountToKeep": 0,
  "tags": [
  ],
  "user": "admin"
}
```

Related REST command: Create a component.

createComponentProcess

Create a new component process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createComponentProcess [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "true",
  "component": "Component ID",
  "configActionType": "ADD",
  "defaultWorkingDir": "${p:resource/work.dir}/${p:
  component.name}",
  "description": "Description. This template includes two
  steps: Download Artifacts and Run Shell as a good starting
  point for your component process.",
  "inventoryActionType": "ADD",
  "name": "Name of the component process",
  "propDefs": [],
  "rootActivity": {
    "children": [
      {
        "allowFailure": false,
        "children": [],
```

```
      "commandName": "Download Artifacts",
      "impersonationUseSudo": false,
      "name": "First step",
      "pluginName": "Versioned File Storage",
      "pluginVersion": 16,
      "properties": {
        "artifactSetBaseDir": "",
        "compId": "${p:component.id}",
        "directoryOffset": ".",
        "fileExcludePatterns": "",
        "fileIncludePatterns": "**/*",
        "fullVerification": true,
        "label": "${p:version.name",
        "repositoryId": "${p:
component/code_station/repository}",
        "repositoryUrl": "${p:server.url}/vfs",
        "resId": "${p:resource.id}",
        "serverUrl": "${p:server.url}",
        "setFileExecuteBits": false,
        "syncMode": true,
        "verifyFileIntegrity": false
      },
      "showHidden": false,
      "type": "plugin",
      "useImpersonation": false
    },
    {
      "allowFailure": false,
      "children": [],
      "commandName": "Shell",
      "impersonationUseSudo": false,
      "name": "Second step",
      "pluginName": "Shell",
      "pluginVersion": 3,
      "properties": {
        "directoryOffset": ".",
        "outputFile": "",
        "runAsDaemon": false,
        "scriptBody": "echo \"Hello World\"",
        "shellInterpreter": ""
      },
      "showHidden": false,
      "type": "plugin",
      "useImpersonation": false
    },
    {
      "children": [],
      "name": "FINISH",
      "type": "finish"
    }
  ],
  "edges": [
    {
      "to": "First step",
      "type": "ALWAYS",

}
```

Related REST command: Create a new component process.

createComponentTemplate

Create a component template from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createComponentTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "componentType": "STANDARD or ZOS",
  "description": "Component template description",
  "importAutomatically": "Optional, boolean. Force
  components to import versions automatically (true) or
  never import automatically (false). Leave blank to specify
  value when component is created.",
  "integrationAgent": "ID of the Agent to use for
  importing new component versions (Optional)",
  "integrationTag": "Tag name of the Agent to use for
  importing new component versions (Optional)",
  "name": "Component template name or ID",
  "properties": {"Source configuration plugin property
  name": "Property value"},
  "sourceConfigPluginName": "Name of the source
  configuration type"
}
```

Related REST command: Create a component template from a JSON file.

createDeploymentTrigger

Create a deployment trigger.

This command creates a deployment trigger for the given environment, component, application process, and user.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createDeploymentTrigger [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationProcess": "Required. ID of the application
  process.",
  "component": "Required. Name or ID of the component.",
  "environment": "Required. ID of the environment.",
  "executingUser": "Required. Name or ID of the user to
  execute the deployment."
}
```

Related REST command: Create a deployment trigger..

createEnvironment

Create a new environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createEnvironment [parameters] [JSON file]
```

Parameters

Table 828. Parameters

Parameter	Type	Required	Description
application	string	false	Application to add the environment to
name	string	false	Name of the new environment
description	string	false	Description of the new environment
color	string	false	Color of the new environment, in hex format. For a REST call, URL encode the # symbol; for example, %23ff0000 for pure red. For a udclient command, put the color in hex format in quotes; for example '#ff0000'.
requireApprovals	boolean	false	Whether the environment requires approvals

Table 828. Parameters (continued)

Parameter	Type	Required	Description
noSelfApprovals	boolean	false	Whether the environment allows self approvals

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationId": "Application ID associated with the
  Environment template.",
  "cleanupCountToKeep": "Number of most recently deployed
  versions to keep (optional)",
  "cleanupDaysToKeep": "Number of days to keep versions
  deployed to this environment (optional)",
  "color": "HTML color code for the environment (optional)",
  "description": "Description (optional)",
  "exemptProcessesArray": "An array of process Ids. These
  processes will be exempt from approvals for this
  environment (optional).",
  "externalApprovalAgent": "Name or id of agent to run
  external approval processes on (optional).",
  "externalApprovalAgentPool": "Name or id of agent pool
  to run external approval processes on (optional).",
  "externalApprovalProcess": "Name or id of external
  approval process(optional).",
  "historyCleanupDaysToKeep": "Number of days to keep
  application process history for this environment
  (optional)",
  "inheritSystemCleanup": "Inherit the system cleanup
  settings. If set to true, this overrides the other cleanup
  attributes. (optional, boolean)",
  "lockSnapshots": "Whether snapshots will be locked when
  deployed to this environment (optional)",
  "name": "Environment name",
  "noSelfApprovals": "When this option is selected, users
  that submit deployment requests cannot approve their own
  requests (optional)",
  "requireApprovals": "Whether approvals will be required
  (optional)",
  "requireSnapshot": "If enabled, all deployments must use
  a snapshot instead of loose versions (optional)",
  "snapshotDaysToKeep": "Number of days to keep snapshots
  deployed to this environment (optional)",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
```

```
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "useSystemDefaultDays": "Whether or not to use the
  system default number of days to keep application process
  history for this environment (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createEnvironment
  -application JPetStore
  -name NewEnvironment
  -color '#ff0000'
```

Related REST command: Create a new environment.

createEnvironmentFromTemplate

Create a new environment from template

This command creates and Environment from a template and attaches it to the specified application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createEnvironmentFromTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationId": "Application ID associated with the
  Environment template.",
  "description": "Description (optional)",
  "name": "Environment name",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
```

```
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "templateId": "ID of the template to use, either this
  field or templateName are required.",
  "templateName": "Name of a template to use, either this
  field or templateId are required.",
  "templateProperties": [{
    "name": "The name of the property defined on the
  template. Required properties must be included here",
    "value": "Value of the property to set on the new
  environment"
  }]
}
```

Related REST command: Create a new environment from template.

createEnvironmentTemplate

Create a new environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createEnvironmentTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationTemplateId": "ID of the application template
  to which the environment template belongs",
  "cleanupCountToKeep": "Number of most recently deployed
  versions to keep (Optional)",
  "cleanupDaysToKeep": "Number of days to keep versions
  deployed to this environment (Optional)",
  "color": "HTML color code for the environment template",
  "description": "description of the template (Optional)",
  "environmentType": "type of environment, leave blank for
  Standard Environment",
  "exemptProcessesArray": "An array of process Ids. These
  processes will be exempt from approvals for this
  environment (Optional).",
  "externalApprovalAgent": "Name or id of agent to run
  external approval processes on (Optional).",
  "externalApprovalAgentPool": "Name or id of agent pool
  to run external approval processes on (Optional).",
  "externalApprovalProcess": "Name or id of external
  approval process(Optional).",
  "historyCleanupDaysToKeep": "Number of days to keep
  application process history for this environment
```

```
  (Optional)",
  "lockSnapshots": "Whether snapshots will be locked when
  deployed to this environment (Optional)",
  "name": "name of the environment template",
  "noSelfApprovals": "When this option is selected, users
  that submit deployment requests cannot approve their own
  requests (Optional)",
  "requireApprovals": "Whether approvals will be required
  (Optional)",
  "requireSnapshot": "If enabled, all deployments must use
  a snapshot instead of loose versions (Optional)",
  "resourceTemplate": "ID of the resource template to use",
  "snapshotDaysToKeep": "Number of days to keep snapshots
  deployed to this environment (Optional)",
  "snapshotLockType": "type of snapshot lock: ALL,
  VERSIONS, CONFIGURATION (Required with \"lockSnapshots\"",
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (Optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (Optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ],
  "useSystemDefaultDays": "Whether or not to use the
  system default number of days to keep application process
  history for this environment (Optional)"
}
```

Related REST command: Create a new environment template.

createGenericProcess

Create a generic process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createGenericProcess [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "defaultResourceId": "DEPRECATED, legacy format which is
```

```
single default resource ID.",
"defaultResourceIds": ["JSONArray of Default resource ID
(s) This property takes precedence when both
defaultResourceIds and defaultResourceId are present"],
"description": "Description. This template includes two
steps: Download Artifacts and Run Shell as a good starting
point for your process.",
"name": "Process name or ID",
"notificationScheme": "Name of notification scheme",
"propDefs": [{
  "allowedValues": [{"label": "value"}],
  "defaultLabel": "defaultLabel",

      },
      {
        "name": "Second step",
        "x": "-70",
        "y": "210"
```

```
      },
      {
        "name": "FINISH",
        "x": "-60",
        "y": "450"
      }
    ],
    "type": "graph"
  },
  "workingDir": "${p:resource/work.dir}/${p:process.name}"
}
```

Related REST command: Create a generic process.

createGroup

Create an empty group

Groups can only be created in Internal Storage authorization realms.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createGroup [parameters]
```

Parameters

Table 829. Parameters

Parameter	Type	Required	Description
group	string	true	Name of the group
description	string	false	Description of the group
authorizationRealm	string	true	Name of the Internal Storage authorization realm

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createGroup
  -group group1
  -authorizationRealm "Internal Security"
```

Note: Adding groups to LDAP and SSO realms is deprecated.

Example

Example response

```
{
  "id": "a5be904f-d65a-41ae-9bfd-0a0384c90eeb",
  "name": "group1",
  "enabled": true
}
```

Related REST command: Create an empty group.

createMaintenanceBlackout

Create a maintenance blackout for the given date range. The date range cannot overlap with any existing maintenance blackout date ranges.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createMaintenanceBlackout [parameters]
```

Parameters

Table 830. Parameters

Parameter	Type	Required	Description
startDate	string	true	The date the maintenance blackout starts. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time.
endDate	string	true	The date the maintenance blackout ends. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time.
name	string	false	(Optional) The name or description of the blackout.
recurrence	string	false	(Optional) A recurrence character for repeating blackouts (D - daily, W - weekly, M - monthly)

Related REST command: Create a maintenance blackout for the given date range.

createManyVersions

Create multiple component versions

Do not use the keywords latest, latestVersion, or newest as the version name.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createManyVersions [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"wrappedArray": [{
  "componentId": "Component identifier. If not specified
  componentName is required",
  "componentName": "Component name. If not specified
  componentId is required",
  "links": [{
    "isPriority": "Optional. If true, prioritize the link
  by placing it in the version page header for quicker
  access",
    "link": "Link url",
    "name": "Link name"
  }],
  "status": [{"name": "Status name"}],
  "version": "Version name to create"
}]}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createManyVersions
  newVersions.json
```

Example

Example JSON request

```
[
  {
    "version": "New version 1",
    "componentName": "MyComponent",
    "links": [
      {
        "name": "New link",
        "link": "http://www.foo.com"
      }
    ],
    "status": [
      {
        "name": "MyStatus"
      }
    ]
  },
  {
    "version": "New version 2",
    "componentName": "MyComponent",
    "links": [
      {
```

```
        "name": "New link",
        "link": "http://www.foo.com"
      }
    ],
    "status": [
      {
        "name": "MyStatus"
      }
    ]
  }
]
```

Related REST command: Create multiple component versions.

createPostProcessingScript

Create a post processing script from a JSON file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createPostProcessingScript [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "body": "The body of the script (required)",
  "description": "The description of the script (optional)",
  "name": "The name of the script (required)",
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ]
}
```

Related REST command: Create a post processing script from a JSON file.

createResource

Create a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createResource [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agent": "Name or ID of an agent to use for automation
  (Optional)",
  "agentPool": "Name or ID of an agent pool to use for
  automation (Optional)",
  "component": "Name or ID of a component to associate
  with the resource (Optional)",
  "componentTag": "Name or ID of a component tag to
  associate with the resource; any components with that tag
  can be deployed to this resource (Optional)",
  "description": "Description",
  "impersonationForce": "Specify true to prevent children
  or steps from specifying their own impersonation settings
  (Optional)",
  "impersonationGroup": "Group for default impersonation
  (Optional)",
  "impersonationPassword": "Password for default
  impersonation. Agents running on Linux and Unix machines
  will ignore this value (Optional)",
  "impersonationUseSudo": "Specify true to use the sudo
  command for impersonation. Agents running on Windows
  machines will ignore this value (Optional)",
  "impersonationUser": "User name for default
  impersonation (Optional)",
  "inheritTeam": "Whether or not to set inherit teams for
  resource. teamMappings will be ingored if true. Defaults
  to true (Optional)",
  "name": "Name for the new resource; leave blank to
  inherit the name from an agent, pool, or role",
  "parent": "ID or path to parent resource; leave blank to
  create a root resource (Optional)",
  "role": "Name or ID of a resource role to associate with
  the agent; if this resource is for a component, specify
  the component name instead (Optional)",
  "roleProperties": {"Property name": "Property value
  (Optional)"},
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
```

```
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createResource newResource.json
```

Example

Example JSON requests

This JSON request creates a new top-level resource:

```
{
  "name": "My new resource",
  "description": "New resource for command example"
}
```

This JSON request creates a resource group within an existing resource tree:

```
{
  "name": "New child resource",
  "description": "New resource for command example",
  "parent": "/TopLevelResource/subgroup"
}
```

This JSON request creates a component resource. In this case, the parent resource must be an agent resource.

```
{
    "name":"ComponentA",
    "role":"ComponentA",
    "description": "Description of ComponentA",
    "roleProperties": {"MyProp":"Value1"},
    "parent": "/TopLevelResource/agent1",
    "impersonationUser":"user1",
    "impersonationGroup":"group1",
    "impersonationPassword":"password",
    "impersonationUseSudo":false,
    "impersonationForce":true

}
```

This JSON request creates an agent resource. In this case, the **agentID** parameter is the ID of an agent.

```
{
  "agentId": "0ac81f92-aeb9-34ce-a6c5-93b6aed380f5",
  "name": "agent1",
  "parent": "/agents"
}
```

Example

Example response

```
{
  "id": "6a2b106b-ce03-44cd-88db-b89de202013c",
  "name": "My new resource",
  "path": "/My new resource",
  "active": true,
  "description": "New resource for command example",
  "inheritTeam": false,
  "impersonationPassword": "****",
  "impersonationUseSudo": false,
  "impersonationForce": false,
  "hasAgent": false,
  "tags": [
  ]
}
```

Related REST command: Create a resource.

createResourceTemplate

Create a resource template from a JSON file

This method supports importing a resource template from a cloud system.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createResourceTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "cloudResourceId": "ID of cloud resource; leave blank
  when not cloud-based template (Optional)",
  "connection": "ID of cloud connection; leave blank when
  not cloud-based template (Optional)",
  "description": "Description",
  "isVsys": "Specify 'true' when cloud resource is Virtual
  System Pattern (non-classic) in IPAS 2.0 or ICO 2.0 cloud
  product, otherwise specify 'false' when cloud resource is
  using Weaver (for IWD, SCO, ICO, and IPAS versions before
  2.0 and 'classic' virtual system pattern in IPAS 2.0 or
  ICO 2.0); leave blank when not cloud-based template
  (Optional)",
  "name": "Name for the resource template",
  "parentId": "ID of parent resource template; leave blank
  when none or creating cloud-based template (Optional)",
  "rootTeamMappings": "Array of team ids; if not
```

```
  specified, no teams will be mapped to Root Resource;
  format: [ {teamId: '<ID-of-team-1>'}, {teamId: '<ID-of-
  team-2>'}, ... ]; (Optional)",
  "teamMappings": "Array of team ids; if not specified, no
  teams will be mapped to Template; format: [ {teamId: '<ID-
  of-team-1>'}, {teamId: '<ID-of-team-2>'}, ... ];
  (Optional)"
}
```

Related REST command: Create a resource template from a JSON file.

createResourceTemplateWithAgentPrototypes

Create a resource template with agent prototypes from a JSON file

This method supports creating a resource template with multiple agent prototypes

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createResourceTemplateWithAgentPrototypes [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agentPrototypes": [{
    "agentNamePatterns": "List of name patterns (one per
  line) for matching agents; (Optional)",
    "componentTags": "List of component tags to be mapped
  to the prototype; format: [ {componentTag: '<name-or-id-of-
  comp-tag-1>'}, {componentTag: '<name-or-id-of-comp-tag-
  2>'}, ... ]; (Optional)",
    "components": "List of components to be mapped to the
  prototype; format: [ {component: '<name-or-ID-of-comp-
  1>'}, {component: '<name-or-ID-of-comp-2>'}, ... ];
  (Optional)",
    "description": "Description",
    "name": "Name for the agent prototype",
    "teamMappings": "Array of team ids; if not specified,
  no teams will be mapped to Template; format: [ {teamId:
  '<ID-of-team-1>'}, {teamId: '<ID-of-team-2>'}, ... ];
  (Optional)"
  }],
  "description": "Description",
  "name": "Name for the resource template",
  "teamMappings": "Array of team ids; if not specified, no
  teams will be mapped to Template; format: [ {teamId: '<ID-
  of-team-1>'}, {teamId: '<ID-of-team-2>'}, ... ];
  (Optional)"
}
```

Related REST command: Create a resource template with agent prototypes from a JSON file.

createSnapshot

Create a snapshot

This command creates a snapshot by specifying the components (optional, by IDs and/or names) for the snapshot, rather than taking a snapshot of an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createSnapshot [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Application name or ID",
  "description": "Description",
  "name": "Snapshot name",
  "versions": "JSON array of mappings from components by
  name or ID to versions by name or ID, such as [{\"
  JPetStore-APP\": \"latest\"}, {\"JPetStore-DB\": \"1.0\"},
  {\"3d6cd2fd-3381-4b95-b851-1aa7f83e225e\":\"c2c61215-c20a-
  4bc9-8f34-7f9f41de385b\"}]"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createSnapshot newSnapshot.json
```

Example

Example JSON request

```
{
  "name": "My snapshot",
  "application": "JPetStore",
  "description": "JPetStore snapshot",
  "versions": [
    {"JPetStore-APP": "1.1"},
    {"JPetStore-DB": "1.0"},
    {"JPetStore-WEB": "1.1"}
  ]
}
```

Example

Example JSON request

You can also use the keywords `latest`, `latestVersion`, and `newest` in place of component version names. In this case, the process uses the most recently created component version. The following example shows how you can use these keywords in the JSON request.

```
{
  "name": "My snapshot",
  "application": "JPetStore",
  "description": "Snapshots of most recently created component versions",
  "versions": [
    {"JPetStore-APP": "latest"},
    {"JPetStore-DB": "latestVersion"},
    {"JPetStore-WEB": "newest"}
  ]
}
```

Example

Example response

```
{
  "id": "ff9274d4-bc3d-493c-90aa-5020e2fda56d",
  "name": "My snapshot",
  "description": "JPetStore snapshot",
  "created": 1391451659050,
  "active": true,
  "locked": false
}
```

Related REST command: Create a snapshot.

createSnapshotOfEnvironment

Take a snapshot of an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createSnapshotOfEnvironment [parameters]
```

Parameters

Table 831. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID

Table 831. Parameters (continued)

Parameter	Type	Required	Description
name	string	true	Name of the new snapshot
description	string	false	Snapshot description
excludeUnmapped	boolean	false	Exclude components with no resource in this environment (default false)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createSnapshotOfEnvironment
  -environment newEnvironment
  -application JPetStore
  -name NewSnapshot
```

Example

Example response

```
{
  "id": "41eab076-deb6-4746-8b2d-9f491103a06c",
  "name": "NewSnapshot"
}
```

Related REST command: Take a snapshot of an environment.

createStatus

Create a status

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createStatus [parameters]
```

Parameters

Table 832. Parameters

Parameter	Type	Required	Description
type	string	true	Type of status (inventory, version, or snapshot)
status	string	true	Name of the new status

Table 832. Parameters (continued)

Parameter	Type	Required	Description
color	string	false	Color of the new status (HTML color strings or valid color names) (Optional)
description	string	false	Description of the new status (Optional)
unique	string	false	Specify true to make this status unique (Optional)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createStatus
  -type version
  -status Documented
  -color "#0077FF"
```

Example

Example response

```
{
  "id": "abff7bb6-bf95-417e-bf00-b0a8678e832a",
  "type": "VERSION",
  "name": "Documented",
  "active": true,
  "color": "#0077FF",
  "unique": false
}
```

Related REST command: Create a status.

createTeam

Create a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createTeam [parameters]
```

Parameters

Table 833. Parameters

Parameter	Type	Required	Description
team	string	true	Name of the team

Table 833. Parameters (continued)

Parameter	Type	Required	Description
description	string	false	Description of the team

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createTeam
  -team MyNewTeam
  -description "MyNewTeamDescription"
```

Example

Example response

```
{
  "id": "769c2486-ed40-4a3a-ac52-faa33d30cfd5",
  "name": "MyNewTeam",
  "description": "MyNewTeamDescription",
  "isDeletable": true
}
```

Related REST command: Create a team.

createUser

Create a user

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createUser [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "authenticationRealm": "Authentication realm ID",
  "email": "Email address",
  "name": "User name",
  "password": "Password"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createUser
  newUser.json
```

Example

Example JSON request

```
{
  "name": "jsmith",
  "password": "password",
  "actualName": "Jane Smith",
  "email": "jsmith@example.org",
  "authenticationRealm": "Internal Security"
}
```

Example

Example response

```
{
  "id": "2507eaaf-c98e-46ee-936d-bc538bee9dc4",
  "name": "jsmith",
  "actualName": "Jane Smith",
  "displayName": "Jane Smith (jsmith)",
  "email": "jsmith@example.org",
  "deleted": false,
  "deletedDate": 0,
  "authenticationRealm": "20000000000000000000000000000001",
  "isLockedOut": false,
  "isDeletable": true
}
```

Related REST command: Create a user.

createVaultAppRole

Create a new Vault App Role

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createVaultAppRole [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "The Vault App Role Name (Required, Unique per
```

```
  Vault store)",
  "roleId": "The Vault Role ID (Required)",
  "secretId": "The Vault Secret ID (Optional)",
  "store": "Name/ID of the Vault store (Required)"
}
```

Related REST command: Create a new Vault App Role.

createVaultCertificate

Create a new Vault Certificate

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createVaultCertificate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "certificatePEM": "The certificate to be stored in PEM
  format(Required)",
  "name": "The Vault Certificate Name (Required, Unique
  per Vault store)",
  "privateKeyPEM": "The private key to be stored in PEM
  format(Required)",
  "store": "Name/ID of the Vault store (Required)"
}
```

Related REST command: Create a new Vault Certificate.

createVaultLdapUser

Create a new Vault Ldap User

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createVaultLdapUser [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "The Vault Ldap User Name (Required, Unique per
  Vault store)",
```

```
  "password": "The Vault Ldap Users password (Optional)",
  "store": "Name/ID of the Vault store (Required)"
}
```

Related REST command: Create a new Vault Ldap User.

createVaultSecretStore

Create a secret store.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createVaultSecretStore [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Secret Store description",
  "name": "Secret Store name",
  "namespace": "Vault Server Namespace (optional)",
  "teamMappings": {
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  },
  "type": "vault",
  "url": "Vault Server URL"
}
```

Related REST command: Create a secret store..

createVersion

Create a component version

Do not use the keywords latest, latestVersion, or newest as the version name.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createVersion [parameters]
```

Parameters

Table 834. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the new version
description	string	false	Description of the new version
type	string	false	Type to use for the new version (incremental or full) - full is the default.
sourceConfigExecutionRecordId	string	false	A system parameter. This should not be provided by the user or by user scripts.
importing	boolean	false	Whether or not to mark this version as importing. Version marked as importing cannot be used in deployments. Default false

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  createVersion
  -component JPetStore-APP
  -name 1.2
```

Example

Example response

```
{
  "id": "c0198aaf-6f4b-4d2e-b103-a7f6a257f580",
  "name": "1.2",
  "type": "FULL",
  "created": 1390572847946,
  "active": true,
  "archived": false
}
```

Related REST command: Create a component version.

createWebhookTemplate

Create a new webhook template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  createWebhookTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "body": "The webhook template body specified with Apache
  Velocity template syntax",
  "description": "Description (Optional)",
  "name": "Name of the new webhook template",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the webhook
  template to, either this field or teamId are needed to
  specify a team"
  }],
  "type": "Webhook template type [PROCESS_SUCCESS,
  PROCESS_FAILURE, PROCESS_STARTED, APPROVAL_COMPLETED,
  APPROVAL_FAILED, EXTERNAL_APPROVAL_COMPLETED,
  EXTERNAL_APPROVAL_FAILED, SCHEDULED_PROCESS_NOT_STARTED,
  TASK_CREATED]"
}
```

Related REST command: Create a new webhook template.

deleteAgent

Delete an agent

Agents should be shut down before deletion.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAgent [parameters]
```

Parameters

Table 835. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteAgent
  -agent Agent1
```

Related REST command: Delete an agent.

deleteAgentPool

Delete an agent pool

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAgentPool [parameters]
```

Parameters

Table 836. Parameters

Parameter	Type	Required	Description
pool	string	true	Name or ID of the agent pool

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteAgentPool
  -pool Pool1
```

Related REST command: Delete an agent pool.

deleteAgentProperty

Remove a property from an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAgentProperty [parameters]
```

Parameters

Table 837. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteAgentProperty
  -agent Agent1
  -name Prop1
```

Related REST command: Remove a property from an agent.

deleteAllDesiredInventoryVersions

Delete all versions for a component in an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAllDesiredInventoryVersions [parameters]
```

Parameters

Table 838. Parameters

Parameter	Type	Required	Description
deleteVersions	boolean	false	If set to true, versions will be removed from the environment's inventory.
retainDays	int	false	If set to greater than 0, inventory will only be removed if created more than this many days ago.
environmentId	string	true	
componentId	string	true	Name or ID of the component

Related REST command: Delete all versions for a component in an environment.

deleteApplication

Delete an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteApplication [parameters]
```

Parameters

Table 839. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Related REST command: Delete an application.

deleteApplicationPipeline

Delete an application pipeline

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteApplicationPipeline [parameters]
```

Parameters

Table 840. Parameters

Parameter	Type	Required	Description
application	string	false	Application name or id. Required if pipeline specified by name.
pipeline	string	true	Pipeline name or id.

Related REST command: Delete an application pipeline.

deleteApplicationProcess

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteApplicationProcess [parameters]
```

Parameters

Table 841. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
processName	string	true	Name of the application process

Related REST command: Delete an application process.

deleteApplicationTemplate

Delete an application template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteApplicationTemplate [parameters]
```

Parameters

Table 842. Parameters

Parameter	Type	Required	Description
applicationTemplate	string	true	Name or ID of the application

Related REST command: Delete an application template.

deleteAuthenticationRealm

Delete an AuthenticationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAuthenticationRealm
```

Parameters

Table 843. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the AuthenticationRealm

Related REST command: Delete an AuthenticationRealm.

deleteAuthorizationRealm

Delete an AuthorizationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteAuthorizationRealm [parameters]
```

Parameters

Table 844. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the authorization realm

Related REST command: Delete an AuthorizationRealm.

deleteBlueprintDesignerIntegration

Delete a blueprint designer integration

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteBlueprintDesignerIntegration [parameters]
```

Parameters

Table 845. Parameters

Parameter	Type	Required	Description
patternIntegration	string	true	UUID or Name of the Blueprint Pattern Integration

Related REST command: Delete a blueprint designer integration.

deleteComponent

Delete a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteComponent [parameters]
```

Parameters

Table 846. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Related REST command: Delete a component.

deleteComponentVersionPropDef

Delete a component version property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteComponentVersionPropDef [parameters]
```

Parameters

Table 847. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the property to delete

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteComponentVersionPropDef
  -component JPetStore-APP
  -name Prop1
```

Related REST command: Delete a component version property.

deleteDeploymentTrigger

Delete a deployment trigger.

This command deletes a deployment trigger with the given ID.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteDeploymentTrigger
```

Parameters

Table 848. Parameters

Parameter	Type	Required	Description
deploymentTriggerId	string	true	ID of the deployment trigger.

Related REST command: Delete a deployment trigger..

deleteEnvironment

Delete an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteEnvironment [parameters]
```

Parameters

Table 849. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
deleteAttachedResources	boolean	false	Specify true to delete all resources in this environment, including all subresources. If this value and 'deleteCloudInstances' is set to true, then all agent objects in use by this environment will be deleted when the agent goes offline. (Optional)

Table 849. Parameters (continued)

Parameter	Type	Required	Description
deleteCloudInstances	boolean	false	Specify true to delete any associated instances in the cloud provider; this parameter is valid only for environments that were created dynamically along with the environment (Optional)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteEnvironment
  -application JPetStore
  -environment NewEnvironment
```

Related REST command: Delete an environment.

deleteEnvironmentGate

Delete the environment gate of a given environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteEnvironmentGate [parameters]
```

Parameters

Table 850. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of environment
application	string	false	Name or ID of application (required if environment is specified by name)

Related REST command: Delete the environment gate of a given environment.

deleteEnvironmentTemplate

Delete an environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteEnvironmentTemplate [parameters]
```

Parameters

Table 851. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	ID of the environment template

Related REST command: Delete an environment template.

deleteEnvironmentTemplateGate

Delete the environment gate of a given environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteEnvironmentTemplateGate [parameters]
```

Parameters

Table 852. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	Name or ID of environment template
applicationTemplate	string	false	Name or ID of application template (required if environment template is specified by name)

Related REST command: Delete the environment gate of a given environment template.

deleteFrontendServer

Delete a frontend server.

Used to remove frontend servers which are no longer active.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteFrontendServer
```

Parameters

Table 853. Parameters

Parameter	Type	Required	Description
serverId	string	true	Unique id of the server from installed.properties.

Related REST command: Delete a frontend server..

deleteGroup

Delete a group

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteGroup [parameters]
```

Parameters

Table 854. Parameters

Parameter	Type	Required	Description
group	string	true	Name of the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteGroup
  -group group1
```

Related REST command: Delete a group.

deleteJavaPackage

Delete a java package.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteJavaPackage [parameters]
```

Parameters

Table 855. Parameters

Parameter	Type	Required	Description
package	string	true	Name or ID of the java package

Related REST command: Delete a java package..

deleteMaintenanceBlackout

Cancel the given maintenance blackout. If it is a real event (synthetic=false) in a recurring, only the individual event is canceled. Synthetic events cannot be cancelled with this API.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteMaintenanceBlackout
```

Parameters

Table 856. Parameters

Parameter	Type	Required	Description
id	string	true	The id of the maintenance blackout to cancel.

Related REST command: Cancel the given maintenance blackout.

deletePostProcessingScript

Delete a post processing script.

Used to remove processing scripts.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deletePostProcessingScript [parameters]
```

Parameters

Table 857. Parameters

Parameter	Type	Required	Description
script	string	true	Name/ID of the post processing script.

Related REST command: Delete a post processing script..

deleteRedundantDesiredInventoryVersions

Delete all redundant versions for a component in an environment

A version is considered redundant if all of its files have been replaced by versions that have been deployed more recently to the same environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteRedundantDesiredInventoryVersions [parameters]
```

Parameters

Table 858. Parameters

Parameter	Type	Required	Description
deleteRedundant	boolean	false	If set to true, redundant versions will be removed from the environment's inventory.
retainDays	int	false	If set to greater than 0, inventory will only be removed if created more than this many days ago.
environmentId	string	true	
componentId	string	true	Name or ID of the component

Related REST command: Delete all redundant versions for a component in an environment.

deleteResource

Delete a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteResource [parameters]
```

Parameters

Table 859. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Example

Example

```
udclient  -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteResource
  -resource "/ResourceGroup/My resource"
```

Note: When you specify the name of the resource, type the complete path to the resource, including the initial '/' character if the resource is not in any higher-level group.

Related REST command: Delete a resource.

deleteResourceProperty

Delete a resource property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteResourceProperty [parameters]
```

Parameters

Table 860. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)

Table 860. Parameters (continued)

Parameter	Type	Required	Description
application	string	false	Name or ID of the application (Required to look up blueprint by name)
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteResourceProperty
  -resource "/ResourceGroup/My resource"
  -name property1
```

Note: When you specify the name of the resource, type the complete path to the resource, including the initial '/' character if the resource is not in any higher-level group.

Related REST command: Delete a resource property.

deleteResourceRoleProperty

Delete a resource role property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteResourceRoleProperty [parameters]
```

Parameters

Table 861. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
name	string	true	Name of the property

Related REST command: Delete a resource role property.

deleteSecretStore

Delete a secret store.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteSecretStore [parameters]
```

Parameters

Table 862. Parameters

Parameter	Type	Required	Description
store	string	true	Name or id of the secret store.

Related REST command: Delete a secret store..

deleteServerKeystoreEntry

Delete a server keystore entry

Deletes an entry from the server keystore which contains key pairs and certificates used for agent communication. This keystore is the file at path appdata/conf/server.keystore. A 409 Conflict status is returned if the alias no longer corresponds to the same certificate at the time of the request. If the alias was never present or was removed concurrently, this operation reports success.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteServerKeystoreEntry [parameters]
```

Parameters

Table 863. Parameters

Parameter	Type	Required	Description
alias	string	true	The alias that will be removed.
certificateFingerprint	string	true	The certificate fingerprint that must match to check for concurrent modification.

Related REST command: Delete a server keystore entry.

deleteSnapshot

Delete a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteSnapshot [parameters]
```

Parameters

Table 864. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteSnapshot
  -application MyApplication
  -snapshot Snapshot1
```

Related REST command: Delete a snapshot.

deleteStatus

Delete a status

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteStatus [parameters]
```

Parameters

Table 865. Parameters

Parameter	Type	Required	Description
type	string	false	Type of status (inventory, version, or snapshot); this parameter is required you specify the name of the status instead of the ID
status	string	true	Name or ID of the status

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteStatus
  -type version
  -status Tested
```

Related REST command: Delete a status.

deleteTeam

Delete a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteTeam [parameters]
```

Parameters

Table 866. Parameters

Parameter	Type	Required	Description
team	string	true	Name of the team

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteTeam
  -team MyNewTeam
```

Related REST command: Delete a team.

deleteUser

Delete a user

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteUser [parameters]
```

Parameters

Table 867. Parameters

Parameter	Type	Required	Description
user	string	true	Name/ID of the user. The name will be case-sensitive if a case-sensitive realm is provided.
realm	string	false	Limit any user name search to given AuthenticationRealm.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteUser
  -user jsmith
```

Related REST command: Delete a user.

deleteVaultAppRole

Delete a Vault AppRole

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteVaultAppRole [parameters]
```

Parameters

Table 868. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultAppRole	string	true	Name or ID of the Vault App Role

Related REST command: Delete a Vault AppRole.

deleteVaultCertificate

Delete a Vault Certificate

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteVaultCertificate [parameters]
```

Parameters

Table 869. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultCertificate	string	true	Name or ID of the Vault Certificate

Related REST command: Delete a Vault Certificate.

deleteVaultLdapUser

Delete a Vault Ldap User

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteVaultLdapUser [parameters]
```

Parameters

Table 870. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Store ID/Name
vaultLdapUser	string	true	Name or ID of the Vault Ldap User

Related REST command: Delete a Vault Ldap User.

deleteVersion

Delete a version from a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteVersion [parameters]
```

Parameters

Table 871. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component
version	string	true	Name or ID of the version(s) to be deleted. This option can be repeated to delete multiple versions.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  deleteVersion
  -component MyComponent
  -version 1.0
```

Related REST command: Delete a version from a component.

deleteWebhookTemplate

Delete a webhook template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  deleteWebhookTemplate [parameters]
```

Parameters

Table 872. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	Name or ID of the webhook template to remove

Related REST command: Delete a webhook template.

downloadJavaPackage

Download available Java package.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  downloadJavaPackage [parameters]
```

Parameters

Table 873. Parameters

Parameter	Type	Required	Description
package	string	true	Name or ID of the java package

Related REST command: Download available Java package..

downloadVersionArtifacts

Download the artifacts of a component version

This command exports the artifacts of a component version into an archive file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  downloadVersionArtifacts [parameters]
```

Parameters

Table 874. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version
location	string	true	Path to download the artifacts to. You must have permission to create files in this location.
singleFilePath	string	false	Optional path to an individual version artifact to download. If specified, only that file will be downloaded.
encoding	string	false	Optional character encoding to determine the file names of the artifacts. Defaults to the encoding of the file system.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  downloadVersionArtifacts
  -component JPetStore-WEB
  -version 1.0
  -location .
```

Related REST command: Download the artifacts of a component version.

executeApplicationPipeline

Execute an application pipeline

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  executeApplicationPipeline [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Application name or id. Only required
  when pipeline is referenced by name.",
  "pipeline": "Pipeline name or id",
  "snapshot": "Name or id of snapshot. Only snapshot or
  versions should be specified.",
  "versions": [{
    "component": "Name or id of component. Required when
  version referenced by name",
    "version": "Version name or id."
  }]
}
```

Related REST command: Execute an application pipeline.

exportApplication

Export an application to a json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportApplication [parameters]
```

Parameters

Table 875. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Related REST command: Export an application to a json file..

exportApplicationProcess

Export an application process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportApplicationProcess [parameters]
```

Parameters

Table 876. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
applicationProcess	string	true	Name of the process

Example

Command to export an application process in JSON format

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  exportApplicationProcess
  -application JPetStore
  -applicationProcess "Deploy JPetStore"
```

Example

Response

```
File written to: ./application-process-Deploy JPetStore.json
```

Related REST command: Export an application process.

exportComponent

Export a component to a json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportComponent [parameters]
```

Parameters

Table 877. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Related REST command: Export a component to a json file..

exportComponentProcess

Export a component process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportComponentProcess [parameters]
```

Parameters

Table 878. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
componentProcess	string	true	Name or ID of the component process

Related REST command: Export a component process.

exportComponentTemplate

Export a component template to a json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportComponentTemplate [parameters]
```

Parameters

Table 879. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template

Example

Command to export a component template process in YAML format

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  exportComponentTemplateProcess
  -componentTemplate JPetStoreTemplate
  -componentProcess "Deploy JPetStore Comp"
```

Example

Response

```
File written to: ./component-process-Deploy JPetStore Comp.yml
```

Related REST command: Export a component template to a json file..

exportComponentTemplateProcess

Export a component template process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportComponentTemplateProcess [parameters]
```

Parameters

Table 880. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template
componentProcess	string	true	Name or ID of the component process

Related REST command: Export a component template process.

exportDetailedGroup

List the members of a group (detailed)

This command lists the members of a group, including IDs and e-mail addresses.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportDetailedGroup [parameters]
```

Parameters

Table 881. Parameters

Parameter	Type	Required	Description
group	string	true	Name of the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  exportDetailedGroup
  -group teamA
```

Example

Example response

```
[
  {
    "userName": "jdoe",
    "userId": "a459dffd-e057-494d-b119-16e85d7cd911",
    "userEmail": "jdoe@example.org"
  },
  {
    "userName": "jsmith",
    "userId": "7794dee7-d4c6-4f6f-b1ce-56c5d3cbfdda",
    "userEmail": "jsmith@example.org"
  }
]
```

Related REST command: List the members of a group (detailed).

exportGenericProcess

Export a process to a json file

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportGenericProcess [parameters]
```

Parameters

Table 882. Parameters

Parameter	Type	Required	Description
process	string	true	Name or ID of the generic process

Related REST command: Export a process to a json file.

exportGroup

List the members of a group

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportGroup [parameters]
```

Parameters

Table 883. Parameters

Parameter	Type	Required	Description
group	string	true	Name of the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  exportGroup
  -group group1
```

Example

Example response

```
{
  "name": "group1",
  "users": [
    "jsmith",
    "jdoe"
```

```
  ]
}
```

Related REST command: List the members of a group.

exportSnapshot

Export a snapshot to a zip file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  exportSnapshot [parameters]
```

Parameters

Table 884. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Related REST command: Export a snapshot to a zip file..

finishedImporting

Mark a version as completed importing

Mark a version as completed importing so it is available for use in deployments

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  finishedImporting [parameters]
```

Parameters

Table 885. Parameters

Parameter	Type	Required	Description
version	string	true	Name or id of version
component	string	false	Name or id of the component. This is required if version name is used

Related REST command: Mark a version as completed importing.

forceCancelWorkflow

Force cancel a workflow in progress

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  forceCancelWorkflow [parameters]
```

Parameters

Table 886. Parameters

Parameter	Type	Required	Description
workflow	string	true	ID of the workflow to force cancel.

Related REST command: Force cancel a workflow in progress.

forceRenameAgent

Rename an agent

Rename an agent. Use this command if running the agent configuration script in the agent bin directory is not convenient. Only the administrator can run this method.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  forceRenameAgent [parameters]
```

Parameters

Table 887. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent to rename
name	string	true	The new name for the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  forceRenameAgent
```

```
  -agent Agent1
  -name NewAgentName
```

Related REST command: Rename an agent.

forgetAgentCert

Forget Agent Certificates

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  forgetAgentCert [parameters]
```

Parameters

Table 888. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent. This can be repeated for multiple agents.

Related REST command: Forget Agent Certificates.

getAgent

Get information about an agent

This command returns a JSON representation of an agent.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgent [parameters]
```

Parameters

Table 889. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
```

```
  getAgent
  -agent Agent1
```

Example

Example response

```

  }
}
```

Related REST command: Get information about an agent.

getAgentJavaHomes

Get list of managed Java installations

This command returns a list of managed Java installations for an agent.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentJavaHomes [parameters]
```

Parameters

Table 890. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Related REST command: Get list of managed Java installations.

getAgentMaintenanceTask

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentMaintenanceTask [parameters]
```

Parameters

Table 891. Parameters

Parameter	Type	Required	Description
task	string	true	ID of maintenance task

Related REST command: Get agent maintenace task.

getAgentMaintenanceTasks

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentMaintenanceTasks [parameters]
```

Parameters

Table 892. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Related REST command: Get agent maintenace tasks.

getAgentPool

Get information about an agent pool

Returns a JSON representation of an agent pool.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentPool [parameters]
```

Parameters

Table 893. Parameters

Parameter	Type	Required	Description
pool	string	true	Name or ID of the agent pool

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAgentPool
  -pool Pool1
```

Example

Example response

```
{
  "id": "8bfa2e62-2376-466c-91c5-3f79b3e6f655",
  "name": "Pool1",
  "active": true,
  "description": "",
```

```
  "status": "ONLINE",
  "security": {
    "read": true,
    "write": true
  },
  "agentIds": "897fa851-fab1-455f-bd84-fe83ae43c441,bdc2019c-78ae-403c-a528-22b31ae3c183",
  "extendedSecurity": {
    "read": true,
    "write": true,

    "Edit Agent Pools": true,
    "View Agent Pools": true,
    "teams": [
      {
        "teamId": "ea307e2e-d6be-4092-a7e8-e8e02274de7e",
        "teamLabel": "My team"
      }
    ]
  }
}
```

Related REST command: Get information about an agent pool.

getAgentPools

Get information about all agent pools

Return a JSON representation of all agent pools.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentPools [parameters]
```

Parameters

Table 894. Parameters

Parameter	Type	Required	Description
active	boolean	false	

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAgentPools
```

Example

Example response

```
[
  {
    "id": "11dda768-525d-4055-a7d2-5fb0e86ad236",
    "name": "Pool1",
    "active": true,
    "description": "",
    "status": "ONLINE"
  },
  {
    "id": "8bfa2e62-2376-466c-91c5-3f79b3e6f655",
    "name": "Pool2",
    "active": true,
    "description": "",
    "status": "ONLINE"
  }
]
```

Related REST command: Get information about all agent pools.

getAgentProperty

Get the value of a property on an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentProperty [parameters]
```

Parameters

Table 895. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAgentProperty
  -agent Agent1
  -name JAVA_HOME
```

Related REST command: Get the value of a property on an agent.

getAgentPrototypes

Get all agent prototypes with this resource template as their ancestor

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentPrototypes [parameters]
```

Parameters

Table 896. Parameters

Parameter	Type	Required	Description
template	string	true	Name or ID of resource template

Related REST command: Get all agent prototypes with this resource template as their ancestor.

getAgentStatuses

Returns a JSONObject with count of agents to status. Expected format: { "ONLINE":4, "UPGRADE_RECOMMENDED":1 }
Requires Settings Tab permission

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgentStatuses
```

Parameters

None.

Related REST command: Get agent statuses.

getAgents

Get information about all agents

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAgents [parameters]
```

Parameters

Table 897. Parameters

Parameter	Type	Required	Description
active	boolean	false	

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAgents
```

Example

Example response

```
[
  {
    "id": "bdc2019c-78ae-403c-a528-22b31ae3c183",
    "name": "Agent1",
    "active": true,
    "licensed": false,
    "licenseType": "NONE",
    "status": "ONLINE",
    "version": "6.0.1.0.452394",
    "workingDirectory": "/opt/devops-deploy/agent/var/work/",
    "impersonationPassword": "****",
    "impersonationForce": false,
    "tags": [
    ]
  }
]
```

Related REST command: Get information about all agents.

getAllApplicationProcessesForApplication

Get all application processes of an application

Returns a JSON representation of all application processes for a specific application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllApplicationProcessesForApplication [parameters]
```

Parameters

Table 898. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Related REST command: Get all application processes of an application.

getAllComponentProcessRequestCount

Get all component process requests submitted after a certain time

This command returns a count of all the component process requests submitted after a certain time.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllComponentProcessRequestCount [parameters]
```

Parameters

Table 899. Parameters

Parameter	Type	Required	Description
submittedAfter	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server counts all CPRs that were created after the specified timestamp.
includeGhosted	boolean	false	True or false, whether to include ghosted components in the result.

Related REST command: Get all component process requests submitted after a certain time.

getAllComponentsForTemplate

Get a list of all components using this template

This command returns a JSON representation of a list of components.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllComponentsForTemplate [parameters]
```

Parameters

Table 900. Parameters

Parameter	Type	Required	Description
template	string	true	Name or ID of the component template

Related REST command: Get a list of all components using this template.

getAllLatestDesiredInventory

Get all of the latest desired inventory for an environment.

This command returns a JSON array of all of the desired inventory for an environment. It optionally groups the desired inventory by component.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllLatestDesiredInventory
```

Parameters

Table 901. Parameters

Parameter	Type	Required	Description
environmentId	string	true	Name or ID of the environment
groupVersions	boolean	true	True if the versions should be grouped by component.

Related REST command: Get all of the latest desired inventory for an environment..

getAllProcesses

Get information on all generic processes

This command returns a JSON representation of all generic processes.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllProcesses
```

Parameters

None.

Related REST command: Get information on all generic processes.

getAllTeams

List teams

This command lists all teams on the server, all users in each team, and all of the roles that each user has on each team.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllTeams
```

Parameters

None.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAllTeams
```

Example

Example response

```

```

Related REST command: List teams.

getAllUsersInRoleForTeam

List all users with a given role on a team

This command returns all users in a role for a given team, including users that are associated via a group membership

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllUsersInRoleForTeam [parameters]
```

Parameters

Table 902. Parameters

Parameter	Type	Required	Description
role	string	true	Name or id of the role
team	string	true	Name or id of the team

Related REST command: List all users with a given role on a team.

getAllUsersWithEmail

Get all users with a given e-mail address

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAllUsersWithEmail [parameters]
```

Parameters

Table 903. Parameters

Parameter	Type	Required	Description
email	string	true	E-mail address of the user

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  allUsersWithEmail
  -email jsmith@us.ibm.com
```

Example

Example response

```
[{"id":"bade154b-c8c9-4aa6-a875-4b56d7132be5","name":"jsmith"},
{"id":"2c1c9012-2111-4d6a-b5f0-b6cabff94713","name":"janesmith"}]
```

Related REST command: Get all users with a given e-mail address.

getApplication

Get information about an application

This command returns a JSON representation of an application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplication [parameters]
```

Parameters

Table 904. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplication
  -application JPetStore
```

Example

Example response

```
{
  "id": "c8a45972-da39-4450-87f0-21fae710e0f5",
  "name": "JPetStore",
  "description": "",

    "Run Component Processes": true,
    "View Applications": true,
    "teams": [
    ]
  }
}
```

Related REST command: Get information about an application.

getApplicationPipeline

Get an application pipeline definition

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationPipeline [parameters]
```

Parameters

Table 905. Parameters

Parameter	Type	Required	Description
application	string	false	Application name or id. Required if pipeline specified by name.
pipeline	string	true	Pipeline name or id.

Related REST command: Get an application pipeline definition.

getApplicationPipelineExecution

Get an application pipeline execution

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationPipelineExecution [parameters]
```

Parameters

Table 906. Parameters

Parameter	Type	Required	Description
executionId	string	false	Id of the pipeline execution.

Related REST command: Get an application pipeline execution.

getApplicationPipelineExecutions

Get a list of up to 100 application pipeline executions

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationPipelineExecutions [parameters]
```

Parameters

Table 907. Parameters

Parameter	Type	Required	Description
application	string	false	Application name or id. Required if pipeline argument is a name.

Table 907. Parameters (continued)

Parameter	Type	Required	Description
pipeline	string	false	Pipeline name or id.
startIndex	int	false	Index of the first result to return. At most 100 results will be returned.
dateRangeBegin	long	false	Specifies the date range beginning in miiliseconds since epoch.
dateRangeEnd	long	false	Specifies the date range end in miiliseconds since epoch.

Related REST command: Get a list of up to 100 application pipeline executions.

getApplicationPipelines

Get a list of up to 100 application pipelines

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationPipelines [parameters]
```

Parameters

Table 908. Parameters

Parameter	Type	Required	Description
application	string	true	Application name or id.
startIndex	int	false	Index of first pipeline to be returned.

Related REST command: Get a list of up to 100 application pipelines.

getApplicationProcess

Get information about an application process

Returns a JSON representation of an application process.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcess [parameters]
```

Parameters

Table 909. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
applicationProcess	string	true	Name of the process

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProcess
  -application JPetStore
  -applicationProcess "Deploy JPetStore"
```

Example

Example response

```
{
  "id": "b02d0960-e878-45b5-88d9-7461159f0e19",
  "name": "Deploy JPetStore",

}
```

Related REST command: Get information about an application process.

getApplicationProcessExecution

Get an application process request's activity trace.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessExecution
```

Parameters

Table 910. Parameters

Parameter	Type	Required	Description
request	string	true	The ID of the application process request.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProcessExecution
  -request 151cd268-ef32-4e55-903b-86ee66314e1e
```

Related REST command: Get an application process request's activity trace..

getApplicationProcessRequest

Get information about a specific application process request

This command retrieves a specific application process request by id.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessRequest
```

Parameters

Table 911. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the application process request.

Related REST command: Get information about a specific application process request.

getApplicationProcessRequestProperties

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessRequestProperties
```

Parameters

Table 912. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the application process request.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProcessRequest
  -requestID 134t52le97-3f75-6783-333f-3b54d48c8d88
```

Example

Example response for a manual task approval

```
"tasks": [
     {
       "id": "19523fdc-3f75-6783-333f-3b54d48c8d88",
       "name": "Environment Approval for Test",
       "commentRequired": false,
       "commentPrompt": "Env MTask",

       "comment": ""
     }
   ]
```

Related REST command: Get application process request properties.

getApplicationProcessRequestStatus

Request the status of an application process request

Will return both the status of the request (which indicates if it is still running) and the request result (which indicates the result of the process if it completed).

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessRequestStatus [parameters]
```

Parameters

Table 913. Parameters

Parameter	Type	Required	Description
request	string	true	ID of the application process request

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProcessRequestStatus
  -request 47610d75-25c8-420d-a696-f006c34f5423
```

Example

Example response

```
{
  "status": "CLOSED",
  "result": "SUCCEEDED"
}
```

This command returns the following statuses:

- `CANCELING`
- `CLOSED`
- `COMPENSATING`
- `EXECUTING`
- `FAULTED`
- `FAULTING`
- `INITIALIZED`
- `PENDING`
- `UNINITIALIZED`

This command returns the following results:

- `APPROVAL REJECTED`
- `AWAITING APPROVAL`
- `CANCELED`
- `COMPENSATED`
- `FAILED TO START`
- `FAULTED`
- `NONE`

- `SCHEDULED FOR FUTURE`
- `SUCCEEDED`
- `UNINITIALIZED`

Related REST command: Request the status of an application process request.

getApplicationProcessRequestVersions

Get the Versions for an application process request

Get the Versions for an application process request

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessRequestVersions
```

Parameters

Table 914. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the application process request.

Related REST command: Get the Versions for an application process request.

getApplicationProcessUnfilledProperties

List properties that must be specified for a process

If a snapshot name or ID is specified, results include any component process steps which have some properties marked to receive values later for a specific version based on the snapshot.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProcessUnfilledProperties [parameters]
```

Parameters

Table 915. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Table 915. Parameters (continued)

Parameter	Type	Required	Description
processName	string	true	Name of the application process
snapshot	string	false	Name or ID of the snapshot (optional)
environment	string	false	Get the properties based on if they were deployed to the specified environment (optional)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProcessUnfilledProperties
  -application MyApplication
  -processName MyProcess
```

Example

Example response

```
[
  {
    "id": "decc3570-17ae-4b46-b640-6a7180edafa9",
    "name": "MyProperty",
    "label": "MyProperty",
    "pattern": "",
    "type": "TEXT",
    "value": "",
    "required": false,
    "description": "",
    "placeholder": ""
  }
]
```

Related REST command: List properties that must be specified for a process.

getApplicationProperties

Get all application properties and their values.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProperties [parameters]
```

Parameters

Table 916. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProperties
  -application JPetStore
```

Example

Example response

```
[
  {
    "id": "8b383d28-f64f-4f94-8ea1-1e85a323f527",
    "name": "Prop1",
    "value": "value1",
    "description": "",
    "secure": false
  },
  {
    "id": "e3a54008-6c73-4c72-b197-72b830b2ac6d",
    "name": "Prop2",
    "value": "value2",
    "description": "",
    "secure": false
  },
  {
    "id": "cce49826-a236-4bee-a8f4-cd015f2a6e8b",
    "name": "Prop3",
    "value": "value3",
    "description": "",
    "secure": false
  }
]
```

Related REST command: Get all application properties and their values..

getApplicationProperty

Get the value of a custom property on a application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationProperty [parameters]
```

Parameters

Table 917. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationProperty
  -application JPetStore
  -name Prop1
```

Related REST command: Get the value of a custom property on a application.

getApplicationTemplate

Get information about an application template

This command returns a JSON representation of an application template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationTemplate [parameters]
```

Parameters

Table 918. Parameters

Parameter	Type	Required	Description
applicationTemplate	string	true	Name or ID of the application template

Related REST command: Get information about an application template.

getApplicationTemplatePropDefs

Get information about the property definitions for the application template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationTemplatePropDefs [parameters]
```

Parameters

Table 919. Parameters

Parameter	Type	Required	Description
applicationTemplate	string	true	Name or ID of the application template

Related REST command: Get information about the property definitions for the application template.

getApplicationTemplates

Get information about all application templates on the server

This command returns a JSON representation of all application templates.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationTemplates
```

Parameters

None.

Related REST command: Get information about all application templates on the server.

getApplications

Get information about all applications on the server

This command returns a JSON representation of all applications.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplications
```

Parameters

None.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplications
```

Example

Example response

```
[
  {
    "id": "c8a45972-da39-4450-87f0-21fae710e0f5",
    "name": "JPetStore",
    "description": "",
    "created": 1387378155981,
    "enforceCompleteSnapshots": false,
    "active": true,
    "tags": [
    ],
    "user": "admin"
  },
  {
    "id": "b0d47a25-c90e-4286-8b9e-6a08a1da45bc",

    "description": "",
    "created": 1390502070483,
    "enforceCompleteSnapshots": false,
    "active": true,
    "tags": [
    ],
    "user": "admin"
  }
]
```

Related REST command: Get information about all applications on the server.

getApplicationsProcessRequests

Get information about all application process requests on the server

This command returns a JSON representation of all application process requests, up to a maximum of 100.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationsProcessRequests [parameters]
```

Parameters

Table 920. Parameters

Parameter	Type	Required	Description
startedAfter	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server includes the application process requests that were created after the specified timestamp.
startIndex	int	false	An index number that specifies the application process request to start with. You can use this index number to page through results.

Table 920. Parameters (continued)

Parameter	Type	Required	Description
useExecutionTime	boolean	false	Set to true to use execution start time instead of submission time for startedAfter

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationsProcessRequests
  -startedAfter 1471603999000
  startIndex 200
```

Example

Example response

```

  }
]
```

Related REST command: Get information about all application process requests on the server.

getApplicationsProcessRequestsCount

Count all application process requests

This command returns the total number of application process requests for all applications.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApplicationsProcessRequestsCount [parameters]
```

Parameters

Table 921. Parameters

Parameter	Type	Required	Description
startedAfter	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server counts all application process requests that were created after the specified timestamp.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getApplicationsProcessRequestsCount
  -startedAfter 1471603999000
```

Example

Example response

```
{
  "appProcReqCount": 223
}
```

Related REST command: Count all application process requests.

getApprovalTasks

List recent approval tasks

This command returns the approval tasks that have been modified since the given time.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getApprovalTasks [parameters]
```

Parameters

Table 922. Parameters

Parameter	Type	Required	Description
modifiedAfter	long	false	Include approval tasks that have been created or edited since this provided time. (Optional)

Related REST command: List recent approval tasks.

getAuthToken

Get details for an authentication token

Returns the details for a specific authentication token identified by database ID or token secret. Only metadata for the token is returned; the token secret itself is not available. Only users with 'Manage Security' permission can use this function for a token they do not own.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthToken [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"token": "Authentication token ID or secret"}
```

Example

Example command to get auth tokens using a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAuthToken filename.json
```

Example

JSON example

```
{
  "token": "194dba21-0199-cddb-1f04-4ad922fc5385"
}
```

Related REST command: Get details for an authentication token.

getAuthTokens

Get all auth tokens

Returns a page of authentication token details out of the list of all tokens. Only metadata for the tokens is returned; the token secrets themselves are not available. Pages are numbered starting at 1 and a page can range from 1 to 100 tokens. Only users with 'Manage Security' permission can use this function.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthTokens [parameters]
```

Parameters

Table 923. Parameters

Parameter	Type	Required	Description
page	int	true	Page number starting at 1
pageSize	int	true	Page size starting at 1 and to at most 100

Example

Example command to get auth tokens by pagination

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAuthTokens
  -page 1
  -pageSize 10
```

Related REST command: Get all auth tokens.

getAuthTokensForUser

Get active authentication tokens for user

Returns the list of authorization tokens for a user. Only metadata for the tokens is returned; the token secrets themselves are not available. Only users with 'Manage Security' permission can use this function for users other than themselves.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthTokensForUser [parameters]
```

Parameters

Table 924. Parameters

Parameter	Type	Required	Description
user	string	false	The user for which tokens are returned. Required if querying tokens for a user other than the one making the request.

Example

Example command to get auth tokens of a specific user

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getAuthTokensForUser
  -user jsmith
```

Example

Example response for a specific user

```
{
  "tokens": [{
    "id": "194dba1b-ff4a-473e-19a8-c96d1246b690",
    "expiration": 1740208500000,
    "host": "",
    "description": "dummyuser",
    "createdDate": 1738851598324,
    "verbToUrls": [{
      "verb": "ALL",
      "url": "*"
    }]
  }],
  "userId": "a51fe9df-9625-48c2-bd01-4b50acf4c72b",
  "userName": "jsmith"
}
```

Related REST command: Get active authentication tokens for user.

getAuthenticationRealm

Get information about an AuthenticationRealm

This command returns a JSON representation of an AuthenticationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthenticationRealm
```

Parameters

Table 925. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the AuthenticationRealm

Related REST command: Get information about an AuthenticationRealm.

getAuthenticationRealms

Get information about all AuthenticationRealms

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthenticationRealms
```

Parameters

None.

Related REST command: Get information about all AuthenticationRealms.

getAuthorizationRealm

Get information about an AuthorizationRealm

This command returns a JSON representation of an AuthorizationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthorizationRealm [parameters]
```

Parameters

Table 926. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the AuthorizationRealm

Related REST command: Get information about an AuthorizationRealm.

getAuthorizationRealms

Get information about all AuthorizationRealms

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAuthorizationRealms
```

Parameters

None.

Related REST command: Get information about all AuthorizationRealms.

getAvailablePlugins

Get a list of all available plugins for installing into the server.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getAvailablePlugins
```

Parameters

None.

Related REST command: Get available plug-ins.

getBlueprintNodePropertiesTemplate

Get blueprint properties

This command returns a JSON template of the properties that are required to provision a blueprint.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getBlueprintNodePropertiesTemplate [parameters]
```

Parameters

Table 927. Parameters

Parameter	Type	Required	Description
blueprint	string	true	Name or ID of the blueprint
application	string	false	Name of the application; this parameter is required if you specify the blueprint name instead of ID

Related REST command: Get blueprint properties.

getBlueprintsInApplication

Get all blueprints in an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getBlueprintsInApplication [parameters]
```

Parameters

Table 928. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getBlueprintsInApplication
  -application JPetStore
```

Example

Example response

```
[
  {
    "id": "7e0a196f-41ca-40e8-aed8-4f47cafcedc9",
    "name": "My blueprint",
    "description": ""
  },
  {
    "id": "362cfc88-e5f7-4d98-aaee-a53edec5c8d2",
    "name": "Other blueprint",
    "description": ""
  }
]
```

Related REST command: Get all blueprints in an application.

getComponent

Get information about a component

This command returns a JSON representation of a component.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponent [parameters]
```

Parameters

Table 929. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponent
  -component JPetStore-APP
```

Example

Example response

```

Related REST command: Get information about a component.

getComponentEnvironmentProperties

Get component environment properties for an environment

These properties are defined on the component and their values are set on the environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentEnvironmentProperties [parameters]
```

Parameters

Table 930. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment

Table 930. Parameters (continued)

Parameter	Type	Required	Description
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
component	string	true	Name or ID of the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentEnvironmentProperties
  -component JPetStore-APP
  -environment 1f97af86-cde3-4ba2-803b-0e4580dcc05b
```

Example

Example response

```
[
  {

    "name": "Environment property 1",
    "value": "false",
    "description": "",
    "secure": false
  }
]
```

Related REST command: Get component environment properties for an environment.

getComponentProcess

Get information about a component process

This command returns a JSON representation of a component process.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProcess [parameters]
```

Parameters

Table 931. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
componentProcess	string	true	Name or ID of the component process
draft	boolean	false	Whether to get the latest draft process. Default is false

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentProcess
  -component JPetStore-APP
  -componentProcess "Deploy application component"
```

Example

Example response

```
{
  "id": "c59721d1-a02c-4b3f-9eb7-bde5358210d0",
  "name": "Deploy application component",
  "description": "",

}
```

Related REST command: Get information about a component process.

getComponentProcessRequest

Get information about a specific component process request

Generally used as an endpoint to retrieve APRs that were scheduled in advance.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProcessRequest
```

Parameters

Table 932. Parameters

Parameter	Type	Required	Description
requestID	string	true	The ID of the component process request.

Related REST command: Get information about a specific component process request.

getComponentProcessRequestCount

Get the number of component process requests submitted after a certain time given a specified component

This command returns a count of all the component process requests of a specific componentsubmitted after a certain time.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProcessRequestCount [parameters]
```

Parameters

Table 933. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
submittedAfter	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server counts all CPRs that were created after the specified timestamp.

Related REST command: Get the number of component process requests submitted after a certain time given a specified component.

getComponentProcessRequests

Get information about all component process requests

This command returns a JSON representation of a list of up to 100 component process requests at a time.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProcessRequests [parameters]
```

Parameters

Table 934. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
submittedAfter	long	false	Time value that marks the oldest CPR we want to retrieve.

Related REST command: Get information about all component process requests.

getComponentProperties

Get values for component properties

This command returns all component properties.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProperties [parameters]
```

Parameters

Table 935. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentProperties
  -component JPetStore-APP
```

Example

Example response

```
[
  {
```

```
    "id": "3702f391-09e1-4550-903a-d5ae286c94aa",
    "name": "Prop1",
    "value": "value1",
    "description": "",
    "secure": false
  }
]
```

Related REST command: Get values for component properties.

getComponentProperty

Get the value of a property on a component. Property names can be prefixed to specify which set of propertieswill be searched. Unprefixed properties will search custom 'Component Properties' on a component while a propertynamed such as template/propertyName will search the properties inherited from a component templates property definitions.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentProperty [parameters]
```

Parameters

Table 936. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the property.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentProperty
  -component JPetStore-APP
  -name Prop1
```

Related REST command: Get the value of a property on a component.

getComponentTemplatePropDefs

Get information about the property definitions for the component template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentTemplatePropDefs [parameters]
```

Parameters

Table 937. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template

Related REST command: Get information about the property definitions for the component template.

getComponentTemplates

Get information about all component templates on the server

This command returns a JSON representation of all component templates.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentTemplates
```

Parameters

None.

Related REST command: Get information about all component templates on the server.

getComponentVersionPropDefs

List the version property definitions for a component

These properties are available to each version of the component.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentVersionPropDefs [parameters]
```

Parameters

Table 938. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentVersionPropDefs
  -component JPetStore-APP
```

Example

Example response

```
[
  {
    "id": "870bc2f5-55e2-4cb9-b3ab-f750688754b9",
    "name": "Prop1",
    "label": "Prop1",
    "pattern": "",
    "type": "CHECKBOX",
    "value": "true",
    "required": false,
    "description": ""
  },
  {
    "id": "ee02cbf0-9fc9-465e-a37f-754c40222d0d",

    "label": "",
    "pattern": "",
    "type": "TEXT",
    "value": "prop2",
    "required": false,
    "description": ""
  }
]
```

Related REST command: List the version property definitions for a component.

getComponentVersions

Get the versions of a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentVersions [parameters]
```

Parameters

Table 939. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Table 939. Parameters (continued)

Parameter	Type	Required	Description
inactive	boolean	false	Specify true to include archived versions; the default is false
numResults	int	false	Specify a number greater than 0 to limit the number of results. If numResults is not specified, or is given to be < 1, no limit is applied.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentVersions
  -component MyComponent
```

Example

Example response

```
[
  {

]
```

Related REST command: Get information about all components on the server.

getComponentsInApplication

Get all components in an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getComponentsInApplication [parameters]
```

Parameters

Table 941. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getComponentsInApplication
  -application JPetStore
```

Example

Example response

```

```

Related REST command: Get all components in an application.

getConfigurableAgentLicenseTypes

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getConfigurableAgentLicenseTypes
```

Parameters

None.

Related REST command: Get configurable agent license types.

getCurrentActivityList

Returns all child workflows of a parent request id if specified else returns all running workflow activities.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getCurrentActivityList [parameters]
```

Parameters

Table 942. Parameters

Parameter	Type	Required	Description
parentRequestId	string	false	Parent request id. If specified, this returns any child workflows running under the process request.

Related REST command: Get all child workflows of a parent request id.

getDatabaseLatency

Gather statistics by runnning a database latency test. Result times are in milliseconds. This may take several seconds.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getDatabaseLatency
```

Parameters

None.

Related REST command: Gather statistics by runnning a database latency test.

getDeploymentTrigger

Get information about a single deployment trigger.

This command returns a JSON representation of a single deployment trigger.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getDeploymentTrigger
```

Parameters

Table 943. Parameters

Parameter	Type	Required	Description
deploymentTriggerId	string	true	ID of the deployment trigger.

Related REST command: Get information about a single deployment trigger..

getDeploymentTriggers

Get information about all deployment triggers for an environment.

This command returns a JSON representation of all deployment triggers for an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getDeploymentTriggers [parameters]
```

Parameters

Table 944. Parameters

Parameter	Type	Required	Description
environment	string	true	ID of the environment.

Related REST command: Get information about all deployment triggers for an environment..

getEnvironment

Get information about an environment

This command returns a JSON representation of an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironment [parameters]
```

Parameters

Table 945. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name of the application; this value is required if you specify the environment name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getEnvironment
  -application JPetStore
  -environment "Tutorial environment 1"
```

Example

Example response

```
{
  "id": "1f97af86-cde3-4ba2-803b-0e4580dcc05b",

      }
    ]
  }
}
```

Related REST command: Get information about an environment.

getEnvironmentBaseResources

Get all base resources for an environment

This command returns a listing of all resources added as base resources to an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentBaseResources [parameters]
```

Parameters

Table 946. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name of the application; this value is required if you specify the environment name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getEnvironmentBaseResources
  -application JPetStore
  -environment "Tutorial environment 1"
```

Example

Example response

```
[
  {

    "type": "agent",
    "status": "ONLINE",
    "hasAgent": true,
    "tags": [
    ]
  }
]
```

Related REST command: Get all base resources for an environment.

getEnvironmentCompliancy

Get an inventory compliancy report for an environment.

Returns an inventory compliancy report for an environment. By default, it returns the complete inventory organized by component and then by version. Alternatively, it can return a summary of inventory compliancy counts

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentCompliancy [parameters]
```

Parameters

Table 947. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; optional if the environment is referenced by ID
summary	boolean	false	True to get a summary of environment compliance. The default is false.

Related REST command: Get an inventory compliancy report for an environment..

getEnvironmentGate

Get the environment gate of a given environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentGate [parameters]
```

Parameters

Table 948. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of environment
application	string	false	Name or ID of application (required if environment is specified by name)

Related REST command: Get the environment gate of a given environment.

getEnvironmentProperties

Get environment property values

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentProperties [parameters]
```

Parameters

Table 949. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getEnvironmentProperties
  -application JPetStore
  -environment "Tutorial environment 1"
```

Example

Example response

```
[
  {
```

```
    "id": "9dbcf2f6-a96e-4ee5-ba65-07c5fa8422c9",
    "name": "db.url",

    "name": "tomcat.manager.url",
    "value": "http://localhost:8080/manager",
    "description": "",
    "secure": false
  },
  {
    "id": "167fa275-bb95-460b-97b2-e27e713a1400",
    "name": "tomcat.start",
    "value": "/opt/apache-tomcat-6.0.37/bin/startup.sh",
    "description": "",
    "secure": false
  }
]
```

Related REST command: Get environment property values.

getEnvironmentProperty

Get the value of a custom property on an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentProperty [parameters]
```

Parameters

Table 950. Parameters

Parameter	Type	Required	Description
name	string	true	Name of the property
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getEnvironmentProperty
  -application JPetStore
  -environment "Tutorial environment 1"
  -name tomcat.start
```

Related REST command: Get the value of a custom property on an environment..

getEnvironmentResourceTree

Get resource tree for an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentResourceTree [parameters]
```

Parameters

Table 951. Parameters

Parameter	Type	Required	Description
includeSecurity	boolean	false	Include security json. Not including security json can be much faster. Defaults to true.
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application. This is required when using environment name.

Related REST command: Get resource tree for an environment.

getEnvironmentTemplate

Get information about an environment template

This command returns a JSON representation of an environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentTemplate [parameters]
```

Parameters

Table 952. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	ID of the environment template

Related REST command: Get information about an environment template.

getEnvironmentTemplateGate

Get the environment gate of a given environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentTemplateGate [parameters]
```

Parameters

Table 953. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	Name or ID of environment template
applicationTemplate	string	false	Name or ID of applicationTemplate (required if environment template is specified by name)

Related REST command: Get the environment gate of a given environment template.

getEnvironmentTemplatePropDefs

Get information about the property definitions for the environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentTemplatePropDefs [parameters]
```

Parameters

Table 954. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	ID of the environment template

Related REST command: Get information about the property definitions for the environment template.

getEnvironmentsInApplication

Get information about all environments in an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getEnvironmentsInApplication [parameters]
```

Parameters

Table 955. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getEnvironmentsInApplication
  -application JPetStore
```

Example

Example response

```
[
  {
    "id": "1f97af86-cde3-4ba2-803b-0e4580dcc05b",
    "name": "Tutorial environment 1",
    "description": "",
    "color": "#ffffff",
    "requireApprovals": false,
    "lockSnapshots": false,
    "calendarId": "e237199e-8bbc-497e-97eb-ca2568dff91c",
    "active": true,
    "cleanupDaysToKeep": 0,
```

```
    "cleanupCountToKeep": 0,
    "conditions": [
    ]
  }
]
```

Related REST command: Get information about all environments in an application.

getExternalApprovalProcess

Get information about an external approval process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getExternalApprovalProcess [parameters]
```

Parameters

Table 956. Parameters

Parameter	Type	Required	Description
externalApprovalProcess	string	true	Name or ID of the external approval process

Related REST command: Get information about an external approval process.

getExternalApprovalProcesses

Get all external approval processes

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getExternalApprovalProcesses
```

Parameters

None.

Related REST command: Get all external approval processes.

getFirstUserWithEmail

Get the first user with a given e-mail address

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getFirstUserWithEmail [parameters]
```

Parameters

Table 957. Parameters

Parameter	Type	Required	Description
email	string	true	E-mail address of the user

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  firstUserWithEmail
  -email jsmith@us.ibm.com
```

Example

Example response

```
{"id":"2c1c9012-2111-4d6a-b5f0-b6cabff94713","name":"janesmith"}
```

Related REST command: Get the first user with a given e-mail address.

getFrontendServers

Get a list of frontend servers.

Get information about all frontend servers.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getFrontendServers
```

Parameters

None.

Related REST command: Get a list of frontend servers..

getHighWatermarks

Return high watermarks for agent usage

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getHighWatermarks
```

Parameters

None.

Related REST command: Return high watermarks for agent usage.

getInstalledPlugins

Get a list of all currently installed plugins.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getInstalledPlugins
```

Parameters

None.

Related REST command: Get installed plug-ins.

getInventoryChangesForSnapshot

Get inventory changes for application process run with snapshot in environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getInventoryChangesForSnapshot [parameters]
```

Parameters

Table 958. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of snapshot
application	string	true	Name or ID of the application
environment	string	true	Name or ID of environment
applicationProcess	string	true	Name or ID of application process

Related REST command: Get inventory changes for application process run with snapshot in environment.

getJavaPackage

Get available Java packages.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getJavaPackage [parameters]
```

Parameters

Table 959. Parameters

Parameter	Type	Required	Description
package	string	true	Name or ID of the java package

Related REST command: Get available Java packages..

getJavaPackages

Get available Java packages.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getJavaPackages
```

Parameters

None.

Related REST command: Get available Java packages..

getJavaPackagesForAgent

Get Java packages compatible with a specific agent.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getJavaPackagesForAgent [parameters]
```

Parameters

Table 960. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Related REST command: Get Java packages compatible with a specific agent..

getLLMVendorModels

Gets the list of supported models for the given vendor.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getLLMVendorModels [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "accessTokenEndpoint": "The uri for getting an access
  token for authenticating with the LLM if neccessary.",
  "apiKey": "The API Key provided by the LLM Vendor. This
  may be required for Vendors such as Watsonx and OpenAI.",
  "endpoint": "The base URI pointing to the LLM provider
  API. Required.",
  "organization": "The organization if exists.",
  "project": "The project id if exists.",
  "vendor": "The name of the LLM Vendor. Options for this
  are returned by the getVendors endpoint. Required."
}
```

Related REST command: Gets the list of supported models for the given vendor..

getLLMVendors

Gets the list of supported LLM vendors.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getLLMVendors
```

Parameters

None.

Related REST command: Gets the list of supported LLM vendors..

getLatestDesiredInventory

Get the latest desired inventory for an environment.

This command returns a JSON array of all of the desired inventory for an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getLatestDesiredInventory
```

Parameters

Table 961. Parameters

Parameter	Type	Required	Description
environmentId	string	true	Name or ID of the environment

Related REST command: Get the latest desired inventory for an environment..

getLatestSnapshotForEnvironment

Get the latest snapshot deployed to an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getLatestSnapshotForEnvironment [parameters]
```

Parameters

Table 962. Parameters

Parameter	Type	Required	Description
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
environment	string	true	Name or ID of the environment

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getLatestSnapshotForEnvironment
  -application MyApplication
  -environment MyEnvironment
```

Example

Example response

```
{
  "id": "2ef3189b-af8f-49f1-8476-a3d4ed440722",
  "name": "Snap5",
  "created": 1441388592826,
  "active": true,
  "versionsLocked": false,
  "configLocked": false,
  "applicationId": "2d741420-fd31-443d-95eb-472d334f8ec9",
  "user": "admin"
}
```

Related REST command: Get the latest snapshot deployed to an environment.

getLoggingConfig

Get logging configuration

Returns the current logging configuration. The output is suitable for input to the setLoggingConfig command.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getLoggingConfig
```

Parameters

None.

Related REST command: Get logging configuration.

getMaintenanceBlackouts

Returns a list of all real and synthetic maintenance blackouts that start or end within the specified range. If no range is provided then all real maintenance blackouts will be returned (synthetic blackouts are not returned as the result would be infinite).

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getMaintenanceBlackouts [parameters]
```

Parameters

Table 963. Parameters

Parameter	Type	Required	Description
rangeStart	string	false	Start time of the search range. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time. (Optional) If rangeStart is provided then rangeEnd must also be provided

Table 963. Parameters (continued)

Parameter	Type	Required	Description
rangeEnd	string	false	End time of the search range. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time. (Optional)

Related REST command: Get a list of all real and synthetic maintenance blackouts that start or end within a specified range.

getOpenIDConnectRealms

Get all realms that support OpenID Connect login.

This command returns a list of all enabled authentication realms that support OpenID Connect login. This includes LDAP realms with the OpenID login mechanism configured.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getOpenIDConnectRealms
```

Parameters

None.

Related REST command: Get all realms that support OpenID Connect login..

getOverlappingArtifacts

Get all artifacts overlapped in the given version

Get all artifacts that are overlapped by later versions. A version is considered safe to rollback if it does not contain overlapping artifacts. It is risky to roll back a version if that version contains overlapping artifacts. This command applies only to z/OS component versions.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getOverlappingArtifacts
```

Parameters

Table 964. Parameters

Parameter	Type	Required	Description
resourceId	string	true	Name or ID of the resource

Table 964. Parameters (continued)

Parameter	Type	Required	Description
versionId	string	true	Name or ID of the version to check risky status
environmentId	string	true	Name or ID of the environment
componentId	string	true	Name or ID of the component

Related REST command: Get all artifacts overlapped in the given version.

getPostProcessingScript

Get information about a post processing script

This command returns a JSON representation of a post processing script.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getPostProcessingScript [parameters]
```

Parameters

Table 965. Parameters

Parameter	Type	Required	Description
script	string	true	Name/ID of the script

Related REST command: Get information about a post processing script.

getPostProcessingScripts

Get a list of post processing scripts.

Get information about post processing scripts.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getPostProcessingScripts
```

Parameters

None.

Related REST command: Get a list of post processing scripts..

getPreferredJavaPackageForAgent

Get the preferred Java package compatible with an agent.

This command gets the preferred Java package compatible with the platform of an agent. If no such package is currently defined, then no content is returned.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getPreferredJavaPackageForAgent [parameters]
```

Parameters

Table 966. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Related REST command: Get the preferred Java package compatible with an agent..

getProcessRequest

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getProcessRequest
```

Parameters

Table 967. Parameters

Parameter	Type	Required	Description
requestId	string	true	Id of process request

Related REST command: Get process request from request ID.

getProcessRequests

Get information about all generic process requests on the server

This command returns a JSON representation of all generic process requests, up to a maximum of 100.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getProcessRequests [parameters]
```

Parameters

Table 968. Parameters

Parameter	Type	Required	Description
startTime	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server includes the process requests that were created after the specified timestamp. Defaults to 24 hours ago.
endTime	long	false	A timestamp, in milliseconds from the UNIX epoch. If you specify this parameter, the server includes the process requests that were created before the specified timestamp. Defaults to the current time.
startIndex	int	false	An index number that specifies the application process request to start with. You can use this index number to page through results.

Related REST command: Get information about all generic process requests on the server.

getRelayStatuses

Returns a JSONObject with count of agent relays to status. Expected format: { "ONLINE":4, "OFFLINE":1, } Requires Settings Tab permission.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getRelayStatuses
```

Parameters

None.

Related REST command: Returns a JSONObject with count of agent relays to status.

getRelays

Get information about all relays a user has access to.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getRelays
```

Parameters

None.

Related REST command: Get information about all relays a user has access to..

getResource

Get information about a resource

This command returns a JSON representation of a resource, including its security settings.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResource [parameters]
```

Parameters

Table 969. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResource
  -resource "/My resource"
```

Example

Example response

```
{
  "id": "e7a3eb3c-a0b2-49d3-80ae-ce788edb101f",

  }
}
```

Related REST command: Get information about a resource.

getResourceInventoryEntriesForComponent

Get current resource inventory entries for a component

This command returns a JSON array of current resource inventory entries for a component deployed to a resource. If there are no versions of the component deployed, the array will be empty. If there is one or more versions deployed, typically the first entry will correspond to a full version and subsequent entries will correspond to incremental versions. The entries are in ascending order by the date the entry was created, which will be when the deploying component process completed.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceInventoryEntriesForComponent [parameters]
```

Parameters

Table 970. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
component	string	true	ID or name of the component

Related REST command: Get current resource inventory entries for a component.

getResourceProperties

List resource properties

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceProperties [parameters]
```

Parameters

Table 971. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResourceProperties
  -resource "/My resource"
```

Example

Example response

```
[
  {
    "id": "bd20924e-8547-4d41-b9b1-36b41278d224",
    "name": "property1",
    "value": "1",
    "description": "A new property",
    "secure": false
  },
  {
    "id": "18963e9e-2cca-47ac-807a-7fc5e67c49ee",
    "name": "property2",
    "value": "",
    "description": "A property with no value",
    "secure": false
  },
  {
    "id": "9cc56712-65f8-41fe-8fd6-d07414364c98",
    "name": "property3",
```

```
    "value": "****",
    "description": "A secure property",
    "secure": true
  }
]
```

Related REST command: List resource properties.

getResourceProperty

Get a resource property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceProperty [parameters]
```

Parameters

Table 972. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResourceProperty
  -resource "/My resource"
  -name property1
```

Related REST command: Get a resource property.

getResourceRoleProperties

List resource role properties

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceRoleProperties [parameters]
```

Parameters

Table 973. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Related REST command: List resource role properties.

getResourceRoleProperty

Get a resource role property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceRoleProperty [parameters]
```

Parameters

Table 974. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
name	string	true	Name of the property

Related REST command: Get a resource role property.

getResourceTemplate

Get a resource template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceTemplate [parameters]
```

Parameters

Table 975. Parameters

Parameter	Type	Required	Description
template	string	true	Name or ID of resource template

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResourceTemplate
  -template MyResourceTemplate
```

Example

Example response

```
{
  "propDefs": [],
  "security": {
    "read": true,
    "Create Resource Templates": true,

  "name": "MyResourceTemplate",
  "description": "",
  "deleted": false
}
```

Related REST command: Get a resource template.

getResourceTemplateChildren

Get all children or descendants of a resource template

Results include the base resource and resources inherited from ancestors of this template.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourceTemplateChildren [parameters]
```

Parameters

Table 976. Parameters

Parameter	Type	Required	Description
template	string	true	Name or ID of the resource template. If this is a blueprint identified by name rather than ID, a parent application must also be specified using the -application flag.
application	string	false	Name or ID of the parent application. Required if the template represents an application blueprint identified by name.
recursive	boolean	false	Get all descendants of the template (not just immediate children). Default is false.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResourceTemplateChildren
  -template MyResourceTemplate
```

Related REST command: Get all children or descendants of a resource template.

getResources

List resources

This command returns a JSONArray representation of all top-level resources, or all children of a specified parent resource.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResources [parameters]
```

Parameters

Table 977. Parameters

Parameter	Type	Required	Description
parent	string	false	Specify the path to a parent resource to show children of that resource, such as /AllAgents/MyAgentGroup. Leave this field blank to show all top-level resources. (Optional)
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
includeInventory	boolean	false	

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResources
  -parent "/JPetStore agents"
```

Example

Example response

```
[
  {
    "id": "5fcc9f43-63eb-40bc-bcd6-3c0b2c124dce",

    "status": "OFFLINE",
    "hasAgent": true,
    "tags": []
  }
]
```

Related REST command: List resources.

getResourcesInRecycleBin

List resources in the recycle bin.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourcesInRecycleBin [parameters]
```

Parameters

Table 978. Parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	Maximum number of resource to return. Default 10.
pageNumber	int	false	1-Indexed page number. Default 1.

Related REST command: List resources in the recycle bin..

getResourcesWithComponentVersion

List resources that have a specified component version

This command returns a JSONArray representation of all resources that have the specified component version installed.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getResourcesWithComponentVersion [parameters]
```

Parameters

Table 979. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
version	string	true	Version name

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getResourcesWithComponentVersion
  -component "JPetStore-APP"
  -version "1.0"
```

Example

Example response

```
[
  {
    "id": "53b4b54f-5b3f-4fef-91dd-dea8ffe15dc3",
    "name": "JPetStore-APP",
    "path": "/JPetStore agents/vm192-168/JPetStore-APP",
    "active": true,
    "description": "",
    "inheritTeam": true,
    "impersonationPassword": "****",
    "impersonationUseSudo": false,
    "impersonationForce": false,
    "type": "subresource",
    "status": "ONLINE",
    "hasAgent": true,
    "tags": [
    ]
  }
]
```

Related REST command: List resources that have a specified component version.

getSecretStore

Get information about a secret store.

This command returns a JSON representation of a secret store.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSecretStore [parameters]
```

Parameters

Table 980. Parameters

Parameter	Type	Required	Description
store	string	true	Name or id of the secret store.

Related REST command: Get information about a secret store..

getSecretStores

Get information about all secret stores.

This command returns a JSON representation of all secret stores.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSecretStores
```

Parameters

None.

Related REST command: Get information about all secret stores..

getServerKeystoreImportTask

Get a keystore import task

Returns a representation of a keystore import task.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getServerKeystoreImportTask [parameters]
```

Parameters

Table 981. Parameters

Parameter	Type	Required	Description
task	string	true	ID of an import task.

Related REST command: Get a keystore import task.

getServerKeystoreInfo

Get information about the server keystore

Returns a representation of the content of the server keystore, which contains key pairs and certificates used for agent communication. This keystore is the file at path appdata/conf/server.keystore.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getServerKeystoreInfo
```

Parameters

None.

Related REST command: Get information about the server keystore.

getSnapshot

Get information about a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSnapshot [parameters]
```

Parameters

Table 982. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getSnapshot
  -application JPetStore
  -snapshot mySnapshot
```

Example

Example response

Related REST command: Get information about a snapshot.

getSnapshotConfiguration

Get the list of configuration objects in a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSnapshotConfiguration [parameters]
```

Parameters

Table 983. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Related REST command: Get the list of configuration objects in a snapshot.

getSnapshotVersions

Get the list of versions in a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSnapshotVersions [parameters]
```

Parameters

Table 984. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot

Table 984. Parameters (continued)

Parameter	Type	Required	Description
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getSnapshotVersions
  -application JPetStore
  -snapshot mySnapshot
```

Related REST command: Get the list of versions in a snapshot.

getSnapshotsInApplication

Get information about snapshots in an application

Snapshots are listed from most recent to least recent.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSnapshotsInApplication [parameters]
```

Parameters

Table 985. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
maxResults	int	false	Cap the number of results. Any value less than 1 returns all results.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getSnapshotsInApplication
  -application MyApplication
```

Example

Example JSON request

```
[
  {

]
```

Related REST command: Get information about snapshots in an application.

getStatus

Get information about a status

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getStatus [parameters]
```

Parameters

Table 986. Parameters

Parameter	Type	Required	Description
type	string	false	Type of status (inventory, version, or snapshot); this parameter is required you specify the name of the status instead of the ID
status	string	true	Name or ID of the status

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
```

```
  getStatus
  -type inventory
  -status Active
```

Example

Example response

```
[
  {
    "id": "061056cc-9433-4036-ac11-b3c0b84e7018",

    "color": "#B3D66D",
    "unique": true
  }
]
```

Related REST command: List statuses.

getSystemConfiguration

List system configuration properties

These properties are available on the System Settings page of the server.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSystemConfiguration
```

Parameters

None.

Example

Example response

```

```

Related REST command: List system configuration properties.

getSystemProperties

List system properties

This command returns a JSONArray representation of the system properties, which behave like global variables for the server.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSystemProperties
```

Parameters

None.

Example

Example response

```
[
  {
    "id": "af25c8b2-a69a-4d1b-a0ed-ddb226dfac18",
    "name": "System property 1",
    "value": "value001",
    "description": "This is a system property",
    "secure": false
  }
]
```

Related REST command: List system properties.

getSystemProperty

Get the value of a system property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getSystemProperty [parameters]
```

Parameters

Table 989. Parameters

Parameter	Type	Required	Description
name	string	true	Name of the property

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getSystemProperty
  -name property1
```

Example

Example response

```
value001
```

Related REST command: Get the value of a system property.

getTagsForType

Get the Tags for an object type.

This command returns a JSON array containing all active tags for the given object type.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTagsForType [parameters]
```

Parameters

Table 990. Parameters

Parameter	Type	Required	Description
objectType	string	true	Object type for the tags. e.g. Agent, Application, ApplicationTemplate, Component, ComponentTemplate, Resource

Related REST command: Get the Tags for an object type..

getTagsOnAgent

List all tags on an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTagsOnAgent [parameters]
```

Parameters

Table 991. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getTagsOnAgent
  -agent Agent1
```

Example

Example response

```
[
  {
    "id": "34afc9d1-e6d7-420f-a40c-30e6d3bf0c34",
    "name": "Tag1",
    "color": "#FFFFFF",
    "description": "",
    "objectType": "Agent"
  },
  {
    "id": "74c02e58-e532-47d7-ba98-66d1ac20c361",
    "name": "Tag2",
    "color": "#7fff00",
    "description": "",
    "objectType": "Agent"
  }
]
```

Related REST command: List all tags on an agent.

getTagsOnApplication

List all tags on an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTagsOnApplication [parameters]
```

Parameters

Table 992. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getTagsOnApplication
  -application JPetStore
```

Example

Example response

```
[
  {
    "id": "f3c52993-ffe4-464a-b34c-0abc1df7f995",
    "name": "Tag1",
    "color": "#dda0dd",
    "description": "",
    "objectType": "Application"
  },
  {
    "id": "ae47b2dc-8153-42c9-8094-207703a439e4",
    "name": "Tag2",
    "color": "#ffff00",
    "description": "",
    "objectType": "Application"
  }
]
```

Related REST command: List all tags on an application.

getTagsOnComponent

Return all tags on a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTagsOnComponent [parameters]
```

Parameters

Table 993. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getTagsOnComponent
  -component JPetStore-APP
```

Example

Example response

```
[
  {
    "id": "13a1604a-ecea-4f07-b85e-6b395ade161a",
    "name": "Tag1",
    "color": "#FFFFFF",
    "description": "",
    "objectType": "Component"
  },
  {
    "id": "d140ae5a-dfb0-477a-910b-762cc0d99cc6",
    "name": "Tag2",
    "color": "#7fff00",
    "description": "",
    "objectType": "Component"
  }
]
```

Related REST command: Return all tags on a component.

getTagsOnResource

List the tags on a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTagsOnResource [parameters]
```

Parameters

Table 994. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getTagsOnResource
  -resource /Resource1/Subresource1
```

Example

Example response

```
[
  {
    "id": "eeff1b7d-ef7c-4052-812b-a97405b97606",
    "name": "Tag1",
    "color": "#FFFFFF",
    "description": "",
    "objectType": "Resource"
  },
  {
    "id": "b03313f2-a3fa-4ac8-a84a-32869958ba06",
    "name": "Tag2",
    "color": "#87ceeb",
    "description": "",
    "objectType": "Resource"
  }
]
```

Related REST command: List the tags on a resource.

getTasksForUser

Return all approval tasks and manual tasks assigned to the user

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTasksForUser
```

Parameters

None.

Related REST command: Return all approval tasks and manual tasks assigned to the user.

getTeam

List information about a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getTeam [parameters]
```

Parameters

Table 995. Parameters

Parameter	Type	Required	Description
team	string	true	Name of the team

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getTeam
  -team MyNewTeam
```

Example

Example response

```
{
  "id": "769c2486-ed40-4a3a-ac52-faa33d30cfd5",
  "name": "MyNewTeam",
  "isDeletable": true,

        "isDeletable": true
      }
    }
  ]
}
```

Related REST command: List information about a team.

getUser

List information about a user

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getUser [parameters]
```

Parameters

Table 996. Parameters

Parameter	Type	Required	Description
user	string	true	Name/ID of the user. The name will be case-sensitive if a case-sensitive realm is provided.
realm	string	false	Limit any user name search to given AuthenticationRealm.

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getUser
  -user jsmith
```

Example

Example response

```
{
  "id": "2507eaaf-c98e-46ee-936d-bc538bee9dc4",
  "name": "jsmith",
  "actualName": "Jane C. Smith",
  "displayName": "Jane C. Smith (jsmith)",
  "email": "jsmith@example.org",
  "deleted": false,
  "deletedDate": 0,
  "authenticationRealm": "20000000000000000000000000000001",
  "isLockedOut": false,
  "isDeletable": true,
  "groups": [
  ]
}
```

Related REST command: List information about a user.

getUserByEmail

Get the user or users with a given e-mail address

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getUserByEmail [parameters]
```

Parameters

Table 997. Parameters

Parameter	Type	Required	Description
email	string	true	E-mail address of the user
allUsers	boolean	false	Specify true to retrieve all users with the e-mail address or false to return only the first user that matches the address

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getUserByEmail
  -email jsmith@us.ibm.com
  -allUsers true
```

Example

Example response

```
[{"id":"bade154b-c8c9-4aa6-a875-4b56d7132be5","name":"jsmith"},
{"id":"2c1c9012-2111-4d6a-b5f0-b6cabff94713","name":"janesmith"}]
```

Related REST command: Get the user or users with a given e-mail address.

getUsersThatCanRunDeploymentTriggers

Get all users that can run deployment triggers.

This command returns a JSON representation of all users that can run deployment triggers.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getUsersThatCanRunDeploymentTriggers
```

Parameters

Table 998. Parameters

Parameter	Type	Required	Description
environment	string	true	ID of the environment.

Related REST command: Get all users that can run deployment triggers..

getVaultAppRole

Get information about a Vault AppRole

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultAppRole [parameters]
```

Parameters

Table 999. Parameters

Parameter	Type	Required	Description
store	string	false	Store ID/Name
vaultAppRole	string	true	Name or ID of the Vault App Role

Related REST command: Get information about a Vault AppRole.

getVaultAppRoles

List the Vault AppRoles for a Vault store

This command returns a list of app roles within the given Vault store represented as a JSON Array.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultAppRoles [parameters]
```

Parameters

Table 1000. Parameters

Parameter	Type	Required	Description
store	string	true	Name or ID of the Vault Store to list AppRoles for.

Related REST command: List the Vault AppRoles for a Vault store.

getVaultCertificate

Get information about a Vault Certificate

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultCertificate [parameters]
```

Parameters

Table 1001. Parameters

Parameter	Type	Required	Description
store	string	false	Store ID/Name
vaultCertificate	string	true	Name or ID of the Vault Certificate

Related REST command: Get information about a Vault Certificate.

getVaultCertificates

List the Vault Certificates for a Vault store

This command returns a list of certificates within the given Vault store represented as a JSON Array.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultCertificates [parameters]
```

Parameters

Table 1002. Parameters

Parameter	Type	Required	Description
store	string	true	Name or ID of the Vault Store to list Certificates for.

Related REST command: List the Vault Certificates for a Vault store.

getVaultLdapUser

Get information about a Vault Ldap User

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultLdapUser [parameters]
```

Parameters

Table 1003. Parameters

Parameter	Type	Required	Description
store	string	false	Store ID/Name
vaultLdapUser	string	true	Name or ID of the Vault Ldap User

Related REST command: Get information about a Vault Ldap User.

getVaultLdapUsers

List the Vault Ldap Users for a Vault Secret Store

This command returns a list of ldap users within the given Vault store represented as a JSON Array.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVaultLdapUsers [parameters]
```

Parameters

Table 1004. Parameters

Parameter	Type	Required	Description
store	string	true	Name or Id of the Vault Store to list Ldap Users for.

Related REST command: List the Vault Ldap Users for a Vault Secret Store.

getVersionId

Get a version ID

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVersionId [parameters]
```

Parameters

Table 1005. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getVersionId
  -component MyComponent
  -version 1.2
```

Example

Example response

```
1a53a4a6-bfcd-4014-a0ab-83f97077a4d4
```

Related REST command: Get a version ID.

getVersionLink

Get a link on a component version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVersionLink [parameters]
```

Parameters

Table 1006. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version

Table 1006. Parameters (continued)

Parameter	Type	Required	Description
linkName	string	true	Name of the link

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getVersionLink
  -component JPetStore-APP
  -version 1.0
  -linkName "Link to MyCompany example web site"
```

Example

Example response

```
{
  "name": "Link to foo web site",
  "value": "http://www.foo.com"
}
```

Related REST command: Get a link on a component version.

getVersionLinks

List links on a version

This command lists all links that are associated with a specified component version.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVersionLinks [parameters]
```

Parameters

Table 1007. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  getVersionLinks
  -component JPetStore-APP
  -version 1.0
```

Example

Example response

```
[
  {
    "name": "Link to MyCompany example web site",
    "value": "http://mycompany.example.com"
  },
  {
    "name": "Link to foo web site",
    "value": "http://www.foo.com"
  }
]
```

Related REST command: List links on a version.

getVersionProperties

List the properties on a component version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getVersionProperties [parameters]
```

Parameters

Table 1008. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
```

```
  getVersionProperties
  -component JPetStore-APP
  -version 1.0
```

Example

Example response

```
[
  {
    "id": "33528ab5-a7be-46cb-9f0c-916a42bd2f62",
    "name": "Prop1",
    "value": "value1",
    "description": "",
    "secure": false
  },
  {
    "id": "92339074-ab59-4fe3-936f-9ceec16ce5e6",
    "name": "Prop2",
    "value": "value1",
    "description": "",
    "secure": false
  }
]
```

Related REST command: List the properties on a component version.

getWebhookTemplate

Get information about a webhook template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getWebhookTemplate [parameters]
```

Parameters

Table 1009. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	Name or ID of the webhook template to retrieve

Related REST command: Get information about a webhook template.

getWebhookTemplates

List the viewable webhook templates

This command returns a list of webhook templates represented as a JSON Array.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getWebhookTemplates
```

Parameters

None.

Related REST command: List the viewable webhook templates.

getWorkflowTraceLogs

Returns full workflow trace with execution logs as a zip file in the current directory.If the underlying workflow is not complete, an HTTP 412 response is returned.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getWorkflowTraceLogs [parameters]
```

Parameters

Table 1010. Parameters

Parameter	Type	Required	Description
workflow	string	true	ID of the workflow.

Related REST command: Get full workflow trace with execution logs as a zip file in the current directory.

getZOSVersionCumulativeManifest

Get the cumulative manifest for a linked z/OS version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getZOSVersionCumulativeManifest [parameters]
```

Parameters

Table 1011. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID

Table 1011. Parameters (continued)

Parameter	Type	Required	Description
version	string	true	Name or ID of the version

Related REST command: Get the cumulative manifest for a linked z/OS version.

getZOSVersionDeployManifest

Get a deploy manifest for deploying a version into an environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getZOSVersionDeployManifest [parameters]
```

Parameters

Table 1012. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID.
version	string	true	Name or ID of the version for which to generate the deploy manifest.
fromVersion	string	false	Name or ID of the current version from which to generate the deploy manifest.

Related REST command: Get a deploy manifest for deploying a version into an environment..

getZOSVersionsWithCommitId

Get the versions from a component with a given commit ID.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  getZOSVersionsWithCommitId [parameters]
```

Parameters

Table 1013. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component.
commitId	string	true	Commit ID of the version.
parentCommitId	string	false	Commit ID of the parent version.

Related REST command: Get the versions from a component with a given commit ID..

importApplication

Import application from json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importApplication [parameters]
```

Parameters

Table 1014. Parameters

Parameter	Type	Required	Description
componentUpgradeType	string	false	Supported values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
applicationUpgradeType	string	false	Supported values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
processUpgradeType	string	false	Supported values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
resourceTemplateUpgradeType	string	false	Supported values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.

Table 1014. Parameters (continued)

Parameter	Type	Required	Description
importFullResourceTrees	boolean	false	Whether to import full resource tree or just base resources. true or false. Default false
disposition	string	true	create or update.

Related REST command: Import application from json file..

importApplicationProcess

Import an application process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importApplicationProcess [parameters]
```

Parameters

Table 1015. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
processUpgradeType	string	false	Supported values are, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, FAIL_IF_EXISTS, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS.

Example

Command to import application process from a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
      importApplicationProcess
      -application JPetStore
      application-process-JPetStoreprocess.json
```

Example

Command to print available options

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
      importApplicationProcess -h
```

Example

Example response

```
{
  "id": "187b908b-570f-1121-b943-e058185063d5",
  "name": "Deploy JPetStore",
  "description": "",
  "active": true,
  "inventoryManagementType": "AUTOMATIC",
  "offlineAgentHandling": "PRE_EXECUTION_CHECK",
  "versionCount": 4,
  "version": 4,

  "path":
 "applications\/187b908b-3bc1-0bcb-0233-abff5fa79d79\/processes\/187b908b-570f-1121-b943-e058185063d5",
  "deleted": false,
  "metadataType": "applicationProcess",
  "disableSnapshots": false
}
```

Related REST command: Import an application process.

importComponent

Import component from json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importComponent [parameters]
```

Parameters

Table 1016. Parameters

Parameter	Type	Required	Description
componentTemplateUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
processUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.

Table 1016. Parameters (continued)

Parameter	Type	Required	Description
disposition	string	true	create or update

Related REST command: Import component from json file..

importComponentProcess

Import a component process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importComponentProcess [parameters]
```

Parameters

Table 1017. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
processUpgradeType	string	false	Supported values are, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, FAIL_IF_EXISTS, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS.

Example

Command to import component process from a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
      importComponentProcess
      -component JPetStore-APP
      component-process-JPetStorecomponent.json
```

Example

Example response

```
{
  "id": "187b908b-570f-1121-b943-e058185063d5",
  "name": "JPetStore-APP",
  "description": "",
  "active": true,
  "inventoryManagementType": "AUTOMATIC",
```

```
  "offlineAgentHandling": "PRE_EXECUTION_CHECK",
  "versionCount": 4,
  "version": 4,
  "commit": 963,
  "path": "components\/187b908b-3bc1-0bcb-0233-abff5fa79d79\/processes\/187b908b-570f-1121-b943-e058185063d5",
  "deleted": false,
  "metadataType": "componentProcess",
  "disableSnapshots": false
}
```

Example

Command to print available options

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
      importComponentProcess -h
```

Related REST command: Import a component process.

importComponentTemplate

Import component template from json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importComponentTemplate [parameters]
```

Parameters

Table 1018. Parameters

Parameter	Type	Required	Description
processUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
disposition	string	true	create or update.

Example

Command to import a component template process from a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  importComponentTemplate
  -componentTemplate componentTemplates
  -processUpgradeType FAIL_IF_DOESNT_EXIST
  -disposition update
  ./component-process-file.json
```

Example

Response

```
{
  "id": "1849bc16-e5e8-2705-58b1-33e021705448",
  "securityResourceId": "1849bc16-e5b8-0d7f-b050-473e9b11e726",
  "versionCount": 28,
  "version": 28,

  "tags": [],
  "active": true,
  "created": 1669060456020,
  "user": "jsmith",
  "importConfigurationStrategy": "default"
}
```

Related REST command: Import component template from json file..

importComponentTemplateProcess

Import a component template process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importComponentTemplateProcess [parameters]
```

Parameters

Table 1019. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template
processUpgradeType	string	false	Supported values are, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, FAIL_IF_EXISTS, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS.

Related REST command: Import a component template process.

importGenericProcess

Import process from json file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importGenericProcess [parameters]
```

Parameters

Table 1020. Parameters

Parameter	Type	Required	Description
disposition	string	true	create or update

Related REST command: Import process from json file..

importGroup

Import a group

Specify the details about the group in the JSON file. You can list one or more members of the new group in the 'users' array, or you can leave the array blank to create an empty group. Groups can be created only in Internal Storage authorization realms.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importGroup [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "authorizationRealm": "Authorization realm name",
  "description": "Group description. Optional.",
  "name": "Group name",
  "users": ["User names"]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  importGroup newGroup.json
```

Example

Example JSON request

```
{
  "name": "group1",
  "authorizationRealm": "Internal Security",
  "users": [
    "jdoe",
    "jsmith"
  ]
}
```

Example

Example response

```
{
  "id": "9dc44e77-e241-480e-8fbb-50f84b64b24b",
  "name": "group1",
  "enabled": true
}
```

Related REST command: Import a group.

importLdapUser

Import a user from LDAP

This command adds one or more users from an LDAP realm to the server.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importLdapUser [parameters]
```

Parameters

Table 1021. Parameters

Parameter	Type	Required	Description
user	string	true	Name or pattern of the users to be imported. Supports wildcard character *.
authenticationRealm	string	true	Authentication realm name or ID

Example

Example of importing a user with auth token

```
curl -sku 'PasswordIsAuthToken:23453425-dfgfgd-23432-sdfsf'
  'https://deployserver.example.com:8443/cli/user/import?user=jsmith
  &authenticationRealm=Internal Security'
  -X PUT
```

Example

Example of importing users using a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
      importLdapUser importUsers.json
```

Example

Example JSON request

```
{
        "name": "importUsers",
        "authorizationRealm": "Internal Security",
        "users": [
                  "jdoe",
                  "jsmith"
                 ]
}
```

Example

Example response

```
{
  "id":"18b3e4ac-13d2-9ecb-f12c-d078fe0f06e5",
  "name":"jdoe",
  "actualName":"John Doe",
  "displayName":"JOHN DOE",
  "email":"john.doe@example.org",
  "deleted":false,
  "deletedDate":0,
  "authenticationRealm":"18b3e49e-987d-6595-7a67-8b6d47c8cbf8",
  "isLockedOut":false,
  "lastLoginDate":1697793306115,
  "isDeletable":true,
  "namePattern":"john.doe@example.org"
}
```

Related REST command: Import a user from LDAP.

importSnapshot

Import snapshot from zip file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importSnapshot [parameters]
```

Parameters

Table 1022. Parameters

Parameter	Type	Required	Description
componentUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
applicationUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
processUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
resourceTemplateUpgradeType	string	false	Suppport values are UPGRADE_IF_EXISTS, CREATE_NEW_IF_EXISTS, FAIL_IF_DOESNT_EXIST, UPGRADE_IF_EXISTS, USE_EXISTING_IF_EXISTS. Default is UPGRADE_IF_EXISTS.
importFullResourceTrees	boolean	false	Whether to import full resource tree or just base resources. true or false. Default false
disposition	string	true	create or update.

Related REST command: Import snapshot from zip file..

importVersions

Import new component versions

This command polls the source configuration for new component versions. Add property name/value pairs as necessary - this can be used to add specific versions.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  importVersions [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Component name or ID",
  "properties": {"Source configuration plugin property
  name": "Property value"}
```

```
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  importVersions newVersions.json
```

Example

Example JSON request

```
{
  "component": "JPetStore-WEB",
  "properties": {
    "Prop1": "value1"
  }
}
```

Related REST command: Import new component versions.

installAgent

Install an agent

This command installs an agent over SSH.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  installAgent [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "host": "Host name or IP address of the system to
  install the agent on",
  "installDir": "Installation directory for the agent",
  "javaHomePath": "Path to Java on the agent system",
  "name": "Name of the agent resource",
  "port": "SSH port of the agent system; the default port
  is 22",
  "sshPassword": "SSH password for the agent system; leave
  blank to use public key authentication instead",
  "sshUsername": "SSH user name to use to connect to the
  agent system",
  "tempDirPath": "Path to directory to install from on the
  agent system",
  "webProxyUri": "Web socket URI for the relay server (e.
```

```
  g. https://relay:20080).",
  "webUri": "Web socket URI for the Deploy server (e.g.
  wss://server:7919)."
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  installAgent
  -name NewAgent
  -host agenthost.example.com
  -port 22
  -sshUsername root
  -sshPassword 12345
  -installDir /opt/devops-deploy/agent
  -javaHomePath /usr/lib/java
  -tempDirPath /tmp
  -serverHost host.example.com
  -serverPort 7918
```

Related REST command: Install an agent.

installAgentJava

Install a Java package as a new managed Java installation

This command requests the agent install Java, but does not wait for or report the result. The returned maintenance task can be used to query the result.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  installAgentJava [parameters]
```

Parameters

Table 1023. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
package	string	true	Name or ID of the Java package

Related REST command: Install a Java package as a new managed Java installation.

installLocalPlugin

Installs a plugin into the server from a local zip file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  installLocalPlugin
```

Parameters

None.

Related REST command: Install a local plug-in.

installPlugin

Installs a plugin into the server from a remote location defined in the plugin manifest.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  installPlugin [parameters]
```

Parameters

Table 1024. Parameters

Parameter	Type	Required	Description
pluginId	string	true	The full plugin id of the plugin to be installed.

Related REST command: Install a plug-in.

listArtifacts

Get the list of artifacts for a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  listArtifacts [parameters]
```

Parameters

Table 1025. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID

Table 1025. Parameters (continued)

Parameter	Type	Required	Description
version	string	true	Name or ID of the version
singleFilePath	string	false	Optional path to an individual version artifact to list.

Example

Examples

Note: By default, this command lists only the files and folders in the root folder, as in the following example. The command does not recurse into other folders.

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  listArtifacts
  -component MyComponent
  -version 1.0
```

The result of this command looks like the following example code:

```
[
  {
    "name": "fileA.txt",
    "path": "fileA.txt",
    "version": 1,
    "$ref": "fileA.txt/",
    "type": "file",
    "children": false,
    "lastModified": 1449262065000,
    "length": 0,
    "metaOnly": false
  },
  {
    "name": "folderA",
    "path": "folderA",
    "version": 1,
    "$ref": "folderA/",
    "type": "folder",
    "children": true,
    "lastModified": 1449262065000,
    "length": 0,
    "metaOnly": false
  },
  {
    "name": "folderB",
    "path": "folderB",
    "version": 1,
    "$ref": "folderB/",
    "type": "folder",
```

```
    "children": true,
    "lastModified": 1449262065000,
    "length": 0,
    "metaOnly": false
  }
]
```

Note: To list files and folders that are not in the root folder, you must specify the **singleFilePath** parameter, as in the following example:

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  listArtifacts
  -component MyComponent
  -version 1.0
  -singleFilePath folderA
```

The result of this command includes only the contents of the specified folder, as in the following example:

```
[
  {
    "name": "fileA.txt",
    "path": "folderA/fileA.txt",
    "version": 1,
    "$ref": "folderA/fileA.txt/",
    "type": "file",
    "children": false,
    "lastModified": 1451488971000,
    "length": 0,
    "metaOnly": false
  }
]
```

Related REST command: Get the list of artifacts for a version.

loadEnvironmentCompliancy

Get the compliancy of a given environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  loadEnvironmentCompliancy [parameters]
```

Parameters

Table 1026. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of environment

Table 1026. Parameters (continued)

Parameter	Type	Required	Description
snapshot	string	false	Name or ID of snapshot (required if environment is specified by name)
application	string	false	Name or ID of application (required if snapshot is specified by name)

Related REST command: Get the compliancy of a given environment.

lockSnapshotConfiguration

Lock a snapshot's configuration

This command locks the configuration included in a snapshot. This prevents the snapshot from being affected by any future changes to the relevant configuration and also prevents users from manually changing which configuration the snapshot is using. This cannot be reversed.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  lockSnapshotConfiguration [parameters]
```

Parameters

Table 1027. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Related REST command: Lock a snapshot's configuration.

lockSnapshotVersions

Lock a snapshot's version list

This command locks the list of component versions included in a snapshot. This cannot be reversed and prevents any future changes to the list of versions included in the snapshot.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  lockSnapshotVersions [parameters]
```

Parameters

Table 1028. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID

Related REST command: Lock a snapshot's version list.

lockUser

Lock a user account

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  lockUser [parameters]
```

Parameters

Table 1029. Parameters

Parameter	Type	Required	Description
user	string	true	Name/ID of the user. The name will be case-sensitive if a case-sensitive realm is provided.
realm	string	false	Limit any user name search to given AuthenticationRealm.

Related REST command: Lock a user account.

login

Log in to the server

This command creates an authentication token on the server. Subsequent udclient commands that you run use this token, so you do not have to specify credentials. The token is recorded locally in the user's home directory in the file .ucd/authToken. The token expires 24 hours after it was created. Use the logout command to delete the token and the authtoken file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  login
```

Parameters

None.

Example

Example

```
udclient -username admin -password admin
  -weburl https://myserver.example.com:8443
  login
```

logout

Log out of the server

This command deletes the authentication token that is currently in use, and deletes the local file that contains information about this token.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  logout
```

Parameters

None.

Example

Example

```
udclient
  -weburl https://myserver.example.com:8443
  logout
```

moveResource

Update a resource's parent

To update a resource's parent with this command, you must specify, at a minimum, the resource path or id, and optionally provide info for the resource template, blueprint, and application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  moveResource [parameters] [JSON file]
```

Parameters

Table 1030. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
parent	string	true	The path or id of the new parent

Table 1030. Parameters (continued)

Parameter	Type	Required	Description
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agent": "Name or ID of an agent to use for automation
  (Optional)",
  "agentPool": "Name or ID of an agent pool to use for
  automation (Optional)",
  "component": "Name or ID of a component to associate
  with the resource (Optional)",
  "componentTag": "Name or ID of a component tag to
  associate with the resource; any components with that tag
  can be deployed to this resource (Optional)",
  "description": "Description",
  "impersonationForce": "Specify true to prevent children
  or steps from specifying their own impersonation settings
  (Optional)",
  "impersonationGroup": "Group for default impersonation
  (Optional)",
  "impersonationPassword": "Password for default
  impersonation. Agents running on Linux and Unix machines
  will ignore this value (Optional)",
  "impersonationUseSudo": "Specify true to use the sudo
  command for impersonation. Agents running on Windows
  machines will ignore this value (Optional)",
  "impersonationUser": "User name for default
  impersonation (Optional)",
  "inheritTeam": "Whether or not to set inherit teams for
  resource. teamMappings will be ingored if true. Defaults
  to true (Optional)",
  "name": "Name for the new resource; leave blank to
  inherit the name from an agent, pool, or role",
  "parent": "ID or path to parent resource; leave blank to
  create a root resource (Optional)",
  "role": "Name or ID of a resource role to associate with
  the agent; if this resource is for a component, specify
  the component name instead (Optional)",
  "roleProperties": {"Property name": "Property value
  (Optional)"},
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
```

```
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  moveResource
  -resource /container1/subfolder1a/subfolder1b
  -parent /container2/subfolder2a
```

Related REST command: Update a resource's parent.

pauseWorkflow

Pause a workflow in progress

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  pauseWorkflow [parameters]
```

Parameters

Table 1031. Parameters

Parameter	Type	Required	Description
workflow	string	true	ID of the workflow to pause.

Related REST command: Pause a workflow in progress.

prepareServerKeystoreImportTask

Prepare for importing server keystore entries

Prepares for importing server keystore key pair entries by creating a new import task.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  prepareServerKeystoreImportTask [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "format": "One of 'JKS' or 'PKCS12'.",
  "keystoreEntryPassword": "The password for decrypting
  individual entries. All entries must use the same
  password.",
  "keystorePassword": "The password for decrypting or
  verifying the keystore."
}
```

Related REST command: Prepare for importing server keystore entries.

previewUserLockEvent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  previewUserLockEvent
```

Parameters

None.

Related REST command: Preview user lock event.

provisionEnvironment

Provision a cloud environment

This command provisions an instance of an application blueprint and creates an application environment based on that blueprint.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  provisionEnvironment [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Application name or ID (required if you
  are specifying the blueprint by name",
  "baseResource": "Path to the resource node to create
```

```
  this environment in",
  "blueprint": "Blueprint name or ID",
  "description": "Description (optional)",
  "name": "Environment name",
  "nodeProperties": {"Path to the resource node, such as
  /path/to/resource/node": {"Name of node property": "Value
  or node property"}}
}
```

Example

Examples

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  provisionEnvironment newEnvironment.json
```

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  provisionEnvironment -file newEnvironment.json
```

Example

Example JSON requests

How you structure the JSON request depends on whether you assign the virtual nodes to a cloud group or an environment profile. For more information on cloud groups and environment profiles, see the documentation for your cloud system.

The following example creates an environment that is named `CloudEnv1` from a blueprint that is named `My application`. In this case, the `cloud_group` property is at the root of the JSON string, which specifies that the nodes will receive IP addresses from the same cloud group.

```
{
  "name": "CloudEnv1",
  "application": "My application",
  "baseResource": "/environments",
  "blueprint": "Blueprint 1",
  "description": "New cloud environment from blueprint 1",
  "lockSnapshots": "false",
  "requireApprovals": "false",
  "cloud_group": "2",
  "nodeProperties": {
    "/Deploy Agent/os_part": {
      "multiplicity": "1",
      "numvcpus": "1",
      "memsize": "1024",
      "password": "password",
      "password_0": "password"
    }
  }
}
```

You can also specify IP addresses for the nodes individually. In this case, you specify an environment profile to use for the request and then a cloud group and IP group for each node. The following example has two nodes, and each uses a different cloud group and IP group.

```
{
  "name": "CloudEnv2",
  "application": "My application",
  "baseResource": "/environments",
  "blueprint": "Blueprint 1",
  "description": "New cloud environment from blueprint 1",
  "lockSnapshots": "false",
  "requireApprovals": "false",
  "environment_profile": "1",
  "nodeProperties": {
    "/Deploy Agent/os_part": {
      "cloud_group": "1",
      "ip_group": "1",
      "multiplicity": "1",
      "numvcpus": "1",
      "memsize": "1024",
      "password": "password",
      "password_0": "password"
    },
    "/Deploy Agent/os_part0": {
      "cloud_group": "2",
      "ip_group": "2",
      "multiplicity": "1",
      "numvcpus": "1",
      "memsize": "1024",
      "password": "password",
      "password_0": "password"
    }
  }
}
```

Note: You must specify cloud groups, IP groups, and environment profiles by ID, not by name. In most cases, to get the ID, open the cloud system console, open the group or profile, and find the ID in the URL in your web browser. In other cases, the ID is shown on the cloud system console.

To specify parameters on script packages on the nodes, add the information to the `nodeProperties` array. The following example assumes a script package named `iwd_registration` with a parameter named `cloud_hostname`:

```
{
  "name": "CloudEnv3",
  "application": "My application",
  "baseResource": "/environments",
  "blueprint": "Blueprint 1",
  "description": "New cloud environment from blueprint 1",
  "lockSnapshots": "false",
  "requireApprovals": "false",
  "cloud_group": "2",
  "nodeProperties": {
    "/Deploy Agent/os_part": {
      "multiplicity": "1",
      "numvcpus": "1",
      "memsize": "1024",
      "password": "password",
      "password_0": "password",
      "iwd_registration/cloud_hostname": "cloudserver.example.org"
    }
```

```
  }
}
```

Example

Example response

```
{
  "id": "d84f5683-b05f-4e8b-afdf-f28a38b0fece",
  "securityResourceId": "2eb5db02-b07e-4010-a0cf-3b84509d0ca4",
  "name": "CloudEnv1",
  "description": "New cloud environment",
  "color": "#ffffff",
  "requireApprovals": false,
  "lockSnapshots": false,
  "calendarId": "7aac87db-3984-4cde-98be-a935fd38bdb0",
  "active": true,
  "cleanupDaysToKeep": 0,
  "cleanupCountToKeep": 0,
  "conditions": [
  ]
}
```

Related REST command: Provision a cloud environment.

removeAgentFromPool

Remove an agent from an agent pool

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeAgentFromPool [parameters]
```

Parameters

Table 1032. Parameters

Parameter	Type	Required	Description
pool	string	true	Name or ID of the agent pool
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeAgentFromPool
  -pool Pool1
  -agent Agent1
```

Related REST command: Remove an agent from an agent pool.

removeAgentFromTeam

Remove an agent from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeAgentFromTeam [parameters]
```

Parameters

Table 1033. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Application".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeAgentFromTeam
  -agent MyAgent
  -team MyTeam
```

Related REST command: Remove an agent from a team.

removeAgentPoolFromTeam

Remove an agent pool from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeAgentPoolFromTeam [parameters]
```

Parameters

Table 1034. Parameters

Parameter	Type	Required	Description
agentPool	string	true	Name or ID of the agent pool
team	string	true	Name or ID of the team

Table 1034. Parameters (continued)

Parameter	Type	Required	Description
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard agent pool".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeAgentPoolFromTeam
  -agentPool MyAgentPool
  -team MyTeam
```

Related REST command: Remove an agent pool from a team.

removeAgentServerPin

Remove public key pin for a server host from an agent

This command requests the agent remove a public key pin for a server host, but does not wait for or report the result. The returned maintenance task can be used to query the result.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeAgentServerPin [parameters]
```

Parameters

Table 1035. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
host	string	true	The host name, as it is known by the agent, from which the public key pin is removed
publicKeyFingerprint	string	true	The fingerprint for the public key pin to remove

Related REST command: Remove public key pin for a server host from an agent.

removeApplicationFromTeam

Remove an application from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeApplicationFromTeam [parameters]
```

Parameters

Table 1036. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application.
team	string	true	Name or ID of the team.
type	string	false	Name of the security type to use. Leave blank if you are using the type "Standard Application".

Related REST command: Remove an application from a team.

removeComponentFromApplication

Remove a component from an application.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeComponentFromApplication [parameters]
```

Parameters

Table 1037. Parameters

Parameter	Type	Required	Description
component	string	true	Name of the component. This can be repeated for multiple components.
application	string	true	Name of the application

Related REST command: Remove a component from an application..

removeComponentFromTeam

Remove a component from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeComponentFromTeam [parameters]
```

Parameters

Table 1038. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Component".

Related REST command: Remove a component from a team.

removeComponentResourcePropDef

Delete a component resource property definition

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeComponentResourcePropDef [parameters]
```

Parameters

Table 1039. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the property definition to remove

Related REST command: Delete a component resource property definition.

removeComponentTemplateFromTeam

Remove a component template from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeComponentTemplateFromTeam [parameters]
```

Parameters

Table 1040. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Component Template".

Related REST command: Remove a component template from a team.

removeEnvironmentBaseResource

Remove a base resource from an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeEnvironmentBaseResource [parameters]
```

Parameters

Table 1041. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name of the application; this value is required if you specify the environment name instead of ID
resource	string	true	Path or ID of the resource to remove

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeEnvironmentBaseResource
  -application JPetStore
  -environment "Tutorial environment 1"
  -resource "/JPetStore agents/Tutorial agent 1"
```

Related REST command: Remove a base resource from an environment.

removeEnvironmentFromTeam

Remove an environment from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeEnvironmentFromTeam [parameters]
```

Parameters

Table 1042. Parameters

Parameter	Type	Required	Description
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
environment	string	true	Name or ID of the environment
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Environment".

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeEnvironmentFromTeam
  -application MyApplication
  -environment MyEnvironment
  -team MyTeam
```

Related REST command: Remove an environment from a team.

removeEnvironmentProperty

Delete a component environment property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeEnvironmentProperty [parameters]
```

Parameters

Table 1043. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
name	string	true	Name of the property to remove

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeEnvironmentProperty
  -name MyProperty
  -component d2e59ca4-a2f5-4851-9c85-629c1019ba20
```

Related REST command: Delete a component environment property.

removeGroupFromRoleOnTeam

Remove a group from a role on a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeGroupFromRoleOnTeam [parameters]
```

Parameters

Table 1044. Parameters

Parameter	Type	Required	Description
group	string	true	Name or ID of the group
team	string	true	Name or ID of the team
role	string	true	Name or ID of the role to remove from the group

Related REST command: Remove a group from a role on a team.

removeInventoryForUnmappedComponents

Removes environment inventory for components with no resources in the enviroment resources.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeInventoryForUnmappedComponents [parameters]
```

Parameters

Table 1045. Parameters

Parameter	Type	Required	Description
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID
environment	string	true	Name or ID of the environment

Related REST command: Remove environment inventory for components with no resources in the enviroment resources..

removeProcessFromTeam

Remove a process from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeProcessFromTeam [parameters]
```

Parameters

Table 1046. Parameters

Parameter	Type	Required	Description
process	string	true	Name or ID of the process.
team	string	true	Name or ID of the team.
type	string	false	Name of the security type to use; the default is Standard Process.

Related REST command: Remove a process from a team.

removeResourceFromTeam

Remove a resource from a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeResourceFromTeam [parameters]
```

Parameters

Table 1047. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
team	string	true	Name or ID of the team
type	string	false	Name of the type to use. Leave blank if you are using the type "Standard Resource".

Related REST command: Remove a resource from a team.

removeTagFromAgent

Delete a tag from an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeTagFromAgent [parameters]
```

Parameters

Table 1048. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
tag	string	true	Name of the tag

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeTagFromAgent
  -agent Agent1
  -tag Tag1
```

Related REST command: Delete a tag from an agent.

removeTagFromApplication

Remove a tag from an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeTagFromApplication [parameters]
```

Parameters

Table 1049. Parameters

Parameter	Type	Required	Description
application	string	true	Name or ID of the application
tag	string	true	Name of the tag

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeTagFromApplication
  -application JPetStore
  -tag Tag1
```

Related REST command: Remove a tag from an application.

removeTagFromComponent

Delete a tag from a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeTagFromComponent [parameters]
```

Parameters

Table 1050. Parameters

Parameter	Type	Required	Description
component	string	true	Name or ID of the component
tag	string	true	Name of the tag

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeTagFromComponent
  -component JPetStore-APP
  -tag Tag1
```

Related REST command: Delete a tag from a component.

removeTagFromResource

Remove a tag from a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeTagFromResource [parameters]
```

Parameters

Table 1051. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)
tag	string	true	Name of the tag

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeTagFromResource
  -resource /Resource1/Subresource1
  -tag Tag1
```

Related REST command: Remove a tag from a resource.

removeUserFromGroup

Remove a user from a group

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeUserFromGroup [parameters]
```

Parameters

Table 1052. Parameters

Parameter	Type	Required	Description
user	string	true	Name of the user
group	string	true	Name of the group

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeUserFromGroup
  -user jsmith
  -group group1
```

Related REST command: Remove a user from a group.

removeUserFromRoleOnTeam

Remove a user from a role on a team

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeUserFromRoleOnTeam [parameters]
```

Parameters

Table 1053. Parameters

Parameter	Type	Required	Description
user	string	true	Name or ID of the user
team	string	true	Name or ID of the team
role	string	true	Name or ID of the role to remove from the user

Related REST command: Remove a user from a role on a team.

removeVersionFromSnapshot

Remove a component version from a snapshot

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeVersionFromSnapshot [parameters]
```

Parameters

Table 1054. Parameters

Parameter	Type	Required	Description
snapshot	string	true	Name or ID of the snapshot
application	string	false	Name of the application; this value is required if you specify the snapshot name instead of ID
version	string	true	Name or ID of the component version
component	string	false	Name of the component; this value is required if you specify the component name instead of ID

Related REST command: Remove a component version from a snapshot.

removeVersionLink

Remove a link from a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeVersionLink [parameters]
```

Parameters

Table 1055. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version

Table 1055. Parameters (continued)

Parameter	Type	Required	Description
linkName	string	true	Name of the link to remove

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeVersionLink
  -component JPetStore-APP
  -version 1.0
  -linkName "Link to MyCompany example web site"
```

Related REST command: Remove a link from a version.

removeVersionLinkByName

Remove a link from a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeVersionLinkByName [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Name or ID of the component; this value is
  required if you specify the version name instead of ID",
  "name": "Name of the link",
  "version": "Name or ID of the version"
}
```

Related REST command: Remove a link from a version.

removeVersionStatus

Remove a status from a version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeVersionStatus [parameters]
```

Parameters

Table 1056. Parameters

Parameter	Type	Required	Description
component	string	false	Name or ID of the component; this value is required if you specify the version name instead of ID
version	string	true	Name or ID of the version
status	string	true	Name of the status to apply

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  removeVersionStatus
  -component JPetStore-APP
  -version 1.0
  -status Approved
```

Related REST command: Remove a status from a version.

removeWebhookFromApplication

Removes a webhook from a process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeWebhookFromApplication
```

Parameters

Table 1057. Parameters

Parameter	Type	Required	Description
webhook	string	true	ID of webhook
application	string	true	ID or name of application

Related REST command: Removes a webhook from a process.

removeWebhookFromProcess

Removes a webhook from a process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  removeWebhookFromProcess
```

Parameters

Table 1058. Parameters

Parameter	Type	Required	Description
process	string	true	Id or name of process
webhook	string	true	Id of webhook

Related REST command: Removes a webhook from a process.

repeatApplicationProcessRequest

Repeat an application process request

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  repeatApplicationProcessRequest [parameters]
```

Parameters

Table 1059. Parameters

Parameter	Type	Required	Description
request	string	true	ID of the application process request to repeat

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  repeatApplicationProcessRequest
  -request 47610d75-25c8-420d-a696-f006c34f5423
```

Example

Example response

```
{
  "requestId": "8ece2acb-b8d6-4748-809a-44bf19f4f8f0"
}
```

Related REST command: Repeat an application process request.

requestApplicationProcess

Run an application process

A version may be set to 'latest' to deploy the latest version of that component.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  requestApplicationProcess [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Application name or ID",
  "applicationProcess": "Application process name or ID",
  "date": "Date and time to schedule the process for.
  (Optional) Supports unix timecodes or the format yyyy-mm-
  dd HH:mm",
  "description": "Description for the request (Optional)",
  "environment": "Environment name or ID",
  "onlyChanged": "Specify false to force deployment of
  versions that are already in the inventory (Optional)",
  "post-deploy-message": "The body of the PUT message. You
  can use the variable ${p:finalStatus}, which holds the
  state of the process. The possible states are: Success,
  Failure, Approval Rejected, Awaiting Approval, Running,
  Scheduled, Cancelled, and Unknown. You can use the
  variable ${p:warningCount}, which holds the number of
  warnings that occurred on the process. (Optional)",
  "post-deploy-put-url": "The URL that the post-deploy-
  message is PUT to. (Optional)",
  "properties": {"Property name": "Property value
  (Optional)"},
  "recurrencePattern": "To make a scheduled process recur,
  specify 'D' (daily), 'W' (weekly), 'M' (monthly), or 'WD'
  (week days). (Optional)",
  "snapshot": "Snapshot name or ID (Optional)",
  "versions": [{
    "component": "Component name or ID for the version, if
  you are using version name instead of ID.",
    "version": "Version name or ID (Repeat as necessary.
  Not used with snapshots)"
```

```
  }]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  requestApplicationProcess runProcess.json
```

Example

Example JSON request

```
{
  "application": "JPetStore",
  "description": "Requesting deployment",
  "applicationProcess": "Deploy JPetStore",
  "environment": "Tutorial environment 1",
  "onlyChanged": false,
  "properties": {
    "Prop1": "value1"
  },
  "versions": [
    {
      "version": "1.0",
      "component": "JPetStore-APP"
    },
    {
      "version": "1.0",
      "component": "JPetStore-WEB"
    },
    {
      "version": "1.0",
      "component": "JPetStore-DB"
    }
  ]
}
```

Example

Example JSON request

You can also use the keywords `latest`, `latestVersion`, and `newest` in place of component version names. In this case, the process uses the most recently created component version. The following example shows how you can use these keywords in the JSON request.

```
{
  "application": "JPetStore",
  "description": "Deploying newest versions",
  "applicationProcess": "Deploy JPetStore",
  "environment": "Tutorial environment 1",
  "onlyChanged": false,
  "properties": {
    "Prop1": "value1"
  },
```

```
  "versions": [
    {
      "version": "newest",
      "component": "JPetStore-APP"
    },
    {
      "version": "latest",
      "component": "JPetStore-WEB"
    },
    {
      "version": "latestVersion",
      "component": "JPetStore-DB"
    }
  ]
}
```

Example

Example response

```
{
  "requestId": "f7e7b00d-8ea6-4a95-ad74-0ff853125232"
}
```

Related REST command: Run an application process.

requestProcess

Executes new generic process request(s) for resource(s)

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  requestProcess [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "processId": "ID of generic process",
  "processVersion": "(Optional) Version number of the
  process to run against. -1 (default) represents latest
  version",
  "properties": {"Property name": "Property value
  (Optional)"},
  "resource": "Deprecated, use 'resources'(ID or path of
  resource to run the process against)",
  "resources": ["Comma-separated list of IDs or paths of
  resources to run the process against. 'resource' parameter
  would be ignored if this is present"]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  requestProcess [JSON File]
```

Example

Example response

```
[{
  "id": "1710e3a8-b52f-02e3-d5ed-421c17f24af2",
  "submittedTime": 1585081649980,
  "userName": "admin",
  "processPath": "processes\/1710e0b0-eb7e-e9b7-38ab-c7be3e828f56",
  "processVersion": 4
}]
```

Example

Example response

```
[{
  "id": "1710e506-b23a-ab88-7634-563464e20ef0",
  "submittedTime": 1585083083529,
  "userName": "admin",
  "processPath": "processes\/1710e0b0-eb7e-e9b7-38ab-c7be3e828f56",
  "processVersion": 2
}]
```

Example

Example response

```
[
  {
    "id": "1710e526-9d32-1fc1-299f-f7562b3b33f3",
    "submittedTime": 1585083214272,
    "userName": "admin",
    "processPath": "processes\/1710e0b0-eb7e-e9b7-38ab-c7be3e828f56",
    "processVersion": 4
  },
  {
    "id": "1710e526-9ee8-a8f1-676c-dbb25d9885a2",

    "processVersion": 4
  }
]
```

Example

Example response

```
[{
  "id": "1710e560-809e-477f-d5ef-d260dbf4578c",
  "submittedTime": 1585083451381,
  "userName": "admin",
  "processPath": "processes\/1710e0b0-eb7e-e9b7-38ab-c7be3e828f56",
  "processVersion": 4
}]
```

Related REST command: Executes new generic process request(s) for resource(s).

restartAgent

Restart an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  restartAgent [parameters]
```

Parameters

Table 1060. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  restartAgent
  -agent Agent1
```

Related REST command: Restart an agent.

restoreArtifacts

Restore artifacts of an archived version

Restore Artifacts of an archived version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  restoreArtifacts [parameters]
```

Parameters

Table 1061. Parameters

Parameter	Type	Required	Description
component	string	false	Name/ID of the Component (Optional, required if version name specified instead of id
version	string	true	Name/ID of the version

Related REST command: Restore artifacts of an archived version.

restoreFromRecycleBin

Restore from recycle bin.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  restoreFromRecycleBin [parameters]
```

Parameters

Table 1062. Parameters

Parameter	Type	Required	Description
resource	string	true	Id of the resource to be restored. This parameter can be repeated to restore multiple resources at once.

Related REST command: Restore from recycle bin..

resumeWorkflow

Resume a workflow in progress

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  resumeWorkflow [parameters]
```

Parameters

Table 1063. Parameters

Parameter	Type	Required	Description
workflow	string	true	ID of the workflow to resume.

Related REST command: Resume a workflow in progress.

revokeAuthToken

Revoke an authentication token

Revokes and deletes an authentication token identified by database ID or token secret. Only users with 'Manage Security' permission can use this function for a token they do not own.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  revokeAuthToken [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"token": "Authentication token ID or secret"}
```

Example

Example command to delete auth tokens using a JSON file

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  revokeAuthToken filename.json
```

Example

JSON example

```
{
  "token": "194dba21-0199-cddb-1f04-4ad922fc5385"
}
```

Related REST command: Revoke an authentication token.

rollbackZInventoryEntries

Rollback Z inventory.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  rollbackZInventoryEntries [parameters]
```

Parameters

Table 1064. Parameters

Parameter	Type	Required	Description
application	string	false	Application name or id. This is required when specifying environment by name.
environment	string	true	Environment name or id.
component	string	false	Component name or id. This is required when specifying version by name.
version	string	true	Version name or id.
overwriteUpdatedFiles	boolean	false	Whether or not to rollback files updated by later versions. Defaults to true for backwards compatability.

Related REST command: Rollback Z inventory..

saveEnvironmentGate

Save the environment gate of a given environment. Environment gates are JSON objects consisting of operators "OR", "AND", and "NOT", as well as status UUIDs. A valid operator is a JSON Object with a single key corresponding to one of the three operator types, and with a list of operators or UUIDs as its value. A valid gate begins with an enclosing OR operator containing one or more AND operators. AND operators can contain only UUIDs or NOT operators. NOT operators must contain a single UUID which corresponds to a known version or snapshot status.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  saveEnvironmentGate [parameters] [JSON file]
```

Parameters

Table 1065. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of environment

Table 1065. Parameters (continued)

Parameter	Type	Required	Description
application	string	false	Name or ID of application (required if environment is specified by name)

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"OR": [{"AND": [
  "<uuid>",
  "<uuid>",
  "...",
  {"NOT": ["<uuid>"]},
  {"NOT": ["<uuid>"]},
  "..."
]}]}
```

Related REST command: Save the environment gate of a given environment.

saveEnvironmentTemplateGate

Save the environment gate of a given environment template. Environment gates are JSON objects consisting of operators "OR", "AND", and "NOT", as well as status UUIDs. A valid operator is a JSON Object with a single key corresponding to one of the three operator types, and with a list of operators or UUIDs as its value. A valid gate begins with an enclosing OR operator containing one or more AND operators. AND operators can contain only UUIDs or NOT operators. NOT operators must contain a single UUID which corresponds to a known version or snapshot status.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  saveEnvironmentTemplateGate [parameters] [JSON file]
```

Parameters

Table 1066. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	Name or ID of environment template
applicationTemplate	string	false	Name or ID of applicationTemplate (required if environment template is specified by name)

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"OR": [{"AND": [
  "<uuid>",
  "<uuid>",
  "...",
  {"NOT": ["<uuid>"]},
  {"NOT": ["<uuid>"]},
  "..."
]}]}
```

Related REST command: Save the environment gate of a given environment template.

savePostProcessingScript

Get information about a post processing script

This command returns a JSON representation of a post processing script.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  savePostProcessingScript [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "body": "The body of the script (required)",
  "description": "The description of the script (optional)",
  "id": "The id of the script (required)",
  "name": "The name of the script (required)",
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ]
}
```

Related REST command: Get information about a post processing script.

searchZInventoryEntries

Search Z inventory.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  searchZInventoryEntries [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applications": ["Application name or id. Only one of
  applications, environments, or components may be
  specified."],
  "components": ["Component name or id. Only one of
  applications, environments, or components may be
  specified."],
  "environments": ["Environment name or id. Only one of
  applications, environments, or components may be
  specified."],
  "fileNameGlob": "File names to search for. Either this
  or versionNameGlob must be specified. Only one of
  fileNameGlob or versionNameGlob may be specified when
  filtering by applications, environments or components.",
  "includeInactive": "Boolean: default false. Whether or
  not to include inactive entries in the results.",
  "versionNameGlob": "Version names to search for. Either
  this or fileNameGlob must be specified. Only one of
  fileNameGlob or versionNameGlob may be specified when
  filtering by applications, environments or components."
}
```

Related REST command: Search Z inventory..

setAgentJavaHome

Set the configured JAVA_HOME of an agent

This command requests the agent set JAVA_HOME, but does not wait for or report the result. The new JAVA_HOME will not take effect until the agent is restarted. The returned maintenance task can be used to query the result.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setAgentJavaHome [parameters]
```

Parameters

Table 1067. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
javahome	string	true	Name of managed Java install or absolute path of a valid JAVA_HOME directory

Related REST command: Set the configured JAVA_HOME of an agent.

setAgentKeypairPolicy

Set or modify an agent's keypair policy

This command requests the agent set or modify its keypair policy, but does not wait for or report the result. The returned maintenance task can be used to query the result. If the maximum age of the keypair is changed to be less than its current age, keypair rotation may begin immediately, but the outcome of the returned maintenance task does not depend on that.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setAgentKeypairPolicy [parameters]
```

Parameters

Table 1068. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
maxAgeDays	int	true	The maximum age in days of the agent's keypair, or zero to disable rotation

Related REST command: Set or modify an agent's keypair policy.

setAgentLicenseType

Set the license for an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setAgentLicenseType [parameters]
```

Parameters

Table 1069. Parameters

Parameter	Type	Required	Description
licenseType	string	true	The License Type to set on the agent(s)
agent	string	true	Name or ID of the agent. This can be repeated for multiple agents.

Related REST command: Set the license for an agent.

setAgentProperty

Set a property on a agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setAgentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agent": "Name or ID of the agent",
  "description": "The description of the property
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property",
  "value": "New value for the property (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setAgentProperty
  -agent Agent1
  -name Prop1
  -value value1
```

Example

Example response

```
{
  "id":"cdf5e901-f19a-48b8-82fc-c92c256e31df",
  "name":"newProperty",
  "value":"newValue",
  "secure":false
}
```

Related REST command: Set a property on a agent.

setAgentUnavailable

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setAgentUnavailable [parameters]
```

Parameters

Table 1070. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
unavailable	boolean	true	The desired unavailable state.

Related REST command: Set an agent unavailable.

setApplicationProperty

Set a property on an application

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setApplicationProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or ID of the application",
  "description": "The description of the property
```

```
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Property name",
  "value": "Property value (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setApplicationProperty
  -application JPetStore
  -name Prop4
  -value value4
```

Example

Example response

```
{
  "id": "7b818dfe-efd9-465a-bee3-775f60dc297d",
  "name": "Prop4",
  "value": "value4",
  "secure": false
}
```

Related REST command: Set a property on an application.

setComponentEnvironmentProperty

Set a component environment property value

This command will set a component property value specifically for this environment.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setComponentEnvironmentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or ID of the application; this
  value is required if you specify the environment name
  instead of ID",
  "component": "Name or ID of the component",
```

```
  "environment": "Name or ID of the environment",
  "name": "Name of the property to set",
  "value": "Value of the property to set (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setComponentEnvironmentProperty
  -name Prop1
  -value value1
  -component JPetStore-APP
  -environment Environment1
  -application JPetStore
```

Related REST command: Set a component environment property value.

setComponentProperty

Set a property on a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setComponentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Name or ID of the component",
  "description": "The description of the property
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property",
  "value": "Value of the property (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setComponentProperty
  -component JPetStore-APP
```

```
  -name Prop1
  -value value1
```

Example

Example response

```
{
  "id": "3702f391-09e1-4550-903a-d5ae286c94aa",
  "name": "Prop1",
  "value": "value1",
  "secure": false
}
```

Related REST command: Set a property on a component.

setComponentVersionPropDef

Set a version property for a component

Component version properties are available to each version of the component.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setComponentVersionPropDef [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "allowedValues": "Comma separated list of allowed values
  in SELECT or MULTI_SELECT properties (Optional)",
  "component": "Name or ID of the component",
  "description": "Description for the property (Optional)",
  "label": "Label of the property (Optional)",
  "name": "Name of the property to set",
  "pattern": "A regular expression that specifies valid
  values for the property. Follows java.util.regex.Pattern
  (Optional)",
  "required": "Whether the property is required (Optional,
  Boolean)",
  "type": "the type of property definition; valid values
  are TEXT (the default), , TEXTAREA, CHECKBOX, SELECT,
  MULTI_SELECT, DATETIME, and SECURE)",
  "value": "Default value of the property definition
  (Optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setComponentVersionPropDef
  -component JPetStore-APP
  -name Prop1
  -value true
  -type CHECKBOX
```

Example

Example response

```
{
  "id": "870bc2f5-55e2-4cb9-b3ab-f750688754b9",
  "name": "Prop1",
  "type": "CHECKBOX",
  "value": "prop1",
  "required": false
}
```

Related REST command: Set a version property for a component.

setEnvironmentProperty

Set a property on environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setEnvironmentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or ID of the application; this
  value is required if you specify the environment name
  instead of ID",
  "description": "The description of the property
  (optional)",
  "environment": "Name or ID of the environment",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property to set",
  "value": "Value of the property to set (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setEnvironmentProperty
  -application JPetStore
  -environment "Tutorial environment 1"
  -name Prop1
  -value value1
```

Example

Example response

```
{
  "id": "ba3f8bd4-c26e-4529-a2a3-66e283242244",
  "name": "Prop1",
  "value": "value1",
  "secure": false
}
```

Related REST command: Set a property on environment.

setLoggingConfig

Get logging configuration

Sets the current logging configuration. The output of the getLoggingConfig command is acceptable input. To support this, several elements of the input template are optional and ignored, but must be valid if supplied. Regardless, the input is still subject to the constraints reported by these ignored elements. For example, objects for which 'deletable' is false must be present in the input as their absense is interpreted as a request for deletion.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setLoggingConfig [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "createdDate": "Timestamp when the object was created;
  ignored and optional",
  "logs": {
    "createdDate": "Timestamp when the object was created;
  ignored and optional",
    "deletable": "Reports if log can be deleted; ignored
  and optional",
    "enabled": "Reports if log is enabled; the main log
  cannot be disabled",
    "enabledMutable": "Reports if 'enabled' can be
```

```
  changed; ignored and optional",
    "fileCount": "Number of rotated logs; must be at least
  1",
    "fileMegabytes": "Maximum log file size; ignored and
  optional if rotation is not SIZE",
    "loggers": [{
      "createdDate": "Timestamp when the object was
  created; ignored and optional",
      "deletable": "Reports if the logger can be deleted;
  ignored and optional",
      "level": "The logging level; one of
  OFF|FATAL|ERROR|WARN|INFO|DEBUG|TRACE|ALL",
      "logMutable": "Reports if the log assoctation can be
  changed; ignored and optional",
      "modifiedDate": "Timestamp when the object last
  modified; ignored and optional",
      "name": "Name of the logger; must be unique across
  all logs; '*' is the name of the root logger which must
  only be in the main log; up to 255 printable ASCII
  characters (no whitespace or control codes)",
      "root": "Reports if this logger is the root logger;
  ignored and optional"
    }],
    "main": "Reports if this log is the main log; ignored
  and optional",
    "modifiedDate": "Timestamp when the object last
  modified; ignored and optional",
    "name": "Name of the log; must be unique; up to 64
  characters from [-_0-9a-z]",
    "rotation": "Rotation strategy: one of
  SIZE|HOURLY|DAILY|WEEKLY|MONTHLY",
    "rotationMutable": "Reports if 'rotation' can be
  changed; ignored and optional"
  },
  "modifiedDate": "Timestamp when the object last
  modified; ignored and optional"
}
```

Related REST command: Get logging configuration.

setPreferredJavaPackage

Sets a package as preferred for its OS and CPU, unsetting the previously preferred package if there was one.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setPreferredJavaPackage [parameters]
```

Parameters

Table 1071. Parameters

Parameter	Type	Required	Description
package	string	true	Name or ID of the java package

Related REST command: Set a package as preferred for its OS and CPU.

setResourceProperty

Set a property on a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setResourceProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or ID of the application (Required
  to look up blueprint by name)",
  "blueprint": "Name or ID of the blueprint (optional)",
  "description": "The description of the property
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property",
  "resource": "ID of resource or Path to the resource,
  such as /ResourceGroup/Agents/Agent1",
  "template": "Name or ID of the resource template
  (optional)",
  "value": "New value for the property (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setResourceProperty
  -resource "/My resource"
```

```
  -name property1
  -value value1
```

Example

Example response

```
{
  "id": "bd20924e-8547-4d41-b9b1-36b41278d224",
  "name": "property1",
  "value": "value1",
  "secure": false
}
```

Related REST command: Set a property on a resource.

setResourceRoleProperty

Set a property on a resource

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setResourceRoleProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "application": "Name or ID of the application (Required
  to look up blueprint by name)",
  "blueprint": "Name or ID of the blueprint (optional)",
  "description": "The description of the property
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property",
  "resource": "ID of resource or Path to the resource,
  such as /ResourceGroup/Agents/Agent1",
  "template": "Name or ID of the resource template
  (optional)",
  "value": "New value for the property (optional)"
}
```

Related REST command: Set a property on a resource.

setSystemConfiguration

Update the system configuration

Use this command to set any of the properties on the System Settings page of the server. The JSON template for this command lists all of the properties that you can change, but you can omit properties that you are not changing.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setSystemConfiguration [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agentAutoLicense": "Specify true to automatically
  assign licenses to agents",
  "artifactAgent": "Specify a default agent for component
  version imports.",
  "auditLogCleanupEnabled": "Whether the audit logs will
  be deleted after a given number of days.",
  "auditLogCleanupHour": "The hour when audit logs are
  cleaned; the value must be an integer from 0 (midnight) to
  23 (11pm).",
  "auditLogCleanupMinute": "The minute when audit logs are
  cleaned; the value must be an integer from 0 to 59.",
  "auditLogReadEntriesEnabled": "Controls whether READ
  events are captured in the audit log.",
  "auditLogRetentionLength": "The number of days to retain
  audit log entries.",
  "bearerTokenRealm": "The realm to use for bearer
  authentication.",
  "cleanupArchivePath": "The path for archived component
  versions",
  "cleanupCountToKeep": "The number of component versions
  to keep",
  "cleanupDaysToKeep": "The number of days component
  versions are kept",
  "cleanupHourOfDay": "The time when versions are cleaned;
  the value must be an integer from 0 (midnight) to 23 (11
  pm)",
  "codestationMaxSizeDisplayMBs": "Defines the size in
  megabytes of '100%' storage in the dashboard server
  storage display.",
  "defaultLocale": "The default locale to use for the
  system (determines language and date formats.)",
  "deleteEnvResources": "Enable deleting resources
  globally from an environment's resource tree or when
  deleting an environment.",
  "deployMailHost": "The host name of the mail server that
  is used for notifications",
  "deployMailPassword": "The user password for sending
  email notifications",
  "deployMailPort": "The SMTP port that is used by the
  notifications mail server",
  "deployMailSecure": "Specifies whether the SMTP
```

```
connection is secure",
"deployMailSender": "The sender address for email
notifications",
"deployMailUsername": "The user name for sending email
notifications",
"enableAllowFailure": "Controls whether the 'allow
failure' option can be used on the steps in a workflow.",
"enableInactiveLinks": "Specify true to show links to
inactive objects",
"enablePromptOnUse": "Controls whether user-entered
values can be specified at process run time",
"enableUIDebugging": "Changes how the UI resources are
loaded so it is easier to debug problems in the UI if set.
Enabling reduces UI performance.",
"envCompPropsOverrideEnvProps": "Determines whether or
not environment component properties will override
environment properties.",
"environmentCountToKeep": "The number of versions to
retain for this environment. Lists the versions in order
of the time of deployment to this environment, and exempts
the first N from artifact cleanup. If an archive path is
set, the versions that are cleaned up will be archived. If
no archive path is set, the versions will be deleted. To
retain all versions of a component, enter -1.",
"environmentDaysToKeep": "The number of days since
deployment to retain component versions which have been
deployed to this environment. If an archive path is set,
the versions that are cleaned up will be archived. If no
archive path is set, the versions will be deleted. To
retain component versions indefinitely, enter -1.",
"externalApprovalAgent": "Specify a default agent to use
for running External Approval Processes. Superseded by
approvalAgentPool.",
"externalApprovalAgentPool": "Specify a default agent
pool to use for running External Approval Processes.
Supersedes approvalAgent.",
"externalURL": "The URL that agents use to connect to
the server",
"externalUserURL": "The URL that users enter to connect
to the server",
"failProcessesWithUnresolvedProperties": "Determines
whether or not a process will fail when it encounters a
property that cannot be resolved.",
"historyCleanupDaysToKeep": "The number of days
application process history is to be kept. -1 will disable
application process history cleanup.",
"historyCleanupDuration": "The maxiumum number of hours
per day the history cleanup process can take; the value
must be an integer from 1 to 23.",
"historyCleanupEnabled": "The system will not delete any
process history unless this is enabled.",
"historyCleanupHour": "The time when application process
history is cleaned; the value must be an integer from 0
(midnight) to 23 (11pm).",
"historyCleanupMinute": "The minute when process history
is cleaned; the value must be an integer from 0 to 59.",
"integrationTag": "Specify an agent tag to use any agent
with the given tag for version imports.",
```

```
"licenseServerUrl": "The host name and port of the
license server",
"llmApiKey": "The API key used to make requests to the
AI provider.",
"llmEndpoint": "The base endpoint used to construct
requests to the AI provider.",
"llmModel": "The Model name or id. Only modifiable if
llmVendor, llmApiKey, and llmEndpoint are present.",
"llmOrganization": "The organization ID for the relevant
organization.",
"llmProject": "The project ID for the relevant project.",
"llmVendor": "The AI provider used to service AI
requests.",
"maintenanceModeEnabled": "When this option is enabled,
the server will be in maintenance mode.",
"messageOfTheDay": "Message you want to display",
"minimumPasswordLength": "Determines the minimum length
for passwords",
"repoAutoIntegrationPeriod": "The number of seconds
between the times that the server polls components for new
versions",
"requireCommentForProcessChanges": "When enabled, the
user must provide a comment when saving changes to any
process design.",
"requireDigits": "Require new passwords to contain at
least one number character.",
"requireDuplicate": "Require new passwords to not match
the username, actual name, or configured email.",
"requireLowercase": "Require new passwords to contain at
least one lowercase character.",
"requireSpecials": "Require new passwords to contain at
least one special character.",
"requireUppercase": "Require new passwords to contain at
least one uppercase character.",
"showCompliancyOnLoad": "Load visible environment
compliancies when viewing the application page, rather
than on demand.",
"snapshotDaysToKeep": "The number of days to retain
snapshots. Snapshots are always kept if they are the most
recently deployed snapshot in an environment. Each
environment  can override this setting and retain
snapshots longer. In this case a snapshot will only be
deleted if it is not retained by an environment. If no
environment is retaining the snapshot and the snapshot is
older than the number of days in this setting, the server
deletes the snapshot. To retain all snapshots
indefinitely, enter -1.",
"use.default.atr.if.not.specified": "Use the Default
Auth Token Restriction for plugin steps that do not have
an auth token restriction set. If false this will not
restrict auth token usage at all. Any new version will
have an auth token restriction.",
"userIdleDaysToDelete": "The number of days before
deleting a user account due to inactivity.",
"userIdleDaysToLock": "The number of days before locking
a user account due to inactivity.",
"validateAgentIp": "Controls validation of agent IPs and
hostnames. The first time the agent connects, its IP and
```

```
  hostname will be saved. In subsequent connections, if
  either has changed, the agent will be prevented from
  coming online."
}
```

Example

Example JSON request

```
{
  "minimumPasswordLength": "9",
  "requireComplexPasswords": "true"
}
```

Related REST command: Update the system configuration.

setSystemProperty

Set a system property

System properties behave like global variables for the server.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setSystemProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The description of the property
  (optional)",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "label": "The label of the property (optional)",
  "name": "Name of the property",
  "value": "Value of the property (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setSystemProperty
  -name "System property 1"
  -value value001
```

Example

Example response

```
{
  "id": "f3bec2ee-3f3e-461f-b5b0-e844efafbdbe",
  "name": "System property 1",
  "value": "value001",
  "secure": false
}
```

Related REST command: Set a system property.

setVersionProperty

Set a property on a component version

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  setVersionProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Name or ID of the component; this value is
  required if you specify the version name instead of ID",
  "isSecure": "Whether the property is secure; the default
  is the current state of the property, or false if the
  property is not yet specified (optional)",
  "name": "Name of the property to set",
  "value": "Value of the property to set (optional)",
  "version": "Name or ID of the version"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  setVersionProperty
  -component JPetStore-APP
  -version 1.0
  -name Prop1
  -value value1
```

Example

Example response

```
{
  "id": "33528ab5-a7be-46cb-9f0c-916a42bd2f62",
```

```
  "name": "Prop1",
  "value": "value1",
  "secure": false
}
```

Related REST command: Set a property on a component version.

shutdownAgent

Shut down an agent

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  shutdownAgent [parameters]
```

Parameters

Table 1072. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  shutdownAgent
  -agent Agent1
```

Related REST command: Shut down an agent.

testAgent

Test the connection from an agent to the server

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  testAgent [parameters]
```

Parameters

Table 1073. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  testAgent
  -agent Agent1
```

Related REST command: Test the connection from an agent to the server.

testVaultAppRole

Test resolving a value from a Vault AppRole.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  testVaultAppRole [parameters] [JSON file]
```

Parameters

Table 1074. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultAppRole	string	true	Name or ID of the Vault App Role

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "property": "Property to resolve from vault. i.e.
  vault/KV/Holder:key. (Required)",
  "secretId": "The secretId to use for authentication.
  (Required if not set on Vault AppRole. Ignored if already
  set on Vault AppRole)"
}
```

Related REST command: Test resolving a value from a Vault AppRole..

testVaultCertificate

Test resolving a value from a Vault Certificate.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  testVaultCertificate [parameters] [JSON file]
```

Parameters

Table 1075. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultCertificate	string	true	Name or ID of the Vault App Role

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"property": "Property to resolve from vault. i.e.
  vault/KV/Holder:key. (Required)"}
```

Related REST command: Test resolving a value from a Vault Certificate..

testVaultLdapUser

Test resolving a value from a Vault Ldap User.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  testVaultLdapUser [parameters] [JSON file]
```

Parameters

Table 1076. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultLdapUser	string	true	Name or ID of the Vault Ldap User

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "password": "The Vault Ldap User Password (Required if
  not set on ldap user. Ignored if already set on ldap
  user)",
  "property": "Property to resolve from vault. i.e.
  vault/KV/Holder:key. (Required)"
}
```

Related REST command: Test resolving a value from a Vault Ldap User..

uninstallAgentJava

Uninstall a managed Java installation

This command requests the agent uninstall Java, but does not wait for or report the result. If an installation is the active JAVA_HOME or configured as JAVA_HOME, that installation is not removed.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  uninstallAgentJava [parameters]
```

Parameters

Table 1077. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent
package	string	true	Name of a package to uninstall from the agent

Related REST command: Uninstall a managed Java installation.

unlockUser

Unlock a user account and clear failed login attempts.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  unlockUser [parameters]
```

Parameters

Table 1078. Parameters

Parameter	Type	Required	Description
user	string	true	Name/ID of the user. The name will be case-sensitive if a case-sensitive realm is provided.
realm	string	false	Limit any user name search to given AuthenticationRealm.

Related REST command: Unlock a user account and clear failed login attempts..

unsetPreferredJavaPackage

Unsets a package as preferred for its OS and CPU, leaving no package as preferred.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  unsetPreferredJavaPackage [parameters]
```

Parameters

Table 1079. Parameters

Parameter	Type	Required	Description
package	string	true	Name or ID of the java package

Related REST command: Unset a package as preferred for its OS and CPU.

updateAgent

Update agent settings

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateAgent [parameters] [JSON file]
```

Parameters

Table 1080. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "configurationTemplate": "Name or id of the Agent
  Configuration Template to set for this agent",
  "description": "The description of the agent",
  "impersonationForce": "Force impersonation. When set to
  true, do not allow steps or resource configuration to
  change impersonation settings",
  "impersonationGroup": "Default group to use for
  impersonation",
  "impersonationPassword": "Password to use for
  impersonation (only applicable for Windows)",
```

```
  "impersonationUseSudo": "Use sudo for impersonation
  (only applicable for *nix)",
  "impersonationUser": "Default user to use for
  impersonation",
  "licenseType": "License type to use for this agent",
  "name": "Name of the agent"
}
```

Related REST command: Update agent settings.

updateApplicationPipeline

Update an application pipeline definition

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateApplicationPipeline [parameters] [JSON file]
```

Parameters

Table 1081. Parameters

Parameter	Type	Required	Description
application	string	false	Application name or id. Required if pipeline specified by name.
pipeline	string	true	Pipeline name or id.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "name of the application pipeline",
  "stages": [{
    "blocks": [{
      "environment": "name of the environment for this
  block",
      "processes": ["process-name"]
    }],
    "name": "name of the stage"
  }]
}
```

Related REST command: Update an application pipeline definition.

updateApplicationTemplate

Update an application template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateApplicationTemplate [parameters] [JSON file]
```

Parameters

Table 1082. Parameters

Parameter	Type	Required	Description
applicationTemplate	string	true	The name or ID of an existing application template

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Application template description
  (Optional)",
  "enforceCompleteSnapshots": "Specify true to require an
  explicit version for each component",
  "name": "Application template name",
  "notificationScheme": "Notification scheme (Optional)",
  "onlyChangedVersions": "If true, the 'Only Deploy
  Changed Versions' deployment option will be checked by
  default (default: true)",
  "tagRequirements": [
    {
      "name": "Name of the Component tag",
      "number": "Number of components for the tag",
      "type": "GREATER_THAN, LESS_THAN, or EQUALS"
    },
    " (Optional)"
  ],
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    " (Optional)"
  ],
  "useWizard": "Specify true to use the Deployment Wizard
  when submitting application process request (default:
  false)"
```

```
}
```

Related REST command: Update an application template.

updateApplicationTemplatePropDefs

Update an application template prop sheet def from a JSON file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateApplicationTemplatePropDefs [parameters] [JSON file]
```

Parameters

Table 1083. Parameters

Parameter	Type	Required	Description
applicationTemplate	string	true	Name or ID of the application template

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "allowedValues": "Optional, array of elements {\"
  value\":\"Required, a value\",\"label\":\"Optional,
  defaults to value\"}",
    "description": "Optional",
    "httpAuthenticationType": "Optional, BASIC or BEARER",
    "httpBasePath": "Optional",
    "httpFormat": "JSON or XML",
    "httpLabelPath": "Optional",
    "httpPassword": "Optional",
    "httpUrl": "Optional, required for Http property types",
    "httpUsername": "Optional",
    "httpValuePath": "Optional",
    "label": "Optional, label displayed to user",
    "name": "Required, the property name",
    "pattern": "Optional, regular expression for the value",
    "required": "Optional boolean, if the property is
  required",
    "resolveHttpValuesUrl": "Optional",
    "type": "Optional, Default TEXT, Type of property
  definition",
    "value": "Optional, Default value"
  }]
}
```

Related REST command: Update an application template prop sheet def from a JSON file..

updateAuthenticationRealm

Update the basic settings of an AuthenticationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateAuthenticationRealm [JSON file]
```

Parameters

Table 1084. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the AuthenticationRealm

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "authorizationRealmIds": ["AuthorizationRealms"],
  "description": "A descrption (optional)",
  "name": "AuthenticationRealm name",
  "properties": {
    "auth-endpoint": "OIDC: The URI for authorization with
  the OpenID Provider",
    "authentication-mech": "LDAP: Simple or DIGEST-MD5",
    "client-id": "OIDC: The Client ID which is registered
  with the OpenID Provider",
    "client-secret": "OIDC: The Client Secret which is
  provided by the OpenID Provider upon registration",
    "connection-name": "LDAP: The username to use for
  Simple binding to LDAP for searches. If not specified, an
  anonymous connection is made.",
    "connection-password": "LDAP: The password to use for
  Simple binding to LDAP for searches.",
    "email-claim": "OIDC: The claim containing the user's
  email.",
    "end-session-endpoint": "OIDC: Optional: The URI for
  RP-initiated logout",
    "end-session-id-token-hint": "OIDC: If an ID token
  hint parameter (id_token_hint) is appended to the End
  Session Endpoint URL.",
    "groups-delim": "SSO: A string that acts as the
  delimiter between groups that are passed in the headers.
  For example, if the user should be added to groups GROUP1
  and GROUP2, and the header value was \"GROUP=GROUP1;
  GROUP=GROUP2\" the delimiter would be ';'. Note: special
  regex characters such as '+' must be escaped with one
  backslash ''.",
```

```
    "groups-header": "SSO: The header name that denotes
  the user groups to which user will be added.",
    "groups-regex": "SSO: The regular expression to find
  the groups in the header value. If a capturing group is
  specified, only the first will be caught (per delimited
  string). If no capturing group is specified with
  parentheses, then the whole delimited string will be
  captured.",
    "issuer": "OIDC: The issuer identifier for the issuer
  of the token response.",
    "jwks-uri": "OIDC: The JSON Web Key Sets URI endpoint",
    "name-claim": "OIDC: The claim containing user's name.",
    "sasl-realm": "LDAP: The sasl Realm for DIGEST-MD5
  authentication",
    "token-endpoint": "OIDC: 'The URI for token requests
  with the OpenID Provider",
    "url": "LDAP: The URL of the LDAP server. It should
  begin with 'ldap://' or 'ldaps://'. Failover servers can
  be added by separating the URLs with a space. Example:
  ldap://ldap.mydomain.com:389 ldap://ldap.mydomain2.com",
    "user-base": "LDAP: When you search multiple
  directories, specify the starting directory that is used
  for searches, such as ou=employees,dc=mydomain,dc=com.",
    "user-pattern": "LDAP: LDAP users exist in a single
  directory; use a pattern to create the DN for users.",
    "user-search": "LDAP: The LDAP filter expression to
  use when searching for user directory entries. The
  username is put in place of {0} in the search pattern. If
  this is an attribute and not part of the user DN, wrap in
  parentheses. E.g. uid={0} or (sAMAccountName={0})",
    "user-search-subtree": "LDAP: Search the full subtree
  for the user, as opposed to a single-level search only
  covering users directly inside the specified search base.
  \"true\" or \"false\"",
    "userinfo-endpoint": "OIDC: The URI for userinfo
  requests with the OpenID Provider"
  },
  "type": [
    "Any one of:",
    "INTERNAL",
    "LDAP",
    "SSO",
    "OIDC"
  ]
}
```

Related REST command: Update the basic settings of an AuthenticationRealm.

updateAuthorizationRealm

Update the basic settings of an AuthorizationRealm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateAuthorizationRealm [parameters] [JSON file]
```

Parameters

Table 1085. Parameters

Parameter	Type	Required	Description
realm	string	true	Name or ID of the AuthorizationRealm

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "A descrption (optional)",
  "name": "AuthorizationRealm name",
  "properties": {
    "authentication-mech": "LDAP: Simple or DIGEST-MD5",
    "connection-name": "LDAP: The username to use for
  Simple binding to LDAP for searches. If not specified, an
  anonymous connection is made.",
    "connection-password": "LDAP: The password to use for
  Simple binding to LDAP for searches.",
    "group-attribute": "LDAP: The name of the attribute
  that contains group names in the user directory entry.",
    "group-base": "LDAP: The base directory to execute
  group searches in.",
    "group-name": "LDAP: The name of the entry that
  contains the user's group names in the directory entries
  returned by the group search. If this is not specified, no
  group search will take place.",
    "group-search": "LDAP: The LDAP filter expression to
  use when searching for group entries. The username will be
  put in place of {1} in the search pattern and the full
  user DN will be put in place of {0}.",
    "group-search-iterative": "LDAP: Perform additional
  lookups to find indirectly assigned groups. This option
  may significantly increase the amount of time required to
  authenticate users. Consult your LDAP administrators
  before enabling this option.",
    "group-search-subtree": "LDAP: Search the full subtree
  for the groups, as opposed to a single-level search only
  covering groups directly inside the specified search
  base.",
    "groups-delim": "SSO: A string that acts as the
  delimiter between groups that are passed in the headers.
  For example, if the user should be added to groups GROUP1
  and GROUP2, and the header value was \"GROUP=GROUP1;
  GROUP=GROUP2\" the delimiter would be ';'. Note: special
  regex characters such as '+' must be escaped with one
  backslash ''.",
    "groups-header": "SSO: The header name that denotes
  the user groups to which user will be added.",
    "groups-regex": "SSO: The regular expression to find
  the groups in the header value. If a capturing group is
  specified, only the first will be caught (per delimited
```

```
  string). If no capturing group is specified with
  parentheses, then the whole delimited string will be
  captured.",
    "sasl-realm": "LDAP: The sasl Realm for DIGEST-MD5
  authentication",
    "url": "LDAP: The URL of the LDAP server. It should
  begin with 'ldap://' or 'ldaps://'. Failover servers can
  be added by separating the URLs with a space. Example:
  ldap://ldap.mydomain.com:389 ldap://ldap.mydomain2.com",
    "user-base": "LDAP: When you search multiple
  directories, specify the starting directory that is used
  for searches, such as ou=employees,dc=mydomain,dc=com.",
    "user-pattern": "LDAP: LDAP users exist in a single
  directory; use a pattern to create the DN for users.",
    "user-search": "LDAP: The LDAP filter expression to
  use when searching for user directory entries. The
  username is put in place of {0} in the search pattern. If
  this is an attribute and not part of the user DN, wrap in
  parentheses. E.g. uid={0} or (sAMAccountName={0})",
    "user-search-subtree": "LDAP: Search the full subtree
  for the user, as opposed to a single-level search only
  covering users directly inside the specified search base.
  \"true\" or \"false\""
  }
}
```

Related REST command: Update the basic settings of an AuthorizationRealm.

updateComponent

Update the basic settings of a component

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateComponent [parameters] [JSON file]
```

Parameters

Table 1086. Parameters

Parameter	Type	Required	Description
component	string	true	The name or id of an existing component

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "cleanupCountToKeep": "Number of most recent versions to
  keep; omit this parameter to inherit the system settings
  (Optional)",
  "cleanupDaysToKeep": "Number of days to keep versions;
  omit this parameter to inherit the system settings
```

```
  (Optional)",
  "defaultVersionType": "The default type to create
  versions with; valid values are FULL and INCREMENTAL
  (Optional)",
  "description": "Description (Optional)",
  "importAutomatically": "Specify true to import new
  versions automatically (Optional)",
  "inheritSystemCleanup": "Inherit the system cleanup
  settings. If set to true, this overrides the other cleanup
  attributes. (Optional, Boolean)",
  "integrationAgent": "ID of the Agent to use for
  importing new component versions (Optional)",
  "integrationTag": "Tag name of the Agent to use for
  importing new component versions (Optional)",
  "properties": {"Source configuration plugin property
  name": "Property value"},
  "sourceConfigPlugin": "The name of the source
  configuration plug-in to use (Optional)",
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ],
  "template/nameOfTemplateProperty": "value of a template-
  inherited property with name prefixed by 'template/'
  (Optional)",
  "templateId": "ID of the template to use (Optional)",
  "templateName": "Name of a template to use; this
  parameter is ignored if  templateId is specified
  (Optional)",
  "templateVersion": "Version number of the specified
  template (Optional)",
  "useVfs": "Boolean (Optional)"
}
```

Related REST command: Update the basic settings of a component.

updateComponentResourcePropDef

Update a component resource property definition

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateComponentResourcePropDef [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "allowedValues": "Comma separated list of allowed values
  in SELECT or MULTI_SELECT properties (Optional)",
  "component": "Name or ID of the component",
  "description": "Description for the property (Optional)",
  "label": "Label of the property (Optional)",
  "name": "Name of the property to set",
  "pattern": "A regular expression that specifies valid
  values for the property. Follows java.util.regex.Pattern
  (Optional)",
  "required": "Whether the property is required (Optional,
  Boolean)",
  "type": "the type of property definition; valid values
  are TEXT (the default), , TEXTAREA, CHECKBOX, SELECT,
  MULTI_SELECT, DATETIME, and SECURE)",
  "value": "Default value of the property definition
  (Optional)"
}
```

Related REST command: Update a component resource property definition.

updateComponentTemplatePropDefs

Update a component template prop-def sheet from a JSON file. Replaces the property definitions.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateComponentTemplatePropDefs [parameters] [JSON file]
```

Parameters

Table 1087. Parameters

Parameter	Type	Required	Description
componentTemplate	string	true	Name or ID of the component template

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
```

```
    "allowedValues": "Optional, array of elements {\"
  value\":\"Required, a value\",\"label\":\"Optional,
  defaults to value\"}",
    "description": "Optional",
    "httpAuthenticationType": "Optional, BASIC or BEARER",
    "httpBasePath": "Optional",
    "httpFormat": "JSON or XML",
    "httpLabelPath": "Optional",
    "httpPassword": "Optional",
    "httpUrl": "Optional, required for Http property types",
    "httpUsername": "Optional",
    "httpValuePath": "Optional",
    "label": "Optional, label displayed to user",
    "name": "Required, the property name",
    "pattern": "Optional, regular expression for the value",
    "required": "Optional boolean, if the property is
  required",
    "resolveHttpValuesUrl": "Optional",
    "type": "Optional, Default TEXT, Type of property
  definition",
    "value": "Optional, Default value"
  }]
}
```

Related REST command: Update a component template prop-def sheet from a JSON file.

updateEnvironment

Update an environment

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateEnvironment [parameters] [JSON file]
```

Parameters

Table 1088. Parameters

Parameter	Type	Required	Description
environment	string	true	Name or ID of the environment
application	string	false	Name or ID of the application; this value is required if you specify the environment name instead of ID

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationId": "Application ID associated with the
  Environment template.",
```

```
  "cleanupCountToKeep": "Number of most recently deployed
  versions to keep (optional)",
  "cleanupDaysToKeep": "Number of days to keep versions
  deployed to this environment (optional)",
  "color": "HTML color code for the environment (optional)",
  "description": "Description (optional)",
  "exemptProcessesArray": "An array of process Ids. These
  processes will be exempt from approvals for this
  environment (optional).",
  "externalApprovalAgent": "Name or id of agent to run
  external approval processes on (optional).",
  "externalApprovalAgentPool": "Name or id of agent pool
  to run external approval processes on (optional).",
  "externalApprovalProcess": "Name or id of external
  approval process(optional).",
  "historyCleanupDaysToKeep": "Number of days to keep
  application process history for this environment
  (optional)",
  "inheritSystemCleanup": "Inherit the system cleanup
  settings. If set to true, this overrides the other cleanup
  attributes. (optional, boolean)",
  "lockSnapshots": "Whether snapshots will be locked when
  deployed to this environment (optional)",
  "name": "Environment name",
  "noSelfApprovals": "When this option is selected, users
  that submit deployment requests cannot approve their own
  requests (optional)",
  "requireApprovals": "Whether approvals will be required
  (optional)",
  "requireSnapshot": "If enabled, all deployments must use
  a snapshot instead of loose versions (optional)",
  "snapshotDaysToKeep": "Number of days to keep snapshots
  deployed to this environment (optional)",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }],
  "useSystemDefaultDays": "Whether or not to use the
  system default number of days to keep application process
  history for this environment (optional)"
}
```

Related REST command: Update an environment.

updateEnvironmentProperty

Update a component environment property

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateEnvironmentProperty [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "component": "Name or ID of the component",
  "default": "Default value (Optional)",
  "description": "Description for the property (Optional)",
  "label": "Label of the property (Optional)",
  "name": "Name of the property",
  "pattern": "A regular expression that specifies valid
  values for the property. Follows java.util.regex.Pattern
  (Optional)",
  "required": "Whether the property is required (Optional,
  Boolean)"
}
```

Related REST command: Update a component environment property.

updateEnvironmentTemplate

Update the basic settings of an environment template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateEnvironmentTemplate [parameters] [JSON file]
```

Parameters

Table 1089. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	ID of the environment template

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "applicationTemplateId": "ID of the application template
  to which the environment template belongs",
  "cleanupCountToKeep": "Number of most recently deployed
  versions to keep (Optional)",
```

```
  "cleanupDaysToKeep": "Number of days to keep versions
  deployed to this environment (Optional)",
  "color": "HTML color code for the environment template",
  "description": "description of the template (Optional)",
  "environmentType": "type of environment, leave blank for
  Standard Environment",
  "exemptProcessesArray": "An array of process Ids. These
  processes will be exempt from approvals for this
  environment (Optional).",
  "externalApprovalAgent": "Name or id of agent to run
  external approval processes on (Optional).",
  "externalApprovalAgentPool": "Name or id of agent pool
  to run external approval processes on (Optional).",
  "externalApprovalProcess": "Name or id of external
  approval process(Optional).",
  "historyCleanupDaysToKeep": "Number of days to keep
  application process history for this environment
  (Optional)",
  "lockSnapshots": "Whether snapshots will be locked when
  deployed to this environment (Optional)",
  "name": "name of the environment template",
  "noSelfApprovals": "When this option is selected, users
  that submit deployment requests cannot approve their own
  requests (Optional)",
  "requireApprovals": "Whether approvals will be required
  (Optional)",
  "requireSnapshot": "If enabled, all deployments must use
  a snapshot instead of loose versions (Optional)",
  "resourceTemplate": "ID of the resource template to use",
  "snapshotDaysToKeep": "Number of days to keep snapshots
  deployed to this environment (Optional)",
  "snapshotLockType": "type of snapshot lock: ALL,
  VERSIONS, CONFIGURATION (Required with \"lockSnapshots\"",
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (Optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (Optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ],
  "useSystemDefaultDays": "Whether or not to use the
  system default number of days to keep application process
  history for this environment (Optional)"
}
```

Related REST command: Update the basic settings of an environment template.

updateEnvironmentTemplatePropDefs

Update an environment template prop sheet def from a JSON file.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateEnvironmentTemplatePropDefs [parameters] [JSON file]
```

Parameters

Table 1090. Parameters

Parameter	Type	Required	Description
environmentTemplate	string	true	ID of the environment template

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "README": "See entity attribute for the template
  description expected by this endpoint.",
  "entity": [{
    "allowedValues": "Optional, array of elements {\"
  value\":\"Required, a value\",\"label\":\"Optional,
  defaults to value\"}",
    "description": "Optional",
    "httpAuthenticationType": "Optional, BASIC or BEARER",
    "httpBasePath": "Optional",
    "httpFormat": "JSON or XML",
    "httpLabelPath": "Optional",
    "httpPassword": "Optional",
    "httpUrl": "Optional, required for Http property types",
    "httpUsername": "Optional",
    "httpValuePath": "Optional",
    "label": "Optional, label displayed to user",
    "name": "Required, the property name",
    "pattern": "Optional, regular expression for the value",
    "required": "Optional boolean, if the property is
  required",
    "resolveHttpValuesUrl": "Optional",
    "type": "Optional, Default TEXT, Type of property
  definition",
    "value": "Optional, Default value"
  }]
}
```

Related REST command: Update an environment template prop sheet def from a JSON file..

updateExternalApprovalProcess

Update the basic settings of an external approval process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateExternalApprovalProcess [parameters] [JSON file]
```

Parameters

Table 1091. Parameters

Parameter	Type	Required	Description
externalApprovalProcess	string	true	Name or ID of the external approval process

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Description of the process",
  "name": "Name of the process",
  "propDefs": ["(Optional)"],
  "teamMappings": [
    {
      "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (Optional, can specify either this or
  resourceRoleLabel",
      "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (Optional, can specify either this or
  resourceRoleId",
      "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
      "teamLabel": "Name of the team to map the
  environment to, either this field or teamId are needed to
  specify a team"
    },
    "(Optional)"
  ],
  "workingDir": "The working directory of the process"
}
```

Related REST command: Update the basic settings of an external approval process.

updateMaintenanceBlackout

Modifies the given maintenance blackout. A date cannot be modified if it has already occurred. For recurring blackouts, only real events (synthetic=false) can be updated. For recurring blackouts, updating the date of the real event also alters the start and duration of future events within each recurrence time interval (day, week, or month).

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateMaintenanceBlackout [parameters]
```

Parameters

Table 1092. Parameters

Parameter	Type	Required	Description
id	string	true	The id of the maintenance blackout to cancel.
startDate	string	false	(Optional) The date the maintenance blackout starts. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time. (Optional)
endDate	string	false	(Optional) The date the maintenance blackout ends. In the format MM-dd-yyyy-HH:mm or in milliseconds since the UNIX epoch time. (Optional)
name	string	false	(Optional) The name or description of the blackout.

Related REST command: Modify the given maintenance blackout.

updateResource

Update a resource

To update a resource with this command, you must specify all of the existing data for the resource.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateResource [parameters] [JSON file]
```

Parameters

Table 1093. Parameters

Parameter	Type	Required	Description
resource	string	true	ID or path to the resource, such as /ResourceGroup/Agents/Agent1
template	string	false	Name or ID of the resource template (Optional)
blueprintId	string	false	Name or ID of the blueprint (Optional)
application	string	false	Name or ID of the application (Required to look up blueprint by name)

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agent": "Name or ID of an agent to use for automation
  (Optional)",
  "agentPool": "Name or ID of an agent pool to use for
  automation (Optional)",
  "component": "Name or ID of a component to associate
  with the resource (Optional)",
  "componentTag": "Name or ID of a component tag to
  associate with the resource; any components with that tag
  can be deployed to this resource (Optional)",
  "description": "Description",
  "impersonationForce": "Specify true to prevent children
  or steps from specifying their own impersonation settings
  (Optional)",
  "impersonationGroup": "Group for default impersonation
  (Optional)",
  "impersonationPassword": "Password for default
  impersonation. Agents running on Linux and Unix machines
  will ignore this value (Optional)",
  "impersonationUseSudo": "Specify true to use the sudo
  command for impersonation. Agents running on Windows
  machines will ignore this value (Optional)",
  "impersonationUser": "User name for default
  impersonation (Optional)",
  "inheritTeam": "Whether or not to set inherit teams for
  resource. teamMappings will be ingored if true. Defaults
  to true (Optional)",
  "name": "Name for the new resource; leave blank to
  inherit the name from an agent, pool, or role",
  "parent": "ID or path to parent resource; leave blank to
  create a root resource (Optional)",
  "role": "Name or ID of a resource role to associate with
  the agent; if this resource is for a component, specify
  the component name instead (Optional)",
  "roleProperties": {"Property name": "Property value
  (Optional)"},
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  }]
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  updateResource
  -resource "/My resource"
  updateResource.json
```

Example

Example JSON request

```
{
  "name": "New resource name",
  "description": "An updated resource",
}
```

Related REST command: Update a resource.

updateResourceTemplate

Update a resource template from a JSON file

To update a resource template with this command, you must specify all of the existing data for the resource template as defined in the JSON data template, except 'teamMappings' which is optional.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateResourceTemplate [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Description",
  "existingId": "ID of resource template; leave blank when
  creating new template",
  "name": "Name for the resource template",
  "rootTeamMappings": "Array of team ids; if not
  specified, no teams will be mapped to Root Resource;
  format: [ {teamId: '<ID-of-team-1>'}, {teamId: '<ID-of-
  team-2>'}, ... ]; (Optional)",
  "teamMappings": "Array of team ids; if not specified, no
  teams will be mapped to Template; format: [ {teamId: '<ID-
  of-team-1>'}, {teamId: '<ID-of-team-2>'}, ... ];
  (Optional)"
}
```

Related REST command: Update a resource template from a JSON file.

updateRoleActions

Update any number of Actions for one or more Roles + Types

Update the Actions for one or more Roles. Only explicitly specified mappings will be added/removed.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateRoleActions [JSON file]
```

Parameters

None.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{"[Role Name]": {"[Object Type]": {"[Type Name]":
  {"[Action]": "true|false"}}}}
```

Related REST command: Update any number of Actions for one or more Roles + Types.

updateTeam

Update a team

Specify the team name in the 'team' parameter and use the 'name' and 'description' parameters to specify the desired changes.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateTeam [parameters]
```

Parameters

Table 1094. Parameters

Parameter	Type	Required	Description
team	string	true	Name of the team to be changed
name	string	false	New name of the team
description	string	false	New description of the team

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
```

```
  updateTeam
  -team MyNewTeam
  -name ADifferentTeamName
  -description "ADifferentTeamDescription"
```

Related REST command: Update a team.

updateUser

Update a user

Specify the user name in the 'user' parameter and use the JSON string to specify new information about the user. This command can update the name and email address of the user, but not the password.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateUser [parameters] [JSON file]
```

Parameters

Table 1095. Parameters

Parameter	Type	Required	Description
user	string	true	Name/ID of the user. The name will be case-sensitive if a case-sensitive realm is provided.
realm	string	false	Limit any user name search to given AuthenticationRealm.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "actualName": "User real name (optional)",
  "email": "Email address (optional)"
}
```

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  updateUser
  -user jsmith
  updateUser.json
```

Example

Example JSON request

```
{
  "password": "password",
  "actualName": "Jane Smith",
  "email": "jsmith@example.org"
}
```

Related REST command: Update a user.

updateUsersInAuthRealm

Update all users in an authentication realm

This command updates all users in an authentication realm

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateUsersInAuthRealm
```

Parameters

Table 1096. Parameters

Parameter	Type	Required	Description
authenticationRealm	string	true	Name of the authentication realm

Related REST command: Update all users in an authentication realm.

updateVaultAppRole

Update a Vault AppRole

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateVaultAppRole [parameters] [JSON file]
```

Parameters

Table 1097. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultAppRole	string	true	Name or ID of the Vault App Role

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "The Vault App Role Name (Optional, Unique per
  Vault store)",
  "roleId": "The Vault Role ID (Optional)",
  "secretId": "The Vault Secret ID (Optional)"
}
```

Related REST command: Update a Vault AppRole.

updateVaultCertificate

Update a Vault Certificate

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateVaultCertificate [parameters] [JSON file]
```

Parameters

Table 1098. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Secret Store ID/Name
vaultCertificate	string	true	Name or ID of the Vault Certificate

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "certificatePEM": "The certificate to be stored in PEM
  format(Optional - required if privateKeyPEM set)",
  "name": "The Vault Certificate Name (Optional, Unique
  per Vault store)",
  "privateKeyPEM": "The private key to be stored in PEM
  format(Optional - required if certificatePEM set)"
}
```

Related REST command: Update a Vault Certificate.

updateVaultLdapUser

Update a new Vault Ldap User

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateVaultLdapUser [parameters] [JSON file]
```

Parameters

Table 1099. Parameters

Parameter	Type	Required	Description
store	string	false	Vault Store ID/Name
vaultLdapUser	string	true	Name or ID of the Vault Ldap User

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "name": "The Vault Ldap User Name (Required, Unique per
  Vault store)",
  "password": "The Vault Ldap Users password (Optional)"
}
```

Related REST command: Update a new Vault Ldap User.

updateVaultSecretStore

Update a secret store.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateVaultSecretStore [parameters] [JSON file]
```

Parameters

Table 1100. Parameters

Parameter	Type	Required	Description
store	string	true	Name or id of the secret store.

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "Secret Store description",
```

```
  "name": "Secret Store name",
  "namespace": "Vault Server Namespace (optional)",
  "teamMappings": {
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the environment
  to, either this field or teamId are needed to specify a
  team"
  },
  "type": "vault",
  "url": "Vault Server URL"
}
```

Related REST command: Update a secret store..

updateWebhookForApplication

Update an application webhook

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateWebhookForApplication [parameters]
```

Parameters

Table 1101. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	false	ID or name of webhook template
url	string	false	Url for the webhook
environment	string	false	ID of environment to add the webhook to. This can be repeated for multiple environments.
webhookProxyHost	string	false	Host name of http proxy.
webhookProxyPort	string	false	Port of http proxy.
webhookProxyUsername	string	false	Username for authentication with http proxy.

Table 1101. Parameters (continued)

Parameter	Type	Required	Description
webhookProxyPassword	string	false	Password for authentication with http proxy.
webhook	string	true	ID of webhook
application	string	true	ID or name of application

Related REST command: Update an application webhook.

updateWebhookForApplicationWithCredentials

Update an application webhook

Update the settings for an application webhook.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateWebhookForApplicationWithCredentials [JSON file]
```

Parameters

Table 1102. Parameters

Parameter	Type	Required	Description
webhook	string	true	ID of webhook
application	string	true	ID or name of application

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "environments": ["Name or ID of environments"],
  "proxyHost": "Proxy Host. Updating proxy host will unset
  proxy username and password if those are not provided",
  "proxyPassword": "Password to use for basic
  authentication with the proxy",
  "proxyPort": "Proxy Port. Updating proxy port will unset
  proxy username and password if those are not provided",
  "proxyUsername": "Username to use for basic
  authentication with the proxy",
  "url": "Url for the webhook",
  "webhookTemplate": "Name or ID of the webhook template"
```

```
}
```

Related REST command: Update an application webhook.

updateWebhookForProcess

Updates a webhook for a process

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateWebhookForProcess [parameters]
```

Parameters

Table 1103. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	Id or name of webhook template.
url	string	true	Url for the webhook
webhookProxyHost	string	false	Host name of http proxy.
webhookProxyPort	string	false	Port of http proxy.
webhookProxyUsername	string	false	Username for authentication with http proxy..
webhookProxyPassword	string	false	Password for authentication with http proxy.
process	string	true	Id or name of process
webhook	string	true	Id of webhook

Related REST command: Updates a webhook for a process.

updateWebhookForProcessWithCredentials

Updates a webhook for a process.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateWebhookForProcessWithCredentials [JSON file]
```

Parameters

Table 1104. Parameters

Parameter	Type	Required	Description
process	string	true	Id or name of process
webhook	string	true	Id of webhook

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "proxyHost": "Proxy Host. Updating proxy host will unset
  proxy username and password if those are not provided",
  "proxyPassword": "Password to use for basic
  authentication with the proxy",
  "proxyPort": "Proxy Port. Updating proxy port will unset
  proxy username and password if those are not provided",
  "proxyUsername": "Username to use for basic
  authentication with the proxy",
  "url": "Url for the webhook",
  "webhookTemplate": "Name or ID of the webhook template"
}
```

Related REST command: Updates a webhook for a process..

updateWebhookTemplate

Update a webhook template

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  updateWebhookTemplate [parameters] [JSON file]
```

Parameters

Table 1105. Parameters

Parameter	Type	Required	Description
webhookTemplate	string	true	Name or ID of the webhook template to update

Template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "body": "The webhook template body specified with Apache
  Velocity template syntax",
  "description": "Description (Optional)",
  "id": "ID of the webhook template to update",
  "name": "Name of the new webhook template",
  "teamMappings": [{
    "resourceRoleId": "Id of Resource Type to apply to
  this team mapping (optional, can specify either this or
  resourceRoleLabel",
    "resourceRoleLabel": "Name of Resource Type to apply
  to this team mapping (optional, can specify either this or
  resourceRoleId",
    "teamId": "ID of a team, either this field or
  teamLabel are needed to specify a team",
    "teamLabel": "Name of the team to map the webhook
  template to, either this field or teamId are needed to
  specify a team"
  }],
  "type": "Webhook template type [PROCESS_SUCCESS,
  PROCESS_FAILURE, PROCESS_STARTED, APPROVAL_COMPLETED,
  APPROVAL_FAILED, EXTERNAL_APPROVAL_COMPLETED,
  EXTERNAL_APPROVAL_FAILED, SCHEDULED_PROCESS_NOT_STARTED,
  TASK_CREATED]"
}
```

Related REST command: Update a webhook template.

upgradeAgent

Upgrade an agent

The agent will be upgraded to the agent version corresponding with the server version.

Format

```
udclient [global-args...] on page 2592 [global-flags...] on page 2592
  upgradeAgent [parameters]
```

Parameters

Table 1106. Parameters

Parameter	Type	Required	Description
agent	string	true	Name or ID of the agent

Example

Example

```
udclient -username jsmith -password passwd
  -weburl https://deployserver.example.com:8443
  upgradeAgent
  -agent Agent1
```

Related REST command: Upgrade an agent.

Process-as-code feature

Programmatically manage processes with PAC language.

The process as code feature (PAC) lets you use the command line to create HCL DevOps Deploy (Deploy) processes. You can create scripts that define processes and then upload them to the server. You can download process designs and modify them in your text editor.

The PAC language supports Deploy processes. You write PAC scripts in the PAC language. The PAC language provides elements that describe process step commands, step properties, and connecting steps, such as Switch. PAC files are identified by the `pac` file extension.

Using the PAC commands

Use the PAC language to create HCL DevOps Deploy (Deploy) processes.

Before you begin

To get started, install the PAC tools.

1. On the dashboard, click **Help > Tools > Process-as-code Compiler**.
2. Extract the downloaded `pacc-version_number` file.
3. Optionally, if you want to reference PAC commands from anywhere on your computer, add the folder to your `path` system variable.

About this task

To use PAC scripts in your applications, upload valid PAC files to the Deploy server. You initially create processes in the process designer and then download them as PAC files. When you finish editing the PAC script, you upload them to the server. The processes that you define in PAC files are identical to the processes that you define in the process designer.

The PAC tools consist of a number of command files. The primary commands are upload and download. The primary commands are further organized by type: application, component, and generic. For example, the PAC command to upload an application process is: `upload-application-process`. The PAC command to download a generic process is: `download-generic-process`. Similarly, you can upload and download a component process using the PAC commands.

Upload examples

The command format for uploading PAC files is provided in the following code example:

```
upload-<process-type>-process <user-name> <server-url> <process-id> <next-version> input.pac
```

All PAC scripts have the same arguments and differ only by the type of process referenced. For example, to upload an application-type file named `my_command.pac`, the command might look like the following code example:

```
upload-application-process my_user_name https://my_server:4540 17542df8-a0a3-7b7d-ffa9-88ebe19324a9 2
 my_command.pac
```

This command example uploads a new version of the application process defined in the `my_command.pac` file.

Download examples

The command format for downloading PAC files is provided in the following code example:

```
download-<process-type>-process <user-name> <server-url> <process-id> <next-version> input.pac
```

For example, to download an application-type file named `my_command.pac`, the command might look like the following code example:

```
download-application-process my_user_name https://my_server:4540 17542df8-a0a3-7b7d-ffa9-88ebe19324a9 3
 my_command.pac
```

This command example downloads the process identified by the version ID to a PAC file named `my_command.pac`. If the version is not specified, the latest version is downloaded.

Silent upload and download of PAC files

The upload and download commands prompt you to enter your password manually. However, you can upload and download the PAC files silently by adding the following parameters to the commands:

- `--password <your_PAC_password>`

  For example, the following command uploads the PAC file silently:

  ```
  upload-<process-type>-process <user-name> <server-url> <process-id> <next-version> input.pac --password
   <your_PAC_password>
  ```

- `--password-variable MY_PAC_PASSWORD`, where MY_PAC_PASSWORD is an environment variable that defines your PAC password. You can use this option in automation and scripts to supply the password without exposing it directly in the commands.

  For example, the following command uploads the PAC file without exposing your password in the command:

  ```
  upload-<process-type>-process <user-name> <server-url> <process-id> <next-version> input.pac
   --password-variable MY_PAC_PASSWORD
  ```

Notes:

- If you use both parameters in a command, the `--password` parameter is used in preference to the `--password-variable` parameter.
- If you use `--password-variable` but the named environment variable is not set, then the parameter does not work. In this case, the console prompts you to provide the password manually.

To implement PAC processes, complete the following steps:

1. From the dashboard, create a process.
   The process can be of any type, application, component, or generic. You use the ID assigned by the server to the process in your PAC files to identify the process. You do not need to define steps with the process designer.
2. From the command line, download the PAC file using the `download-<process-type>-process` PAC command.
3. In any text editor, edit the PAC file.
4. Upload the PAC file using the process ID assigned to it by the server.
   Along with the process ID you obtained from the server, you must assign a unique process version number to the uploaded process.

Results

The next time that you open the process designer, the designer displays the new process defined in the PAC file.

Understanding the PAC file format

Overall Syntax

```
-- Comments are indicated by a lead pair of dashes
```

The `start` block defines which steps will begin the process. Multiple steps can be started concurrently by listing multiple starts

```
start is
    start "step-1"
    start "step-2"
end
```

Step blocks define steps and begin with a keyword for the kind of step and declare the name of the step. Steps are linked together by name, so every step must have a unique name.

```
plugin step "step-1" is
    ...   -- explained later
end
```

Steps define what action to take after the step ends depending on the outcome.

```
plugin step "step-1" is
    ...
on success
    -- actions when the step succeeds
    start "step-2"
on failure
    -- actions when the step fails
    start "step-3"
on complete
    -- actions when the step completes regardless of success or failure
    start "step-4"
end
```

Each outcome can specify multiple actions. The action 'finish' means to start the implicit finish step.

```
plugin step "step-1" is
    ...
on success
```

```
    start "step-2"
    start "step-3"
    start "step-4"
on failure
    finish
```

Certain steps allow nesting processes.

```
for-each-resource-tag step "frt1" is
    ... -- explained later

    start is
        start "step-1"
    end

    plugin step "step-1" is
        ...
    on success
        finish
    end
on success
    start "step-2"
end
```

Step names must unique across top-level and nested processes. Nested process steps may only reference their nest mates.

String Syntax

Strings are used to specify step names and other custom values. Strings are specified by text surrounded by double quote characters.

```
"single quote"
```

Special characters can be embedded by escaping with a backslash. Double quote, carriage return, new line, horizontal tab, and backslash itself may be escaped this way.

```
" \" \r \n \t \\ "
```

Strings can also be specified by triple quotes. These strings do not allow escape characters, but they can extend over multiple lines or embed other special characters without quoting. When using triple quotes, triple quotes must be placed on newline. This restriction may be lifted later.

```
"""
cd C:\workdir
copy *.* "C:\Program Files\My Program"
"""
```

Triple quotes can be embedded in a triple quote string by doubling.

```
""" """""" <- becomes " repeated 3 times """
```

Multi-line triple quoted strings have the leading indent removed, where the indent is determined by the identation of the opening triple quote.

For example,

```
    """
    for x in *.txt
    do
        echo $x
        cat $x
    done
    """
```

becomes

```
for x in *.txt
do
    echo $x
    cat $x
done
```

Implemented Step Types

These are the currently implemented step types. Refer to the main product documentation for more information about the behavior of each step in a process.

Any type of process can be defined with this language, but not all steps are valid in every type of process.

`start`

The `start` block is a pseudo-step that defines the beginning of the process. As it is not a true step, it does not use the `step` keyword. The only completion condition is success, so `on success` is not required or permitted.

```
start is
    -- list one or more actions
    start "foo"
    start "bar"
end
```

Application process steps

Lists the various application steps that can be used in a process.

application-run-component-process

The `application-run-component-process` step executes a component process and waits for it to complete. This step is only valid in an application process.

Format

```
application-run-component-process step "foo" is
    -- name of the component to deploy; required
    component "my-component"

    -- name of the component process to run for each component; required
    process "deploy-my-component"

    -- select resources to run on by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "res-tag-1"
```

```
    -- select resources to run on based on inventory changes in other components; optional
    select-resources-by-changed-component-list
        -- select components to monitor for inventory changes; optional, repeatable
        -- before 7.1.1.0, the component must be specified by internal database ID
        component "comp-1"
        component "comp-2"

        -- specify which resources of this process's component are selected; required
        --   all - select all resources where this process's component is mapped
        --   with-changed-component - select only resources where both this process's component
        --                            and a monitored component are mapped and the monitored
        --                            component has changed
        select-resources all
    end

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"
on success
    finish
end
```

Table 1107.

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name
Component Process	The component process to run.

Example

Example

```
start is

    start A
```

```
    start B
    start C
    start D
end

application-run-component-process step A is
    component "comp-1"
    process "proc-1"
    select-resources-by-tag "resource-tag-1"
    select-resources-by-changed-component-list
        component "component-1"
        component "component-2"
        component "component-3"
        select-resources all
    end
    fail-fast true
    ignore-child-warnings true
    run-on-first-online-resource-only true
    max-concurrent-processes 101
    precondition-script "script-1"
    property "comp-1-prop-1" = "comp-1-prop-value-1"
    property "comp-1-prop-2" = "comp-1-prop-value-2"
    property "comp-1-prop-3" = "comp-1-prop-value-3"
on success
    finish
end
```

```
application-run-component-process step B is

    component "comp-2"

    process "proc-2"

    select-resources-by-changed-component-list

        select-resources with-changed-component

    end

on success

    finish

end

application-run-component-process step C is

    component "comp-3"

    process "proc-3"

    select-resources-by-tag "resource-tag-2"

    fail-fast true

    ignore-child-warnings true

    run-on-first-online-resource-only true

    max-concurrent-processes 102

    precondition-script "script-2"

    property "comp-3-prop-1" = "comp-3-prop-value-1"

    property "comp-3-prop-2" = "comp-3-prop-value-2"

    property "comp-3-prop-3" = "comp-3-prop-value-3"

on success

    finish

end

application-run-component-process step D is

    component "comp-4"
```

```
    process "proc-4"

on success

    finish

end
```

apply-configuration

The `apply-configuration` step starts child component processes for applying configuration changes. This step is only valid in an application process.

Format

```
apply-configuration step "foo" is
    -- name of the component to configure; required
    component "my-component"

    -- name of the component process to run; required
    -- must be a configuration deployment or a no-version-needed operational process
    process "deploy-component-process-property"

    -- select resources to apply to by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "my-tag"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"

on success
    start "bar"
end
```

Properties

Table 1108. Apply Configuration properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Maximum number of concurrent jobs	The maximum number component instances to apply the new configuration to simultaneously. For example, if you set the maximum number of concurrent processes to 2, the server applies the configuration to only two instances of a component at a time, even if many instances of the component are installed. To apply the configuration to every component instance simultaneously, specify `-1`. To limit the number of components to change at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Example

Example

```
start is
    start A
    start B
end

apply-configuration step A is
    component "component-a"
    process "process-a"
    select-resources-by-tag "res-tag-a"
    fail-fast true
    ignore-child-warnings true
    max-concurrent-processes 42
    precondition-script "script-a"
    property "prop-a1" = "prop-a1-value"
    property "prop-a2" = "prop-a2-value"
    property "prop-a3" = "prop-a3-value"
on success
```

```
    finish
end

apply-configuration step B is
    component "component-b"
    process "process-b"
on success
    finish
end
```

for-each-agent

The for-each-agent application process step lets you run a process for each agent in an environment.

Format

```
for-each-agent step "loop1" is
    -- define target resource tags; optional, repeatable
    -- before 7.1.1.0, the tag must be specified by internal database ID
    tag "res-tag-1"
    tag "res-tag-2"

    -- maximum number of agents to target concurrently; optional
    -- default is unlimited
    max-concurrent-agents unlimited

    -- must contain an embedded 'start' block that works like the top-level version
    start is
        start "install-c1"
    end

    -- contains one or more embedded steps of any type except for other for-each steps
    install-component step "install-c1" is
        component "c1"
        process "deploy"
        without-status "Active"
        fail-fast true
        ignore-child-warnings true
        max-concurent-processes 43

    -- on success/failure/complete reference steps inside the for-each
    -- 'finish' refers to the implied finish step inside the for-each
    on success
        finish
    end

-- on success/failure/complete outside an embedded step reference steps in the top-level process
on success
    start "next-step"
end
```

Properties

Table 1109. For Each Agent properties

Field	Description
Name	A name for the iteration container.
Limit to Resource Tags	A list of resource tags that limit the container. The subprocess runs only on the agent resources that have one or more of the specified resource tags.
Maximum number of concurrent processes	The maximum number of agents that run the subprocess at a time. To run the subprocess on every agent at once, specify `-1`. To limit the number of agents to deploy to at once, as in blue/green deployments or rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Example

Example

```
start is
    start A
    start B
end

for-each-agent step A is
    tag "res-tag-a1"
    tag "res-tag-a2"
    tag "res-tag-a3"

    max-concurrent-agents 42

    start is
        start A1
    end

    set-final-process-status step A1 is
        status success
    on success
        finish
    end
on complete
    finish
end

for-each-agent step B is
    start is
        start B1
    end

    set-final-process-status step B1 is
```

```
        status success
    on success
        finish
    end
on complete
    finish
end
```

for-each-resource-tag

The for-each-resource-tag application process step lets you run processes for resources selected by tag. This step is only valid in an application process.

Format

The for-each-resource-tag step is called For Each Tag in the HCL DevOps Deploy (Deploy) web application.

```
for-each-resource-tag step "loop1" is
    -- define target resource tags; required, repeatable
    -- before 7.1.1.0, the tag must be specified by internal database ID
    tag "res-tag-a1"
    tag "res-tag-a2"

    -- maximum number of tags to target concurrently; optional
    -- default is 1
    max-concurrent-tags 1

    -- must contain an embedded 'start' block that works like the top-level version
    start is
        start "install-c1"
    end

    -- contains one or more embedded steps of any type except for other for-each steps
    install-component step "install-c1" is
        component "c1"
        process "deploy"
        without-status "Active"
        fail-fast true
        ignore-child-warnings true
        max-concurent-processes 43

    -- on success/failure/complete reference steps inside the for-each
    -- 'finish' refers to the implied finish step inside the for-each
    on success
        finish
    end

-- on success/failure/complete outside an embedded step reference steps in the top-level process
on success
    start "next-step"
end
```

Properties

Table 1110. For Each Tag properties

Field	Description
Name	A name for the iteration container.
Tags	A list of resource tags to use in the container. The subprocess runs once for each resource tag. You can order the resource tags by dragging and dropping them.
Max Concurrent Tags	The maximum number of tags for which to run the subprocess at a time. To run the subprocess on all of the tags at the same time, specify `-1`. To run the subprocess on only a few of the tags at a time, as in blue/green deployments or rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Example

Example

```
start is
    start A
    start B
end

for-each-resource-tag step A is
    tag "res-tag-a1"
    tag "res-tag-a2"
    tag "res-tag-a3"

    max-concurrent-tags 10

    start is
        start A1
    end

    shell step A1 is
        "echo A1"
    on success
        finish
    end
on complete
    finish
end

for-each-resource-tag step B is
    tag "res-tag-b1"

    max-concurrent-tags unlimited

    start is
        start B1
    end
```

```
    shell step B1 is
        "echo B1"
    on success
        finish
    end
on complete
    finish
end
```

install-component

The install-component application process step starts child component processes that install a single component. This step is only valid in an application process.

Format

```
install-component step "foo" is
    -- name of the component to deploy; required
    component "my-component"

    -- name of the component process to run for each component; required
    process "deploy-component-process-property"

    -- select versions for deployment without this inventory status; required
    select-versions-without-inventory-status "Active"

    -- select resources to deploy to by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "my-tag"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"

on success
```

```
    start "bar"
end
```

Properties

Table 1111. Install Component properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. To install another component, add another install step to the process.
Use Versions Without Status	Restricts the components that can be used by the step. Components with the selected status are ignored. Available statuses: `Active` means ignore components that are currently deployed.
Component Process	The component process to run.
Limit to Tag	User-defined roles can be used in processes; see Adding tags to objects on page 2521.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously to deploy the component. For example, if you set the maximum number of concurrent processes to 2, only two instances of the component are installed at a time, even if many instances of the component are mapped to agents. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Example

Example

```
start is
    start A
    start B
end

install-component step A is
    component "component-a"
    process "process-a"
    select-versions-without-inventory-status "status-a"
    select-resources-by-tag "tag-a"
    fail-fast true
    ignore-child-warnings true
    max-concurrent-processes unlimited
    precondition-script "script-a"
    property "prop-a1" = "prop-a1-value"
    property "prop-a2" = "prop-a2-value"
    property "prop-a3" = "prop-a3-value"
on success
    finish
end

install-component step B is
    component "component-b"
    process "process-b"
    select-versions-without-inventory-status "status-b"
    fail-fast false
    ignore-child-warnings false
    max-concurrent-processes 10
on success
    finish
end
```

install-multiple-components

The `install-multiple-components` step runs child component processes that install multiple components. This step is only valid in an application process.

Format

```
install-multiple-components step "foo" is
    -- name of the component process to run for each component; required
    process "deploy"

    -- select versions for deployment without this inventory status; required
    select-versions-without-inventory-status "Active"

    -- select components to deploy by component tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-components-by-tag "comp-tag-a"

    -- select resources to deploy to by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "res-tag-a"
```

```
    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes per component; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- maximum number of components to deploy concurrently; optional
    -- default is 100
    max-concurrent-components 100

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

on success
    start "bar"
end
```

Properties

Table 1112. Install Multiple Components properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	A process for the components that contain the selected tag. The process name must be the same for each tagged component. Only components that contain the specified process run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Use Versions Without Status	Restricts the components that can be used by the step. Components with the selected status are ignored. Available statuses: `Active` means ignore components that are currently deployed.
Maximum number of	The maximum number of components to deploy at one time. For example, if you specify 5, this step deploys five components at a time to all agents to which the components are mapped. To run this step on all

Table 1112. Install Multiple Components properties (continued)

Field	Description
concurrent components	components at the same time, specify `-1`. To limit the number of components to access at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously to deploy each component. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are installed at a time, even if many instances of the component are mapped to agents. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Example

Example

```
start is
    start A
    start B
end

install-multiple-components step A is
    process "process-a"
    select-versions-without-inventory-status "status-a"
    select-components-by-tag "comp-tag-a"
    select-resources-by-tag "res-tag-a"
    fail-fast true
    ignore-child-warnings true
```

```
    max-concurrent-processes unlimited
    max-concurrent-components unlimited
    precondition-script "script-a"
on success
    finish
end

install-multiple-components step B is
    process "process-b"
    select-versions-without-inventory-status "status-b"
    max-concurrent-processes 1
    max-concurrent-components 2
on success
    finish
end
```

join

The join application process step.

Format

The `join` step halts processing until all connected steps are completed. The only valid completion condition is success, so `on success` is not required or permitted.

This step does not have properties.

Example

Example

```
join step "foo" is
    finish
end
```

release-lock step

The release-lock step releases a process lock.

Format

```
join step "foo" is
    finish
end
```

Properties

Table 1113. Release lock properties

Field	Description
Lock Name	A string value that identifies the lock.

Example

Example

```
start is
    start "A"
end

release-lock step "A" is
    lock "lock-name"
on success
    finish
end
```

rollback-component step

The rollback-component step starts child component processes for rolling back a single component. This step is only valid in an application process.

Format

```
rollback-component step "foo" is
    -- name of the component to deploy; required
    component "my-component"

    -- name of the component process to run for each component; required
    process "deploy-component-process-property"

    -- mode for selecting versions to rollback; required
    --   remove-undesired-incremental-versions - rollback incremental versions
    --   replace-with-last-deployed - rollback to previous version
    rollback-type replace-with-last-deployed

    -- select versions for rollback with this inventory status; required
    select-versions-with-inventory-status "Active"

    -- select resources to rollback on by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "my-tag"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
```

```
        true
        """

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"

on success
    start "bar"
end
```

Properties

Table 1114. Rollback Component properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. If you want to roll back another component, add another rollback step to the process or use the Rollback Multiple Components on page 2486 step.
Remove Versions with Status	Restricts the component versions that are affected by the step. Only versions with the selected status are affected. By default, the status `Active` refers to versions that are currently deployed.
Component Process	The component process to run. In most cases, select a component process that uninstalls the component.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Rollback type	Determines the type of rollback. If you specify `Remove Undesired Incremental Versions`, the server runs the uninstall process for each version that is not in the specified snapshot. See Rolling back to a snapshot on page 2437. If you specify `Replace with Last Deployed`, the server runs the specified process on the version that was installed when the process began. See Uninstalling components with an application process on page 2436.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously. For example, if you set the maximum number of concurrent processes to 2, only two instances of a component are rolled back at a time, even if there are many instances of the component. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

Field	Description
mponents	
Maximum number of concurrent processes	The maximum number of concurrent processes to run, per component. This setting limits the number of processes that run simultaneously. For example, if you set the maximum number of concurrent processes to 2, the process runs on only two instances of a component at a time, even if many instances of the component are installed. To run an unlimited number of concurrent processes, specify `-1` . To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Run on First Online Resource Only	Instead of being run by all agents that are mapped to the environment, the step runs only on the first online agent that the server identifies. The mechanism that is used to identify the "first" agent is database-dependent, and thus indeterminate. If no agents are online, the server skips the step and marks its status as "Not Mapped." This setting may cause the environment to become noncompliant or to provide unexpected results, because only one agent runs the process, even if many agents are mapped to the environment.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.
Run If Co	To run this step only if another step in the application process changes the inventory of a component, select this option. If you select a component tag, for this step to run, a component that contains that tag must have an inventory change. If you do not select a component tag, any inventory change that is caused by the application process causes

Table 1116. Operational component process properties (continued)

Field	Description
mponentwithTagChanges	this step to run. **Note:** Do not select the same component tag that you selected in the **Component Tag** list. Select an option in the **Resource Selection Mode** list to control the agent resources that this step runs on. To run the step on only resources where the inventory of other components changes, select **Only resources where component with selected tag is changed**. For example, you might have a component that contains some operational processes, such as "Restart HTTP Server." If you add the operational process to the application process, you can select this option to run only on machines where you are deploying changes to websites that are hosted. To run the operational process on all possible resources, select **All resources mapped to this process's component**. For example, if you deploy changes to a website, you might want to restart a load balancer that is on a different machine than the website. You can select this option to run the operational process wherever the "Load Balancer" component that contains the "Restart Load Balancer" operational process is mapped.

Example

end

run-operational-process-for-multiple-components step E is
    process "proc-5"
on success
    finish
end
```

uninstall-component

The `uninstall-component` step starts child component processes for uninstalling a single component. This step is only valid in an application process.

Format

```
uninstall-component step "foo" is
    -- name of the component to deploy; required
    component "my-component"

    -- name of the component process to run for each component; required
    process "deploy-component-process-property"
```

```
    -- mode for selecting versions to uninstall; required
    --   all - uninstall all versions installed
    --   selected-with-process - uninstall versions selected with the process
    select-versions all

    -- select versions for deployment with this inventory status; required
    select-versions-with-inventory-status "Active"

    -- select resources to uninstall from by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "my-tag"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"

on success
    start "bar"
end
```

Table 1117. Uninstall Component Properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component	Component that is used by the step; a step can affect a single component. All components that are associated with the application are available. To uninstall more than one component, add another uninstall step to the process.
Remove Versions with	Restricts the component versions that are affected by the step. Only versions with the selected status are affected. By default, the status `Active` refers to versions that are currently deployed.

Table 1117. Uninstall Component Properties (continued)

Field	Description
Status	
Component Process	The component process to run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Uninstall Type	The **All Existing** option removes all the versions of this component that are in the inventory. The **All Selected For Process** option removes only the versions that you specify when you start the application process.
Maximum number of concurrent processes	The maximum number of concurrent processes to run. This setting limits the number of processes that run simultaneously to uninstall component instances. For example, if you set the maximum number of concurrent processes to 2, only two instances of the component are uninstalled at a time, even if many instances of the component are currently installed. To run an unlimited number of concurrent processes, specify `-1`. To limit the number of processes to run at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer. **Note:** The maximum number of component processes that can run concurrently is limited by the hardware that hosts the agent.
Fail Fast	If this check box is selected, the step does not start more processes after one process fails.
Precondition	A JavaScript 1.7 script that defines a condition that must exist before the step can run. The condition must resolve to `true` or `false`. In the script, do not use the `${p:component.myProperty}` notation. For example, to check the value of a component property in a component process, use `properties.get("myProperty") == "myValue"`. See Property contexts on page 2508 for information about property access.

Example

Example

```
start is

    start A

    start B

end

uninstall-component step A is

    component "component-a"

    process "process-a"

    select-versions all

    select-versions-with-inventory-status "status-a"

    select-resources-by-tag "tag-a"

    fail-fast true

    ignore-child-warnings true

    max-concurrent-processes 100

    precondition-script "script-a"

    property "prop-a1" = "prop-a1-value"

    property "prop-a2" = "prop-a2-value"

    property "prop-a3" = "prop-a3-value"

on success

    finish

end

uninstall-component step B is

    component "component-b"

    process "process-b"

    select-versions selected-with-process

    select-versions-with-inventory-status "status-b"
```

```
on success

    finish

end
```

uninstall-multiple-components

The `uninstall-multiple-components` step starts child component processes for uninstalling multiple components. This step is only valid in an application process.

Format

```
uninstall-multiple-components step "foo" is
    -- name of the component process to run for each component; required
    process "deploy"

    -- mode for selecting versions to uninstall; required
    --   all - uninstall all versions installed
    --   selected-with-process - uninstall versions selected with the process
    select-versions all

    -- select versions for uninstall with this inventory status; required
    select-versions-with-inventory-status "Active"

    -- select components to uninstall by component tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-components-by-tag "comp-tag-a"

    -- select resources to uninstall from by resource tag; optional
    -- before 7.1.1.0, the tag must be specified by internal database ID
    select-resources-by-tag "res-tag-a"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes per component; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- maximum number of components to uninstall concurrently; optional
    -- default is 100
    max-concurrent-components 100

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """
```

```
on success
    start "bar"
end
```

Table 1118. Uninstall Multiple Components properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Component Tag	A user-defined component tag that is used to select components. Only components with the specified tag are modified by this step.
Component Process	The component process to run.
Limit to Resource Tag	The user-defined resource tag that determines which resource runs the process. Only a resource with this tag, or a resource that has a parent with this tag, runs the process. See Adding tags to objects on page 2521.
Remove Versions With Status	Restricts the components that are affected by the step. Only components with the selected status are affected. Available statuses: `Active` refers to components that are currently deployed.
Maximum number of concurr	The maximum number of components to uninstall at one time. For example, if you specify 5, this step runs the uninstall component processes for five components at a time. To run this step on all components at the same time, specify `-1`. To limit the number of components to access at once, as in rolling deployments, specify an integer. The server attempts to resolve the value to an integer. If the value does not resolve to an integer, then the `-1` value is used by default. You can use a property in this field, as long as the property resolves to an integer.

    select-versions-with-inventory-status "status-b"

on success

    finish

end
```

Core component process steps

Lists the various core component steps that can be used in a process.

add-inventory-status

The `add-inventory-status` step adds a status to a component resource.

Format

```
add-inventory-status step "foo" is
    -- name of the status to add to the component resource; required
    status "Active"
on success
    finish
end
```

Properties

Table 1119. Add Inventory Status properties

Field	Description
Status	The component resource that the process is running against will have an inventory entry created for it with the specified status. `Active` indicates that the component version is deployed to its target resource. You can create other statuses and have those statuses applied to component versions when processes are complete. The status is displayed on the Inventory panes for the component itself and environments that ran the process.

Example

Example

```
start is
    start "A"
    start "B"
end

add-inventory-status step A is
    status Active
on success
    finish
end

add-inventory-status step B is
    status inventory-status-1
on success
    finish
end
```

component-manual-task

The `component-manual-task` step pauses the process until a manual approval is completed. This step is only valid in a component process.

Format

```
component-manual-task step "foo" is
    -- users that can approve the task; required
    -- approval restriction to the deploying user
    restrict-approval-to deploying-user

    -- name of notification template; optional
    notification-template "TaskCompleted"

    -- property-definition establishes a property definition; optional, repeatable

    -- a text property definition with all options
    property-definition p1-text is text with
        -- label for the property definition; optional
        -- common to all property defintion types
        label "p1-label"

        -- description for the property definition; optional
        -- common to all property defintion types
        description "p1-description"

        -- regex pattern for the property definition's property values; optional
        -- an empty pattern is equivalent to ".*"
        -- common to all property defintion types
        pattern "p1-pattern-.*"

        -- a value is required for property defined by this property definition; optional
        -- common to all property defintion types
        required true

        -- default value for text properties created by this property definition; optional
        default "p1-pattern-default"
    end

    -- a text property definition with no options
    property-definition p2-text-simple is text

    -- a text area property definition with all options
    property-definition p3-textarea is text-area with
        -- common options; optional
        label "p3-label"
        description "p3-description"
        pattern ".*"
        required true

        -- default value for text area properties created by this property definition; optional
        default
            """
            p3-default-line1
            p3-default-line2
            p3-default-line3
            """
    end

    -- a text area property definition with no options
    property-definition p4-textarea-simple is text-area
```

```

    end
on success
    finish
end
```

component-run-component-process

The `component-run-component-process` step executes a component process and waits for it to complete. This step is only valid in a component process.

Format

```
component-run-component-process step "foo" is

    -- name of the component process to run; required
    process "deploy-my-component"

    -- set a component process property value; optional, repeatable
    property "component-process-property-1" = "cpp1-value"
    property "component-process-property-2" = "cpp1-value"
on success
    finish
end
```

Example

Example

```
start is

    start A

    start B

end

component-run-component-process step A is

    process "proc-1"

    property "prop-1" = "prop-value-1"

    property "prop-2" = "prop-value-2"

    property "prop-3" = "prop-value-3"

on success

    finish

end

component-run-component-process step B is

    process "proc-2"

on success

    finish

end
```

remove-inventory-status step

The remove-inventory-status step removes a status from a component resource.

Format

```
remove-inventory-status step "foo" is
    -- name of the status to remove from the component resource; required
    status "Active"
on success
    finish
end
```

Properties

Table 1120. Remove Inventory Status properties

Property	Description
Status	The component resource that the process is running against will have the specified inventory entry removed from it.

Example

Example

```
start is
    start "A"
    start "B"
end

remove-inventory-status step A is
    status Active
on success
    finish
end

remove-inventory-status step B is
    status inventory-status-1
on success
    finish
end
```

Generic process steps

Lists the various generic steps that can be used in a process.

add-process-warning

The `add-process-warning` step adds a warning message to the executing process

Format

```
add-process-warning step "foo" is
    -- a string in the body defines the warning; required
    "Warning: process partially successful"
on success
    finish
end
```

Example

Example

```
start is

    start A

end

add-process-warning step A is

    "warning"

on success

    finish

end
```

acquire-lock

The `acquire-lock` step allows acquisition of a process lock.

Format

```
acquire-lock step "foo" is
    -- define the name of the lock; required
    lock "${p:component.name}-${p:componentProcess.name}-${p:resource.name}"
on success
    start "bar"
end
```

Properties

Table 1121. Acquire Lock properties

Field	Description
Lock Name	A string value that identifies the lock.

Table 1121. Acquire Lock properties (continued)

Field	Description
	Note: Lock Name character limit is 4000.
Fail if Lock Exists	Select this checkbox to fail the step immediately if a lock with the specified name has already been created.

Example

Example

```
start is
    start "A"
end

acquire-lock step "A" is
    lock "lock-name"
on success
    finish
end
```

generic-manual-task

The `generic-manual-task` step pauses the process until a manual approval is completed. This step is only valid in a generic process.

Format

```
generic-manual-task step "foo" is
    -- users that can approve the task; required
    -- approval restriction to the deploying user
    restrict-approval-to deploying-user

    -- name of notification template; optional
    notification-template "TaskCompleted"

    -- require a user comment when approving the task; optional
    -- default is false
    comment-required true

    -- the prompt for a user comment when approving the task; optional
    comment-prompt "Enter reason"

    -- property-definition establishes a property definition; optional, repeatable

    -- a text property definition with all options
    property-definition p1-text is text with
        -- label for the property definition; optional
        -- common to all property defintion types
        label "p1-label"

        -- description for the property definition; optional
```

```
        -- common to all property defintion types
        description "p1-description"

        -- regex pattern for the property definition's property values; optional
        -- an empty pattern is equivalent to ".*"
        -- common to all property defintion types
        pattern "p1-pattern-.*"

        -- a value is required for property defined by this property definition; optional
        -- common to all property defintion types
        required true

        -- default value for text properties created by this property definition; optional
        default "p1-pattern-default"
    end

    -- a text property definition with no options
    property-definition p2-text-simple is text

    -- a text area property definition with all options
    property-definition p3-textarea is text-area with
        -- common options; optional
        label "p3-label"
        description "p3-description"
        pattern ".*"
        required true

        -- default value for text area properties created by this property definition; optional
        default
            """
            p3-default-line1
            p3-default-line2
            p3-default-line3
            """
    end

    -- a text area property definition with no options
    property-definition p4-textarea-simple is text-area

    -- a text area property definition with all options
    property-definition p5-secure is secure with
        -- common options; optional
        label "p5-label"
        description "p5-description"
        pattern "p5-pattern-.*" -- currently, patterns for secure properties do not function properly and their
use is not recommended
        required true

        -- default value for secure properties created by this property definition; optional
        -- currently, default values for secure properties do not function properly and their use is not
recommended
        default "p5-pattern-default"
    end

    -- a secure property definition with no options
    property-definition p6-secure-simple is secure
```

```
    -- a checkbox property definition with all options
    property-definition p7-checkbox is checkbox with
        -- common options; optional
        label "p7-label"
        description "p7-description"
        pattern "true|false"
        required true

        -- default value for checkbox properties created by this property definition; optional
        -- permitted values are 'true' or 'false'
        default true
    end

    -- a checkbox property definition with no options
    property-definition p8-checkbox-simple is checkbox

    -- a date-time property definition with all options
    property-definition p9-datetime is date-time with
        -- common options; optional
        label "p9-label"
        description "p9-description"
        pattern ""
        required true

        -- default value for date-time properties created by this property definition; optional
        -- time is specified as milliseconds from 1970-01-01 00:00:00 UTC.
        default millis 1594814965125
    end

    -- a date-time property with an xml schema format default value
    property-definition p10-datetime-xml is date-time with
        -- default value for date-time properties created by this property definition; optional
        -- time is format is specified at https://www.w3.org/TR/xmlschema-2/#dateTime
        default xml "2000-01-20T12:00:00+12:00"
    end

    -- a date-time property definition with no options
    property-definition p11-datetime-simple is date-time

    -- a select property definition with all options
    -- at least one value must be supplied
    -- at most one value may be selected as the default value

        -- if present, at least one group must be listed
        groups of
            -- a group that can approve; repeatable
            group DevOpsTeam
        end
    end
end
```

Properties

Table 1122. Manual Application Task properties

Field	Description
Name	The name for the manual task.
Only Allow Deploying User To Complete	Restrict approval to the user who started the deployment.
Notification Template	Specify a notification template. The individual tasks map to the notification scheme used by the application (see Creating Notifications in a Notification Scheme on page 2081). If you do not want notifications created for the task, select **None**.
Properties	Optionally, add one or more properties to the task.
Require Comment	Select to require that users must add a comment about this manual task.
Comment Prompt	**Note:** This field applies only to generic process steps. Enter the text that requests users to add a comment about this manual task.

Example

Example

```
start is
    start A
    start B
    start C
    start D
end

generic-manual-task step A is
    restrict-approval-to deploying-user

    notification-template template1
    comment-required true
    comment-prompt "comment-prompt1"

    property-definition p1-text is text with
        label "p1-label"
        description "p1-description"
        pattern "p1-pattern-.*"
        required true
        default "p1-pattern-default"
    end
on success
    finish
end

generic-manual-task step B is
    restrict-approval-to identities
        users of
            user user1
            user user2
        end
        groups of
           group group1
           group group2
        end
    end

    comment-prompt "comment-prompt2"
on success
    finish
end

generic-manual-task step C is
    restrict-approval-to identities
        users of
            user user3
            user user4
        end
    end

    comment-required true
on success
    finish
end

generic-manual-task step D is
```

```
    restrict-approval-to identities
        groups of
            group group3
            group group4
        end
    end
on success
    finish
end
```

plugin

The `plugin` step allows you to execute a plug-in command. Note that this step is not valid for an application process.

Format

```
plugin step "foo" is
    -- define name of plugin; required
    plugin "Shell"

    -- define name of plugin command; required
    command "Shell"

    -- absolute path of the working directory for the step; optional
    -- if undefined, the default working directory for the process is used
    working-directory "/working/directory"

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
       """
       true
       """

    -- define properties that configure the step; optional
    -- may be repeated
    property "prop1" = "value1"
    property "prop2" = "value2"
on success
    start "bar"
end
```

Properties

Refer to the plug-in documentation in the HCL official site for detailed information about the specific values required to configure the plug-in.

Example

Example

```

start is
    start A
    start B
end
```

```
plugin step A is
    plugin plugin-value
    command command-value
    property prop1 = prop1-value
    property prop2 = prop2-value
    property prop3 = prop3-value
on success
    finish
end

plugin step B is
    plugin plugin-value
    command command-value
    working-directory "/working/directory"
    precondition-script "true"
on success
    finish
end
```

run-generic-process

The `run-generic-process` step executes a generic process and waits for it to complete.

Format

```
run-generic-process step "foo" is
    -- name of the component process to run; required
    process "generic-process-1"

    -- resource tree path where process will execute; optional
    -- default is the process's default path
    resource-path "${p:resource.path}"

    -- suppress warnings generated by child; optional
    -- default is false
    ignore-child-warnings true

    -- set a process property value; optional, repeatable
    property "prop-1" = "prop-value-1"
```

Properties

Table 1123. Run Generic Process properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Process	The generic process to run.
Resource Path	The resource on which to run the generic process.
Other properties	After you select a generic process, the properties for that process are listed. You can set values here to pass to the process.

Example

Example

```
start is
    start A
    start B
end

run-generic-process step A is
    process "proc-1"
    resource-path "resource-path-1"
    ignore-child-warnings true
    property "prop-1" = "prop-value-1"
    property "prop-2" = "prop-value-2"
    property "prop-3" = "prop-value-3"
on success
    finish
end

run-generic-process step B is
    process "proc-2"
on success
    finish
end
```

run-generic-process-for-each-affected-resource

The `run-generic-process-for-each-affected-resource` step executes a generic process for each resource affected by the application process and waits for it to complete. This step is only valid in an application process.

Format

```
run-generic-process-for-each-affected-resource step "foo" is
    -- name of the generic process to run for each affected resource; required
    process "generic-process-1"

    -- don't start further children after a failure; optional
    -- default is false
    fail-fast false

    -- suppress warnings generated by children; optional
    -- default is false
    ignore-child-warnings false

    -- maximum number of concurrent processes; optional
    -- default is unlimited
    max-concurrent-processes unlimited

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
        """
        true
        """

    -- set a generic process property value; optional, repeatable
```

```
    property "generic-process-property-1" = "cpp1-value"
    property "generic-process-property-2" = "cpp1-value"
on success
    finish
end
```

Properties

Table 1124. Run Generic Process properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Process	The generic process to run.
Resource Path	The resource on which to run the generic process.
Other properties	After you select a generic process, the properties for that process are listed. You can set values here to pass to the process.

Example

Example

```
start is

    start A

    start B

end

run-generic-process-for-each-affected-resource step A is

    process "proc-1"

    fail-fast true

    ignore-child-warnings true

    max-concurrent-processes 10

    precondition-script "script-1"

    property "prop-1" = "prop-value-1"

    property "prop-2" = "prop-value-2"

    property "prop-3" = "prop-value-3"

on success
```

```
    finish

end

run-generic-process-for-each-affected-resource step B is

    process "proc-2"

on success

    finish

end
```

set-final-process-status

The `set-final-process-status` step that also appears as **Set Status** in the Web UI, forces the outcome status of a process to success or failure.

Format

```
set-final-process-status step "foo" is
    -- set workflow result to 'success' or 'failure'; required
    status success
on success
    finish
end
```

Properties

Table 1125. Set Status property

Field	Description
Status	`Failure` or `Success`.

Example

Example

```
start is
    start "A"
    start "B"
end

set-final-process-status step "A" is
    status success
on success
    finish
end
```

```
set-final-process-status step "B" is
    status failure
on success
    finish
end
```

shell

The `shell` step is a shortcut for the `plugin` step that specifies the Shell plug-in and the Shell command. Note that this step is not valid in an application process.

Format

```
shell step "foo" is
    -- a string in the body defines the script; required
    """
    msg="hello world A"
    echo $msg
    """

    -- run the script without waiting for it to complete; optional
    -- "output.log" is the path of a file that captures the output
    run-as-daemon "output.log"

    -- absolute path of the working directory for the step; optional
    -- if undefined, the default working directory for the process is used
    working-directory "/working/directory"

    -- javascript precondition script that must evaluate to true for the step to execute; optional
    precondition-script
       """
       true
       """
on success
    start "bar"
end
```

Properties

Refer to the Shell plug-in documentation for detailed information about the specific properties and values required to configure them.

Example

Example

```
start is
    start A
    start B
    start C
    finish
end

shell step A is
    "echo A"
on success
```

```
    finish
end

shell step B is
    "echo B"
    run-as-daemon "daemon.log"
on success
    finish
end

shell step C is
    "echo B"
    working-directory "/working/directory"
    precondition-script "true"
on success
    finish
end
```

start

The `start` step is a pseudo-step that defines the beginning of the process. As it is not a true step, it does not use the step keyword. The only completion condition is success. So, on success is not required or permitted.

Format

```
start is
    -- list one or more actions
    start "foo"
    start "bar"
end
```

Properties

No properties required.

Example

Example

```
start is
    start A
    start B
    start C
    finish
end
```

switch

The `switch` step allows decision logic in the process. It expands a variable by name or evaluates an expression containing a 'p' expression to a value. Based on the value, one case is selected and its actions are carried out.

Format

```
switch step "foo" is
    -- a variable or ${p:expression} to evaluate
```

```
    evaluate "variable"

-- case selected if the expression evaluates to "A"
on case "A"
    -- one or more start commands
    start "step-a"

-- additional cases follow
on case "B"
    start "step-b"

-- case selected if no other expression matches; optional
-- if present, this must be the final option
on default
    start "step-default"
end
```

Properties

Table 1126. Switch properties

Field	Description
Name	A name for the step. Other process steps can refer to this step by this name.
Property Name	The property to use for the branching. You can specify the property name by itself or in the same form as you would use in other steps, such as `${p:propertyName}`. You cannot use a secure property in this field.

Example

Example

```
start is
    start A
    start B
    start C
    start D
    start E
end

switch step A is
    evaluate prop-name-a
on case case-a1
    start case-a1-step
on case case-a2
    start case-a2-step
on default
    finish
end

switch step B is
    evaluate prop-name-b
on default
    finish
end
```

```
switch step C is
    evaluate prop-name-c
on case case-c1
    finish
end

switch step D is
    evaluate prop-name-d
end

switch step E is
    evaluate "${p:prop-name-e}"
end

shell step case-a1-step is
    "echo case-a1-step"
on success
    finish
end

shell step case-a2-step is
    "echo case-a2-step"
on success
    finish
end
```

DevOps Deploy MCP server

The Model Context Protocol (MCP) server of HCL DevOps Deploy (Deploy) enables AI models (like LLMs) to utilize specialized Deploy MCP tools. By using these tools, you can run crucial deployment tasks on an MCP client simply through chat prompts.

Connecting an MCP client to DevOps Deploy MCP server

To enable an MCP client to communicate with the HCL DevOps Deploy (Deploy) MCP server, you must define Deploy server connection details within an MCP client's configuration.

You must perform the following tasks for a successful connection of the Deploy MCP server to an MCP client:

1. **Install an MCP client:** You can use any MCP client, such as VS Code, Claude, and so on, to connect to the Deploy MCP server. Each MCP client has its own specific UI, command palette, or dedicated settings file for configuration. You must refer to the independent software vendor documentation for client-specific instructions.
2. **Add Deploy MCP server properties:** Edit the client configuration file or settings to add the Deploy MCP server properties. See MCP server properties on page 2994 and Configuration file example on page 2994.
3. **Start the server:** Start the Deploy MCP server from the MCP client.

MCP server properties

Property	Description	Required Value/Format
`"type"`	Indicate the server connection protocol.	`http`
`"url"`	Specify the full Deploy MCP server URL.	`https://deployServer_hostname:deployPort/mcp`

`"Authorization"`	Provide a valid bearer access token ID or basic access token ID.
	
	You must ensure that a realm is selected for the bearer authentication in the **System Settings**. See System settings on page 2086. Microsoft Entra ID and Okta bearer tokens are supported.
		`"Authorization": "Bearer tokenID"`
		
		`"Authorization": "Basic <base64 encoding of 'PasswordIsAuthToken:tokenvalue'>"`

Configuration file example

The following JSON format illustrates how you can define the Deploy MCP server properties in your VS Code MCP configuration file (mcp.json):

```
{
 "servers": {
  "devops-deploy-local": {
   "type": "http",
   "url": "https://deployServer_hostname:deployPort/mcp",
   "headers": {
    "Authorization": "Bearer tokenID"
   }
  }
 },
 "inputs": []
}
```

After a successful connection is established, you can use the integrated MCP tools to perform various deployment tasks. See Using the Deploy MCP tools on page 2994.

Using the Deploy MCP tools

After you have successfully connected to the HCL DevOps Deploy (Deploy) MCP server, you can use the integrated Deploy MCP tools to perform tasks within Deploy.

You can access the following Deploy MCP tools from your MCP client:

Tools	Description	Input
list_applications	Lists all applications.	None

Tools	Description	Input
list_application_processes	Lists all processes defined in an application.	`applicationId`
list_application_environments	Lists the environments for a specific application.	`applicationId`
list_application_snapshots	Lists all snapshots defined in an application.	`applicationId`
get_deployment_status	Returns the application deployment status.	`deploymentId`
deploy_snapshot_to_environment	Deploys an application snapshot to an environment.	`applicationId`, `snapshotId`, `processId`, `environmentId`
schedule_deployment	Schedule a deployment for future execution.	`deploymentId`
get_deployment_failed_status	Retrieves information about the failed steps in a deployment.	`deploymentId`
get_deployment_step_output	Retrieves information on a step in a deployment.	`stepOutputTokenOpaque`, `firstLineIndex`
search_step_output_regex	Searches logs using regular expressions.	`stepOutputTokenOpaque`, `pattern`, `contextLineCount`
search_step_output_hangs	Identifies long intervals (hangs) between output lines in step execution logs by analyzing timestamp information in the log format. Currently, this tool only checks for hangs within failed steps.	

Tip: You can retrieve a complete list of all available tools directly from your MCP client. For specific instructions on how to use your MCP client to view this list, refer to the independent software vendor documentation.

The core functionality of the Deploy MCP tools is accessed through the chat prompts within the MCP client interface. By using these prompts, you can perform complex deployment tasks by using natural language. Examples of the chat prompts that you can use are as follows:

- **List** my applications.
- **List processes for the application** `helloApplication`.
- **Deploy** `helloApplication` **into** `dev_environment1`.
- **Why did deployment** `deployment_id` **fail**?

Note: When crafting your prompts, you can reference objects by their ID or name.

The AI agent interprets your chat prompts to intelligently select and run the appropriate MCP tool to fulfill the request.

Important: The results are highly dependent on the capabilities of the LLM that your MCP client uses, and the results are non-deterministic.

Deploying a snapshot to an environment with the DevOps Deploy MCP server

You can learn perform a basic deployment with the HCL DevOps Deploy (Deploy) MCP server by using chat prompts.

Before you begin

You must have completed the following tasks:

- Defined applications, processes, environments, and snapshots in your Deploy system.
- Connected an MCP client with the Deploy MCP server. See Connecting an MCP client to DevOps Deploy MCP server on page 2993.

About this task

You can use any or all of the following prompts in your MCP client to verify resources and initiate a deployment.

- Prompt: List my applications.

  A list of all your applications is displayed (for example, `App1`, `App2`, etc.).

- Prompt: List environments for `App1`.

  A list of all environments defined within the application `App1` is displayed (for example, `dev`, `test`, `prod`, etc.).

- Prompt: List the application processes for `App1`.

  A list of all application processes defined for the application Product1 is displayed (for example, `appProcess1`, `appProcess2`, etc.).

- Prompt: List snapshots for `App1`.

  A list of all snapshots defined for the application Product1 is displayed (for example, `snapshot1`, `snapshot2`, etc.).

- Prompt: Deploy `snapshot1` of `App1` into `test`.

  The output displays the deployment request ID initiated with the prompt.

Note: Depending on the capabilities of the LLM, you can use this prompt independently of the previous prompts.

- Prompt: Get the deployment status.

  The output displays the deployment status.

Troubleshooting and Support

Learn how to troubleshoot some common issues with HCL DevOps Deploy (Deploy).

For assistance with Deploy, contact support.

Important: Before you initiate a support request for Deploy, you must recreate the unexpected behavior in a standard environment. You must disable or remove all third-party products, including non-standard configurations and monitoring agents (such as Dynatrace or New Relic).

Product support covers only the configurations that are described in the official documentation. You must remove external variables to ensure that the issue can be properly isolated to the core Deploy system.

Logging

The server maintains logs for auditing and troubleshooting.

Audit log

The audit log shows information about who accessed the server and what changes each user made.

Note: After upgrading to HCL DevOps Deploy (Deploy) version 7.2.3.0 or later, you must manually enable the audit log. Starting with version 7.2.3.0, Deploy uses Log4j 2.x for logging configuration to enhance security.

Diagnostics log

The diagnostics log shows a table of information about actions on the server. This table shows which user ran an action, when that action was run and what part of the server API was used.

Server output log

The server output log shows information about all the actions that are performed on the server.

Viewing logs

When you install and run the Deploy server and it's components, the information is logged in the form of install logs, audit logs, diagnostic logs, and server output logs. By using the logs, you can troubleshoot errors.

Installation and upgrade logs

After you install the server, agent, and agent relay, a log file is added to the `var/log` of the installation folder. For example, you can find the:

- Server installation log file in the *`server_installation_directory`*`/var/log/install-<date>-<time>.log` directory.
- Agent installation log file in the *`agent_installation_directory`*`/var/log/agent-install-<date>-<time>.log` directory.
- Agent relay installation log file in the *`relay_installation_directory`*`/var/log/agentrelay-install.log` directory.

Audit logs

The audit log contains entries of user activity. An entry is created whenever a user does one of the following activities:

- Performs an activity that is granted by a security permission, such as creating a component, or creating an application. These activities include permissions granted by the server configuration security type, such as managing plug-ins, system properties, and statuses. Permissions are based on the team roles that are assigned to the user.

  Note: The audit log shows the installation, upgrade, and deletion of plug-ins as well.

- Modifies security settings, such as creating a role, or assigning a user to a role.
- Performs an authentication activity, such as logging on to the Web UI, or accessing the REST API.

To view audit logs, you must be in an administration role, specifically a role with the Web UI **Settings Tab** permission. You can perform the folowing actions on the audit logs:

- Review the audit log files by logging in as an administrator and click **Settings > Audit Log**.
- Filter the log by typing in the fields at the top of each column. For example, to view the admin user's activities, select **admin** in the **User Name** filter field.
- View only actions in which an element was created by specifying `CREATE` in the **Event Type** filter field.
- Remove old entries from the audit log, click **Cleanup Log**, specify the date and time, and click **Submit**. All log entries prior to that date and time are permanently deleted. Deleting audit logs creates a log entry of event type Audit Log Cleanup that are non-deletable.

Note: The activities of the built-in administrator user (with the user name admin) generate entries in the Audit Log page.

Diagnostics

To view the diagnostic logs, **Settings > Diagnostics**. The tabs on this page show diagnostic information:

Diagnostics Bundle

The diagnostics bundle contains information about the recent state of the Deploy server and system settings information. To download a Diagnostics Bundle zip file that contains the diagnostics information, click **Download Diagnostics Bundle** from the **Diagnostics** page.

A diagnostics-(date)-(time).zip file is downloaded to your system. The `diagnostics-(date)-(time).zip` file contains the following folders:

Directory	Contents
`bin`	The classpath.conf and set_env files from the server's `bin` directory.
`conf`	Various configuration details from the server's `conf` directory.
`diagnostics`	JSON files related to performance of the server.
`logs`	The upgrade logs. **Note:** The upgrade logs located in the *`server_installation_directory`*`/var/log/` directory are also copied to the *`server_installation_directory`*`/var/diagnostics-(date)-(time).zip` file.
`opt`	Tomcat settings from the server's `opt` directory.
`patches`	A collection of patches applied to the server. The `patches` folder appears only if the patches are applied.

REST Call Log

This log shows all the requests that the server receives, including requests from the web interface, the REST API, and the command-line client. You can filter this table by typing values in the fields at the top and then pressing Enter.

Metadata Indexing

This page shows the state of the server indexes, which stores information about elements such as components and processes. If indexing is not complete, you might not be able to use certain filters or to open certain processes. Indexing happens after certain server upgrades.

Database

On this page, you can analyze database query performance by clicking **Test Database Latency**. The test result gives you the following information:

- Number of queries that were completed.
- Total time to complete all of the queries.
- Total number of failed queries.
- Minimum latency for any single query.
- Maximum latency for any single query.
- Average latency for all of the queries that were completed.

Note that a maximum of 50 queries are run at a time. From the **Test Results** window, use the **show as text**/**show as table** option to send the result in desired format. The result is available in the diagnostics bundle as well.

Output logs

You can get detailed logs for processes, including the all of the information and logs from each step. To troubleshoot a step, click **View Output Log** from the options column. The **Output Log** window opens and displays the output along with the timestamp. To download these logs, open the process request, and click **Download All Logs**.

To open the server output log file directly from UI, click **Settings > Output Log > Download**. In an HA cluster, logs of all servers are downloaded in a zip format.

The Deploy server log file is also located in the following directory: *`server_installation_directory`*`/var/log/deployserver.out`.

The information that is written to the log file is determined by the settings in the **Logging** tab. You can modify the configuration by clicking **Add Logger** from **Settings > System > Logging**. See Managing loggers on page 3000 for more information.

The `deployserver.out` log displays the output as below:

```
{"ts_utc":"2022-07-07T12:13:44.849Z","ts_loc":"2022-07-07T08:13:44.849-0400","lvl":"INFO","thr":"main","log":"c
om.urbancode.ds.UDeployServer","msg":"License Server URL: "}
{"ts_utc":"2022-07-07T12:13:44.884Z","ts_loc":"2022-07-07T08:13:44.884-0400","lvl":"INFO","thr":"main","log":"c
om.urbancode.ds.UDeployServer","msg":"Database User name: dbUser"}
```

Using the JQ tool, you can see the `deployserver.out` log output in the following format:

```
2022-07-21 17:31:37,274 IST INFO  main com.urbancode.ds.UDeployServer - Cleaning up temp directory
2022-07-21 17:31:37,290 IST INFO  main com.urbancode.ds.UDeployServer - Starting HA Lock Manager...
2022-07-21 17:31:37,507 IST INFO  main com.urbancode.ds.UDeployServer - Configuring Security System...
2022-07-21 17:31:38,060 IST INFO  main com.urbancode.ds.UDeployServer - Configured authentication realms in
 JAAS.
2022-07-21 17:31:42,585 IST INFO  main com.urbancode.ds.UDeployServer - done
```

For more information about the JQ tool, see https://stedolan.github.io/jq/. An example usage of JQ command in a Unix or Linux shell is:

```
jq -r '.ts_loc + " " + .lvl + " " + .thr +  " " + .log + " - " + .msg' "deployserver.out"
```

Note: The below logging exceptions are ignored by the JQ command:

```
(
{"ex_msg", "ex_trc"}
)
```

Managing loggers

You can add loggers to the root log and set their logging level to keep track of errors and some activities.

About this task

The server stores its log by using Apache Log4j version 2.x (Log4j2). The Log4j2 logging settings are stored in the `devops-deploy/server/appdata/conf/server/log4j2.xml` file, where `devops-deploy` is your Deploy installation directory. You can edit the Log4j2 settings by editing the `log4j2.xml` file or from the web UI to change the format of the log and the information that is added to the logs. The `log4j2.xml` file contains a combination of loggers that prints information of specific loggers into the server's main or root log file, that is, `deployserver.out`.

Note: After upgrading to HCL DevOps Deploy (Deploy) version 7.2.3.0 or later, you must manually enable the audit log. Starting with version 7.2.3.0, Deploy uses Log4j 2.x for logging configuration to enhance security.

For more information about customizing the Log4j2 output, see Log4j2 Configuration.

You can edit the agent's log settings using the `agent/conf/log4j2.xml` file and the agent relay's log settings using the `agent-relay/conf/log4j2.xml` file.

To manage the server loggers from web UI:

1. Open the Logging page by clicking **Settings > System > Logging**.
   Loggers are listed in hierarchical order. The first one is the root logger, which is indicated by an `*` in the UI. It typically has no name in the logging library. The other default loggers and log classes are as follows:

   ```
   com.sun.jersey.server.impl.application.WebApplicationImpl
   com.sun.jersey.spi.container.ContainerResponse
   com.urbancode.air.diagnostics
   com.urbancode.air.vc
   com.urbancode.container.tomcat
   com.urbancode.ds
   com.urbancode.encryption.keystore
   net.schmizz
   org.apache.tomcat
   org.hibernate.cache.ReadWriteCache
   org.hibernate.engine.jdbc.spi.SqlExceptionHelper
   org.hibernate.orm.deprecation
   com.urbancode.ds.cleanup
   ```

   Each logger has a level drop-down that allows you to change the logging level. The following log level types are available:
   - ALL
   - TRACE
   - DEBUG
   - INFO
   - WARN
   - ERROR
   - FATAL
   - OFF
2. To edit multiple loggers simultaneously, select the loggers from the selection column, click **Bulk Actions**, set the level as required, and save your changes.

3. To add a logger, click **Add Logger**, specify the logger name, it's logging level, and confirm your changes.
4. To delete a custom logger use the actions column or to delete multiple loggers, use **Bulk Actions**. The root and default loggers cannot be deleted. Removing a logger reverts the logger to the logging level defined by its superior in the hierarchy.

Configuring log rotation settings

You can configure the rotation and increase the size of the main log file.

About this task

Logs include time frames for when problems occur or activities happens on the HCL DevOps Deploy (Deploy) server, agent, and relays. Because log files hold a limited amount of data, data related to a problems might be overwritten. To avoid this scenario, you can increase the size of the log file or the number of rotating files.

To configure log rotation settings:

1. Go to the **Configuration** page.
2. Change one or both of the following settings:
   - **Files**: The number of total logging files, which includes the active log file and the rotated log files. The default value is 10. Note that the value cannot be less than 1.
   - **File Size**: The maximum size (in megabytes) of a log file. Once this size is reached, the active log file is rotated. The default value is 50. Note that the value cannot be less than 1.
3. Click **Save**.

Results

When you increase the number of log files, more disk space is required. A Deploy support specialist can help you determine the appropriate value to specify.

Managing the logs

With appropriate permissions, you can add, edit, enable, and delete the default logs.

About this task

The **Other Logs** page lists some default logs, such as audit, cleanup, license, login audit, and user audit. Each of these logs contains information for different purposes.

You can manage the default logs on this page with several actions.

1. Click **Settings > Logging > Other Logs**.
2. Edit a log from the actions cloumn.
   The **Edit Log** window allows you to edit the following information:
   - The rotation type of the log file, such as hourly, daily, weekly, monthly or with respect to size
   - The number of files to generate
   - The maximum size of log files

    - The enablement status of the log
    - Add or delete loggers
3. Add a log by clicking **New Log** and provide information as mentioned in step 2.

   The **New Log** feature allows you to send log data to a specific file. It is the Log4j 2.x implementation of Log4j 1.x appenders as used in v7.2.2 and earlier versions.
4. Delete a custom log.
   Note that you cannot delete default logs.
5. Enable or disable a log.
   The cleanup log is enabled by default and cannot be disabled. However, some logs are disabled by default, such as server audit and licensing.
6. **Optional:** Perform a bulk operation by selecting one or more logs, and enable, disable, or delete them simultaneously.

Determining the Java heap memory size

The Java heap is memory that contains objects used by Java programs. It contains objects that are currently in use, objects that are no longer needed, and free memory. Objects that are no longer needed are freed by the garbage collection process. The JVM heap size determines how often to run garbage collection and how long the garbage collection runs.

About this task

Tuning the heap size minimizes the amount of garbage collection processing. Insufficient Java heap space can result in out of memory errors or slow performance.

The JVM settings are specified in the `set_env` file which is in the `devops-deploy/server/bin` directory. The **JAVA_OPTS** environment variable contains the following arguments related to heap size:

-Xms

Initial Java heap size.

-Xmx

Maximum Java heap size

For the Agent add **-Xmx** as the first line in the agent's `conf/plugin-javaopts.conf` file.

Troubleshooting the DevOps Deploy server and agents

Troubleshooting information that is specific to the server and agents is provided here.

Troubleshooting security and permissions

To troubleshoot permissions, look carefully at the roles and teams of the user and the teams of the object that the user is trying to access.

User cannot access a page on the server

If a user cannot see pages on the server, make sure that the user's role has the permission to see that page. Open the user's role, go to the Web UI category, and specify the pages that the user can access. See Creating roles and assigning permissions on page 2188.

User cannot access an object

If a user cannot access an object, such as an application or environment, check the following things:

- Ensure that the object is part of a team and that the user is a member of the same team. You can add an object to a team only if you are a member of that team.
- Ensure that the user has a role on that team, and that the role includes permission to access the object.
- If the object has a security type other than the standard security type for that object, make sure that the role includes permissions for that security type.
- Ensure that the user has access to the related pages on the server, such as the **Applications** tab or **Components** tab.
- If the user can create an object but cannot set configuration options for it, make sure that the user's role has the Edit Basic Settings and Manage Teams permissions for that type, because otherwise the options for creating the object are limited.

Troubleshooting agent connections

You can answer a number of questions to help isolate the issue behind problems with agents.

By default, the logs for the agent are in the folder *agent_install*`/var/log`.

Starting with V7.0.3, you can download and display agent logs from the user interface. This feature is only available for web agents V7.0.3 and later. The **Request Agent Logs** option is displayed on the selected agent page. After clicking **Request Agent Logs**, the *agent.out* (default file name) appears under the **Available Logs** section on the same page.

If you are having trouble with an agent, see the following troubleshooting information for the state of the agent:

- A new agent isn't displayed in the user interface, or the agent is reported as `offline` on page 3004.
- The agent is reported as `connecting` on page 3006.
- The agent is reported as `online` on page 3006.
- The agent fails to connect to the server and returns errors on page 3006.

If the agent isn't displayed in the user interface, or if the agent is reported as `offline`, complete these actions:

- Verify that the agent started successfully:
  - Look for error messages in the log. If the agent started successfully, the `agent.out` file has a message that says something like this:

    ```
    2017-07-18 08:37:47,575 INFO  AgentWorkerThread com.urbancode.air.agent.AgentWorker - Agent
     started
    ```

  - Check the prerequisites for the agent. See Installing agents.

- If the agent prompt returns right away or the window flashes and closes after you try to start it, check the Java version and Java home. This situation typically happens when Java cannot be found.
- Verify that the system that hosts the agent has enough free disk space, and that the file system and permissions are properly configured.
- If the agent is configured as a service on Linux, start the agent from the command line. If you cannot start the agent from the command line, the problem is likely related to the way that the service was configured. See Running agents as services on Linux.
- Verify that the agent installation properties are correct. See Agent installation properties.
- If the agent is configured as a service on Windows, complete these actions:
    1. Remove the service and add it again. See Removing and reinstalling agents as Windows services on page 2109.
    2. Remove the service and try to start the agent from the command line. If it starts, check permissions for the user who is running the service. See step 3 of Installing agents from the command line.

- If the agent started successfully but the server shows the agent as offline or does not show the agent at all, check these things:
    - If the agent connects through an agent relay, verify that the relay is running.
    - Verify that the system that hosts the server has enough free disk space, and that the file system and permissions are properly configured.
    - Search the user interface for the agent endpoint ID from the `installed.properties` file. If an agent with the same name is already in the system, Deploy adds the agent to the user interface as `agent-<agent id>`. It is possible that the agent is there, but not by a name that you might be looking for. This can happen if you clone a virtual machine or create a cloud environment without changing the agent name.
    - If the agent is using failover, make sure that failover is configured correctly.
    - Check for licensing issues.
    - Check the network connection between the agent and the server or between the agent and agent relay:
        - Verify that the Web relays are connected to Web agents.
        - Verify that a firewall is not preventing the agent from connecting to the server or agent relay. Agents always initiate connections to servers and agent relays, not the other way around.
        - Check to see that the agent system can ping the Deploy server or agent relay.
        - If agents are not connecting correctly on high-availability environments, make sure that the servers have cluster connections to each other.
        - Firewalls might prevent the agent from communicating with the server, particularly if the agent is on a public cloud and trying to connect to an Deploy server that is within a firewall. In this case, use an agent relay.
        - If the agent is on a cloud environment and the target cloud environment can connect to the Deploy server, log in to the cloud image and check the `cloud-init` log files in this folder:`/var/lib/cloud/instance/`.
        - If an agent on a cloud environment times out with a message like `Agent did not come online after 6.0 minutes! Process not executed.`, check to see that the agent package was downloaded correctly.

If it did, try lengthening the timeout by increasing the value of the **agent_timeout** parameter in the blueprint or configuration file.
- Check for DNS issues that might prevent the agent from resolving the host name of the server or agent relay.

◦ Can the built-in admin ID see the agent online? If so, permissions might be incorrectly configured on the agent. Remember that the built-in admin ID bypasses the team's checking.

If you do not know the location of the agent that cannot connect to the server, go to the agent properties, which include the last known host name and IP address of the agent.

If the agent is reported as `connecting`, complete these actions:

1. When this situation occurs, the problem is an HTTP communication issue. To resolve this issue:
   a. Check the external agent URL in settings. In the product, click **Settings**, and then click **System Settings**. Make sure that the host name or IP address matches or resolves to the entry in the agents `installed.property` file.
   b. Use Telnet to connect to the HTTP port on the Server.

If the agent is reported as `online` but you continue to have problems, complete these actions:

1. Verify that the agent and agent relay are running the recommended and minimum versions as indicated in the user interface.
2. Check the server, agent relay, and agent logs for errors. Look for matching time stamps among the logs.
3. Enable more detailed logging by adding the following logger, and set the looging level as TRACE:

   ```
   com.urbancode.air
   ```

   Check the output for errors.

If the agent fails to connect to the server to an agent, check if the `agent.log` shows:

- **A clock skew exception** - Set the system time on the server and the computers that agents are running on to times that are the same or within a few minutes of each other. The server and agent clock times must be close together if using end-to-end encryption. They do not need to be in the same time zone, but must agree about the global time within approximately 5 minutes.
- **The SSL handshake error** - When a Web agent fails to connect to the server and returns an error `com.urbancode.ds.subsys.deploy.agent.comm.netty.server.ServerPublicKeyPinHandler - SSL handshake failed`. Configure the load balancer to use the SSL connection instead of the load balancer. In this configuration, you use TCP mode over HTTP mode in both, the front-end and back-end configurations. For instance, if the LB is HAProxy, it should treat the connection as a stream of information to proxy to a server, rather than use its functions available for HTTP requests. The following example is a front-end configuration on HAProxy:

  ```
  frontend localhost
      bind *:80bind *:443
      option tcplog
      mode tcp
      default_backend nodes
  ```

Troubleshooting agent upgrade from the Web UI

You can troubleshoot errors that occur upgrading agents from the Web UI by performing a few checks.

As part of the upgrade process, the Deploy server downloads and extracts the `air-agentupgrade.jar` file to a certain location to perform the agent upgrade. The handling of this file—specifically how it is copied and executed—varies depending on your Deploy version. To understand about the directory structure of a compact agent and non-compact agent, see Compact agent changes: Summary on page 2338.

Note: Your system administrator must monitor the `AGENT_HOME` directory structure during a WebUI upgrade to track the creation, modification and deletion of files and directories.

To resolve errors, perform the following checks:

- Verify that the `air-agentupgrade.jar` file is downloaded from the `<serverInstallDir>/opt/` directory to the `<agentInstallDir>/bin/` or `<agentInstallDir>/var/upgrade/` directory.

  In version 7.2.x and earlier, the `air-agentupgrade.jar` file is downloaded to the `<agentInstallDir>/bin/` directory. Starting with 7.3.x and later versions, the `air-agentupgrade.jar` file is downloaded to the `<agentInstallDir>/var/upgrade/` directory.

  Note: If the `air-agentupgrade.jar` file is missing, you must verify that it exists on the `<serverInstallDir>/opt/` directory. If the file exists, you must check for network connectivity issues or write permission errors on the agent.

- Verify that the agent unzipped the `air-agentupgrade.jar` file into a specific sub-directory if the `air-agentupgrade.jar` file is present in the download path.

  The following table lists the download and unzipped locations of the `air-agentupgrade.jar` file for each version of Deploy:

Version	Download location	Unzipped location
7.2.x and earlier	`<agentInstallDir>/bin/`	`<agentInstallDir>/bin/agent-upgrade/`
7.3.x and later	`<agentInstallDir>/var/upgrade/`	`<agentInstallDir>/var/upgrade/unpack/`

  If the `air-agentupgrade.jar` file is not created and unzipped in the specified location, then you must check for user permission issues.

  Note: If you use Security-Enhanced Linux (SELinux), it might block the agent user from creating directories. To resolve this issue, you must temporarily set SE-Linux to `permissive` mode.

- Refer to the logs for specific error codes if the upgrade fails or stalls for any other reasons.

In version 7.2.x and earlier, you must check the `<agentInstallDir>/bin/upgrade.out` log file. In version 7.3.x and later, you must check the `<agentInstallDir>/var/log/upgrade.log` file. You can view or download the upgrade log directly from the **Log** tab of the agent in the Web UI.

If the log exists, you must review it for the `Permission Denied` or `File Not Found` errors.

Troubleshooting processes

You can answer a number of questions to help isolate the issue behind problems and process failures.

Take these initial approaches to avoid problems with your processes and check these areas before you take more complicated troubleshooting steps:

- If a process is failing, look for information about the failure in the process request. To open a process request, click the application, and go to the **History** tab. Find the process in the table, and click **View Request**. Within the request, expand the steps until you find the step that failed. Failed steps have an error log that provides more information about the failure. All steps have an output log that includes information about the step progress and any logging messages that the step created. For information about viewing logs, see Viewing logs on page 2997.
- Step through each process element. Verify that you refer to properties on page 2509 by using the correct syntax.
- Verify that the steps are wired together, meaning that each step is connected to another step within a process. Then, verify that the correct step result is selected. That is, on the arrow that connects one step with the next, select the correct condition for proceeding: **Run On Success**, **Run On Failure**, or **Run on Both**.
- Verify that the process is wired in to the **Finish** step.
- Consider running each process step's equivalent function in a command-line environment to verify that each step works as planned. For example, if the step runs a shell script, try running the shell script on the command line to see whether the same problem happens. If the step starts an application server, make sure that you can start the application server on the command line by using the same commands.
- Verify that you are using the correct component processes type. For information about component process types, see Component process types on page 2423.
- Trace all the way through your process step-by-step. Steps are essentially commands to be run. See this IBM support article: MustGather: How to trace the execution of a process.
- Verify that no typographical errors are included in the process steps. Review each property and script carefully.
- If properties are a factor in the problem, you can view the properties for an application process by opening the process request and clicking the **Properties** tab. You can also view the properties that each component process step used by clicking **Input/Output Properties**. For more information about properties, see Properties on page 2500 and associated topics.
- Check the log for messages that pertain to memory size. You can generate a report of requirements for your operating systems and product version: Hardware requirements for a specific product.
- If you are using sudo commands, permissions can be a problem. Verify that the command is configured correctly. Also, verify that the user is configured in sudo and does not need to specify a password. Make sure that the directory

can be accessed by the operating system user that is running the Deploy agent, the impersonated user, and the tool that you are calling. For information about sudo commands, see Impersonation on Linux™ systems on page 2463.
- Review the step output for steps that cause problems. On a command line, run a problem line or step as the same user that Deploy uses to run the step or line. Be sure to pass the user and the group.

Other troubleshooting tips

- If your process branches, look closely at the way the process branches to ensure that the process is running in the way that you expect. See Branching and joining steps on page 2402.

What issues are you observing or experiencing?

- A process doesn't start on page 3009.
- A process fails, but no errors are logged on page 3009.
- Process failures occur after an upgrade on page 3010.
- A process runs, but it does not stop on page 3010.
- Processes fail intermittently on page 3010.
- Processes stop before completion on page 3011.
- Processes with branches do not run correctly on page 3011.
- Processes using impersonation do not run correctly on page 3011.

A process doesn't start

- Can you run the process while you use the built-in ID? Running the process that way checks for a permission issue on the resource.
- Is the agent running? For information about agents, see Agents on page 2336.
- Can any processes run on the agent? If required, create a simple “echo Hello World” shell step, and see whether you can run it on the agent. Running this shell step confirms that communication between the server and resource are established.
    - If the simple shell step works, what's different between the working step and the failing step?
- Are the components mapped? See Mapping resources and components to environments on page 2363.
- Are any errors logged in the step output? See Viewing logs on page 2997.
- Check the server log file for errors, permissions issues, or configuration issues. See Viewing logs on page 2997.

A process fails, but no errors are logged

- Confirm that the version of Deploy and the agents and agent relays are the same.
- Check the agent log file for errors that point to a configuration issue. For example, a port might be blocked or a URL is incorrect. Check the server log file for errors. For example, a port might be blocked or URL is incorrect. See Viewing logs on page 2997. See also Firewall and communication configuration.
- If you are using high-availability, check to see whether there was a failover.
- If this result happens for only this process, what might be different between this process and the other processes that succeed at running the step?

- Can the process succeed when the built-in admin ID runs it. When you run the process this way, incorrect permission configuration does not impact process execution.
- Does this problem happen with any other steps? If not, how is this step different?
- If you run a process with just this step, does it fail in the same way?

Process failures occur after an upgrade

- Does the new version support the installed Java™ Runtime Environment or Java™ Development kit? See Java
- Were there any errors in the upgrade process?
- Check the agent log file for errors that point to a configuration issue. For example, a port might be blocked or a URL is incorrect. Check the server log file for errors. For example, a port might be blocked or URL is incorrect. See Viewing logs on page 2997.
- If you use an agent relay, confirm that the agent relay was upgraded to the same version as the server.
    - Check the **Agent Relays** tab to verify that the agent relay version is supported. To open the **Agent Relays** tab, click the main **Resources** tab, and then click the **Agent Relays** tab. See the minimum recommended and minimum required versions for the listed agent relays in the upper-right corner of the tab. You might have to upgrade an agent relay or agent relays. For information about upgrading an agent relay, see Upgrading agent relays from the command line.
- Check the **Agents** tab to verify that the server supports the agent version. To open the **Agents** tab, click the main **Resources** tab, and then click the **Agents** tab. See the minimum recommended and minimum required versions for the listed agents in the upper-right corner of the tab. You might have to upgrade an agent or agents. For information about upgrading an agent, see Upgrading agents.
- Did you create this process in the upgraded version? If the process was created in a previous version, did it work correctly in the previous version? If so, were any changes made to the process after the upgrade?

A process runs, but it does not stop

- Has this process ever run to completion previously? See this IBM support article: MustGather: How to trace the execution of a process.
- Is the process wired to the **Finish** step?
- If the step that fails is a shell step, is the standard output is redirected for child processes to https://developer.ibm.com/urbancode/plugindoc/ibmucd/shell/5-562693/usage/?

Processes fail intermittently

- Does the server log contain exceptions that this issue generated?
- On which step does the process fail? Does the step output contain errors?
- At which times does the process fail? Check for network outages, maintenance intervals during that time.
- Is the Download Artifacts step failing with the error `java.io.FileNotFoundException: Artifact set not found`? Ensure that CodeStation has enough time to store the artifacts before they are requested, particularly in high-availability clusters, in which the servers share the artifacts. The solution for this issue is typically to add a Wait step with a few seconds wait time before the Download Artifacts step.

Processes stop before completion

- Check the agent and server log files for errors.
- Check the process system output.
- Consider running each process step's equivalent function in a command-line environment to verify that each step works as planned.
- Can the built-in admin ID run processes with success?
- If the steps that fail are shell steps, redirect the standard output of child processes to https://developer.ibm.com/urbancode/plugindoc/ibmucd/shell/5-562693/usage/.
- Do you have sufficient memory on the Deploy server?

  Tip: The workflow execution engine that runs the process runs on the Deploy server.

- On which screen or activity do you see no progress?
- How long did the process stop? How long do you expect this activity to take?
- Are there any agents for which this behavior does *not* happen? If so, what differences exist between the processes that work and the processes that do not.
- Did this behavior always happen? If not, what changed immediately before this problem surfaced?

Processes with branches do not run correctly

- Look closely at the way the process branches to ensure that the process is running in the way as expected. See Branching and joining steps on page 2402. See this IBM support article: MustGather: How to trace the execution of a process.

Processes using impersonation do not run correctly

- Reproduce the problem with a simple shell step, use the `#!` syntax at the top to specify the shell to use. For example:

  ```
  #!/bin/sh
  ```

  In the example, `/bin/sh` resolves to different shells depending on the operating system. For example, it resolves to `/bin/ksh` on AIX and Solaris operating systems and to `/bin/bash` on a RedHat Enterprise Linux operating system.
- Put the shell script of the step into a separate file and execute it from the Deploy interface or from a command line.
- Enable logging on the agent to verify that the command ran. To enable logging, add the following logger to the logging and set the logging level as DEBUG. Start the agent again for the change to take affect.

  ```
  com.urbancode.shell.impersonation.unix.UnixImpersonateCommand
  ```

- Add to the separate script file a call to `printenv` and execute the script from a Deploy step or from a command line. Compare the two processes for differences.
- Execute the separate script using the commands configured in the **sudoFormat** and **suFormat** agent properties described in the Impersonation on Linux and UNIX systems on page 2463 topic.
- In the agent `installed.properties` file, add the following property to verify that the command executes successfully after the impersonation.

```
com.urbancode.shell.impersonation.unix.scriptPostExecuteAction=echo
```

- Update your Java fixpack level or Java version to a higher level.

Troubleshooting plug-ins

Use the following procedures and tips to help troubleshoot plug-ins that you use with HCL DevOps Deploy (Deploy):

Installing a plug-in generates an error: `Error loading plugin: undefined` on page 3012.

Loading a plug-in generates errors and steps are not displayed in the process editor on page 3012.

Installing a plug-in generates an error: `Error loading plugin: undefined`

About this task

You attempt to install a plug-in, and you receive this message: `Error loading plugin: undefined`. This error message is displayed when the file system has insufficient space. The plug-in requires more space even though it seems as though enough space is available for installation.

Depending on your hardware, add more space to the file system, and then try to install the plug-in again.

Loading a plug-in generates errors, and steps are not displayed in the process editor

About this task

You installed a trial version of Deploy with IBM® DB2® as database. After starting the server, you cannot see any plug-ins and you are unable to load new plug-ins. Numerous errors are written to the log.

The pagesize must be specified correctly when the DB2 database is created. Deploy DB2 requires a pagesize of 32 k. See Configuring a DB2 database.

Troubleshooting DevOps Deploy when running as a container

When you install HCL DevOps Deploy (Deploy) server by using the provided Helm chart, two containers are created. The first is named `init` that performs some initialization steps, including initialization of your database. The second is `hcl-launch-prod`, which is the main server container. You can debug issues by checking the logs of each of these containers.

Checking the `init` container

- To get logging information for the `init` container, you must run the following command:

```
kubectl logs [pod-name] -c init
```

- A part of the initialization process involves connecting to the database and pulling the Deploy server version information from the database. If you are installing a new release of Deploy with a new database, the database is not initialized and does not contain a Deploy version. In this case, you might get the following error message:

```
[Error] Table DS_DATABASE_VERSION does not exist
```

After this error message, you see another message indicating the database has been initialized. It might take some time for the database to initialize.

When you connect to a previously initialized database, the version of the Deploy server used to initialize the database is displayed.

Checking the server container (`hcl-launch-prod`)

After the `init` container startup finishes, the main server container starts.

- You can view the installation and setup logs by running the following command:

```
kubectl logs [pod-name] -c hcl-launch-prod
```

- After the container has started, you can run the following command inside the container:

```
kubectl exec -it [pod-name] -- /bin/bash
```

The Deploy server is installed in the `/opt/hcl-launch/server` directory. You can navigate to the directory and explore settings and log files as you do with an on-premises Deploy.

Troubleshooting problems on z/OS®

To troubleshoot problems on agent computers that are running IBM® z/OS®, examine the agent log files.

Agent log files

Agent log files are stored in the UTF-8 format. To read agent log files, use an editor that supports the UTF-8 format. For example, use IBM® Rational® Developer for z Systems™ or the z/OS® UNIX™ Directory List Utility.

Alternately, convert the agent log files to a different format. To convert an agent log file to EBCDIC IBM®-1047 encoding, type the following text at a command line:

```
iconv -f utf8 -t ibm1047 agent.out > agent.out.1047
```

Common problems

Out of memory errors

If the agent does not start or the deployment tools do not run, and a message similar to the following message is displayed on the console or written to the *agent*`/var/log/stdout` log file, the OMVS segment is not in the user profile or the memory that is assigned to the user account is not sufficient for the OMVS segment.

```
JVMJ9VM015W Initialization error for library j9jit24(11): cannot initialize JIT.
Could not create the Java virtual machine.
<JIT: fatal error, failed to allocate 8192 Kb data cache>
```

To correct the problem, ensure that the agent user account meets the security requirements. To learn more, see Security requirements on IBM z/OS computers.

ISPF gateway is not configured correctly

The error message `The ISPF gateway is not configured correctly` is typically followed by an XML response that indicates the specific problem. Typical problems include the following issues:

- The user account does not have write access to the *ispf_log_directory*/WORKAREA directory.
- The user account does not have an ISPF profile.
- The ISPF gateway cannot allocate the data sets defined in the `ISPF.conf` file. By default, the `ISPF.conf` file is in the *agent*`/conf/toolkit/` directory.

EDC5112I Response temporarily unavailable

The error message `EDC5112I Response temporarily unavailable` is displayed when no z/OS® UNIX™ processes are available to run the ISPF client gateway. To work around this behavior, set the PROCUSERMAX parameter in the OMVS segment of the user account Resource Access Control Facility profile to the value specified in the security requirements. To learn more, see Security requirements on IBM z/OS computers.

ISPF.SYSTSPRT error: EDC5129I No such file or directory.

The name of the ISPF client gateway log directory must be shorter than 51 bytes. If a directory with longer name is used, you will see the following errors when using the TSO/ISPF command plug-in step or creating a component version.

```
*** fopen() error for
ispf_log_directory/WORKAREA/WORKAREA/UCDUSER.ID00xxxx.ISPF.SYSTSPRT error: EDC5129I No such file
 or
directory.
```

```
Bad call : cp: ispf_log_directory/WORKAREA/UCDUSER.ID00xxxx.ISPF.SYSTSPRT: EDC5129I No such file
 or
directory.
```

To correct the problem, use a log directory which is shorter than 51 bytes. You can do this by reinstalling the agent and toolkit or by modifying the directory in the following two configuration files:

- `agent_dir/conf/toolkit/ISPZXENV`
- `agent_dir/conf/toolkit/installed.properties`

EDC5113I Bad file descriptor or EDC5130I Exec format error

Error message `EDC5133I Bad file descriptor error` or `EDC5130I Exec format error` is produced when a process step runs in z/OS with BPX_SHAREAS=YES. This setting will help shell to run foreground processes in the same address space as the shell is running in. For more details see, Setting _BPX_SHAREAS and _BPX_SPAWN_SCRIPT

- Our guidance is to set BPX_SHAREAS as NO always.

Performing AI analysis on failed deployments

You can perform AI analysis on failed deployments to identify the root cause of the failures and troubleshoot them easily.

Before you begin

You must have completed the following tasks:

- Configured the AI settings. See Configuring the AI settings on page 2117.
- Ensured that the **Use AI** permission is enabled for you. See Permission reference on page 2192.

About this task

When you run a deployment process, it might fail at a step or multiple steps for some reason. You can troubleshoot the failed steps by using the output log files. By using the **Deployment Genie** feature, you can get insights such as an AI interpreted root cause analysis and action items intended to ensure a failure doesn't happen again. To enhance user experience, the AI is instructed to respond in the user's language.

Attention: You must consider the following points before you perform the AI analysis -

- The recommendations from the configured AI service may be inaccurate or contain errors. If suggested solutions for an error do not seem logical or effective, open a support case to investigate the issue with Deploy.
- HCL Support does not resolve problems related to your configured AI service as it is a third-party utility beyond our control.
- Do not apply suggestions that involve deleting files and folders, and executing SQL queries that modify the database.

1. Go to the **Log** tab of a deployment request.
   The **Log** tab displays all steps of the deployment process.
2. Click **Deployment Genie**.
   The **Log** tab displays only the steps that failed in the deployment process.

   Note: You can also use the **Deployment Genie** option from the menu options of a failed step.

   Trouble: When the Deploy server runs as a container in a Kubernetes cluster and you invoke the Deployment Genie, an alert dialog may display stating that a timeout was encountered. To resolve this timeout issue, modify the Emissary Ingress mapping resource for Deploy to change the `timeout_ms` value as follows:
   a. Enter the following command:
      ```
      kubectl edit mapping <releaseName>-hcl-launch-server-prod
      ```
   b. Set the `timeout_ms` value to `0`.
   c. Save your changes.
3. Start the AI analysis of a failed step by clicking the **Deployment Genie** menu option.
   The logs are sent to the AI service for analysis. The AI Analysis window displays the root cause and its probable solution in a human-readable format.

Note: Deployment Genie masks the hostname and IP address from the log file before sharing it with your chosen LLM providers for analysis. However, you must use the Secure Property feature to mask any additional sensitive data. See Output properties on page 2516.

4. Perform the AI analysis for the remaining failed steps as needed.

Results

You have performed the AI analysis of a failed deployment process.

Measure

Measure provides end-to-end visibility into the DevOps Loop, giving teams to track how value is created throughout the work flow. It consolidates testing, security, and performance metrics to identify bottlenecks, team issues, and opportunities for improvement while strengthening governance across the organization.

Introduction to releases and pipelines

A release represents the delivery of multiple applications through one or more phases of a life cycle. A typical release includes many deployments to test environments and a small number of highly orchestrated deployments to staging and production. Release managers can define milestones that lead up to the release, as well as a plan to deliver participating applications to each phase of the life cycle.

Releases can represent all kinds of events, from major events in the life of your company to comparatively minor events, like recurring maintenance. You assign the applications, which are business-meaningful pieces of a system or software that can be independently deployed to the release. You create deployment plans, which define the tasks that must be completed when a deployment runs, for your release.

Pipelines automate releases. Pipeline stages organize inputs and jobs as your code is built, deployed, and tested. Stages accept input from either Source control management (SCM) repositories or other external applications, such as HCL DevOps Deploy (Deploy). Stages and jobs run serially and enable flow control for your work.

Home page

Use the **Home** page to view value streams, releases, and insights defined in your environment.

Access the **Home** page and user interface using the URL provided by your administrator. To access the user interface, the administrator must authenticate your credentials. After logging into Measure, the **Home** page is displayed. From the **Home** page, you can view value streams, releases, and insights.

The Home page task bar allows you to access details and work with value streams, releases, and insights. Click **Value Streams**, **Releases**, or **Insights** to view respective home pages where you can manage value streams, govern software releases, and view real-time report information for your DevOps process.

If you have administrator privileges, there are several functions available. Click **Settings** ( ) on the task bar to perform the following tasks.

- Setup the calendar
- Perform integrations and install plugins
- View license management details
- Manage user authorization
- Manage user authentication
- Configure email server
- View your profile and create User access keys (UAKs)

The **Home page** displays all recently viewed value streams and releases with each represented in respective card views. Click the required card to work with value streams and releases. Click **View all** to access the **Value Streams** and **Releases** pages.

Administering

Configuring Measure

A default Measure administrator ID is included as part of Measure. It is used to install and complete initial configuration tasks.

The Measure administrator can perform the following tasks from the administrator user interface:

- Integrations
- User authentication
- Environment mapping
- Line of business mapping

Users who are part of the Deploy system team can perform the following tasks:

- Environment mapping
- Line of business mapping

Security considerations

To ensure user data security, specify a **logout url** when authenticating users. This ensures that the user is logged out of the system and prevents another person to access their account through the cached browser data.

Configuring an email server

Configuring an email server

Before you begin

To send email, you must define an SMTP (Simple Mail Transfer Protocol) server.

This task requires that you are an Measure administrator.

About this task

You can set up a mail server for sending notifications and email.

1. On the Measure dashboard, click **Settings > Email Server**.
2. Click **Configure email server**.
3. In the **Email server** window, in the **Mail server host** field, enter the mail server URL.
   For example, `smtp.gmail.com`.
4. In the **Port** field, enter the mail server port number.
5. **Optional:** If you want to secure your email communication, check **Secure mail server connection**.
6. In the **Mail server user name** field, enter the email user account name.
7. In the **Mail server password** field, enter the user account password.
8. In the **Mail server sender name** field, enter the mail server sender name.
9. In the **Mail server address** field, enter the mail server address name.
10. Click **Save**.

Note: To delete the email settings, click **Delete Settings**.

Configuring calendar settings

Use the **Calendar Settings** page to manage the appearance of calendar events.

About this task

This task requires that you are an Measure administrator.

Use the **Calendar Settings** page to add, remove, and set the presentation style such as color for events displayed in the calendar. You can define presentation order of events for days with multiple event types. Events types include the following.

- Release events and activities
- Financial blackouts, maintenance windows, release opportunities
- Holidays

The **Preview** portion of the page displays all the defined events.

1. To access the **User authentication settings** page, click the Settings icon ( ) at the top right of the user interface.
   Click **Calendar**.
2. To create an event, click **Add event type** for the type of event to be added.
   There is an **Add event type** for each event type. Type the name of the event and click the check mark icon.

a. To change the presentation style and color, place the cursor over the default style created and right-mouse click. Optionally, click the edit icon ( ).

b. Use the left and right arrow to set the priority for the event.
The left arrow moves the event up and the right arrow moves it down.

3. To remove an event, move the cursor to the event and click the delete icon ( ).

4. To modify an event, move the cursor to the event and click the edit icon ( ).
There are separate edit icons for changing the event name and presentation style.

Configuring security settings

The Measure security model is organization- and team-based. The organization is the base element; teams belong to organizations. Team members manage releases, events, and deployments. Administrators manage teams and assign users to them.

The team-based security model means that teams manage releases, reports, pipelines, events, and run deployments. Only team members can create or modify team-managed objects. Users can be assigned to more than one team. Users are identified by email address. The administrator manages the security system and manages teams and users.

After Measure is integrated with HCL DevOps Deploy on page 1885, Deploy teams and applications can be imported into Measure. When a team is imported, all team members are imported. Users are identified by email address. Administrators can also create users.

Roles and permissions

A number of roles are defined in the product that can be assigned to a user or group. Roles set boundaries on activities that a user or group member can perform.

Roles are assigned to users and groups within the team context. Users or groups are assigned to a team with a specific role. The role assigned to a user is only for the team that the user is a member. A user can be a member of multiple teams and have a different role on each.

The interlocking concept of teams, roles, and permissions ensures that users have the appropriate permissions to perform their work and not affect processes outside of their assigned scope. The interaction of these three concepts provides the mechanisms to create an infrastructure that is secure and flexible.

There are two types of roles, global and team. Global roles provide permissions to access all resources of the product. Team specific roles provide permissions to access team specific resources of the product. Users with team specific roles can view only the resources associated with that team.

You can customize the roles using the following procedure.

1. On the Measure dashboard, click **Settings** , and then click **Authorization > Roles**.
2. On the **Roles** page, click **Create role**.
3. In the **Name** field, enter the name for the role.
4. In the **Description** field, enter the description for the role.
5. In the **Scope** field, select the scope for the role.

   Note: The possible values for the scope of the roles are global and team.

6. In the **Permissions** field, select the required action under each resources.
7. Click **Save**.

Note: The users with **Team manager (global)** and **Product administrator** role can create roles.

You can assign members to global roles using the following procedure.

1. Click to assign members to roles.
2. In the **Members** field, enter or select the member to assign the roles.
3. Click **Save**.

You can use to edit roles and to delete roles.

The roles with label **Custom** are customized roles. The roles with label **static** are system generated roles. **Static** roles cannot be modified or deleted.

Note: Until new users are assigned to teams, they are automatically assigned to the Default team with no assigned role. Administrators grant users elevated permissions when they assign them to roles such as Lead Developer or Release Manager.

Note: When you create a custom role and provide permissions to the deployment plan and deployment template, you must also add group view permissions.

The following tables show the available roles.

Note: For each of the roles, the underlying resources and permissions are also scoped as team or global.

Table 1127. Calendar manager

Resource	Action	Description
Calendar	**View**, **Create**, **Edit**, **Delete**	View, create, edit, and delete calendar settings.

Table 1128. Developer (team)

Resource	Action	Description
Deployment plan	**View**	View deployment plans.
Environment	**Run**	Run team specific deployment in pipelines.
Group	**View**	View groups.
Integration	**View**	View plugin integrations.
Release	**View**	View team specific releases.
Task	**View**, **Create**, **Edit**, **Delete**, **Run**	View, create, edit, run, and delete team specific tasks.
Team	**View**	View teams.
Value stream	**View**	View team specific value streams and pipelines.

Table 1129. Insights manager (global)

Resource	Action	Description
Dashboard	**View**, **Create**, **Edit**, **Delete**	View, create, edit, and delete dashboards.
Integration	**View**	View plugin integrations.
Report	**View**, **Create**, **Run**	View, create, and run reports.
Value stream	**View**	View value streams and pipelines.

Table 1130. Insights viewer

Resource	Action	Description
Dashboard	**View**	View dashboards
Report	**View**	View reports.
Value stream	**View**	View value streams and pipelines.

Value stream	**View**	View team specific value streams and pipelines.

Role mapping limitation

In Loop, Measure uses Keycloak groups to map roles. You can refine the permissions by using the authorization features. Measure supports the following roles:

- Product administrator
- Non-admin user

These roles define the baseline access level. You can extend this baseline access by using authorization within Measure.

Role mapping matrix for Measure

Keycloak group	Loop role	Supported	Notes
User group	Product administrator	No	Users in the Keycloak user group cannot be directly assigned product administrator priviliges in Measure.
User group	Non-admin user	Yes	Standard user access is supported.

Keycloak group	Loop role	Supported	Notes
Admin group	Non-admin user	No	Admin grup users cannot be downgraded to non-admin user via Loop role mapping.
Admin group	Product administrator	Yes	Administrator access is correctly mapped from Keycloak.

Authorization behavior in Measure

You can elevate permission for users in the Keycloak non-admin user group by using the authorization feature in Measure.

When configuring these settings, note the following behavior:

- You can grant non-admin users additional access rights directly at the Measure level.
- You can manage these permissions independently of Keycloak group role mapping.
- Authorization controls what actions a user can perform within Measure, but it does not change the user's Keycloak group.
- Role mapping changes in Measure do not synchronize back to Keycloak groups.

Note:

- Keycloak mapping supports only product administrator and non-admin user roles.
- Keycloak defines baseline access, while Measure authorization extends these permissions for non-admin users.
- Role mapping does not synchronize back to Keycloak groups.

Managing users and authentications

Use **Authorization** and **Authentication** to manage users and authentication.

Users can be created, modified, or removed in Measure.

Users can be authenticated from the systems detailed in the following table:

Table 1145. User authentication methods

Authentication method	UI	API
Local on page 1812	Supported	Not supported
LDAP on page 1813	Supported	Not supported
OpenID Connect (OIDC) on page 1817	Supported	Not supported

Table 1145. User authentication methods (continued)

Authentication method	UI	API
SSO on page 1817	Supported	Not supported
User access key (UAK) on page 1820	Not supported	Supported

API authentication

UAK is the recommended method through the API. An example for UAK is:

`curl -X POST -k -H 'Content-Type: application/json' -H 'Authorization: UserAccessKey xxxxxxxxxxxxxxxxxxxx'`.

Details for configuring UAKs are found here on page 1820.

Managing users

Use the **Users** page to create, edit, or remove users.

About this task

This task requires that you are an Measure administrator.

Users can be created, edited, or removed from **Authorization** on the **Settings** page.

To create a user, complete the following steps:

1. Click **Settings > Authorization > Users > Create user** to display the **Create user** window.
2. Complete the required fields.
3. Click **Save**.

What to do next

To modify or remove a user, click **Settings > Authorization > Users** and perform the following steps.

- To modify a user:
  - Click the overflow menu ⋮ and select **Edit** for the required user.
  - Change the required fields in the **Edit user** window.
  - Click **Save**.

- To remove a user, click the overflow menu ⋮ and select **Delete** for the required user.

  Note: Users are deleted from all teams and groups. Users' access keys are also deleted. You can use a deleted user email address to create a new user. The new user is created with default permissions. The user cannot retain previous roles and permissions after deletion.

Note: Additional user authorization topics include teams, groups, and user access keys.

Authenticating users with LDAP

Use the **User authentication settings** page to manage user authentication.

Before you begin

You must have the URL of the external LDAP server that you intend to authenticate users. This task requires that you are an Measure administrator.

About this task

An LDAP realm identifies users and groups and defines rules how to search users and groups. When unknown users attempt to log on, an external LDAP server authenticates them by using the realm parameters that you configure. To configure an LDAP authentication realm, you identify the URL of the LDAP server, and define valid searches.

To create an LDAP realm, complete the following steps:

1. From the Measure dashboard, page, click **Settings > Authentication**.
2. Click **Configure LDAP** .
3. On **LDAP** page, in the **Name** field, enter a name for the realm configuration.
   The value is an arbitrary label that does not effect the other settings.
4. In the **LDAP URL** field, enter the URL for the LDAP that you use for authentication.
   Separate multiple servers by commas.
   Example
   For example, `ldap://ldap_server.my_domain.com:389,ldap://ldap_server.my_domain2.com:389`.
5. Specify whether anonymous searches are allowed by completing one of the following options:
   Choose from:
   - If the LDAP server allows anonymous searches, select **Search Anonymously**.
   - For authenticated searches, clear the **Search Anonymously** check box, and then enter the **Bind DN** and **Bind credentials**. Velocity uses these fields to authenticate users when it connects to the LDAP server. For example, `cn=velocity,ou=applications,dc=mydomain,dc=com`.
6. **Optional:** In the **Scope when searching LDAP users** area, specify a search scope by selecting one of the following options:
   Choose from:

- **Subtree**. Select this option when user entries are direct children of the **Search base**.
- **One level**. Select this option if all user entries are direct grandchildren of the **Search base**.
- **Base**. Select this if option if user entries are two or more levels below the **Search base**.

The scope is relative to the **Search base** selected in the next step. It is a good practice to make the scope as narrow as possible.

7. In the **Search base** field, enter the user search base.
   Example
   The starting directory for the search, such as `ou=employees,dc=mydomain,dc=com`.
8. In the **Search filter** field, enter the search filter.
   Example
   The LDAP filter expression that is used when searching for user entries. The user name replaces the *{{username}}* variable in the search pattern, for example, `uid={{username}}`.
   If the value is not part of the DN pattern, enclose the value in parenthesis, for example, `(mail={{username}})`. For more information, see the help information for your LDAP server and look for information about creating user search filters.
9. **Optional:** In the **Bind property** field, enter a search expression.
   Example
   This is the name of the LDAP attribute that contains the **Bind DN** specified earlier. The default value is `dn`.
10. **Optional:** In the **Name attribute** field, enter the LDAP user name.
    This is the name of the LDAP attribute that contains the user's full name. Examples are `cn` and `displayName`.
11. In the **Email attribute** field, enter the user email address.
    This is the name of the LDAP attribute that contains the user's email address. For example, `mail`.
12. In the **Role definition** area, specify a role by completing one of the following options:

    a. Select **Role in LDAP reference their members** if you want to find group membership by searching roles, and then define the **Group search filter**.

    Note: The **Group search filter** is the LDAP filter expression that is used when you search for user entries. The user name replaces the {1} variable in the search pattern and the full user distinguished name (DN) replaces the {0} variable, for example, `(&(uniqueMember={dn})(cn=BSO*))`. The user name replaces the `{username}` variable in the search pattern and the full user distinguished name replaces the `{dn}` variable.

    a. Select **User roles are defined as an attribute on that user** if you want to find group membership by using this attribute, and then define the **Group DN Attribute** and **User Group Attribute** fields.
    The **Group DN Attribute** is the name of the LDAP attribute on group entries, whose value is the group's distinguished name. For example, `dn`. The **User Group Attribute** is the name of the LDAP attribute on user entries, whose value is the distinguished name of a group of which the user is a member. For example, `memberOf`.

13. In the **Group search base** field, enter the directory that is used for group searches.
    Example
    For example, `ou=employees,dc=mydomain,dc=com`.

14. In the **Group name attribute** field, enter the name of the entry that contains the users' group names in the directory entries that are returned by the group search.
    If this entry is not specified, no group search runs, for example, `cn`.
15. On the **Search group subtree** box, subtrees (if any) are searched. If the item is not selected, the search is limited to the **Group search base**.
16. Click **Save**.
17. Click **Import users** to verify the **LDAP** configuration settings. For the valid **LDAP** configurations, user import status is successful. For the invalid **LDAP** configurations, user import fails with the error message.

Results

The first time an unknown user attempts to log on, LDAP authorization realms are searched in an attempt to identify the user. If the user is found, a corresponding user ID is created in Measure. In addition, if the user is part of an LDAP group, that group is imported too.

When new users log on to the server and use their LDAP credentials, they are listed on the `Users` page. In most cases, do not manage user passwords or remove users from the list. If an active user is removed, they are still able to log on to the server while their LDAP credentials are valid.

Copying DevOps Deploy authentication and authorization realms into Measure

Transfer authentication and authorization realm settings from DevOps Deploy to Measure.

Before you begin
You must have both the authentication and authorization realms created in Deploy before you can copy them into Measure. This task requires that you are an Deploy and Measure administrator.

1. From the Deploy home page, click **Settings > Authentication (Users)**, and then click the required authentication realm.
2. Click the arrow to the left of **Edit** to display the authentication realm fields to be copied into the Measure fields.
3. From the Measure home page, click **Settings > User Authentication**.
4. Copy information from the DevOps Deploy authentication realm fields to the Measure fields, as described in the following table.

Table 1146. Copying authentication realm fields

Deploy authentication realm field	Measure field
Name	**Name**
Description	**Description**
LDAP URL	**LDAP URL**
Search Anonymously	**Search Anonymously** Note: Match selection to Deploy field.
Search Connection DN	**Bind DN**

Deploy authentication realm field	Measure field
Search Connection Password	**Bind credentials**
User Search Base	**Search base**
User Search Filter	**Search filter** Note: Do not copy the **User Search Filter** field. In the **Search filter** field, enter `mail={{username}}`.
Name Attribute	**Name Attribute**
Email Attribute	**Email Attribute**

5. Match the **Search User Subtree** selection with the **Scope when searching LDAP users** selection.
   If **Search User Subtree** and **Subtree** are not selected, follow these guidelines for making a selection in the **Scope when searching LDAP users** field:

Options
One level indicates that only the immediate children of the entry that is specified as the search base are considered. The base entry itself is not considered, nor any descendants of the immediate children of the base entry.
Base indicates that only the entry that is specified as the search base is considered. None of its subordinates are considered.

6. From the Deploy home page, click **Settings > Authorization (Groups)**, and then click the required authorization realm.
7. Click **Edit** for the required authorization realm to display the fields to be copied into the Measure fields.
   For the following steps, you will be copying information from the Deploy authorization realm fields displayed in the **Create Authorization Realm** fields to the Measure fields.
8. Copy information from the Deploy authorization realm fields to the Velocity fields, as described in the following table.

Table 1147. Copying authorization realm fields

Deploy authorization realm field	Measure field
Group Search Base	**Group Search Base**
Group Search Filter	**Group Search Filter** Note: Do not copy the **Group Search Filter** field, enter `member={{dn}}`
Group Name	**Group Name Attribute**
Search Group Subtree	**Search Group Subtree** Note: Match selection to Deploy field.
User Group Attribute	**User Group Attribute**

9. Click **Save** on the **User authentication** page in Measure.
10. Click **Import users** to verify the **LDAP** configuration settings. For the valid **LDAP** configurations, user import status is successful. For the invalid **LDAP** configurations, user import fails with the error message.

Authenticating users with OpenID Connect (OIDC)

Use the **Authentication** page to manage user authentication with **OpenID Connect**.

Before you begin

To configure the **OIDC** authentication, you must have Measure administrator permission and privileges.

About this task

OpenID Connect is an authentication method which you can use to authenticate users.

To configure an **OIDC** authentication, complete the following steps:

1. From the Measure page, click **Settings > Authentication > OIDC**.
2. Click **Configure OIDC** .
3. On **OIDC** page, in the **Name** field, enter a name for the **OIDC** configuration.
4. In the **Description** field, enter a description for the **OIDC** configuration.
5. In the **OIDC Issuer** field, enter the issuer for **OIDC** authentication.
6. In the **Authorization URL** field, enter the URL of **OIDC** authorization provider .
7. In the **Token URL** field, enter the URL for token request with **OIDC** provider.
8. In the **User info URL** field, enter the URL for user information request with the **OIDC** provider.
9. In the **Client ID** field, enter the client ID that is registered with the **OIDC** provider.
10. In the **Client Secret** field, enter the client secret that the **OIDC** provider issues upon registration.
11. Click **Save**.
    Result

    You have successfully configured **OIDC** authentication. You can log in to Measure using **OIDC** configuration.
12. On the Measure login page, click **Login with OIDC** to log in using OIDC configuration.
    The **Authorization URL** page opens to validate the user for accessing the Measure
13. On the **Authorization URL** page, enter the username in **Username** field and password in **Password** field.
    You have successfully logged in to the Measure.
14. On the **Settings > Authentication > OIDC** configuration page, click **Delete configuration** to delete the **OIDC** configuration.

Results

You have successfully configured the **OIDC** authentication. You can log in to Measure using the **OIDC** authentication.

Creating a header-based SSO authentication integration

A header-based single sign-on (SSO) authentication realm uses an external server for authentication.

1. On the Measure dashboard, click **Settings > User authentication > SSO > Configure SSO**.
2. In the required fields, specify the following parameters:

Table 1148. SSO properties

Field	Description
Name	The name for the integration.
Full name header name	The user name on the SSO server that contains the list of users.
Email header name	The user email on the SSO server that contains the list of users. Note: For **Email header name**, there is a change to lower case in the Measure database.
Logout URL	The SSO server's logout URL.

Note: Measure supports header-based SSO and can integrate with other SSO mechanisms, such as Security assertion markup language (SAML). It is the responsibility of the user to modify the SSO scheme in use to transmit the headers to authenticate with Velocity Measure and then block the login page. The aforementioned method is different for every SSO product and mechanism.

3. Click **Save**.
   Result
   Setting up an SSO user does not automatically add the user on page 1812 to the Measure database and is explained in further detail below.

Results

When users log on to an SSO-configured Measure instance, their **Email header name** SSO credential is compared to the SSO server's user list. If the email address matches an existing user in the Measure database, a user will automatically be created in the database and listed as **SSO** in the **User Type** field.

Note: Once the SSO setup is completed properly by the admin user and that user logs out of Velocity, there is a loss of admin access privileges because of the inability to log back in as the admin. New users created via the SSO login only have the Viewer and Release participant permissions by default and the admin cannot change the permissions as stated previously. Possible solutions for this scenario include the following:

1. Set the Measure server to allow direct access from specific IPs that will allow the admin to login.
2. Create an SSO user with the Measure admin email address of `admin@admin.com`.
3. Perform an SSO login with a different browser while the local Measure admin navigates to **Settings > User authentication > Teams** and grants full admin privileges to the SSO user.

As a guideline, Item 3 is the recommended method for preserving admin access privileges to Measure.

To delete a current SSO configuration after it was created, click the **Delete Configuration** button on the **Settings** page for **SSO**.

Managing user groups

You can combine users into groups. When you grant permissions to the group, you simultaneously grant them to the group members. When you assign a group to a team, all group members are simultaneously assigned to the team.

About this task

Note: Groups cannot be imported from DevOps Deploy.

To create a group, complete the following steps:

1. On the Measure dashboard, click **Settings** , and then click **User authorization > Groups**.
2. On the Groups page, click **Create Group** and in the Add New Group window, enter a name for the group, and then click **Save**.
3. With the group selected, click **Add user**.
4. In the **User** list, select a user, and then click **Save**. The user is added to the **Members** list. You can add a user by typing the user's email address. The email address is used as the user name.

What to do next

If you configure an LDAP server, groups can be imported when new users log on for the first time.

Password management

Password management details how you can change the administrator password and retrieve the RabbitMQ password from Kubernetes on page 1820 and OpenShift on page 1820.

Changing the Administrator password

Use the **Users** page to change the administrator's password.

About this task

The admin user is the Measure super user. You set the initial admin password during installation. To change the admin password, complete the following steps.

Note: This task requires that you are an administrator.

1. Click **Settings > User authorization > Users** to access the **User authentication settings** page.
2. Click the **Change password** action for the admin user, and then enter your own password.

3. Enter the new password.
4. Click **Save**.

Retrieving the RabbitMQ™ password in Kubernetes™

Accessing the RabbitMQ password from Kubernetes.

1. From a command line window, run the following command to retrieve the data contained in the secret.

   ```
   kubectl get secret velocity-rabbitmq -o yaml
   ```

2. On the `password` line, copy the password.
   The password is Base64 encrypted.
   Result
   The screen capture for copying the password is shown in the following illustration.
3. Use a Base64 decoder to decode the password.

   a. For a Linux shell, run the following command to decode the password:
      Paste the password in the command line.
      Example

      ```
      echo -n '<password>' | base64 --decode
      ```

   b. The decoded password is displayed in the shell.

Retrieving the RabbitMQ™ password in OpenShift™

Accessing the RabbitMQ password from OpenShift.

About this task

To retrieve the RabbitMQ password in the OpenShift Container Platform application, use the following procedure.

1. Navigate to the OpenShift Web Console UI.
2. Navigate to the list of secrets (**Resources > Secrets**).
3. Navigate to the **velocity-rabbitmq**.
4. Click on **Reveal Secret** to display the value in the **password** field.

Managing User access keys (UAKs)

Create a key that you can use to authenticate API calls.

About this task

Until new users are assigned to teams, they are automatically assigned to the Default team in the Viewer and Participant roles. Users in these roles can view objects, such as releases and value streams, but they cannot create or edit them. Additionally, users in these roles can auto-generate user access tokens and access API endpoints with GET requests. Administrators grant users elevated permissions when they assign them to roles such as Lead Developer or Release Manager.

1. On the Settings page, click **My Profile**.
2. Click the **Create user access key** button.
3. In the **Name** field, enter the name for the user access key.
4. Click the **Create** button.
5. In the **User access key created** window, click to copy the **Access key** to the clipboard.
6. Save the key to a secure location.

   Note: It's important to save the key because it will not be accessible after you close the **Access key created** window.

7. Click **x** to close the **User access key created** window.

What to do next

You can use the key whenever you use plugins or external clients to integrate tools into Measure.

Integrations support the capability to auto-generate the required user access keys that is implemented on a plugin by plugin basis.

Note: Plugins are not updated at the same time and you can refer to the plugin documentation page for the latest updates. The update status of existing integrations only change when you edit the integration.

The auto-generated user access key process is detailed in the following:

1. On the Measure **Home** page, click **> Integrations > Plugins**.
2. Click the **Add integration** button for the required plugin integration to display the **Add Integration** modal window.
3. The **User Access Key** field is displayed if the plugin is not updated.

   Note: The **User Access Key** field is not displayed if the plugin is updated.

4. Fill in the required fields for the plugin.
5. Click the **Show Hidden Properties** check box to display the auto-generated properties for the integration.

   Note: In the Measure **User Access Key** field, you can enter a user access key if you have one, but it is not required.

6. Click the **Add** button.

7. Click **User Authorization > User Access Keys** to locate the plugin in the **Name** field with the format of **Integration Name** - AutoGen.

   Note: Any existing plugin integrations that are edited and saved automatically auto-generate user access keys in the aforementioned manner.

You can review the issued user access keys on the **User access key management** page, **Settings > User authorization > User access keys**. If you have administrator permissions, you can delete user access keys from that page.

Configuring log level settings

Control the amount of detail sent to log files.

About this task

Log files contain information about the data that your plugin integrations use or create. You can control the amount of information kept in the log files by setting the logging levels. You set the logging level separately for each integration.

The following list contains the logging levels:

- `ALL`
- `TRACE`
- `DEBUG`
- `INFO`
- `WARN`
- `ERROR`
- `FATAL`
- `OFF`

Each level contains less information than the level that precedes it in the list. To keep the most verbose information, select `ALL`. The default logging level is `INFO`.

1. On the **Settings** page, click **Integrations**, and then select the **Edit** action for the integration that you want to change.

   Note: You can also set the logging level when you create an integration.

2. On the **Add Integration** page, select the logging level from the **Logging Level** list.
3. Click **Update**.

What to do next

To see a log file, use the **View log** action associated with the integration.

If you want to troubleshoot an integration, setting the logging level to `DEBUG` is a good place to start.

Configuration of data retention policy

Data retention policies in Measure help you manage the lifecycle of data objects by archiving or deleting resources based on scope, retention rules, and execution schedules.

Data Retention is an administrative governance feature available only for Velocity 5.2.5 or later, which allows you manage the lifecycle of data objects over time automatically. By establishing automated retention policies, Product Administrators can systematically archive or permanently delete versions and their linked resources, such as builds, inventory, and deployments that are no longer required for active operations.

You can create a data retention policy by providing the details, such as **Name**, **Description**, **Retention days**, and **Resource type**. You can also select the following policy **Mode**, which defines the action applied to the resource:

- Archive mode: This mode provides a temporary cleanup step. When resource types, such as versions, reach their archival time threshold, the system moves them out of your daily workspace. The data is removed from the active user interface so it stops cluttering your daily view. The data is still available in the backend and the administrator can still retrieve this data whenever required. The archived data continue to appear in reports such as Pipeline Snapshot, Deployment Audit, and Release Readiness reports.
- Delete mode: In this mode, the system removes the resource data permanently from the system's hard drives and databases. Because Measure maintains data integrity, deleting an object (such as a software version) will also cascade to delete all of its tightly coupled background data (such as its specific builds and deployment history). The deleted resources do not appear in reports such as Pipeline Snapshot, Deployment Audit, and Release Readiness reports.

Both archive and delete operations are soft and hard lifecycle controls, respectively, from a UI perspective, but neither operation preserves full recoverability through bulk restore. Bulk restore is not supported. However, archived resources can be restored manually.

If a resource is shared across multiple teams or applications, the system does not delete or archive the resource until all associated teams and applications are included in the selected scope. This process ensures that shared resources are not removed prematurely.

You can define the policy scope using the **Scope** field. The available scopes are as follows:

- Global: The policy is applied to all the resources across all users.
- Team: The policy is applied to only selected teams. You can select multiple teams for a single policy.
- Application: The policy is applied to only selected applications. You can select multiple applications for a single policy.

You can manage data retention policies from the **Settings > Policies > Data retention policy** page. Available actions include edit, delete, execute, and view logs. You can view the execution details by using **Audit Logs** to track policy runs and results.

You must take a database backup before creating the policies, because the reports, value stream, and insights metrics will be impacted. The linked resources of the Versions are as follows:

- Builds
- Deployments
- Inventory

Adding data retention policy

You can add a data retention policy to archive or delete resources in Measure based on defined scope and retention rules.

Before you begin

You must have the product administrator role. For more information about the roles, see Roles and permissions on page 1801.

1. On the Home page, click the **Settings** icon.
2. On the **Settings** page, select **Policies > Data retention policy**.
3. Click **Add policy**.
4. Enter the following details in the given fields:
    - Name: Add the name of the data retention policy.
    - Description: Add the description about the policy.
    - Retention days: Add the number of days for data retention.
5. Select **Mode** from the drop-down list:
    - Archive: The resource data is removed from the active user interface, so it stops cluttering your daily view.
    - Delete: The resource data is removed from the system.
6. Select **Resource** type, Version, from the drop-down list.

    Note: Currently, only the **Version** resource type is supported.

7. Select **Scope** from the drop-down list:
    - Global: This policy scope is applied to all resources across all users.
    - Team: This policy scope is applied to only selected teams.
    - Application: This policy scope is applied to only selected applications.
8. Click **Create policy**.

    The data retention policy is created as is in a disabled state, which is the default state. To enable the policy, follow the steps:

    a. Select the toggle button under the **Disable / Enable** field.
    b. Review the impacted policy records preview.
    c. Enter the policy name again to confirm enable, and then click **Confirm**.

    The policy is enabled and completed. The policy is scheduled to run every 24-hour interval.

Results

You have added the data retention policy.

What to do next

Click the icon to expand and view the following details about the data retention policy:

- Policy ID
- Resource
- Scope
- Mode
- Last execution detail
- Executed by
- Affected count
- Cutoff time

Managing data retention policy

You can edit, delete, run, and view policies from the policy page.

Before you begin

You must have the product administrator role with at least one data retention policy.

1. On the Home page, click the **Settings** icon.
2. On the **Settings** page, select **Policies > Data retention policy**.
   A list of available data retention policies is displayed.
3. Click the icon adjacent to your data retention policy to select any of the following options:

Options	Description
Edit	Update Name, Description, Retention days, Mode, Scope, or Resource, and click **Save policy**.
Delete	Click **Confirm** to delete the policy. **Note:** The deleted policy cannot be recovered.
Execute	Review the impacted policy records preview. Enter the policy name again to confirm execution and click **Confirm**. A product administrator can use this option to run the policy manually.
View logs	You can review the execution log and details of the data retention policy. Click **Download log file** to download the file.

Viewing the execution history of the data retention policy

You can view the execution history of data retention policies from the Audit Logs page.

Before you begin

You must have the Global viewer role. For more information about the roles, see Roles and permissions on page 1801.

1. On the Home page, click **Settings > Audit Logs**.
2. Filter or search for the policy that is executed as Data Retention category.
3. Review execution status and details.

Results

The system displays the execution details as follows:

- Name: Name of the policy
- Category: Category as DATA_RETENTION
- Operation: Mode of the policy, Archive or Delete
- Resource: Resource type is Version
- Scope: Scope of the policy, Global, Team, or Application
- Records affected: Number of records affected by this data retention policy
- Status: Status of the policy as completed or failed
- Triggered by: Who executed the policy
- Completed at: Timestamp of the data retention policy execution

Measure MCP Server - Tech Preview

A Model Context Protocol (MCP) server provides a structured way for GenAI clients to access tools, data, and actions through a consistent, secure interface. When you connect a GenAI client that supports MCP to the Measure MCP server, you can use natural-language requests to retrieve information from your Measure.

Disclaimer:

This release contains access to the MCP server feature in Velocity Measure as a Tech Preview and can be enabled by passing the `betaFeature=mcp` parameter while running the installer. The Tech Preview is intended for you to view the capabilities of MCP server offered by Velocity, and to provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL® provides the information without obligation of support and "as is" without warranty of any kind.

The Velocity Measure MCP server exposes predefined queries that let you view Value Stream Management data, metrics, build and deployment details, workflow gate statuses, and information about teams, applications, and workspaces. This capability provides a simple, conversational way to obtain operational insights without requiring navigation of the Measure interface or creation of API requests.

The Measure MCP server offers the following tools:

- applicationById
- builds
- deployments
- latestWorkflowGateChecks
- metrics
- teamsForCurrentUser
- teamspacesForTenant
- workflow
- workflowsForTenant
- workflowStatsByIdQuery

To use the Measure MCP server, you must enable the MCP server feature flag when you run the installer. See Prerequisites to connect with the MCP server in Measure on page 1827.

You can currently connect to the Measure MCP server using the following GenAI clients:

- Claude Desktop. See Connecting to the DevOps Velocity MCP server in Claude Desktop on page 1828
- GitHub Copilot in Visual Studio Code. See Connecting to the Measure MCP server by using GitHub Copilot in Visual Studio Code on page 1829.

The MCP deployment is enabled, and the MCP pod is running in the default configuration. To reduce resource consumption, you must disable the MCP deployment when the MCP server is not in use. See Disabling the MCP Deployment in DevOps Velocity.

Prerequisites to connect with the MCP server in Measure

You can find information about the requirements and setup steps needed before connecting to the MCP server in Measure.

Before connecting to the MCP server, you must complete the following prerequisites:

1. Install **Keycloak 26.5.6**.
2. Download and run the script to create the necessary clients for the Velocity application and MCP server.

   Note: Download the compressed file from here: keycloak-setup script. Refer to the `README.md` file included in the bundle for instructions to run the script.

3. Install or upgrade the Velocity instance by providing the Keycloak URL, client secret, and JWKS URL for MCP.

   Here is a sample command to install or upgrade Velocity with the MCP configuration:

```
helm upgrade --install velocity -n <custom_namespace_name> \
                ./accelerate-<version>-helm.tgz \
                --set license=accept \
                --set url.domain= <domain_name or I.P address>\
                --set access.key=<access_key>\
                --set mongo.url=<mongodb url>\
                --set secret.tls=<tls_secrete_name>\
```

```
                --set rabbitmq.nodePort=31672 \
                --set loglevel=ALL \
                --set externalKeycloak.url=https://<keycloak_hostname>/realms/devops-velocity \
                --set
 externalKeycloak.jwksUrl=https://
<keycloak_hostname>/realms/devops-velocity/protocol/openid-connect/certs \
                --set mcp.secretValue="<mcp-velocity-client-secret>"
```

Note: `--set jwksUrl=externalKeycloak.jwksUrl=https://<keycloak_hostname>/realms/devops-velocity/protocol/openid-connect/certs` is required only for Velocity 5.2.4 and earlier versions.

Before running the Helm command, you must replace the following placeholder values with your actual configuration:

- **<keycloak_hostname>**: Replace with your Keycloak server hostname or IP address.
- **<mcp-velocity-client-secret>**: Replace with the secret value configured for the **mcp:velocity** client in Keycloak.

These parameters ensure that Velocity can authenticate users via Keycloak and connect to the MCP server securely.

For more information about installation and upgrading, refer to the following related topics:

- Installing on Kubernetes
- Installing on OpenShift
- Installing on Google Kubernetes Engine
- Upgrading Kubernetes-based installations
- Upgrading an OpenShift installation using Helm charts

Connecting to the DevOps Velocity MCP server in Claude Desktop

You can connect to the Measure Model Context Protocol (MCP) server by using the Claude Desktop application to interact with Velocity and retrieve the necessary data and insights.

Before you begin

You must have completed the following tasks:

- Installed Velocity and configured Key cloak. See Prerequisites to connect with the MCP server in Measure on page 1827.
- Configured OIDC authentication in Velocity. See Authenticating users with OpenID Connect (OIDC) on page 1817
- Obtained the MCP Server URL. For example: `https://<velocity_hostname>/mcp`
- Ensured that Claude Desktop is installed.

1. Open the **Claude Desktop** application.
2. Navigate to **Settings > Connectors**.
3. Click **Add custom connector**.
   The **Add custom connector** window is displayed.
4. Enter the name of the connector. For example: Velocity MCP server
5. Enter the Velocity MCP server URL in the **Remote MCP server URL** field.

6. Click **Add**.
   The MCP server is now added and listed on the **Connectors** page.
7. Click the **Connect** button next to the newly added Velocity MCP server entry.

   Claude Desktop redirects you to the **DevOps Loop** login page.
8. Sign in using the Velocity OIDC user credentials.

   A consent screen is displayed requesting access to MCP tools, Velocity APIs that are used internally for tool execution, and basic profile and role information.
9. Click **Yes** to approve and complete the connection.

   After successful authentication, Claude Desktop displays the list of available MCP tools provided by the Velocity MCP Server.

> **Note:** The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session expires and you are required to re-authenticate.

Results

You have successfully connected to the Velocity MCP server by using Claude Desktop.

What to do next

You can run prompts related to Velocity to confirm a successful connection.

Connecting to the Measure MCP server by using GitHub Copilot in Visual Studio Code

You can connect to the Measure Model Context Protocol (MCP) server by using GitHub Copilot in Visual Studio (VS) Code to interact with Measure and retrieve the necessary data and insights.

Before you begin

You must have completed the following tasks:

- Installed Measure and configured Key cloak. See Prerequisites to connect with the MCP server in Measure on page 1827.
- Configured OIDC authentication in Measure. See Authenticating users with OpenID Connect (OIDC) on page 1817
- Obtained the MCP Server URL. For example: `https://<velocity_hostname>/mcp`
- Ensured that you have installed VS Code and the GitHub Copilot extension.

1. **Optional:** Open the terminal and enter the following command to allow the self-signed certificates if you are using a self-signed certificate during the Measure installation.

   ```
   export NODE_TLS_REJECT_UNAUTHORIZED=0
   ```
2. Enter the following command to open VS Code.

   ```
   code .
   ```

3. Open the **Command Palette** by pressing the keys Ctrl+Shift+P or Cmd+Shift+P.
4. Search and select **MCP: Add Server**.
5. Choose **HTTP** as the server type, when prompted for the transport type.
   The Velocity MCP Server uses HTTP-based transport.
6. Enter the **MCP Server URL** in the **URL** field.
   VS Code automatically generates the required `mcp.json` configuration.
7. Enter a name for the server. For example: Velocity MCP Server.
8. Select **Workspace**, when VS Code prompts you to choose where to save this configuration.
   - **Global** – used for all VS Code workspaces
   - **Workspace** – used only in the current folder/project

     Note: When **Workspace** is selected, a `.vscode` folder is automatically created, and an `mcp.json` file is generated within it.

     A sample `mcp.json` file is as shown below:

```
{
 "servers": {
  "velocity-mcp-server": {
   "url": "<velocity_mcp_server_url>",
   "type": "http"
  }
 },
 "inputs": []
}
```

Property	Description
<velocity_mcp_server_url>	Specifies the full Velocity MCP server URL. For example: `https://<velocity_hostname>/mcp`

   Result

   The `mcp.json` file is opened.
9. Click **Start** for the added MCP server.

   Result

   A prompt appears to authenticate via OAuth.
10. Click **Allow**.

    Result

    The following prompt is displayed:

```
Do you want code to open the external website?
```

11. Click **Open**.

Result

The OIDC login page is displayed.

12. Sign in using the Measure OIDC user credentials.

    Result

    A consent screen is displayed requesting access to MCP tools, Measure APIs (used internally for tool execution), and basic profile and role information.

13. Click **Yes**.

    You are automatically redirected to VS Code or you can also close the browser and switch to VS Code.

14. Verify the connection.

    The Measure MCP Server must display **Running** as the status.

> **Note:** The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session expires and you are required to re-authenticate.

Results

You have successfully connected to the Measure MCP server by using GitHub Copilot in VS Code.

What to do next

You can run prompts related to Measure to confirm a successful connection.

Value Stream Management

A value stream represents the objects and activities that you employ to deliver customer value, from initial concept to final delivered project.

The value stream provides a strategic window into your project workflow and enables you to drill-down to individual objects. The objects, such as builds, pull requests, issues, and tests, come from tools that you integrate into the value stream. Individual objects are represented graphically by small circles called dots. Dots frequently provide information from logically related tools, such as issues linked to source control commits. You filter the value stream by building queries on page 3117 with the *DevOps query language*.

About value streams

Value streams are displayed on the **Value stream** page in individual cards that provide status information and links to the value streams. You can change the page to a table view and customize the rows with metric data taken from the value streams.

When you create a value stream, a minimal value stream is configured and displayed on the **Value stream** view. The highest level of a value stream is a *phase*. Phases represent important, organizational parts of the value stream, such as "Planning," or "Development." On the **Value stream** view, processing is done in left-right order. For example, your first phase might be for planning and contain items created in an issue tracking system. Your next phase, used for development, can track source control activity related to the issues, and any builds triggered by the activity. Your final phase, used for deployment, might track the related build artifacts as they move through your testing environments toward production.

Phases contain *stages* that define process flow within a phase. A development phase that integrates a source control tool might contain an *In Progress* stage followed by *In Review* and *Merged* stages. When you customize a value stream, you define the phases and stages and their order.

Stages are containers for *dots*. Dots represent units of work from Measure or tools that are integrated into the value stream. Git commits or Jira issues, to take just two, are represented by individual dots. Work items, such as commits and builds, can be combined into individual dots. A dot's position in the value stream conveys important information about the object. Dots in a stage named *Merged* might represent items merged into Git repositories. An item's shape and color convey information about the item's type and status. A dot outlined in red, for example, might mean the item is past schedule. When dots change state, they move to new stages in near-real time. Finally, when you click on a dot, the displayed card provides information about the work items, including their history, and provides links to associated tools.

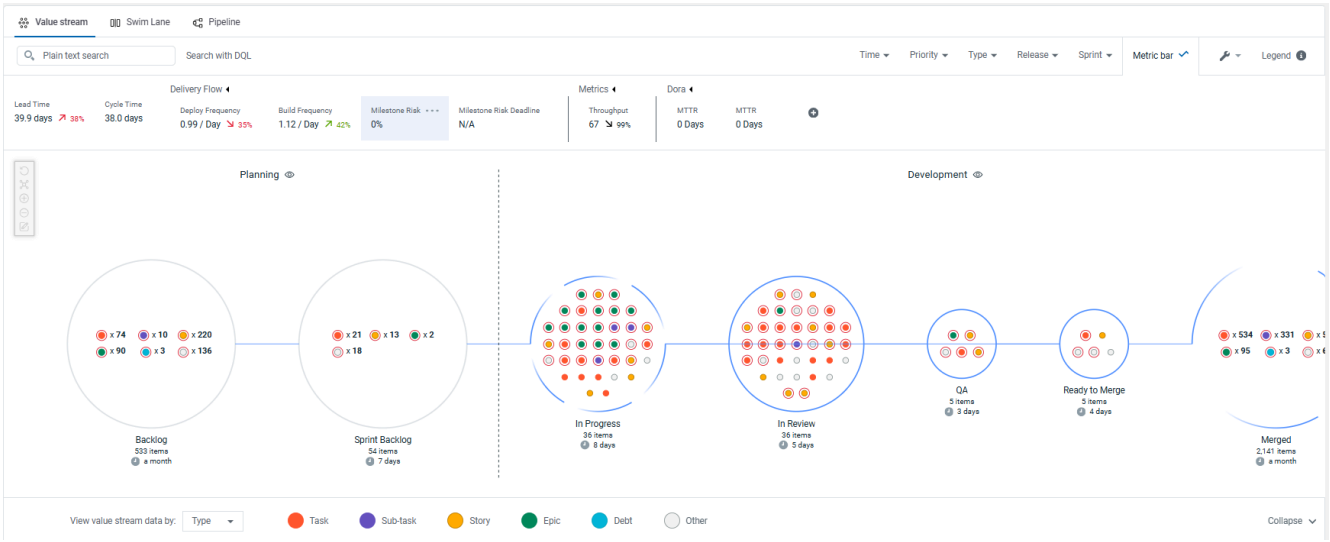
Customizing the value stream

When you create a value stream, default stages and phases are configured, but until you integrate the tools that you use with Measure , the stages will not contain items. You add your tools to a value stream by defining plugin integrations for them. After you integrate a tool, its items, such as pull requests, can be displayed in the appropriate stages. Measure provides plugins for an ever-growing number of 3rd-party tools and services that you can integrate into your value stream.

The JSON file associated with the value stream defines the phases and stages. The value stream default phases are Planning, Development, and Deployment. You can modify the JSON file to display the phases and stages that you normally use in your work.

The following figure shows a typical user-configured value stream. Notice that items are filtered by *Type*. For information about how to manage data displayed in the **Value stream** view, see Navigating value streams on page 3103.

Figure 7. User-configured value stream



Integrating tools into the value stream

You use the same JSON file to create integrations that you use to customize the value stream. After you define an integration, items associated with the integrated tool can appear in the stages on the **Value stream** view, and the integration is listed on the **Integrations** page in the web UI.

You can associate integrated tools by defining link rules for them on page 3066. If you link an issue tracking tool with a source control management tool, for example, you can access information about the linked tools from affected dots.

For information about the value stream integrations, see About value stream integrations on page 3078.

Querying the value stream

To see objects from your integrated tools, add queries to the value stream. You use the Value Stream Query language to filter the information displayed on the value stream. You build simple queries by combining searchable items with operators and values. A searchable item is a query-able object, such as `issue.status`. Queries can be scoped to the entire value stream or a stage. Each stage can have a query. You can create queries on the **Value stream** view, or define them in the value stream JSON file.

For information about the DevOps query language, see DevOps query language (DQL) on page 3117.

Swim lanes

Swim lanes provide a user-based perspective of your value stream data. When you use the swim lanes feature, value stream data is organized into a table where the columns represent value stream stages, and the rows represent users.

For information about swim lanes, see Managing swim lanes on page 3113.

About pipelines

When you create a value stream, a corresponding pipeline is configured. A pipeline is a sequence of stages that retrieve input and run applications and jobs. Pipelines accept input from source control management (SCM) repositories or other external applications, such as HCL DevOps Deploy (Deploy). You add applications to the pipeline from external tools that you integrate with Measure, such as Jenkins, and IBM® DevOps Build. You can run applications, releases, and deployments with the **Pipeline** view.

For information about pipelines, see Pipelines on page 3127.

Creating value streams

Create a value stream and then customize it by defining phases and stages that reflect your typical workflow.

About this task

When you create a value stream, a plain value stream is displayed on the **Value Streams** view. To modify the value stream and integrate external tools, edit the `value_stream_name-vsm.json` file attached to the value stream.

1. To create a value stream and configure, perform the following steps:

    a. On the Measure dashboard, click **Value Streams**, and then click the **Create value stream**.

    b. The **Create Value Stream & Pipeline** window is displayed with three steps: **Basic information** about the value stream, **Integrations** to use in value stream, and **Stages/phases** for value stream.

    c. On the **Create Value Stream** window, under the **Step 1**, in the **Name** field, enter a name for the value stream.

    d. In the **Description** field, enter a description for the value stream.

    e. In the **Team** list, select a team to manage the value stream.
    The teams that are available depend on the permissions granted to your user role. In general, you can select teams to which you belong, or that you administer.

    f. Perform any of the following actions:

- To create a value stream and configure the integration later, click **Create** and go to 2 on page 3054.
- To create and configure a value stream, click **Create & Configure** and go to 1.g on page 3053.

g. Under the **Step 2**, in the **Application Lifecycle Management Integration** field, select the required application lifecycle management integration for the value stream.

> **Note:** You can select **Click here to enable a new integration** to configure a new application lifecycle management integration.

h. In the **Source Code Management Integration** field, select the required source code management integration for the value stream.

> **Note:** You can use **Click here to enable a new integration** to configure a new source code management integration.

i. Click **Next**.

j. In the **Step 3**, under the **PLANNING** section, in the **Select the Backlog stage statuses:** field, select the required status of the application lifecycle management integration to displayed in backlog stage for the value stream.

k. In the **Select the To Do stage statuses** section, select the required status of the application lifecycle management integration to displayed in To do stage for the value stream.

l. Under the **DEVELPOMENT** section, in the **Select the In Progress stage statuses:** field, select the required issue status of the application lifecycle management and select the required pull request statuses of the source code management integration for the value stream.

m. In the **Select the In Review stage statuses:** field, select the required issue status of the application lifecycle management and select the required pull request statuses of the source code management integration for the value stream.

n. Under the **COMPLETED** section, in the **Select the Completed stage statuses:** field, select the required issue status of the application lifecycle management and select the required pull request statuses of the source code management integration for the value stream.

o. Click **Save**.
The new value stream is displayed on the **Value Streams** page in the **All Value Streams** tab.

p. **Optional:** To add a created value stream to **My Favorites**, click the **All Value Streams** tab and then click to display the value streams list view. In the list, locate the **Name** of value stream to add to **My Favorites** and then click on the left side of the field.

The value stream is listed on the **My Favorites** tab.

q. **Optional:** To remove a value stream from **My Favorites**, click ★ and the value stream is removed from the **My Favorites** tab.

2. Click and select **Edit value stream map** to modify the JSON file in the code on page 3067 or tree on page 3071 view editors.

   You can also click and select **Download value stream map**.

   Result

   The `value_stream_name-vsm.json` file is downloaded to the specified location.
3. Using a text editor, modify the `value_stream_name-vsm.json` by completing the following steps:

   a. **Optional:** Customize phases and stages. on page 3062

   You can modify the number of phases and stages, and add queries and gates to stages. A query defined in the heading sets the scope for the entire value stream. Queries defined for a stage are scoped to the stage.

   b. Define integration objects that integrate external tools into the value stream. on page 3077

   c. Define lead- and cycle-times for the value stream. on page 3064

   Lead-time refers to the time a project, represented by a value stream, takes from initial conception to final disposition. Cycle-time refers to the amount a time individual objects take to complete. Lead- and cycle-times can be displayed on the **Value stream** tab.

   d. Define link rules for integrated tools. on page 3066

   Link rules define how the tools integrated into the value stream are related.

   e. Define metrics for the value stream on page 3084.

   f. Define metrics for the metrics bar on page 3084.

   g. Define gates for the value stream. on page 3059

   h. Define mapping rules for the value stream. on page 3064

4. Click , and select **Edit value stream map** > **Import JSON**, and then select the modified file.
5. To modify the integrations in the existing value stream, perform the following steps:

   a. Open the value stream for which you want to modify the integrations.

   b. Click and select **Manage integrations**.

   Result

   The **Edit Value Stream** dialog is displayed.

c. In the **Application Lifecycle Management Integration** field, remove the existing integration and select the required application lifecycle management integration from the list.

Note: You can use **Click here to enable a new integration** to configure a new application lifecycle management integration.

d. In the **Source Code Management Integration** field, remove the existing integration and select the required source code management integration from the list.

Note: You can use **Click here to enable a new integration** to configure a new source code management integration.

e. Click **Save**.

Result

The modified integration details are updated in the `value_stream_name-vsm.json` file and the value stream displays the data from the modified integrations.

What to do next

Next, filter value streams by creating queries with the DevOps query language on page 3117. Learn about the information presented by value streams. on page 3103

Setting up a stage

Setting up a stage with queries you define in the search bar work within the scope set for the value stream.

Before you begin

Set up a value stream stage with defined queries that you need for your project.

About this task

Value stream queries determine on page 3117 the items that are displayed in the value stream stages. Queries that you define in the search bar work within the scope set for the value stream. The scope is set in the `value-stream-name.json` file. The scoping levels are detailed below.

1. Only items from integrations defined for the value stream are available. Define the integrations in the `value-stream-name.json` file.
2. Queries defined at the value stream level. To set this scope, define a query in the heading of the `value-stream-name.json` file.
3. Stage level. To set this scope, define a query in a stage object of the `value-stream-name.json` file.

Results

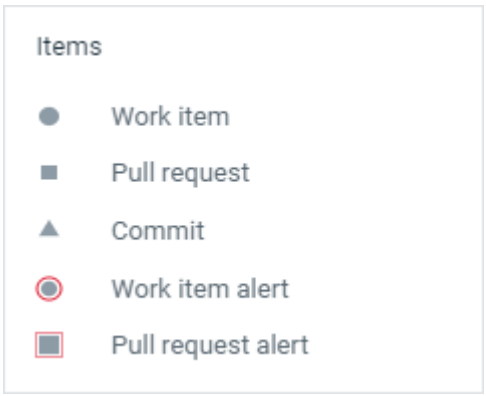
Defined queries are set up for the value stream.

Example

Queries that you define on the **Value streams** view search bar, work within the scope set for the value stream. For example, in the `value-stream-name.json` file you might set the scope by integrating a shared Jira® instance and defining a stream-level query that restricts issues to just those that belong to your project. In the In Progress stage, you might define a query that matches issues with a status of `In progress`. When the user opens the value stream, only items that match the pre-defined scope appear in the In Progress stage. You can then define a query in the search bar to additionally filter the items, perhaps by matching a particular issue ID or name.

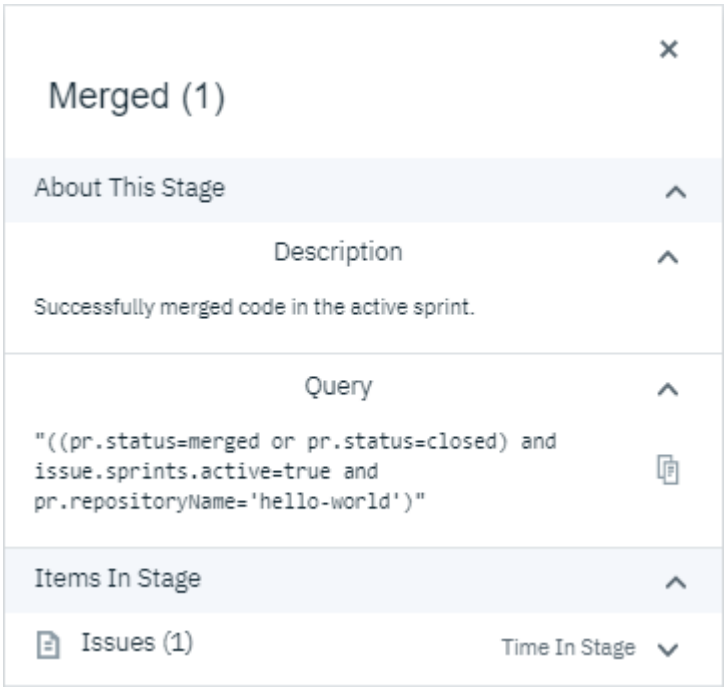
When you open a value stream, items that match the default queries are displayed in their appropriate stages. An items shape indicates what type of item is represented, such as commit or work item. The **Legend** drop-down list describes what the shapes represent, as shown in the following graphic:

Figure 8. Item types



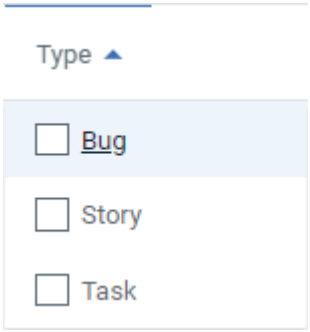
To see the default query defined for a stage, click the mouse on it and then click **About this Stage** on the pop-up that is displayed. The following graphic shows a pop-up for a stage called Merged that contains one item (not shown).

Figure 9. Stage summary



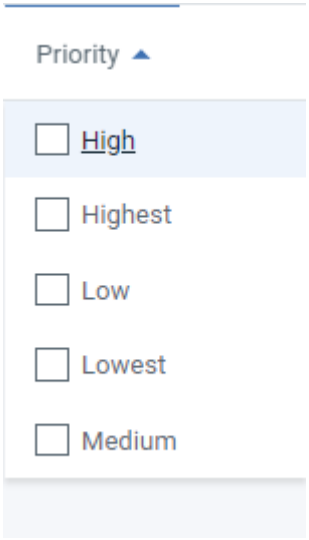
In addition to queries, you can apply other filters to the value stream. By default, when you open a value stream, items are filtered by type. When you click the **Type** drop-down, it lists the issue types, as shown in the following graphic:

Figure 10. Issue types



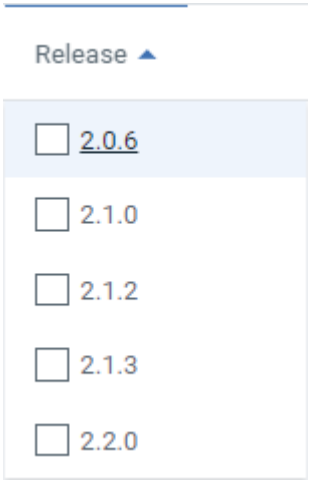
You can also filter items by priority. When you click the **Priority** drop-down, it lists the priority types, as shown in the following graphic:

Figure 11. Priority types



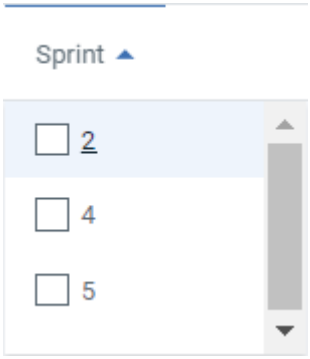
You can also filter items by release. When you click the **Release** drop-down, it lists the release types, as shown in the following graphic:

Figure 12. Release types



You can also filter items by sprint. When you click the **Sprint** drop-down, it lists the sprint types, as shown in the following graphic:

Figure 13. Sprint types



What to do next

Next, filter value streams by creating queries with the DevOps query language on page 3117. Learn about the information presented by value streams. on page 3103

Customizing value streams

Customize the `json` file to reflect your typical workflow.

When you create a value stream, default stages and phases are configured and displayed in the **Value Stream** tab. The structure of the value stream is determined by the `json` file attached to the value stream. You can customize the `json` file by using the following methods:

- VSM JSON code editor on page 3067
- VSM JSON tree editor on page 3071
- Download the file, modify it, and then reattach it to the value stream by uploading it to Measure.

A value stream `json` file consists of the following areas:

- The **heading** identifies the value stream.
- The **phases** defines the value stream's phases and stages. It contains a query that filters the dots appearing in the stage.
- The **leadTimeChange** is the quantity of time it takes a dot to progress from commit to production deployment. The metrics calculation is based on the date of the commit and date of the deployment into production. The lead time for changes metrics is a default metric added to all available value streams metrics bar.
- The **leadTime** defines the lead-time metric. In general, lead-time reflects the time from the start of a project until its final disposition.
- The **cycleTime** defines the cycle-time metric. In general, cycle-time reflects the time project elements take to resolve or complete.
- The **devcycleTime** defines the development cycle-time metric. In general, dev-cycle time reflects the time project elements take to reach from development in-progress to development complete (before the PROD stage).
- The **mapping** defines status levels for issue tracking systems.
- The **integration** defines integration with external tools. The default stages are empty until you integrate tools into the value stream. You add your tools to a value stream by defining integration objects on page 3077.

- The **Metrics** provides metric data to the value stream.
- The **metricsBar** section displays metrics data in the value stream **Metric bar**.
- The **linkRules** defines relationships between integrated tools.

The following code block shows the default value stream `json` file:

```
{
  "_id": "velocity-generated-value",
  "pipelineId": "velocity-generated-value",
  "tenantId": "velocity-generated-value",
  "description": null,

  "metricsBar": null
}
```

Heading

The heading properties are common to all value streams.

Table 1149. Properties for stages object

Property	Description
_id	Value stream identifier. The value is generated by Velocity Measure.
pipelineId	Identifier of the pipeline associated with the value stream. The value is generated by Measure.
tenantId	Tenant identifier. The value is generated by Measure.
description	Value stream description.
query	A query that sets the scope to the entire value stream, not just a stage. If you share a Jira instance, for example, you might define a query that restricts the value stream to a single team's issues.

Phases

The `phases` JSON array defines the value stream phases and stages. The single `phases` array for each value stream contains `stages` objects that define the stages for the containing phase. A `phases` array can contain any number of `stages` objects.

The following code fragment shows a Planning phase that contains stages named Backlog Scrum, and Selected for Development.

```
"phases": [
    {
      "name": "Planning",
      "description": "Planning stage",
      "stages": [
        {
          "name": "Backlog Scrum",
          "query": "issue.status=\"Backlog\"",
          "description": null,
          "wipLimit": null,
          "gates": null
        },
        {
          "name": "Selected For Development",
          "query": "issue.status=\"TO DO\" or issue.status=\"To Do\"",
          "description": null,
          "wipLimit": null,
          "gates": null
        }
      ]
    },
```

Table 1150. Properties for stages object

Property	Description
name	Stage name
query	The DevOps query that defines which dots are displayed in the stage. In general, query parameters reference the tools integrated into the value stream. See the examples later in this topic.
description	Stage description
wipLimit	Represents the 'work in progress' limit. If the number of stage items exceeds the limit, a warning is displayed. To disable warnings, leave the value blank.
showAlerts	Alerts for change in status of dots. By default, the `showAlerts` property is set to `false` for Backlog and Production stages and `true` for any other stages. You can set the `showAlerts` property for any stages. Possible values are `true` and `false`.
showSpeed	Defines whether to show the stage speed or not. By default, the `showSpeed` property is set to true, allowing you to view the stage speed through the visual representation of the stage circle. Click the **Legend** on the **Value streams** page to view the stage speed corresponding to the stage circle representation. You can set this property to false if you don't

Table 1150. Properties for stages object (continued)

Property	Description
	wish to see the stage speed. For more information about the stage circle speed, seeNavigating value streams on page 3103.
gates	Gates determine if objects are valid for a given context. Valid objects are referred to as passing the gate; invalid ones are referred to as failing the gate. Valid objects can appear in value streams.

Lead time, cycle time, and dev-cycle time metrics

The lead time, cycle time, and dev-cycle time properties provide useful metrics about value stream performance. The lead-time property reflects the elapsed-time from project start through final disposition. The cycle time property reflects the time that individual project elements take to complete.

Configure the metrics by assigning a starting stage to the `start` property, and an ending stage to the `end` property. For example, if you set `start` to the `Backlog` stage, items are tracked when they move from the `Backlog` stage to the next stage. To carry the example forward, if you set `end` to the `Deployed` stage, items are finished when they move into the `Deployed` stage.

When you configure the metrics, the calculated values are displayed on the **Value Stream** tab in the **Metric bar**.

The following code example illustrates typical lead- and cycle-time configurations.

```
    "leadTime": {
      "start": "Backlog",
      "end": "Deployed",
    },
     "cycleTime": {
      "start": "In Progress",
      "end": "Merged",
    },
    "devCycleTime": {
      "start": "In Progress",
      "end": "In Review"
  },
```

Mapping

The mappings object defines status values for issue tracking systems. The following code example illustrates the default mappings:

```
"mappings": {
    "priority": {
      "Lowest": [
        "Lowest"
      ],
      "Low": [
        "Low"
```

```
      ],
      "Medium": [
        "Medium"
      ],
      "High": [
        "High"
      ],
      "Highest": [
        "Highest"
      ]
    }
  },
```

Query examples

A DevOps query determines the dots that are displayed. A query at the value stream level filters, or scopes, the entire value stream. A query at the stage level filters the stage, and a query at the gate level filters the gate. Gates are discussed later in this topic.

In general, query parameters reference the tools integrated into the value stream or applications that belong to the associated pipeline. For a Jira integration you might restrict dots appearing in a stage named "In progress" with the following query:

```
"query":"issue.status="In Progress"
```

For a Git integration you can restrict dots appearing in a stage named "Merged" with the following query:

```
"query":"(pr.status=merged OR pr.status=closed) AND deployment.env!=DEV AND deployment.env!=QA AND deployment.env!=PROD and build.status!=success"
```

The following code fragment shows a planning phase with several stages and the corresponding queries.

```
{
      "name": "Development",
      "description": null,
      "stages": [
        {
          "name": "In Progress",
          "query": "issue.status=\"In Progress\" and build.status!=success",
          "description": null,
          "wipLimit": null,
          "gates": null
        },
        {
          "name": "Review",
          "query": "issue.status!=Done and pr.status=open",
          "description": null,
          "wipLimit": null,
          "gates": null
        },
        {
          "name": "Merged",
          "query": "(pr.status=merged OR pr.status=closed) AND deployment.env!=DEV AND deployment.env!=QA AND
 deployment.env!=PROD and build.status!=success",
```

```
          "description": null,
          "wipLimit": null,
          "gates": null
        },
        {
          "name": "Build",
          "query": "build.status=success AND deployment.env!=DEV AND deployment.env!=QA AND
deployment.env!=PROD",
          "description": null,
          "wipLimit": null,
          "gates": null
        }
      ]
    },
```

For more information, see the DevOps query language reference. on page 3117

Link rules

Link rules define how integrated tools are related to one another on page 3080. When tools are linked, objects that appear in a value stream provide information and links to the associated tools. You might link an issue tracking system, for example, to a source control tool

When links are established, you can access information about the linked tools from the affected dots in the value stream. In general, you can define linking rules for any integrated tools, and define multiple linking rules in a single value stream.

Metrics

You can provide metric data to your value stream by querying the data integrated into Measure. The data can originate from plugin integrations, or REST API calls from external clients. DevOps Query Language (DQL) queries can be defined in the `value_stream_name-vsm.json` file.

You can use the default `Work Item Type` metric definition as a template for your metrics.

Metric bar

You can provide metrics data to value streams and display the data in charts and graphs attached to the stream on page 3084. To enable the **Metric bar**, add `metricsBar` definitions to the `value_stream_name-vsm.json` file attached to the value stream.

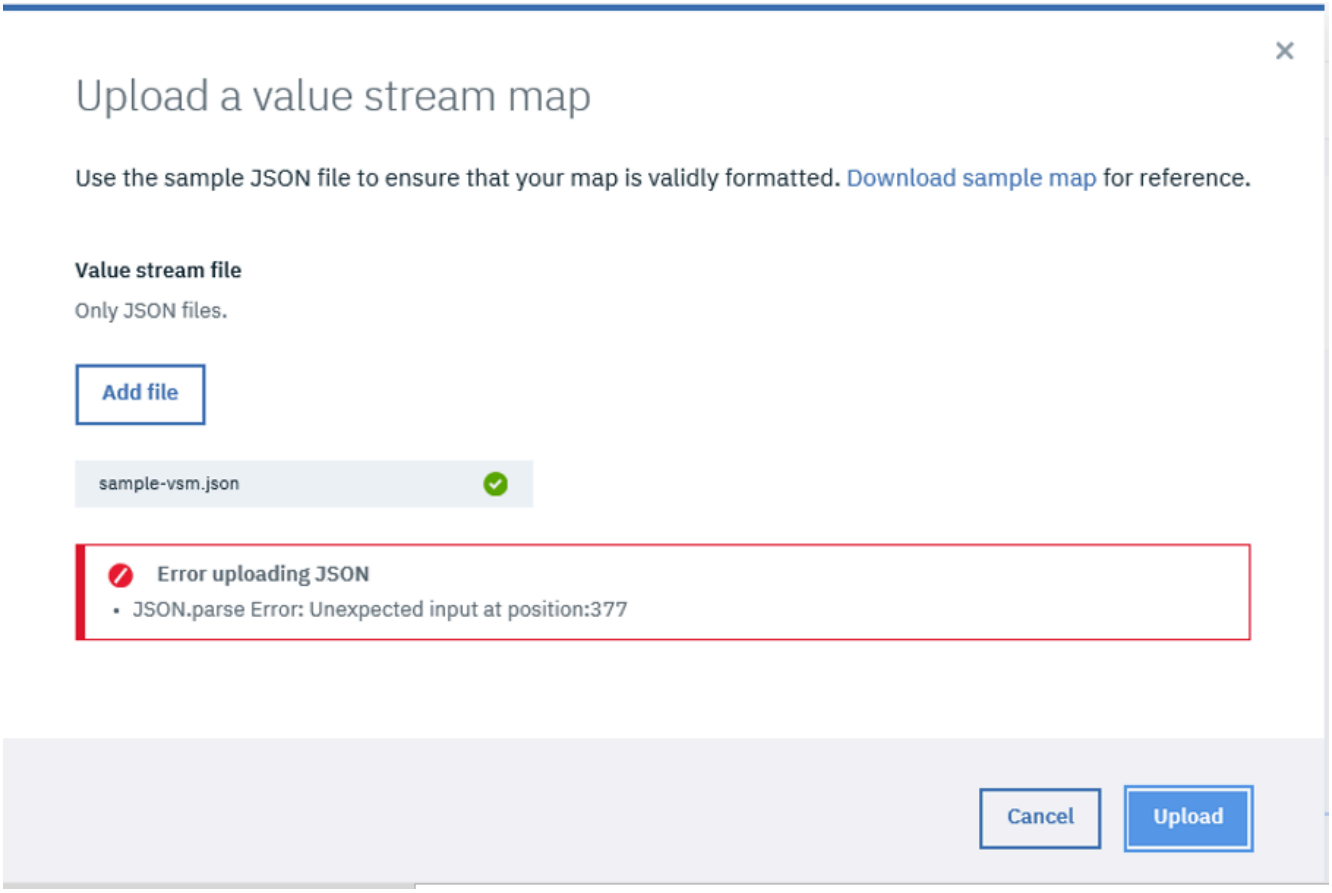
Integrations array

You provide data from external tools to value streams by defining integration objects on page 3077. For information about the supported plugins, see #unique_3272.

Troubleshooting

The figure below displays the error message when the `value_stream_name-vsm.json` file with invalid syntax is uploaded. The error message also displays the `.json` parse error position in the `value_stream_name-vsm.json` file. The system will generate similar error messages whenever an invalid `value_stream_name-vsm.json` file is uploaded.

Figure 14. Error message



VSM JSON code editor

The code editor allows you to directly edit the value stream JSON file from the UI.

About this task

Use the online code editor to edit value stream JSON files. Starting with Measure version 3.0, you no longer need to download the JSON and edit a local copy. Now you can edit value stream JSON files within the product web interface. On the **Value Streams** page, use the VSM JSON code editor to edit and save the value stream workflow file. In code view, the editor allows you to perform the following:

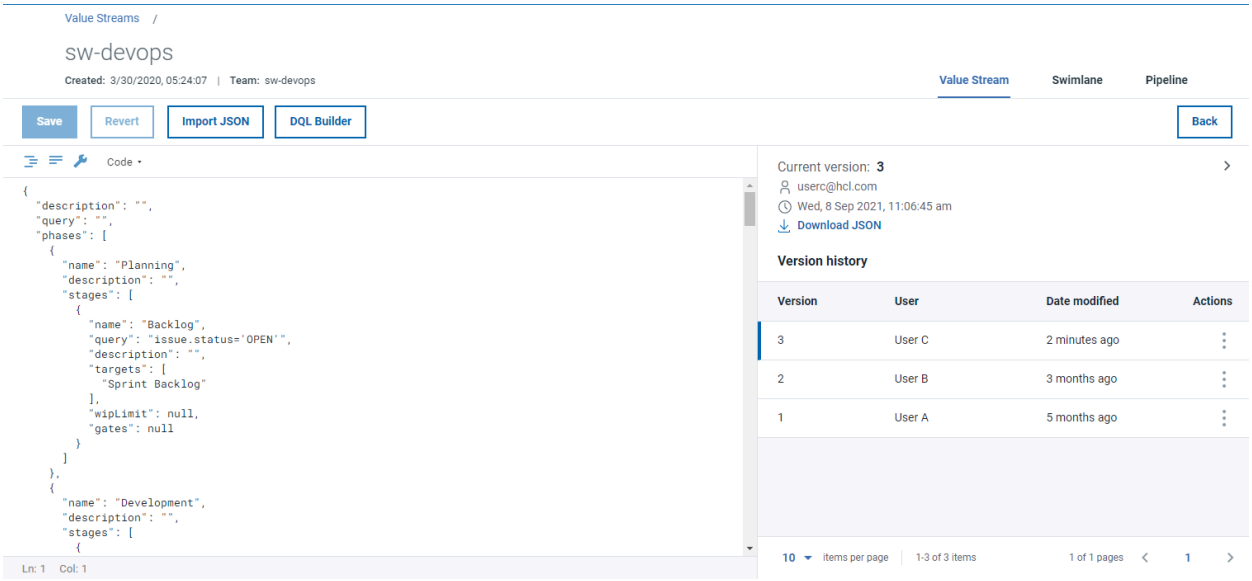
- Create new versions
- Edit versions
- Review versions
- Import and download versions
- View JSON file contents including creator, version number, and date created

Additionally, you can format, compact, repair JSON data, and save with overwrite protection for simultaneous user editing scenarios.

1. On the **Value Streams** page, click the required value stream.
2. Click and select **Edit value stream map** to open the VSM JSON code editor.

   The JSON code editor is shown in the figure below.

   Figure 15. JSON code view



Note: The JSON code editor is the default view mode when you open the editor.

Note: In the **Version history** table on the right side of the display, the current version of the JSON shown on the left side of the display is indicated by a vertical blue bar next to the **Version** field in the table and is the file displayed and open in the editor.

Note: The icons on the left side of the display above the editor include the following:

- Click to format the JSON data with proper identification and line feeds.
- Click to compact the JSON data by removing all whitespaces in the JSON file.
- Click to repair the JSON file including fixing quotation marks and escape characters, removing comments and JSON with padding (JSONP), and converting JavaScript objects into JSON.

- On the right of the icon above the code editor, you can click and select the **Code** or **Tree** on page 3071 view drop-down to choose between a plain text editor or a user-friendly editor respectively.

  Note: When you select **Edit value stream map** to open the editor, the editor is always opened in **Code** view by default.

3. To import, download, view, and edit a JSON file in the editor, perform either of the following:
   - Click **Import JSON**, select the JSON file, and click the **Open** button.

     Note: The file is opened and displayed in the editor.

   - On the right side of the display above the **Version history** table, click **Download JSON** to download the latest JSON file revision shown in the **Current version** field above the creator.

     Note: Above the **Version history** table, you can view detailed information for the latest JSON file with fields including **Current version**, creator, and file creation day, date, year, and time.

   - In the **Version history** table with fields including **Version**, **User**, **Date modified**, and **Actions**, locate the required JSON file version and in the **Actions** field, click and select either **View code** or **Download** according to your requirement.

     If you want to use a previous version JSON file as the current version, perform the following:

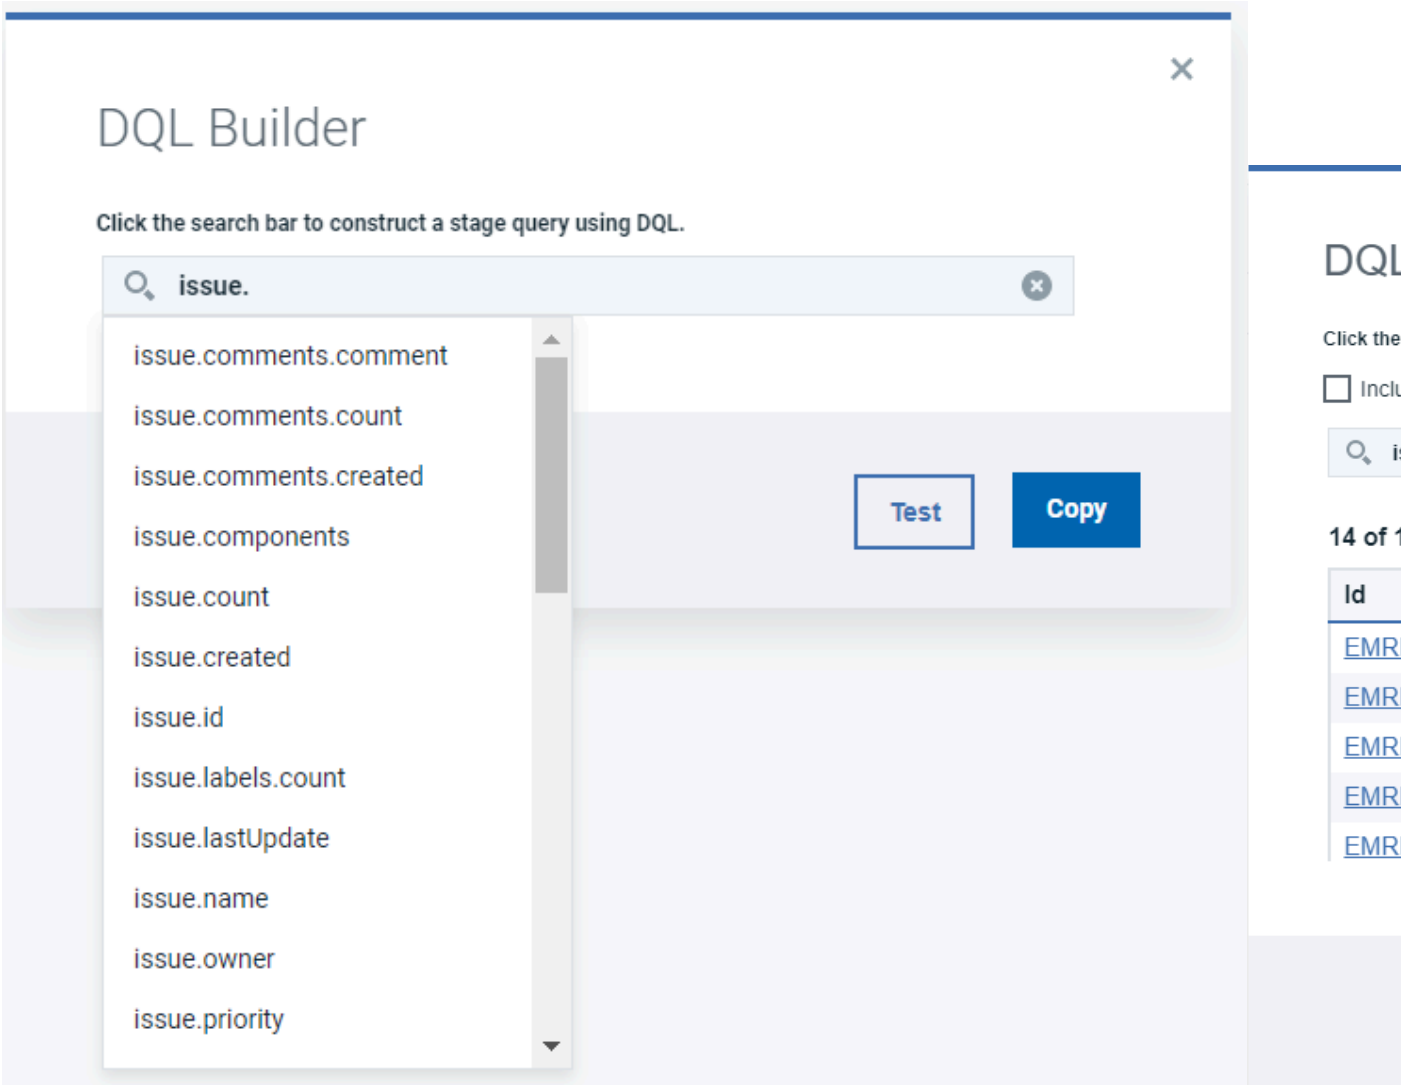
     - In the **Version history** table, click for the required previous version and select **Download**.
     - Click **Import JSON** and navigate to the downloaded file.
     - Click **Open**.
     - Click **Save**.

       Note: After a JSON file is successfully saved, you cannot revert the changes that were made prior to saving the file. If you want to use a previous version JSON file as the current version, use the aforementioned procedure.

     At the bottom of the **Version history** table, you can perform and view the following:

     - In the **items per page** drop-down, you can select **10**, **20**, **50**, or **100** as the number of items to display per page in the **Version history** table.
     - View number of items listed in the table versus total number of items. For example: 1-3 of 3 items.
     - View page number versus total number of pages.
     - View the page number currently displayed in the **Version history** table and click **<** or **>** to go to the previous or next page respectively.

4. To create a query, click **DQL Builder** and then **DQL Builder** window appears. Type the query in search field and select the required one from the list to create query. After creating query, click **Test** to view results for the selected query. Click **copy** to copy the created query. You can use the copied query in JSON code or tree editor.



5. On the left side of the display in the file editor, perform the required editing in the file and click **Save** to capture your changes.

Note: If you make any changes before saving the file, you can click **Revert** to undo all your changes.

Result

When you click **Save**, a notification is displayed containing one of the following messages:

- If all the changes you made to the JSON file are validated when saved, a **Success** notification with a vertical green bar is displayed upon completion.
- If an error is associated with the file, a notification with a vertical red bar is displayed with either of the following information:

- The source of error.
- Selected file type is not supported.

6. Overwrite protection provides visibility to users that attempt to simultaneously edit the same workflow. The following example details the procedure for two users simultaneously attempting changes to the same file. User 1 creates and saves version 78 by editing version 77 and User 2 edits version 77 and attempts to save the file with the result of displaying the **OVERWRITE PROTECTION Confirm changes? Users have made 1 new version since loading this page. Do you want to overwrite the latest changes?** modal prompting to click either the **View latest changes** or **Confirm** buttons detailed in the following table:

Button	Description
View latest changes	Modal closes and refreshes the **Version history** table with new saved version 78 and the text editor displays the changes made by User 2 for this example.
Confirm	Saves the changes to version 77 and selects the same version in the **Version history** table for this example.

What to do next

Documentation for the VSM JSON tree editor is found here on page 3071.

VSM JSON tree editor

The tree editor allows you to directly edit the value stream JSON file from the UI.

About this task

Use the online tree editor to edit value stream JSON files. Starting with Measure version 3.0, you no longer need to download the JSON and edit a local copy. Now you can edit value stream JSON files within the product web interface. On the **Value Streams** page, use the VSM JSON tree editor to edit and save the value stream workflow file. In tree view, the editor allows you to perform the following:

- Change **Type**, **Insert**, or **Append** the **Auto**, **Array**, **Object**, or **String** field types defined in the following:
  - **Auto** is a field type based on the value of a string, number, boolean, or null.
  - **Array** contains an ordered collection of values.
  - **Object** contains an unordered set of key and value pairs.
  - **String** is a field type not based on the value and returned as a string.
- **Duplicate** fields
- **Extract** objects and arrays
- **Remove** fields

Additionally, you can format, compact, repair JSON data, and save with overwrite protection for simultaneous user editing scenarios.

1. On the **Value Streams** page, click the required value stream.
2. Click and select **Edit value stream map** to open the VSM JSON code editor.

   Note: The JSON code editor is the default view mode when you open the editor.

3. On the right of the icon above the code editor, click the **Code** on page 3067 or **Tree** view drop-down and select **Tree**.

   The JSON tree editor opens below the drop-down as shown in the figure below.

   Figure 16. JSON tree view

   Note: In the **Version history** table on the right side of the display, the current version of the JSON shown on the left side of the display is indicated by a vertical blue bar next to the **Version** field in the table and is the file displayed and open in the editor.

   Note: The icons on the left side of the display above the **Select a node** breadcrumb bar include the following:

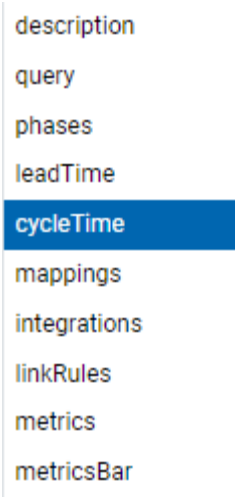
   - Click to expand all fields in the tree view.
   - Click to collapse all fields in the tree view.
   - Click to undo last action in the JSON tree view.
   - Click to redo last action in JSON tree view.
   - On the right of the icon above the tree editor is the **Code** or **Tree** view drop-down selector to choose between a plain text editor or a user-friendly editor respectively.
   - On the right of the drop-down selector toward the center of the display is the search bar where you can query for fields and values in the JSON tree. On the right of the search bar are the next result and

previous result icons shown as and respectively. Queried search items found in the tree editor are highlighted for identification.

- When you click fields in the tree editor, a breadcrumb is displayed in the **Select a node** section based on the selected item in the tree view. For example, if you click **cycleTime** in the tree editor, the breadcrumb is shown in the following figure followed by details:

Figure 17. Select a node breadcrumb

  - On the right side of **object**, click ▶ to display the **object** hierarchy drop-down list shown in the following figure:



Note: Since **cycleTime** was selected, it is highlighted in the drop-down list.

- Click **cycleTime** in the **Select a node** breadcrumb bar and that field is highlighted with a yellow rectangle in the editor.
- On the right side of **cycleTime**, click to display the **cycleTime** hierarchy drop-down list shown in the following figure:

Note: The icons in the tree editor below the **Select a node** breadcrumb bar include the following;

- Click to drag and move fields to different locations within the editor.
- Click to open the actions menu for fields in the tree view. Based on the type of field you click on in the editor, the menus and sub-menus available are detailed in the table below.

Table 1151. Actions menu items

Menu	Sub-menu
Type	**Auto**, **Array**, **Object**, and **String**
Insert	**Auto**, **Array**, **Object**, and **String**
Append	**Auto**, **Array**, **Object**, and **String**
Extract	N/A
Duplicate	N/A
Remove	N/A

Note: Details for items in the table above are located at the top of this page.

- On the right side of , icons are displayed that include the following:
  - Click to expand fields in the tree view.
  - Click to collapse fields in the tree view.

4. To import, download, view, and edit a JSON file in the editor, perform either of the following:

- Click **Import JSON**, select the JSON file, and click the **Open** button.

  Note: The file is opened and displayed in the editor.

- On the right side of the display above the **Version history** table, click **Download JSON** to download the latest JSON file revision shown in the **Current version** field above the creator.

  Note: Above the **Version history** table, you can view detailed information for the latest JSON file with fields including **Current version**, creator, and file creation day, date, year, and time.

- In the **Version history** table with fields including **Version**, **User**, **Date modified**, and **Actions**, locate the required JSON file version and in the **Actions** field, click ⋮ and select either **View code** or **Download** according to your requirement.

  If you want to use a previous version JSON file as the current version, perform the following:

  - In the **Version history** table, click ⋮ for the required previous version and select **Download**.
  - Click **Import JSON** and navigate to the downloaded file.
  - Click **Open**.
  - Click **Save**.

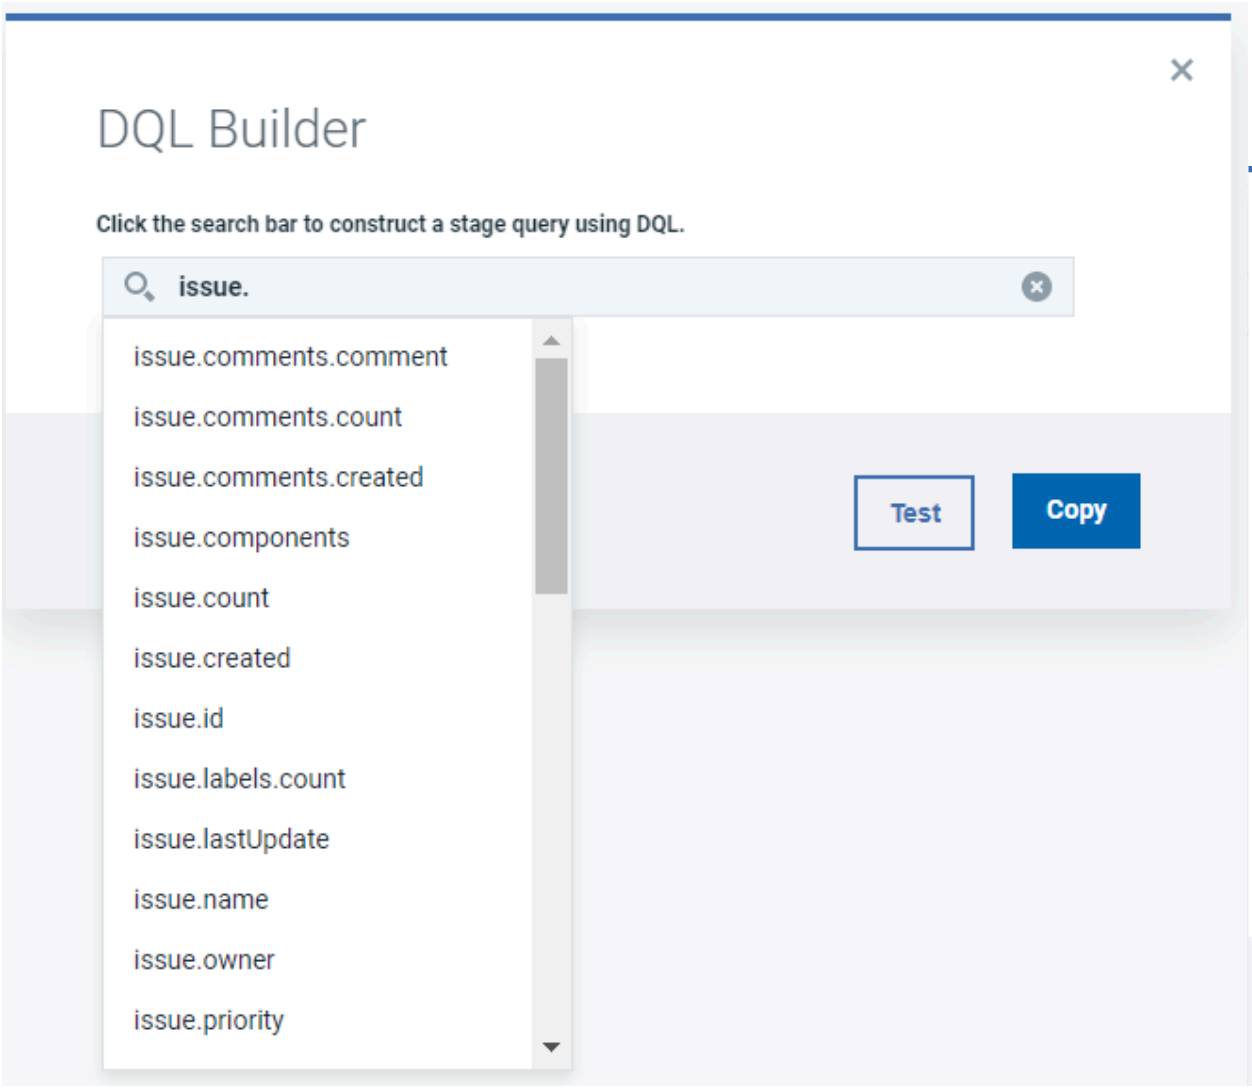
    Note: After a JSON file is successfully saved, you cannot revert the changes that were made prior to saving the file. If you want to use a previous version JSON file as the current version, use the aforementioned procedure.

  At the bottom of the **Version history** table, you can perform and view the following:

  - In the **items per page** drop-down, you can select **10**, **20**, **50**, or **100** as the number of items to display per page in the **Version history** table.
  - View number of items listed in the table versus total number of items. For example: 1-3 of 3 items.
  - View page number versus total number of pages.
  - View the page number currently displayed in the **Version history** table and click **<** or **>** to go to the previous or next page respectively.

5. To create a query, click **DQL Builder** and then **DQL Builder** window appears. Type the query in search field and select the required one from the list to create query. After creating query, click **Test** to view results for the

selected query. Click **copy** to copy the created query. You can use the copied query in JSON code or tree editor.



6. On the left side of the display in the file editor, perform the required editing in the file and click **Save** to capture your changes.

Note: If you make any changes before saving the file, you can click **Revert** to undo all your changes.

Result

When you click **Save**, a notification is displayed containing one of the following messages:

- If all the changes you made to the JSON file are validated when saved, a **Success** notification with a vertical green bar is displayed upon completion.
- If an error is associated with the file, a notification with a vertical red bar is displayed with either of the following information:
  - The source of error.
  - Selected file type is not supported.

7. Overwrite protection provides visibility to users that attempt to simultaneously edit the same workflow. The following example details the procedure for two users simultaneously attempting changes to the same file. User 1 creates and saves version 78 by editing version 77 and User 2 edits version 77 and attempts to save the file with the result of displaying the **OVERWRITE PROTECTION Confirm changes? Users have made 1 new version since loading this page. Do you want to overwrite the latest changes?** modal prompting to click either the **View latest changes** or **Confirm** buttons detailed in the following table:

Button	Description
View latest changes	Modal closes and refreshes the **Version history** table with new saved version 78 and the text editor displays the changes made by User 2 for this example.
Confirm	Saves the changes to version 77 and selects the same version in the **Version history** table for this example.

What to do next

Documentation for the VSM JSON code editor is found here on page 3067.

Integrating tools into value streams

Create value stream integrations by defining integration objects to the `value-stream-name.json` file.

Before you begin

Modify the value stream with the phases, stages, and queries required for your project.

About this task

To define an integration, select the value stream and complete the following steps:

1. On the **Value stream** details page, click and select **Download value stream map**. The `value_stream_name-vsm.json` is downloaded to the specified location.
2. Using a text editor, define an integration object in the `value_stream_name-vsm.json` file.
   The following code example illustrates a Bitbucket™ integration:

```
{
 "type": "ucv-ext-bitbucket-server",
 "tenant_id": "[ID]",
 "name": "my-bitbucket",
 "disabled": false,
 "properties": {
   "baseApiUrl": "[Base URL ex: http://10.134.116.110:7990/rest/api/1.0]",
   "username": "admin",
   "password": "[Basic user password]",
   "projectName": "[Full project name ex: JKE Mortgage Application]",
   "projectKey": "[Project key ex: JMA]",
   "repositoryName": "[app repository name ex: web-application]",
```

```
        "repositorySlug": "[app repository name ex: web-application]"
      }
    }
```

3. **Optional:** Define queries for the stages where data is required from the integrated tool.
   For example, the following query defined for the **In Progress** stage matches open pull requests from source control systems:

```
{
     "name": "Development",
     "description": null,
     "stages": [
       {
         "name": "In Progress",
         "query": "pr.status="open",
         "description": null,
         "wipLimit": null,
         "gates": null
       },
```

4. On the **Value stream** details page, click , select **Edit value stream map > Import JSON**, and then select the JSON file that you modified.
   For more information about creating value stream integrations, see About value stream integrations on page 3078.

Results

Objects from the integrated tool appear in stages of the value stream, and the integration is listed on the **Integrations** page in the web UI.

What to do next

Increase usability by linking integrated tools on page 3066. Linked value stream dots provide information for the linked tools.

About value stream integrations

Integrate external tools into your value streams.

Value stream integrations are specified in the `value_stream_name-vsm.json` file. Each value stream has a unique `value_stream_name-vsm.json` file. You can add any number of integration objects to the JSON file.

You can add integrations to value streams by the following two methods:

1. Create an integration on the Integrations page on page 1881, and then insert a reference to it in the `value_stream_name-vsm.json` file. For example, the following JSON code adds an integration named "DevOps Team" into the value stream, `"name": "DevOps team"`.
2. Define all properties for the integration in the `value_stream_name-vsm.json` file. When you configure an integration with this method, the integration is displayed on the **Integrations** page.

Properties common to all value stream integrations

While all plugins have unique properties, the plugins that you can integrate into a value stream share some common properties. The properties identify the integration and determine if the integration is enabled or disabled.

The properties common to all value stream integrations are detailed in the table below.

Table 1152. Properties common to all integrations

Property	Description
image	The plugin version.
type	The plugin type identifier. See the list of supported plugin types later in this topic.
tenant_id	Tenant identifier. The value is generated by Measure.
name	Integration name. The name should be unique.
disabled	A flag that is used to disable the integration. The default value is `null`, which means the integration is enabled. To disable the integration, change the value to `true`. You can also set this value with the **Disable/Enable** button on the **Integrations** page.
properties	The `properties` object defines properties that are specific to the plugin. See the documentation for the tool that you want to integrate on page 1874.

For information regarding parameters unique to a specific integration, see Introducing plugins on page 1874.

The following code block shows a typical Jira-type integration defined in the `value_stream_name-vsm.json` file:

```
"integrations": [
    {
      "type": "ucv-ext-jira",
      "tenant_id": "tenantid",
      "name": "Jira_Plugin ",
      "properties": {
        "baseUrl": "jira_server_url",
        "username": "jira_server_user_name",
        "password": "jira_server_password",
        "consumer_key": null,
        "consumer_secret": null,
        "access_token": null,
        "access_token_secret": null,
        "jiraProjects": [
          "jira_project_name"
        ],
        "proxyServer": "proxy_server_url",
        "proxyUsername": "proxy_server_user_name",
        "proxyPassword": "proxy_server_password"
```

```
    }
  }  ]
```

Linking rules

Link value stream tools to one another.

Link rules define how integrated tools relate to one another. When tools are linked, objects that appear in a value stream provide information and links to the associated tools. You might link an issue tracking system, for instance, to a source control tool.

To define a link rule, specify a field in the linked-from tool that you want to associate with a field in the linked-to tool, and a regular expression that defines the matching pattern.

The following example illustrates how to link a Git integration with a Pivotal integration:

- The `"fromIntegrationName": "my-github"` property identifies the Git integration defined in the value stream.
- The `"fromField": "pr.name"` or `"fromField": "pr.description"` property links the Git pull request name to the linked-to tool.
- The `"toIntegrationName": "my-pivotal"` property identifies the Pivotal integration defined in the value stream.
- The `"toField": "issue.id"` property links the Pivotal issue ID to the linked-from tool.

  Note: The default format of the Jira `id` is `Board-Number`. For example, if the Jira `issue.id` is `JIR-1` and it was linking to a PR via the aforementioned issue by `pr.name`, the PR name *must* include the text `JIR-1`.

- The `"pattern": "[[A-Z]+-[0-9]+}"` property defines the regular expression that determines if potential links match.

  Note: The `pattern` property uses regex to extract the desired string from a field. PR names often include a description of the PR along with the id of the corresponding Jira issue. When this occurs, it is necessary to specify what value from the `fromField` should be used for linking. If the value extracted from the `fromField` is not an *exact* match with the `toField`, the integrations will *not* be linked.

```
"linkRules": [
  {
    "toIntegrationName": "my-pivotal",
    "toField": "issue.id",
    "pattern": "[[A-Z]+-[0-9]+]",
    "fromIntegrationName": "my-github",
    "fromField": "pr.name",
  },
 ]
```

When links are established, you can access information about the linked tools from the affected dots in the value stream. In general, you can define linking rules for any integrated tools, and define multiple linking rules in a single value stream.

Note: To add linked data to a value stream, you must define linking rules for your integrated tools.

Table 1153. Link rule properties

Property	Description
toIntegrationName	Name of the integration to which you are linking.
toField	Field in the `toIntegrationName` integration that you are linking.
pattern	Regular expression that determines if the linking fields match. For example, `[[A-Z]+-[0-9]+]`.
fromIntegrationName	Name of the integration from which you are linking.
fromField	Field in the `fromIntegrationName` integration that you are linking.

Viewing value streams

Viewing value streams using list and card view layouts.

About this task

After you create one or more value streams, you can view them by clicking **Value Streams > All Value Streams** in either the list or card view layouts. In both the layouts, click icon to view the corresponding pipeline page. You can also add metrics.

1. To view value streams in the list view layout and add metrics, complete the following steps:
    a. On the Measure dashboard, click **Value Streams > All value streams**.
    b. Click to display the list view of value streams. The default fields are **Name**, **Lead Time**, and **Cycle Time**. You can click on the name of any value stream in the list view to display it in the **Value stream** tab. You can also sort the **Name** field in either ascending or descending order by clicking on the triangle in the right side of the field.
    c. Click to display the **Add Metrics** window.
    d. Click to add the required metric *or* click to expand the required metric that is added to the **Metric bar**.

    Note: For metrics having an expand and collapse button, you can define the metric in the following step. For metrics having only an add button, **Metric added!** is displayed when you click the button.

    e. Define the metric by completing the following steps:

i. In the **Metric Title** field, enter a name for the metric.
ii. In the **Relative time** field, select a time range. Data within the time range are calculated.
iii. In the **Filtered values** field, check the required filter based on attributes of add metric.

Note: The **Filtered values** field is only available for certain metrics.

iv. In the **Warn when metric data is missing from applications** field, click either the **Any application** or **All applications** radio button.

Note: The **Warn when metric data is missing from applications** field is only available for certain metrics.

v. Click the **Add** button to display the metric in the value stream tabular list view.

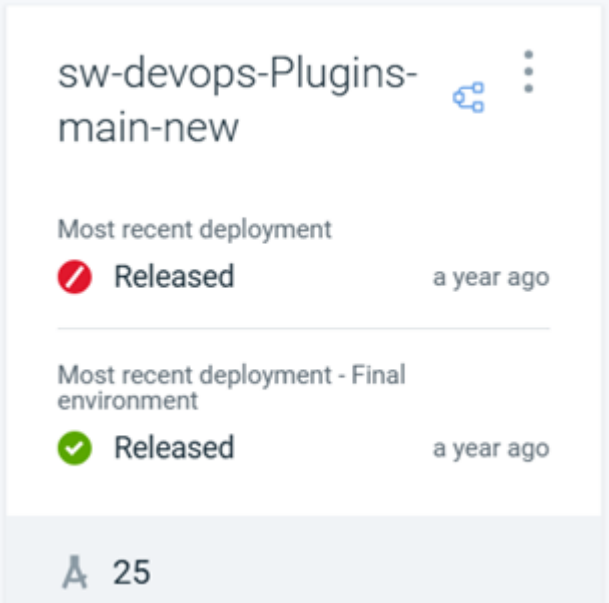
Note: There is no limit on the number of metrics that can be added in a value stream.

vi. To edit an added metric with other metric column options in list view layout, in the required metric field, hover and click ••• toward the right side of the metric column and select one of the following menu items:
- **Edit metric** to display the **Edit Metric** window to modify the metric parameters available for the item. After making the required selections, click the **Update** button to save your changes.
- **Only show value streams missing this data** for the related metric.
- **Remove metric** to delete the metric.

Result

For added metrics in list view layout, there may be color icons appearing in the metric columns. Hover over the icon to display a pop-up with specific details about the metric.

2. To view value streams in the card view layout, complete the following steps:
   a. On the Measure dashboard, click **Value Streams > All Value Streams**.
   b. Click to display the card view of value streams. An example card view for a value stream is shown in the following figure.



Information and menu options on the value stream card view includes the following explained in reference to the above figure:

- **Test** is the name of the value stream. You can click on the name of any value stream in the card view to display it in the **Value stream** tab.
- **Most recent deployment** is **PROD** deployed **2 months ago**. The red slash icon indicates a failed deployment.
- **Most recent deployment - Final environment** is **PROD** deployed **2 months ago**. The green check icon indicates a successful deployment.
- 2 indicates there are two pipeline applications for the value stream.
- Click and select one of the following menu items:
  - **Edit** to display the **Edit Value Stream** window to modify the **Name**, **Description**, or **Team**. Click the **Save** button to save your changes.
  - **Delete** to remove the value stream card.

What to do next

Next, filter value streams by creating queries with the DevOps query language on page 3117. Learn about the information presented by value streams. on page 3103

Value stream metrics

Assess project quality, progress, and performance with the Measure metric data tools.

The ability to measure project status is a core requirement. Measure provides performance metrics for every project area, from initial concept to final delivery. All project areas can be accessed for efficiency and quality. You can add metric performance data to value stream, Insights dashboards, and applications.

To add performance metrics to your value stream, query the data that you want to analyze, and then apply metric performance chats to the data. The data can come from integrations with testing tools, performance monitors, and security scanning applications, to name just a few. You can display performance metrics in charts and graphs on page 3084 on the value stream **Metrics** bar.

You can add custom metrics to your Insights dashboard on page 3091, or use the prebuilt charts.

Displaying the metrics on the value stream

You can enable the **Metric bar** to display the metrics on the value stream.

You can provide metrics data to value streams and display the data in charts on the **Metric bar**. To enable the **Metric bar**, add `metricsBar` definitions to the `value_stream_name-vsm.json` file attached to the value stream.

To display the metric bar data to the `value_stream_name-vsm.json` file, complete the following steps:

1. On the **Value Streams** page, select a value stream.

   Value stream details page is displayed.

2. Click and select **Edit value stream map**.
3. Add `metricsBar` definition to the `value_stream_name-vsm.json` file. The properties are defined later in this topic.
4. Click **Save**.
5. On the **Value stream** details page, click 
.

   Note: The metric bar displays **Lead Time**, **Cycle Time**, **Dev Cycle Time**, **Distribution**, and **Throughput** metrics by default.

After enabling the metric bar, you can click to add metrics to the value stream.

Adding metrics to the metric bar

To add metrics to the **Metric bar**, complete the following steps:

1. On the **Value Streams** details page, click 
to display the metric bar.
2. Click to display the **Add Metrics** window.
3. Click to add the required metric *or* click to expand the required metric that is added to the **Metric bar**.

Note: For metrics having an expand and collapse button, you can define the metric in the following step. For metrics having only an add button, **Metric added!** is displayed when you click the button.

4. Define the metric by completing the following steps:
    a. In the **Metric Title** field, enter a name for the metric.
    b. In the **Relative time** field, select a time range. Data within the time range are calculated.
5. Click **Add** to insert the metric into the **Metric bar**.
6. The **Metric added!** pop-up is displayed next to the icon.
7. To remove a metric, hover over the metric, click and then select **Remove metric**.

Note: In addition to lead time, cycle time and dev cycle time, you can select up to six metrics for a total of eight metrics able for display at one time on the metric bar. Also, when you click on either the **Lead Time**, **Cycle Time**, or **DevCycle Time** on the **Metric bar**, the **Lead time distribution**, **Cycle time distribution**, or **Dev time distribution** graph window is respectively displayed.

Metric bar JSON parameters

Metric bar parameters are defined in the `metricsBar` area of the `value_stream_name-vsm.json` file.

Table 1154. Efficiency metrics

Efficiency Metric	Description
`relativeTime`	Date range for data calculation. Valid values include `HOUR24`, `DAY7`, `DAY30`, `DAY90`, `MONTH6`, `YEAR1`, and `ALL`.
`metricDefinitionId`	Metric definition to apply. Any metric definition defined to Measure can be referenced.
`name`	Metric name
`displayType`	Determines how data is rendered. Valid values are: `bar`, `percent`.
`calculationType`	Determines how the data is aggregated. Valid values include `mostRecent` and `trendMostRecent`. The `mostRecent` value displays the most recent run compared to the average. The `trendMostRecent` adds a trend breakdown to the most recent data.

The following example adds a bar chart for work items over the past 30 days.

```
"metricsBar": [
   {
     "relativeTime": "DAY30",
     "metricDefinitionId": "WORK_ITEM_TYPE_COUNT",
     "name": "Work Item Type Count",
     "displayType": "bar",
```

```
      "calculationType": "trendMostRecent"
    }
  ]
```

Metrics definitions

On the **Value Streams** page metric definitions are detailed in the following tables.

Delivery flow-type charts

Table 1155. Delivery flow-type charts

Chart	Description
Lead Time	The time required for a dot to go from business acceptance to value realization. This includes both engineering time and non-value-added waiting time between sub-processes.
Lead Time Key Performance Indicator (KPI)	The Lead Time KPI measures the efficiency of a dot to reach the defined target. You can define the target using the status rule. To define target for lead time KPI, see here on page 3173.
Cycle Time	This is similar to lead time, except cycle time is measured from when the development team begins work to when that work reaches the customer.
Cycle Time Key Performance Indicator (KPI)	The Cycle Time KPI measures the efficiency of a dot to reach the defined target. You can define the target using the status rule. To define target for cycle time KPI, see here on page 3172.
Dev Cycle Time	This is similar to cycle time, except dev-cycle time is measured from when the development team begins work to when that work reaches end of the development (before the production stage).
Build Counts	Number of builds by type in a specified time period.
Deployment Counts	Number of deploys by status in a specified time period. The metric can be set to process names, environment, result, type, or application. The default metric is result. The data can scoped by data set, environment, process, result, or version.
Load	The number of work items active or waiting in a value stream at a given time. Load measures utilization capabilities of value streams related to productivity in

Table 1155. Delivery flow-type charts (continued)

Chart	Description
	the process flow. "Active" refers to the stages from the lead-time start until the lead-time end.
Throughput	The rate of work items completed during a period of time. Improving throughput can result in better responsiveness to customer requirements and may yield lead time reductions for value streams.
Agile Churn	The ratio of the sum of the values of story points added and removed to the value of the planned story points of a sprint. It calculates the percentage of the change in planned scope for any sprint.
Distribution	The proportion of different types of work items over time. This provides teams visibility into the type of work being completed (features, defects, tasks, and so forth.)
Flow Efficiency	The ratio of actual development time to cycle time. It is expressed as a percentage, which helps teams to understand their performance.
P.R.E Risk	Probabilistic Risk Estimator (P.R.E) Risk provides estimated probability to miss current sprint goal.
P.R.E Deadline	P.R.E Deadline provides estimated complete date for the current sprint.

Table 1156. DORA charts

Chart	Description
Deployment Frequency	The number deployments into production environment.
Lead Time to Change	The time required for a dot to go from commit to production deployment.
Time To Restore Service (MTTR)	The time taken to resolve the incident.
Change Failure Rate (CFR)	The ratio of the number of failed changes to the total number of changes deployed within a specified time period. It is expressed as a percentage, helping teams understand the rate at which their deployments are successful or failed.

For uncommon metric names between the **Value Streams** and **Insights** pages associated with delivery charts, refer to the following equivalence table for details.

Metric name equivalences

Table 1157. Metric name equivalences

Value Streams	Insights
Build Frequency (number per time)	**Build Counts** (Number of builds by type in a specified time period.)
Average Load	**Load**
Bottlleneck A constriction in local throughput that limits the global throughput of a system. Bottlenecks include a set of events or conditions that occur in the value stream that you monitor in the process. Refer to the bottleneck detection page on page 3098 for further details. Note: *Bottleneck is not a metric.* This indicator can be added and viewed only on the metrics bar and the value stream table view.	N/A

Quality-type charts

Table 1158. Quality-type charts

Chart	Description
Coverage By Branch	Percent of branches with associated tests executed during testing.
Coverage By Function	Percent of program functions executed during testing.
Coverage By Line	Percent of lines of code executed during testing.
Functional Tests	Number of functional tests by status in a specified period of time.
Static Code Analysis	Number of issues by severity in a specified period of time.
Unit Tests	Number of tests by status in a specified period of time.
API Tests	Number of tests by status in a specified period of time.

Risk-type charts

Table 1159. Risk-type charts

Chart	Description
Container Vulnerabilities	Number of container vulnerabilities by severity in a specified period of time. The metric can be set to process names, environment, result, type, application, tag, or team. The

Table 1159. Risk-type charts (continued)

Chart	Description
	default metric is result. The data can scoped by data set, process, or version.
Application Vulnerabilities	Number of application vulnerabilities by severity in a specified period of time.

Customizing metric definitions for Lead Time, Cycle Time, and Dev Cycle Time

To customize the metric definitions for calculating the **Lead Time**, **Cycle Time**, and **Dev Cycle Time** metrics, perform the following steps:

1. Hover over the metric, click ••• and then select **Edit**.

   The **Edit Metric** dialog is displayed.

2. Select one or more input stages from the drop-down list of **Start Stage** and **End Stage**.

   The default metric definitions are as follows:

Metric	Start Stage	End Stage
Lead Time	Backlog	Completed
Cycle Time	In Progress	Completed
Dev Cycle Time	In Review	Completed

3. Click **Update**.

   The updated metric definitions are saved in the vsm.json file, and the static metric graphs are updated for **Lead Time**, **Cycle Time**, and **Dev Cycle Time** in Insights dashboard.

Customizing metric definitions for Lead Time, Cycle Time, and Dev Cycle Time

You can now select multiple start and end stage for a metric, enabling a more accurate representation of the actual workflow across teams. Because the definition of work start and end times can vary depending on the tools, processes, and delivery practices used. This provides teams and stakeholders with clearer insights into the actual flow of work, supporting better decision-making, increased transparency, and continuous improvement adaptability for the team.

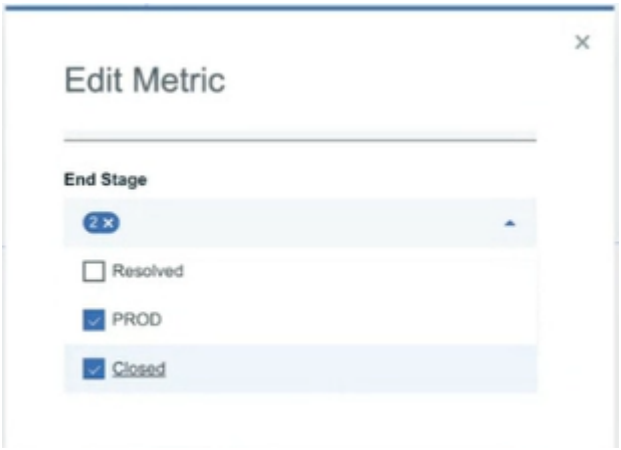
The metric is calculated as the median duration between all selected start and end stages. This ensures the measurement reflects the entire workflow and accurately captures the time spent across all phases.

To customize the metric definitions for calculating the **Lead Time**, **Cycle Time**, and **Dev Cycle Time** metrics, perform the following steps:

1. Hover over the metric, click ••• and then select **Edit**.

   The **Edit Metric** dialog is displayed.

2. Select one or more stages from the drop-down list of **Start Stage** and **End Stage** for the metric.



3. Click **Update**.

   The updated metric definitions are saved in the vsm.json file, and the static metric graphs are updated for **Lead Time**, **Cycle Time**, and **Dev Cycle Time** in Insights dashboard.

Example: Calculation of Cycle time when multiple stages selected for end stage

The following setup describes how the Cycle time is calculated when multiple End stages are selected. In this example, Start stage is selected as **Active**, whereas **Production** and **Closed** are selected as End stage.

Work item	Start Stage	Start date	End Stage	End date	Duration
A	Active	June 1	Closed	June 7	6 days
B	Active	June 3	Production	June 10	7 days
C	Active	June 3	Production	June 7	4 days
D	Active	June 2	Production	June 5	3 days
E	Active	June 7	Production	June 12	5 days
F	Active	June 5	Production	June 10	5 days

Cycle time calculation: The distribution of the cycle times of all work items completed during the last 30 days. The calculated durations from the above table are sorted in ascending order. For example, if the duration values are [6, 7, 4, 3, 5, 5], they are reordered as [3, 4, 5, 5, 6, 7]. The **Median Cycle time** over this period is **5 days**, with 75 percent of items reaching completion within approximately 6.25 days.

Implementing custom metrics

Provide custom metric data to your value streams and dashboards.

Custom metric definitions can be defined in the `value_stream.json` file attached to a value stream. You can add graphs or charts derived from the data to dashboards, the value stream **Metrics** bar, or the list view on the **Value Streams** page.

Note: Until new users are assigned to teams, they are automatically assigned to the Default team in the Viewer and Participant roles. Users in these roles can view objects, such as releases and value streams, but they cannot create or edit them. Additionally, users in these roles can generate user access tokens and access API endpoints with GET requests on page 1820. Administrators grant users elevated permissions when they assign them to roles such as Lead Developer or Release Manager.

The following steps describe how to add custom metric data to Measure:

1. Using the properties defined later in this topic, define a custom metric definition.
2. Upload the metric definition to Measure.
3. Send data to Measure that conforms to the metric definition.
4. Add charts based on the custom data to value streams and dashboards.

Metric definition properties

Metric data properties are described in the following table:

Table 1160. Value stream metrics properties

Property	Description
id	This string-type property is used to link metric records to the metric definition. Required.
name	This string-type property identifies the metric definition. The name appears in the **Add charts** area of the Dashboards page. Required.
category	This string-type property defines the category to which the metric definition belongs. The categories are listed in the **Add charts** area of the Dashboards page. Possible values include: `quality`, `deliveryFlow`, `risk`, `team`, and `effort`. Required.
tenantId	This string-type property is generated by Measure and is used by the product to identify your installation. You can find your tenant ID by downloading a value stream JSON file. Required.
valueType	This string-type property indicates the expected value of the metric data. Possible values include: `percent`, `countset`, and `count`.

Table 1160. Value stream metrics properties (continued)

Property	Description
chartDefaults	This JSON object sets default options for the chart associated with the metric definition. The object properties are: `groupBy` (string), `chartType` (bar or line), `barMode` (stack or group), and `threshold` (number).
aggregation	This JSON object sets the default aggregation logic.
createdBy	Name or ID of the metric definition creator. String
description	Metric definition description. String.

Example to add metric definition

The following example shows the curl command for a metric definition. Measure uses the `"Authorization: UserAccessKey"` property to authenticate client access. You can create an user access token on the **User Access Keys** page, **Settings > My Profile**.

```
curl -X POST "https://localhost/api/v1/metricDefinition" \
 -H "accept: application/json" \
 -H "Authorization: UserAccessKey my_user_access_key" \
 -H "Content-Type: application/json" \
 -k \
 -d '{
       "id": "MY_CUSTOM_DEFINITION",
       "name":"My Custom Definition",
       "category": "quality",
       "tenantId":"my_Velocity_TenantID",
       "chartDefaults":{
         "groupBy":"result",
         "chartType":"bar",
         "barMode": "stack"
       },
       "aggregation":{
         "operation":"sum"
       },
       "createdBy": "A. Coder",
       "description": "New custom metric"
     }'
```

Example to update metric definition

The following example shows the curl command to update an existing metric definition. Measure uses the `"Authorization: UserAccessKey"` property to authenticate client access. You can create an user access token on the **User Access Keys** page, **Settings > My Profile**.

```
curl -X POST "https://localhost/api/v1/metricDefinition" \
 -H "accept: application/json" \
 -H "Authorization: UserAccessKey my_user_access_key" \
 -H "Content-Type: application/json" \
 -k \
 -d '{
```

```
      "operationName":null,
      "variables":{},
      "query":"mutation {
       updateMetricDefinition(input: {
       id:\"TUTORIAL_DEFINITION\",
       tenantId: \"my_Velocity_TenantID\",
       updates:{
       name: \"Tutorial Definition Changed 8\",
       category: \"quality\",
       chartDefaults:{
         groupBy: \"result\",
          chartType: \"bar\",
          "barMode": \"stack\"
         },
         aggregation: {
         operation: \"sum\"
         }
        }
       }){
       id
       name
       }
       }"
       }'
```

Example to delete metric definition

The following example shows the curl command to delete an existing metric definition. Measure uses the `"Authorization: UserAccessKey"` property to authenticate client access. You can create an user access token on the **User Access Keys** page, **Settings > My Profile**.

```
curl -X POST "https://localhost/api/v1/metricDefinition" \

 -H 'accept: application/json' \

 -H "Authorization: UserAccessKey my_user_access_token" \

 -H 'content-type: application/json' \

 -d '{
      "operationName":null,
       "variables":{},
        "query":"mutation {
         removeMetricDefinition(input:{
         id: \"TUTORIAL_DEFINITION\",
         tenantId: \"my_Velocity_TenantID\"
         }
         )
        {
        id
        name
        }
        }"
        }'
```

DevOps Research and Assessment (DORA) metrics

You can use DORA metrics to evaluate the performance of the team.

The following DORA metrics are available in Measure

- Lead Time for Changes
- Deployment Frequency
- Time To Restore Service (MTTR)

Lead Time for Changes

The lead time for changes is the quantity of time it takes a dot to progress from commit to production deployment. The metrics calculation is based on the date of the commit and date of the deployment into production. The lead time for changes metrics is a default metric added to all available value streams metrics bar.

Complete the following steps to add lead time for changes metrics to Insights:

1. On the **Value streams** page, click **All value Streams**.
2. Click a value stream.
3. Click and select **Edit value stream map** to modify the JSON file in the code on page 3067 or tree on page 3071 view editors.

   You can also click and select **Download value stream map**.

   The value_stream_name-vsm.json file is downloaded to the specified location.
4. Update the leadTimeChange metric in the JSON file as shown in the following example:

   The following example is based on the assumption that your commit is queried in the **In Review** stage and the deployment to production is queried in the **PROD** stage of your value stream.

```
"leadTimeChange": {
    "start": In Review,
    "end": PROD
  }
```

Deployment Frequency

Deployment Frequency Counts assess the number of deployments into production over a time. The metrics calculation is based on the deployment start date and end date.

Complete the following steps to add Deployment Frequency metrics to value streams.

1. On the **Value streams** page, click **All value streams**.
2. Click a value stream.
3. On the **Value stream** details page, click to add the required metrics.
4. In the **Add metrics** window, perform any one of the following steps to complete the addition of the production **Deployment Counts** metric:
    a. Click to add a production **Deployment Counts** metric with the default values for parameter fields. See the following table for parameters, descriptions, and default values.

Parameter	Description	Default value
Metric title	The title of the metric to display in value steams metrics bar.	Production deployment counts
Relative time	The time to use for the metric calculation	30 days or a custom value
Stages	The staging environment of the pipeline	Measure takes the last viewed staging environment

    b. Click the down arrow to enter the details for the metric. See the following table for parameters and descriptions:

Parameter	Description
Metric title	The title of the metric to display in value steams metrics bar.
Relative time	The time to use for the metric calculation
Stages	The staging environment of the pipeline

Complete the following steps to add Deployment Frequency metrics to Insights:

1. On the **Insights** page, in the **All dashboards** tab, click any dashboard.
2. On the selected dashboard page, click **Add charts**.
3. In the **Add charts** section, click the right angled arrow for **DORA** to see the list of metrics.
4. Click **Add+** for **Deployment Frequency** to add the metric.
5. The chart area displays the data for **Deployment Frequency** metric.

Time To Restore Service (MTTR)

Time to restore service is a metric to calculate the time that team members spend to resolve the reported incident. This metric calculation is based on the incident creation date and incident resolution date.

To view the severity levels You must integrate the Jira Srrvice Management plug-in to view the severity levels.

Complete the following steps to add Time To Restore Service metrics to value streams.

1. On the **Value streams** page, click **All value streams**.
2. Click any value stream.
3. On the **Value stream** details page, click to add the required metrics.
4. In the **Add Metrics** window, perform any one of the following steps to add **Time To Restore Service** metric:
   a. Click to add **Time To Restore Service** metric with the default values for parameter fields. See the following table for parameters, descriptions, and default values.

Parameter	Description	Default value
Metric title	The title of the metric to display in value steams metrics bar.	Time to Restore Service
Relative time	The time to use for the metric calculation	30 days or a custom value
Aggregation interval	The interval for data aggregation	Days
Severity	The incident severity levels are a measure of the impact an incident has on the business.	SEV1, SEV2, SEV3, SEV4, and SEV5

   b. Click the down arrow to enter the details for the metric. See the following table for parameters and descriptions:

Parameter	Description
Metric title	The title of the metric to display in value steams metrics bar.
Relative time	The time to use for the metric calculation
Aggregation interval	The interval for data aggregation
Severity	The incident severity levels are a measure of the impact an incident has on the business.

Complete the following steps to add time to restore service metrics to Insights:

1. On the **Insights** page, in the **All dashboards** tab, click any dashboard.
2. On the selected dashboard page, click **Add charts**.
3. In the **Add charts** section, click the right angled arrow for to see the list of metrics.
4. Click **Add+** for **Time To Restore Service** to add the metric.

The chart area displays the data for **Time To Restore Service** metric.

5. Click **Time To Restore Service** metric to view the severity levels.

Milestone risk estimation

Milestone risk is a metric which measures the probability of a team that may not complete all of the current in-scope work in an active development iteration (sprint). The milestone risk estimator plug-in uses a stochastic machine learning (ML) algorithm to estimate and predict the potential percentage risk of non-completion of all work during an on-going sprint. To calculate this metric, the model uses all historical work items available in the selected value stream to train the model and extracts the required information to make the prediction.

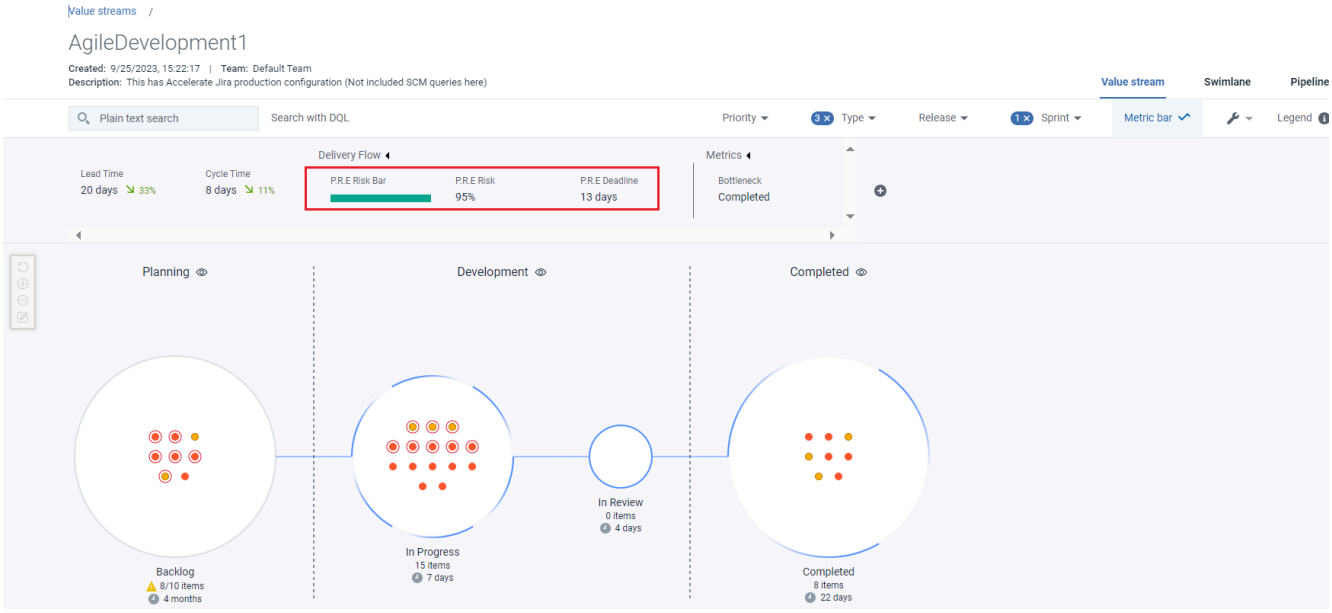
The training data plays a vital role in the process of building, training, and predicting risk. The milestone-risk estimator model uses Cycle time on page 3170 metrics to estimate risk.

The training dataset is updated at regular daily intervals to add the completed work items to improve the efficiency of the risk estimator model. You must select the required value stream when integrating the milestone-risk estimator plug-in in Measure.

The milestone-risk estimator plug-in estimates risk in the current sprint of the value stream and provides estimated results in the form of a Probabilistic Risk Estimator (P.R.E) metrics:

- **P.R.E Risk** displays the evaluated risk as a percentage.
- **P.R.E Deadline** displays an estimated deadline for the sprint.

To view the risk estimation, you must add **P.R.E Risk** and **P.R.E Deadline** metrics under the **Delivery flow** category on the Value streams page. See Displaying the metrics on the value stream on page 3084.



Data restrictions

The restrictions for the milestone-risk estimation model are as follows:

- The risk estimator model does not use stories and epics to train the model or predict the risk. The current model takes in only tasks, sub-tasks, and bugs into consideration for training and predicting risk.
- The risk estimator model considers 7 potential work days a week instead of 5 days.
- The risk estimator model assume serial work from an individual team member. The overlapped time between multiple tickets is divided if a user works on them all and completes them in the same sprint.

  For example, consider a user who works on ticket A from day 1 through day 5, but does not update the ticket to closed until day 10 of the sprint. The user also started working on ticket B from day 6 through day 10, but does not close it until day 15 of the sprint.

Bottleneck detection

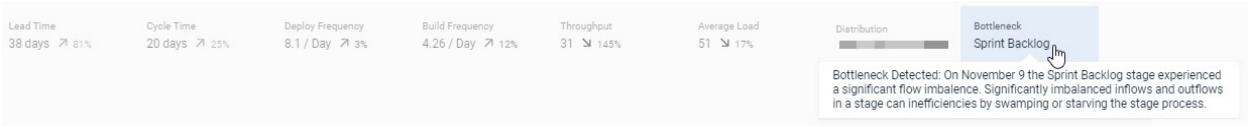
Bottleneck detection monitors, detects, and alerts user of restrictions in a value stream.

Utilizing the power of machine learning and AI, the bottleneck detection algorithm monitors the current and previous state of the value stream to identify which stage the user should focus on first. Bottleneck detection is viewed by either of the following methods:

- On the **Value Streams** page with the required value stream selected, click **Value stream > Metric bar**.
- Click **Value Streams > All Value Streams**. In the tabular view, the **Bottleneck** field will identify the restriction in the value stream.

The bottleneck detection plugin is used to identify a value stream restriction in local throughput that limits the global throughput of a system. The plugin uses work item stage-change data in unison with three algorithms to detect the presence of a specific type of bottleneck in a value stream. Detected bottlenecks are displayed in the metrics bar in the form of the following:

1. Bottleneck location displayed as value stream and stage.
2. Detection message displayed when you hover over the identified bottleneck.
   Figure 18. Bottleneck detection



3. Measure of bottleneck severity level used for display prioritization.

Note: The bottleneck detection parameter is not a value stream metric.

Process

The bottleneck detection plugin runs on a frequency set by the user during the initial configuration. Typically, bottlenecks do not vary continually and a frequency of 24 hours is adequate for most cases.

At runtime, the plugin reads `stageChangeEvents` records via the `stageChangeEventsSince` graphQL API for all value streams defined on an Measure instance. The records for each value stream are then processed through each individual algorithm. Bottleneck detection records are then returned for each value stream. A value stream may have multiple bottleneck detection records created during a given run, or it may have none. If multiple bottlenecks are found in a given run, the Measure UI will only display the highest severity bottleneck while logging the full set of detections in the database.

After the detection process is completed, the identified bottleneck records are written to the `metrics` database via the `uploadMetrics` graphQL API.

Bottleneck algorithms

The plugin uses three algorithms that each detect a unique class of bottlenecks according to different category processes that include the following:

1. Dominant stage bottleneck
2. Batching bottleneck
3. Inflow/outflow asymmetry bottleneck

A **dominant stage bottleneck** occurs when one stage in a value stream has a time-in-stage value greater than or equal to the sum of the time-in-stages of all other stages in that value stream. The dominant stage detection algorithm detects this condition in a value stream and uses the severity value of the dominant stage to non-dominant stages time-in-stages to assess the severity. Each value stream will have only one dominant stage bottleneck detection at a given time.

A **batching bottleneck** occurs when work items exit a given stage in short time intervals separated by large intervals with no associated activity. This algorithm detects batching by calculating stage exit event densities and comparing peak densities to off-peak densities. The severity of the batching bottleneck corresponds to the peak to off-peak density ratio. A value stream may contain multiple stages with batching bottlenecks at a given time.

An **inflow/outflow asymmetry bottleneck** occurs when there is an unusually large difference of work items flowing into and out of a stage on a given day. This algorithms monitors 24 hour periods where the net work item flow for a stage is greater than two standard deviations from the mean net flow, and total stage flow is in the top five percent of the historical stage flow records. The severity of the bottleneck is assessed by the amount value above the net flow detection threshold. A value stream may have multiple stages with inflow/outflow asymmetry bottlenecks at a given time.

Example bottleneck detection output

The following example shows the bottleneck detection output:

```
{
 tenantId : tenantId,
 workflowId : workflowId,
 dataSet : "Bottleneck Detection",
 record : {
               entries : {
                           alertType : "Bottleneck",
                           alertLocation :  bottleneckStageName,
                           alertString : bottleneckMessage,
                           alertLevel : severityMeasure,
                           alertLink : None
                         }
         }
}
```

Bottleneck detection display troubleshooting

For problems and solutions associated with display of the bottleneck detection parameter, refer to the following table:

Table 1161. Bottleneck detection display troubleshooting

Problem	Solution
The plugin instance is not configured or activated.	Verify the plugin instance is enabled and has a valid access key.
For a new or not fully configured value stream (one without valid stage definitions) there will not be sufficient data to detect bottlenecks.	Ensure the value stream definitions are properly configured and associated historical data exists in the system. Preferably at least 30 days of records with a minimum of 10 days.
No bottlenecks are detected. It is possible for a value stream to not have any of the bottleneck conditions which the plugin detects.	Check the plugin logs to verify the plugin is executing successfully.

Metrics FAQs

Metrics frequently asked questions

Example

How do I add to the metric bar? What permission and roles are required to modify the metric bar?

You can select up to eight metrics including lead- and cycle-time along with six more that you choose for your value stream. These metrics are data driven from integrations and value stream data. A user can add metrics by clicking on the **Metric bar** if available and then follow these instructions on page 3084. If it is not available, it means you either do not have permissions or the metric bar already has a maximum of eight metrics displayed.

Note: The

`CreatePipeline` permission is required through either the Lead developer or Pipeline designer roles to add metrics.

What do these metrics mean?

Metric definitions are found here. on page 3084 You can also view metric definitions on the following pages:

- On the **Value stream** details page, click
    1. Metric chart reference on page 3170

  to display the **Add Metrics** window and then hover over the individual metrics underneath the **Delivery flow**, **Quality**, and **Risk** metrics categories to display metrics with definitions in pop-ups.
- On the Insights **Dashboards** page, click **Add charts**. Metric definitions can be viewed by clicking the expand and collapse buttons on the left side of the **Delivery flow**, **Quality**, and **Risk** metrics categories followed by clicking the expand and collapse buttons on the left side of the metrics under the aforementioned categories to display the definition and metric-type of **Built in metric** or **Custom metric** for metrics with definitions.

Can I change the time range for metrics?

Yes for certain metrics and no for the following:

- Lead time
- Load
- Contributors
- Throughput
- Distribution

Why does the lead- and cycle-time have click in while other metrics do not?

Lead- and cycle-time are critical metrics to VSM in terms of operational effectiveness of your teams and quantifying workflow into and through the system.

How do I display charts and graphs for these metrics?

Metrics in the **Metric bar** are available in Insights on page 3170 except Bottleneck which is a measure of current process and is displayed in the **Value stream** tab. Bottleneck is explained in detailed here on page 3098.

Are custom metrics available for use?

Yes, creating custom metrics will show up on this list and be hardcoded time duration of X.

What are these custom metrics representing?

Reference previous answer and it is not directly tied to a single integration. For example, you can not view **Unit Tests** for a single integration because it applies to the whole value stream.

What does blank or zero metrics mean?

This could mean many things. There may be a dependency on lead time or the data is not linked.

How do I set up lead- and cycle-time metrics?

This is set up in the VSM JSON file on page 3059.

What metrics change when I change my definition of lead time?

Value stream metrics including the following:

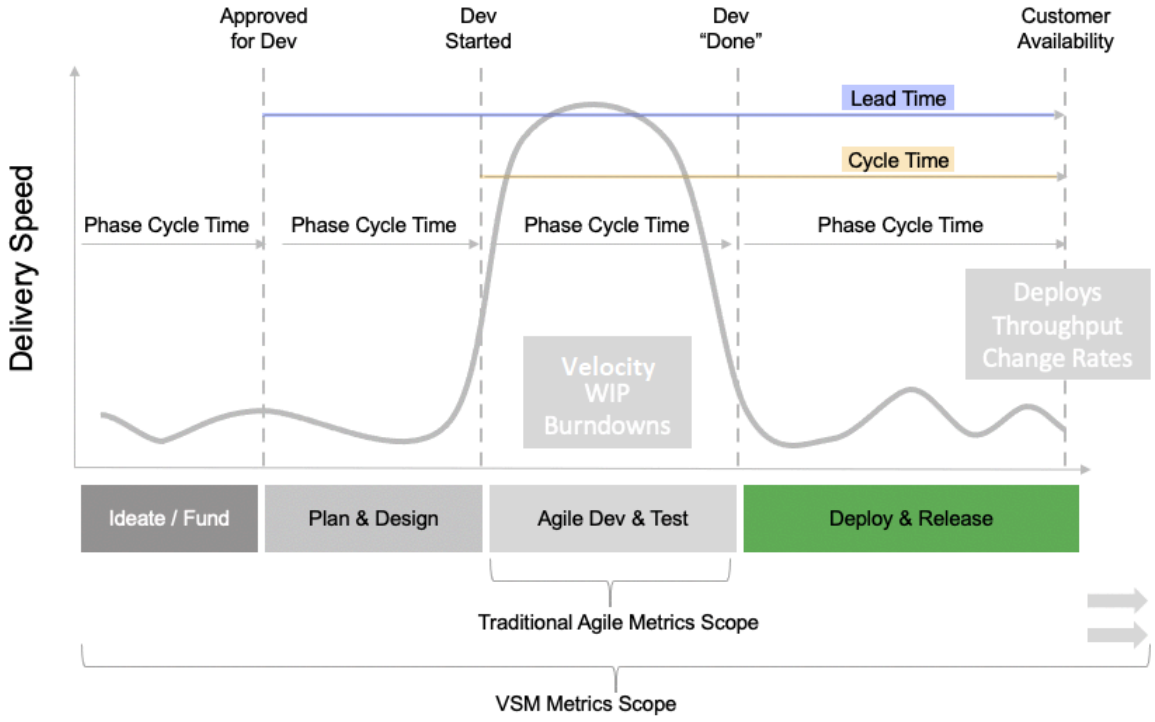
- Average Load
- Throughput
- Distribution

Can I set up multiple lead- and cycle-time metrics.

Not currently.

What is lead- and cycle-time and how are the metrics represented graphically?

Lead- and cycle-time definitions are detailed here on page 3170 and the graph shown in the following figure.



If I have a definition of lead time, can I change the algorithm?

Not currently.

Why are there similarly named metrics in the Value Streams and Insights pages?

Metric name equivalences are detailed here. on page 3084

Navigating value streams

Manage a value stream's displayed data by applying filters and queries.

Value stream visualization provides an overview of the value stream workflow and summary information about the individual items contained in it. The items, sometimes called dots, represent objects from the tools that you use, such as builds, pull requests, issues, and tests. You use the To see objects from your integrated tools, apply filters by using the DevOps query language on page 3117.

You can view value stream data in a user-focused way by using the swim lanes feature. on page 3113

The highest level of a value stream is a *phase*. Phases contain the *stages* that define process flow within the phase. Stages contain data from integrated tools. Each data point is represented by an individual, graphical element. A item's position in the value stream conveys important information about the object. items in a stage named *Merged*, for example, can represent items merged into Git repositories. An item's shape and color convey information about the item's type and status. A item outlined in red, for example, might mean the item is past schedule. The border around a stage indicates how quickly stage items updated. When you hover the mouse over a item, the displayed card contains summary information about the item and links to associated tools.

In outline, to use a value stream, complete the following steps:

1. On the Measure dashboard, click **Value Streams**.
2. On the **Value streams** page, select a value stream. By default, each value stream is displayed on a separate card. You can display a list of value streams instead. The value stream is displayed on the **Value streams/value-stream-name** page.
3. Optionally, click 
to display lead time, cycle time, and devcycle time on page 3064.
4. Filter the view. The items that appear on the value stream are determined by the tools that are integrated into the value stream, and queries that filter data from the integrations. Filtering options and search scope are described later in this topic.
5. Optionally, click and select **Edit value stream map** to modify the value stream and add queries defined in the `value-stream-name.json` file.

Understanding value stream data

Queries that set the value stream scope are defined in the `value-stream-name.json` file. When you display a value stream, items matching the preset queries are displayed. The following graphic displays a value stream with items integrated from an issue tracking system and a source control system. Each stage has a query defined for it that determines the items that are displayed in it. The In Progress stage has a query defined for it similar to this one: `"query": "issue.status=\"In Progress \" and pr.status!=MERGED and pr.status!=closed"`.

You can add a global query to any value stream. The global query is applicable for all phases of the value stream. To add the global query, perform the following steps:

1. Click any value stream where you want to add the global query.
2. On the **Value stream** details page, click and then select **Update global query**.
3. Add the required DQL query to the query field of **Update Global Query** window.
4. Click **Save**.

Figure 19. User-configured value stream

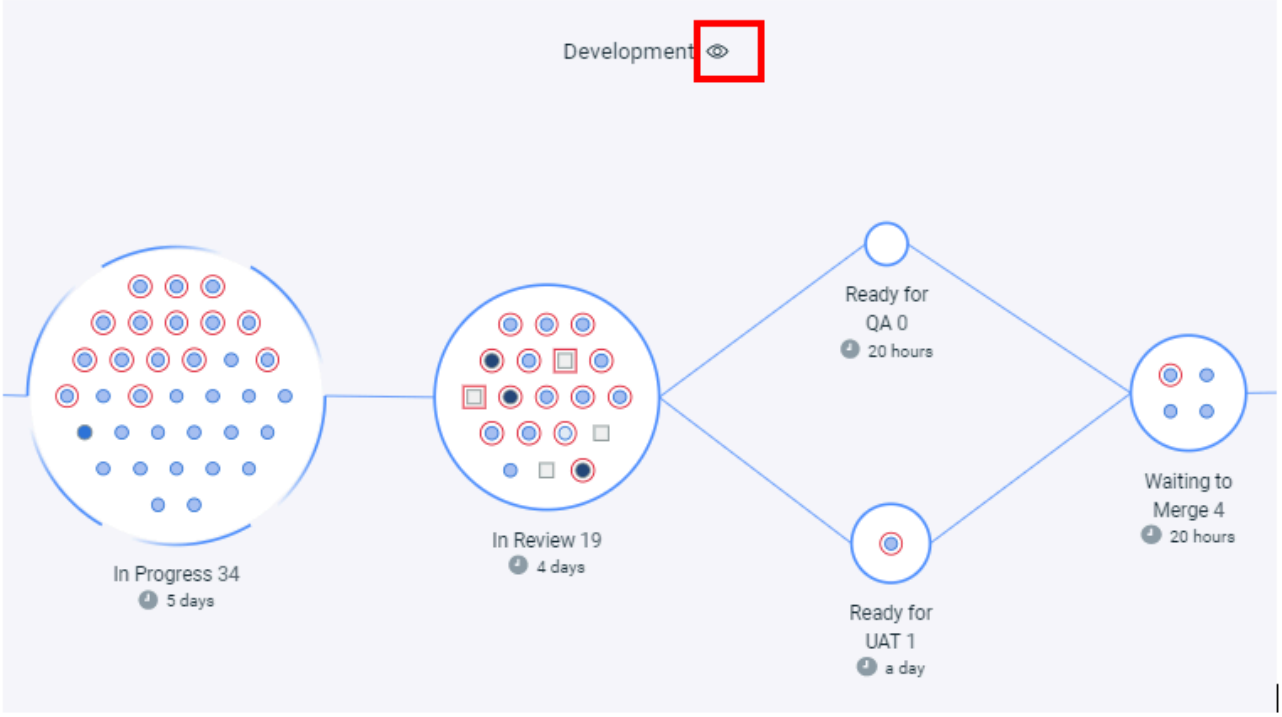
In the preceding image, the display can filtered by the following: **Time**, **Type**, **Priority**, **Release**, and **Sprint**. In addition, under each stage of the value stream, there is a value in days is called **Average wait time**. **Average wait time** is a metric that calculates the average time of dots available in any stage. The wait time metric calculates the difference between the dot transition date to any stage and the current date. Average wait time is average of the all dots wait time dvidided by number of dots. Using this metric, you can identify the dots movement through any stage and helps to take an informed decision to improve the efficiency of the project.

Note: Click **Legend** to view data on **Value stream** page for each filter selection.

If a stage has more than 40 items, summary information replaces the individual items, as shown in the following graphic:

Figure 20. Summary stage data

Use eye icon ( ) to expand or collapse the phases in the value stream.



You can define stage queries in `value-stream-name.json` file to monitor one or more branches of git repository in the value stream.

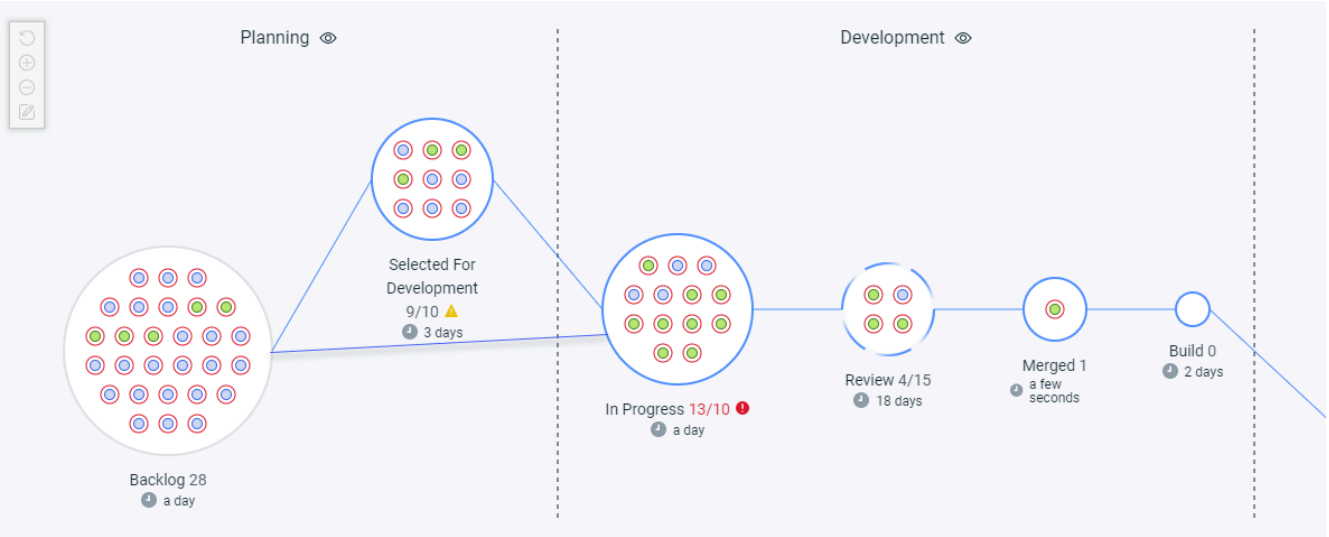
Value stream multi-branching

You can use value stream multi-branching feature to create multiple branches of the stages in the product development lifecycle. You can create multiple branches from the stages using the `targets` property in `vsm.json` file. You can also create multi-branching between the phases of the product development lifecycle. The below code is example of creating multiple branches from the `Backlog` to `Selected For Development` and `In Progress`.

```
{
          "name": "Backlog",
          "query": "",
         "targets":["Selected For Development","In Progress"],
          "description": "",
          "wipLimit": null,
          "gates": null
        },
        {
          "name": "Sprint",
          "query": "",
          "targets":[]
          "description": "",
          "wipLimit": null,
```

```
        "gates": null
      },
{
        "name": "Review",
        "query": "",
        "targets":[]
        "description": "",
        "wipLimit": null,
        "gates": null
      }
```

Note: There is no value for `targets` property in `VSM.json` file, the stage connects to the next available stage. In the above code example, `Sprint` stage connects to `Review` stage.



You can use edit mode button to do drag and drop the stages inside the phases of the development lifecycle. Click to enable/disable the edit mode. When you enable button, eye icons (and disappears. To view eye icons, disable the button. You can use zoom in and zoom out button for the detailed view of dots

clearly. You can use reset button to default view of value stream. You can use button to zoom in, zoom out, and reset controls with the capability of switching to a non-edit view mode in value stream.

Note: The user requires create pipelines permission to do drag and drop for the stages using edit mode button.

Note: You can customize the value stream layout using the value stream multi-branching. The customized layout of value stream is applicable for all users of the value stream.

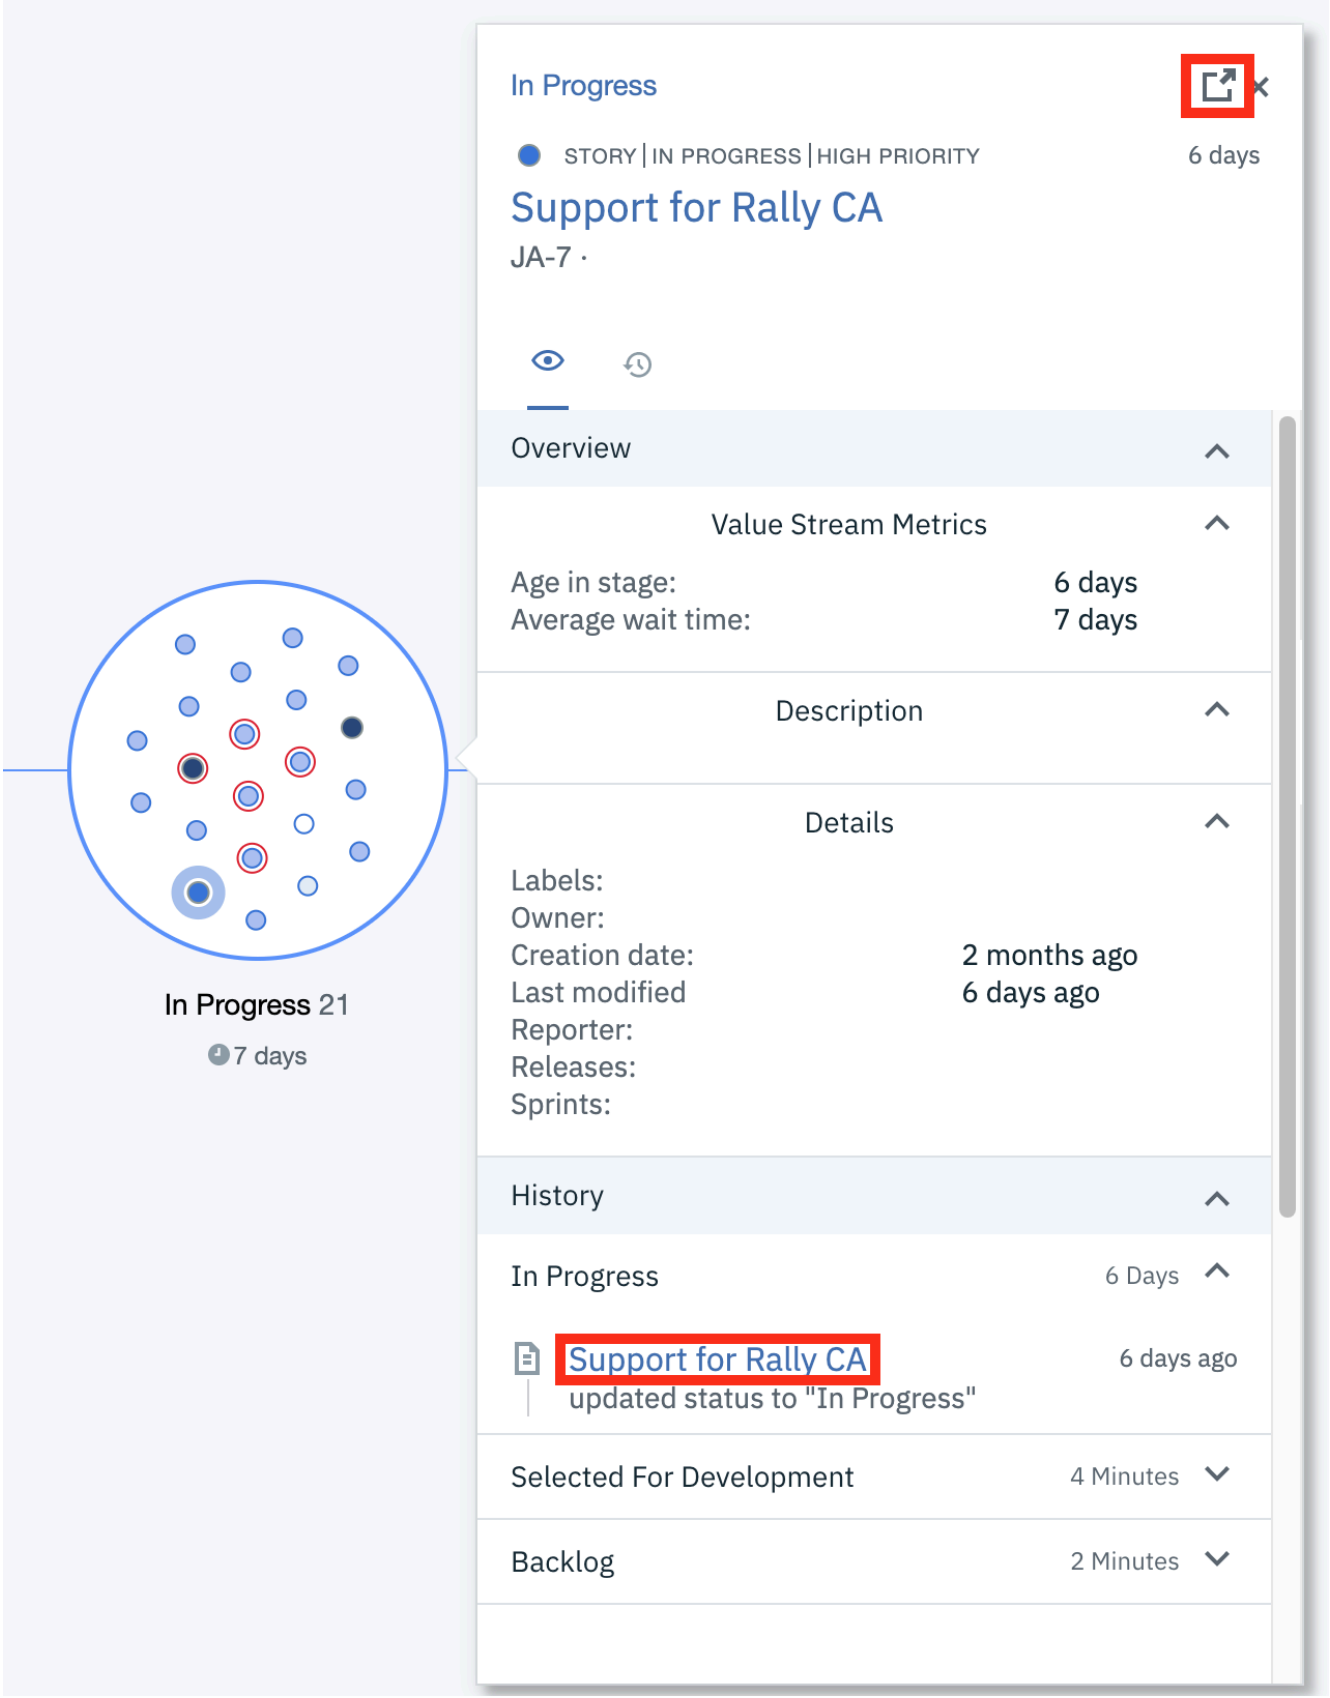
You can use the **Reset Layout** button to restore the layout of the value stream to default layout. In the default layout, all stage circles are aligned in a straight line.

Value stream items

You can display information about the items in a stage. When you click an item, a card is displayed with information about the represented item, such as a Jira issue. Full history about the item is presented in context, including its history. You can use the supplied links to open the item in originating tool.

The following graphic displays a Jira issue in the value stream's In Progress stage. Links, highlighted in red in the graphic, can open the item in the integrated tool.

Figure 21. Item card



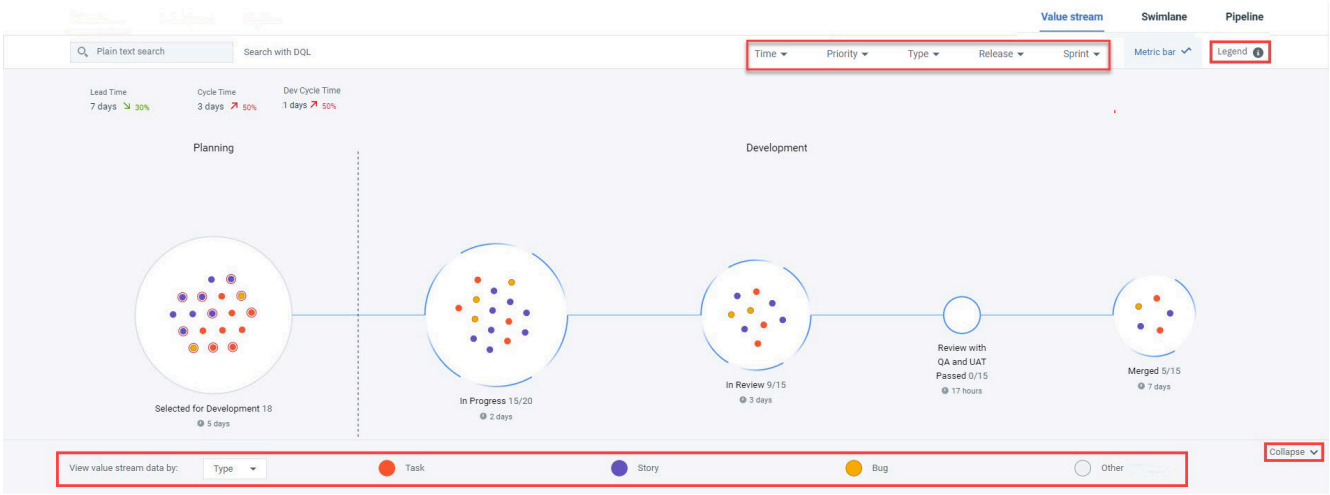
If linking rules are defined for the integrations, information from the linked tools and available on page 3066. Link rules link two integrated tools, such as Git and Jira, to make information from both tools available in the affected items.

Value stream view by

At the bottom of the **Value stream** or **Swim Lanes** pages next to the **View value stream data by** list, you can view your data by selecting one of four criteria applied to the value stream data with an associated color legend and may also be shape coded by the information detailed in the following table and figure:

Table 1162. View value stream data by

View value stream data by	Description
Priority	Level of importance such as lowest, low, medium, high, and highest.
Release	The release versions.
Sprint	Sprint numbers, names, or both.
Type	Dots type such as story, bug, task, epic, pull request, and commit
Time	The waiting time of dots in any particular stage.



Note: If the **View value stream data by** bar is not visible on either the **Value stream** or **Swim Lanes** pages, click **Expand** located toward the bottom right corner of the respective pages to display the bar. Additionally, if the bar is visible and you want to hide it, click **Collapse**.

Toward the top right corner of either the **Value stream** or **Swim Lanes** pages, click **Legend** to display additional identification details for the items including any of the aforementioned shape coded items. To view value stream data by a range of data, click the **View value stream data by** list and select your required criteria

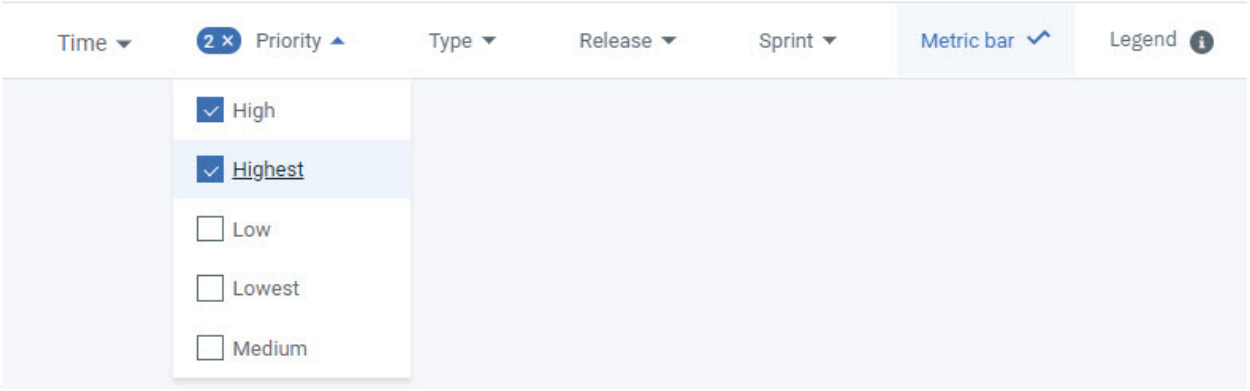
Quick filters for value stream data

At the top of the **Value stream** or **Swim Lanes** pages to the left of the **Metric bar** button shown above, you can use quick filters to limit the amount of value stream data that is displayed based on the selected criteria of priority, release, sprint, or type that is detailed in the above table.

Ensure the **View value stream data by** bar is visible on the bottom of either the **Value stream** or **Swim Lanes** pages and perform the following procedure to search and limit the display of value stream data based on your required criteria.

1. Click the **View value stream data by** list and select your required criteria. The color coded items associated with the selected criteria are displayed in the legend on the bottom bar.
2. To further limit the display of value stream data, you can apply quick filters by clicking on **Priority**, **Release**, **Sprint**, and **Type** and selecting check boxes within each item in any multiple combinations of all filters to the previously selected criteria in the bottom bar for precise narrowing of your required data range. To display the value stream data of all current sprints, select **Current Sprint(s)** check box from the **Sprint** quick filter list.

   An example of the **Priority** quick filter applied with the **High** and **Highest** criteria selected is illustrated below.



3. To remove the quick filters, either click the **x** to the left of any filters that were selected as shown above or individually deselect individual items within each of the criteria.

Dot alerts

You can see the alert for dots in value stream for the following scenarios:

1. Dots that are unassigned.
2. Dots with long wait time.

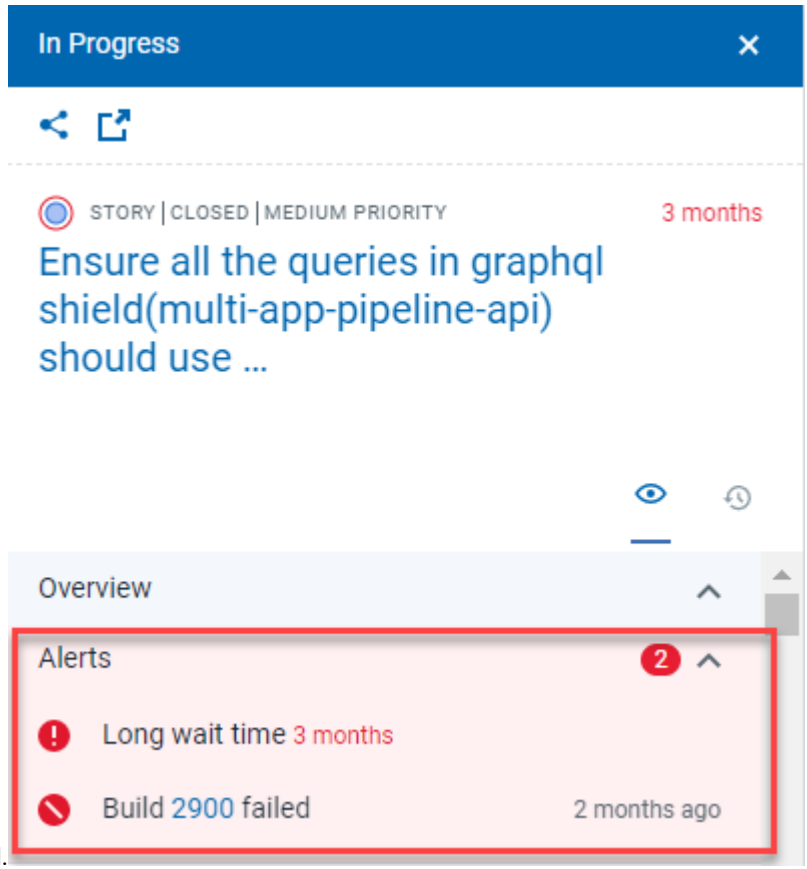
   Note: Wait time is defined as the time between the current time and the last status update of the dot. This alert is generated when a dot's wait time is greater than the average wait time across all dots. Dots alert specifies the value of waiting time.

3. Dots with build status failed.

Note: Dots alert specifies reference of the failed build.

4. Dots with deployment status failed.

The figure below is an example of dot alerts for long wait time and build failed.

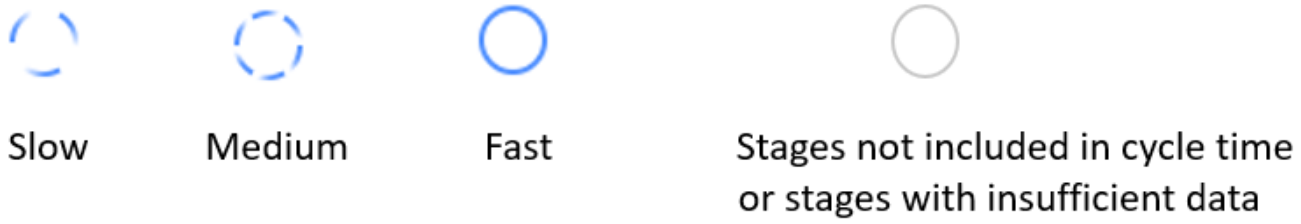


Stage wait time

Stage wait time is the average time of all the dots per workflow. There are four types of stage wait time.

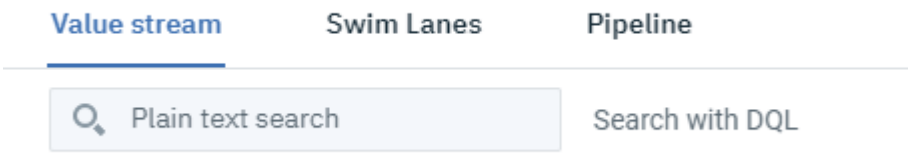
1. Blue circle with three segments - Stages with slow wait time. The dots in the stages are progressing slowly compare to other stages of the workflow.
2. Blue circle with six segments - Stages with medium wait time. The dots in the stages are progressing in medium speed when comparing with fast and slow stages.
3. Blue circle - Stages with fast wait time. The dots in the stages are progressing fast compared to other stages in the workflow.
4. Grey Circle - Stages with insufficient data.

The stage time is displayed below each stage circle.



Searching the value stream

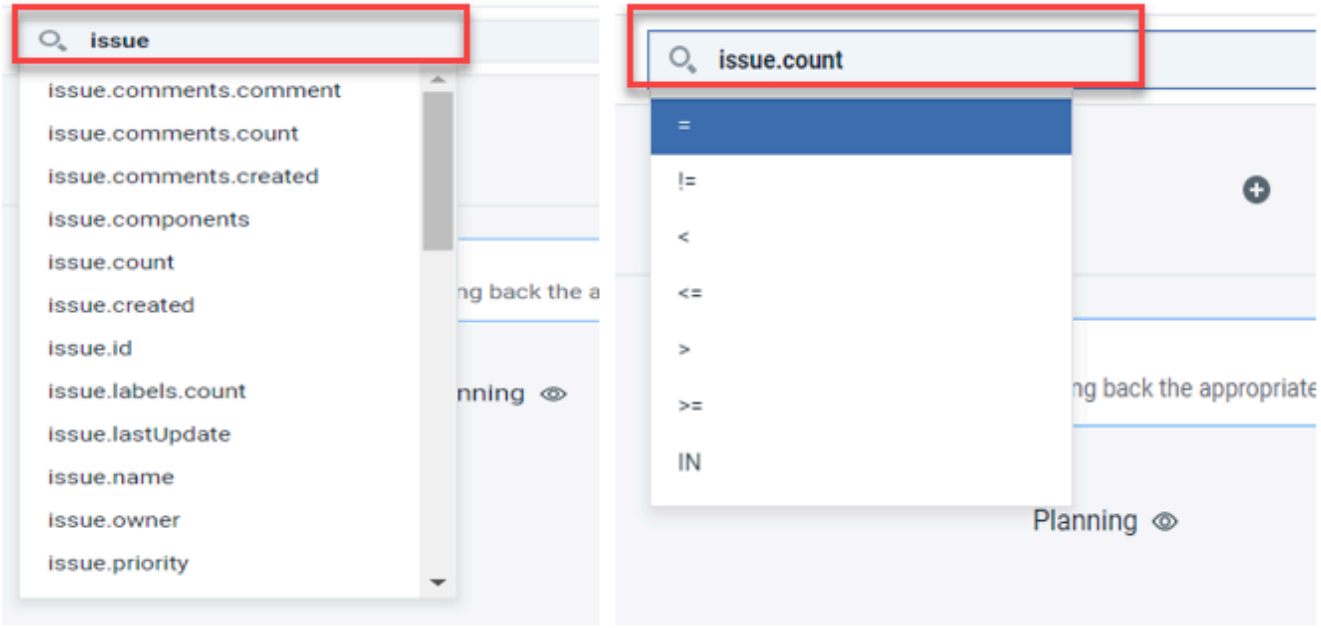
Searching a dot in value stream data is possible in two ways, **Plain text search** and **Search with**



DQL .

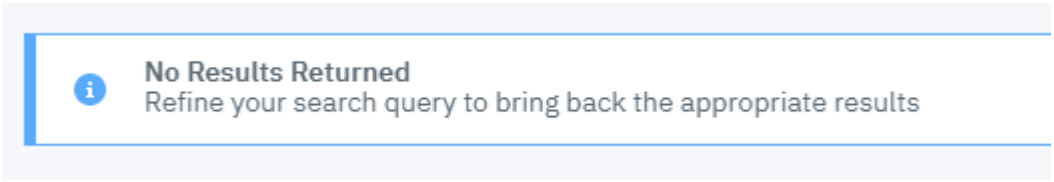
Plain text search is the free text search of the dot in the value stream. When search text is entered in **Plain text search** field, it displays all dots which are associated or contains the search text. Use **Plain text search** field to search the dots with issue id, issue labels, issue name, issue owner, issue priority, issue types, releases, and sprints.

Use **Search with DQL** field to search the dots with DQL queries on page 3118 and DQL operators on page 3121. The **Search with DQL** field displays all possible queries and operators for the typed



query.

Note: In case, no dots is available for the search data, value stream will display a error message.



Managing swim lanes

Use swim lanes to display a user-centered view of your value stream data.

About this task

You can use the dynamic swim lanes feature to quickly display vital project information across various organizational roles enabling informed workflow decisions. Dynamic swim lanes are adaptable and provide tailored data sets according to the different roles and requirements detailed in the following table.

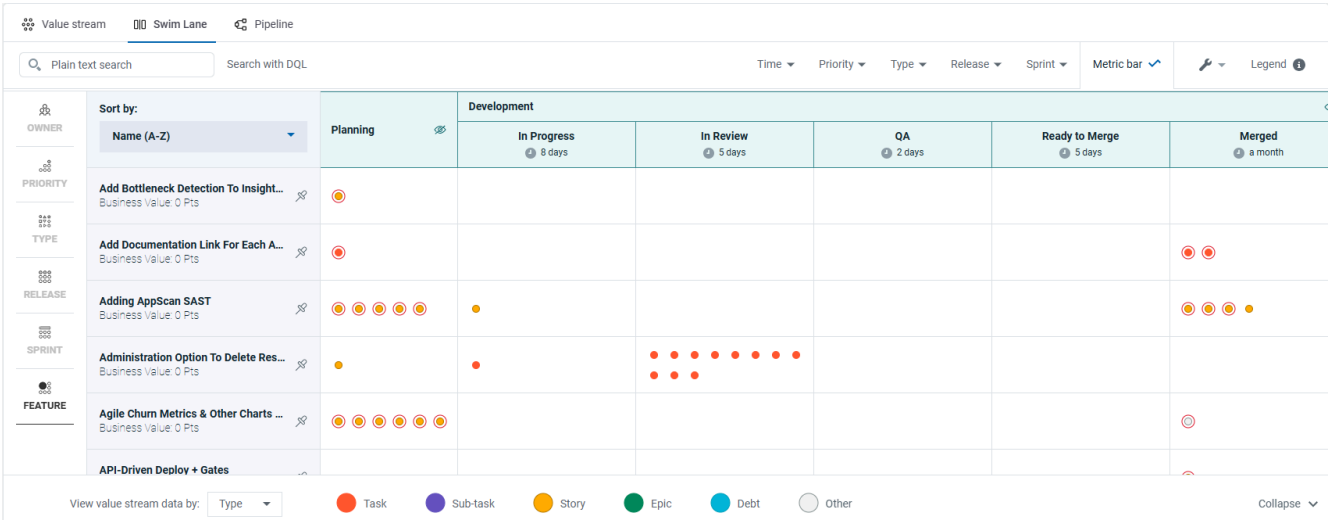
Role	Dynamic swim lanes view
Developers, scrum masters, daily stand-up	View work items per person, show and hide selected stages, and choose sprint view for displaying pointed data sets.
Development managers, director	Check overall sprint status, view stage position of work items, display remaining work from past sprints for possible future sprint allocation, and click **SPRINT** for a consolidated work item view displaying the current status.
Scrum masters, development managers	For tracking targeted Epics, use the pinning feature to keep the prioritized items at the top of the list.
All roles	Dynamic swim lanes display current state of releases, contents of both upcoming and past releases, determine when work items are released, view work items per stage, and click **RELEASE** for a detailed release contents list and click **SPRINT** for the same result.

A swim lane organizes the value stream into a table. The table columns represent value stream phases and associated stages shown above the table data in the illustration below, and the rows represent either:

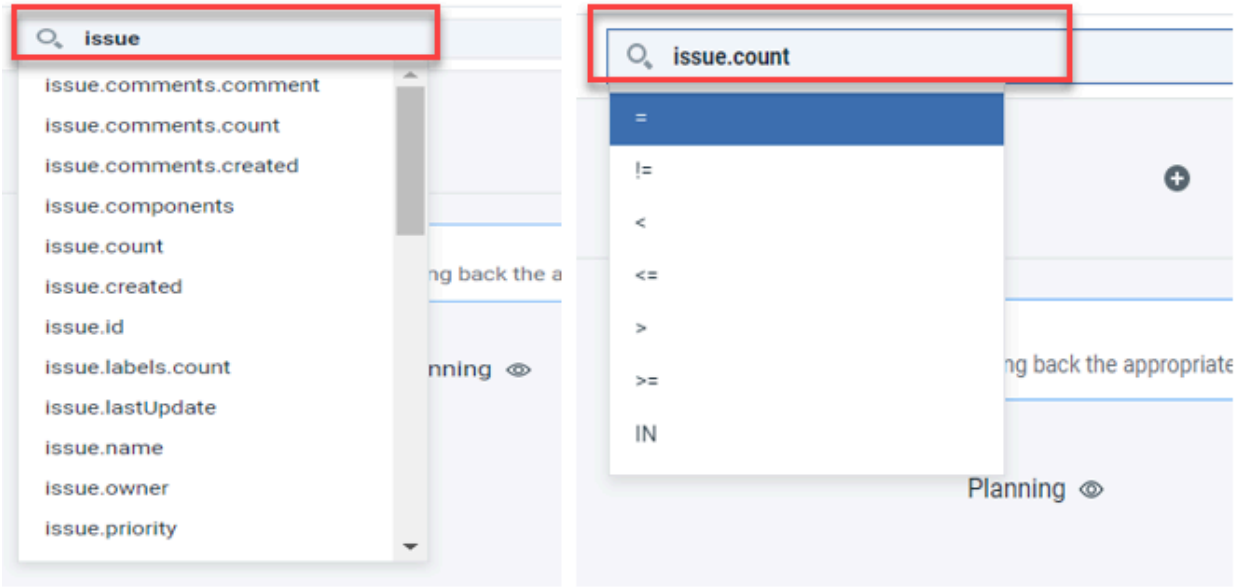
- Owner (all rows displayed)
- Priority (all rows displayed)
- Type (all rows displayed)
- Release (five rows displayed)
- Sprint (five rows displayed)
- Feature(all rows displayed)

properties, as shown in the dynamic row selector on the left side of the following illustration:

Figure 22. Dynamic swim lanes



Note: Based on the property selected in the dynamic row selector, you can search for required information based on the selected property type in the search field located toward the top right of the dynamic row selector shown in the illustration above. Additionally, you can perform DQL queries attached to the value stream on page 3117 by clicking **Search with DQL** field where you can enter the DQL query. The **Search with DQL** field displays all possible queries and operators for the typed

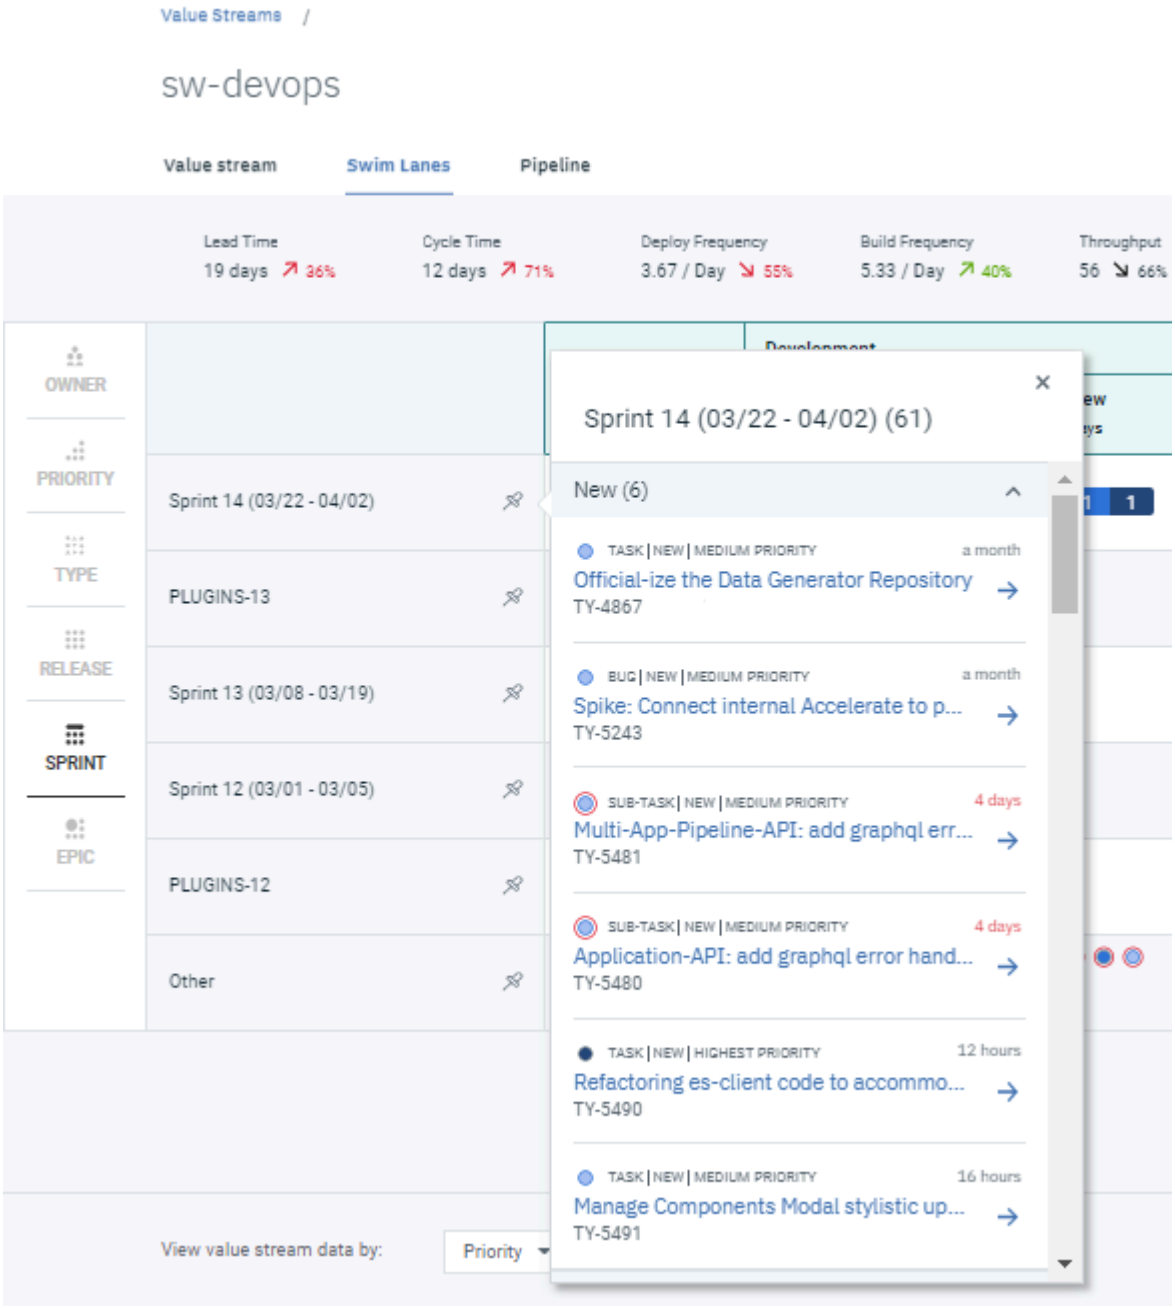


query.

Dynamic swimlanes works with filters and legends detailed on this page on page 3103. If a row does not have dots, it will not display when you filter.

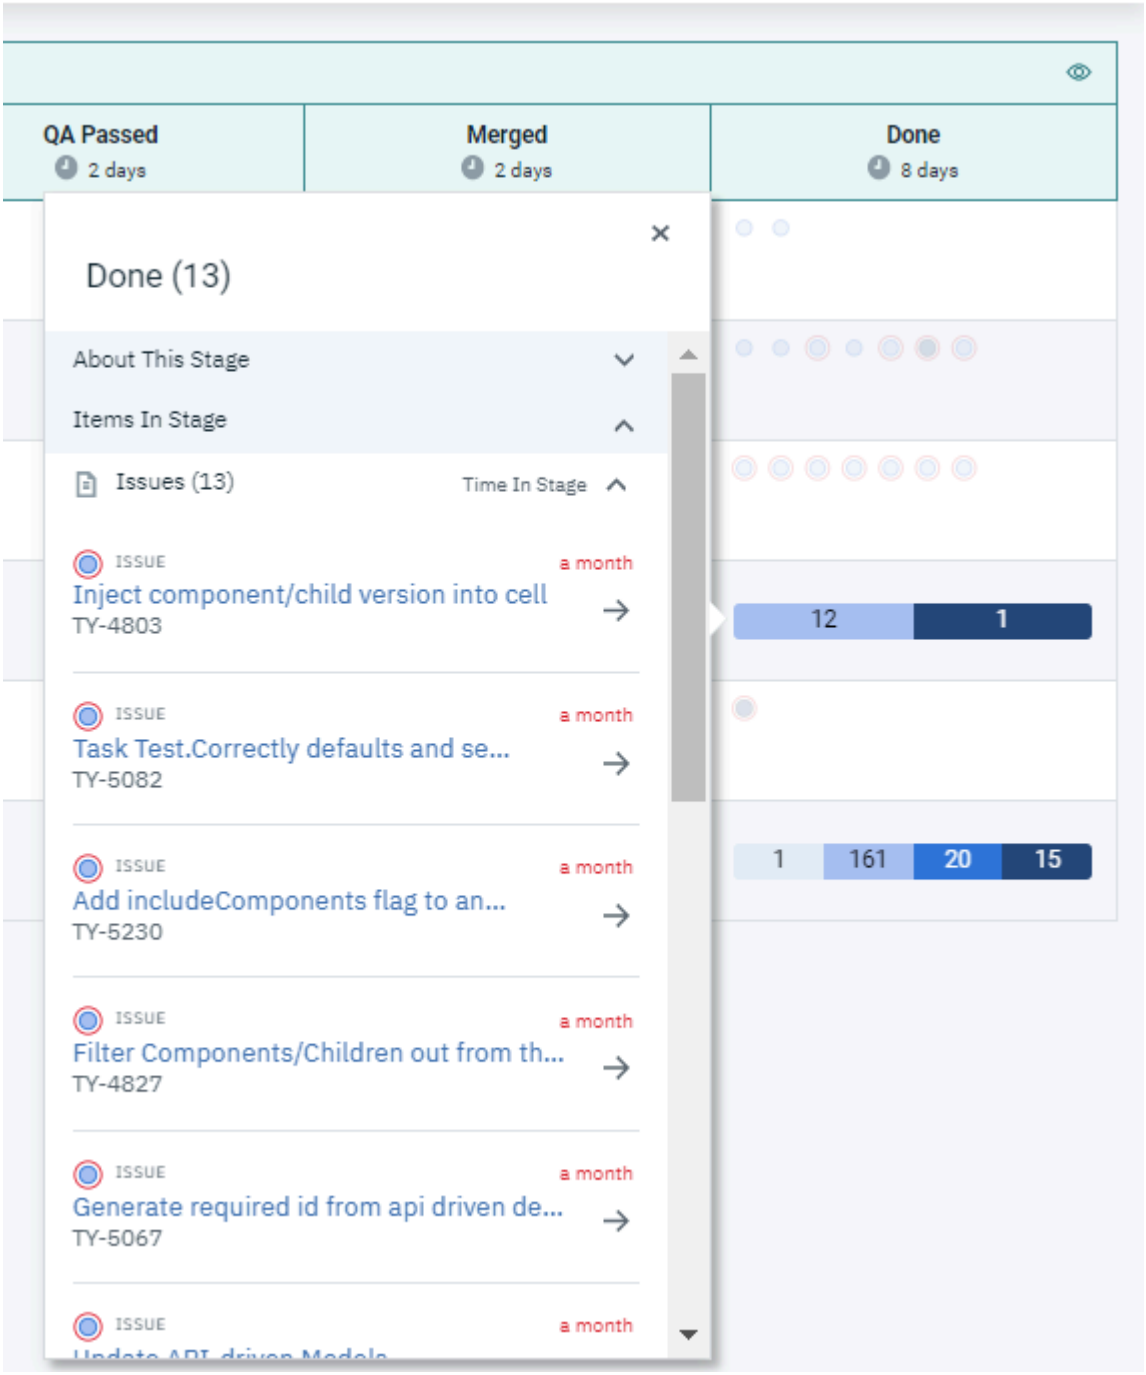
On the right side of the dynamic row selector is the rows overview panel. The row contents vary according to the specific property selected in the dynamic row selector and you can click on any row to display the row panel shown on the right of the

rows overview panel where you can view dots in each stage for a specific row. You can also expand and collapse sections in the row panel by clicking the down and up arrows on the right of the section names as shown in the following illustration.



You can show and hide phases and associated stages by clicking and respectively with both located on the right side of the phase names in the column fields above the data table. When you hide phases, a high-level progression view is displayed. When you show phases, a detailed view of items in stages is displayed. Also, when you click on the phase names in the column fields above the data table, a row panel is displayed containing the associated stages with the phase. You can also expand and collapse stage sections to view phase dots according to the stage position in the phase.

Additionally, you can click on any of the summary bars in the data table to display a row panel with the same aformentioned features as shown in the following illustration.



You can prioritize items for all row categories in the row overview panel by clicking for the required row and it remains at the top of the row overview panel with last item pinned on top. To unpin an item, click to remove the priority item.

Note: The pinning preferences, phase collapse or expand, drop-down filters, and row views are all saved to the user settings for VSM.

The functionally available on the **Value stream** view is available here as well; you can access the **Metric bar** and text and DQL query field.

To display a swimlane, complete the following steps:

1. On the Measures **Home** page, click **Value Streams**, and then select a value stream.
2. On the value stream page, click **Swim Lane**.
   Result
   The swimlane is displayed.

DevOps query language (DQL)

Use the DevOps query language to filter the information displayed in your value stream.

About the DevOps query language

The DevOps query language is a search tool designed to filter value streams. You build simple queries by combining searchable items with operators and values. A searchable item is a query-able object, such as `issue.status`. Nearly all Measure database fields are query-able, and you can search across nested objects, for example, `issue.project.name`.

Query scope

Queries can be scoped to the entire value stream or a stage. You can create queries on the **Value stream** view or define them in the `value_stream_name-vsm.json` file attached to a value stream. Each stage can have a query defined for it.

You set the scope of a query at the value stream level by defining a query in the header of the `value_stream_name-vsm.json` file or on the **Value stream** view. You might do this if you have a shared Jira® instance, for example, and want to restrict the displayed issues to those that belong to your team. For example, `issue.project.name="my_jira_project"`.

If you set the scope to the stream level, other queries work within that scope. After you set the scope to the value stream level, you cannot override it by defining a new stream-level query on the **Value stream** view. To change a value stream scoped query, replace the query in the `value_stream_name-vsm.json` file.

Simple queries

Filter your value streams with queries that restrict the displayed information to the things that you want to see. You build simple queries with the DevOps query language by combining searchable items with operators and values. A searchable item is a query-able object, such as `issue.status`. The query format consists of an item, a period, a query-able parameter, an operator, and a value of a valid type:

```
[item].[field] [operator] [value type]
```

The following list displays some typical queries:

```
issue.status = “In Progress”
issue.owner = “John Doe”
pr.number > 5
issue.status != Done
build.endTime < 1d
issue.created > 10d
issues.sprints.name = "sprint 1"
```

Value types are case insensitive. Text value types can be enclosed in single- or double-quotes.

A list of searchable objects, or items, are provided later in this topic.

Combining queries

You can combine simple queries by using the logical operators ‘and’ and ‘or’. Combined queries are resolved in left-right order.

The following query displays issues for Jane and John Doe with the status of 'In Progress' .

```
issue.owner = “John Doe” or issue.owner = “Jane Doe” and issue.status=“In Progress”
```

The following query displays items with the status of "Open," and that are older than one day.

```
pr.status = Open and pr.created > 1d
```

Priority queries

You can override the default order of precedence by using parenthesis.

Unlike the earlier example, this example displays all issues owned by John Doe, and only issues owned by Jane Doe with the status of "Done."

```
issue.owner = “John Doe” or (issue.owner = “Jane Doe” and issue.status=Done)
```

This example displays John Doe's open issues and with the status of "In Progress."

```
(issue.status = “In Progress” or pr.status = open) and issue.owner = “John Doe”
```

Elements of the DevOps query language

Use items in table to search in their query-able fields. Time-type fields are shown in *italicized* font.

The below table lists all the DevOps queries that you can use in stages of `value_stream_name-vsm.json` file. Using the query, you can view the data of an application integrated in value stream.

Table 1. Searchable items - stages of `value_stream_name-vsm.json`

Table 1163. Searchable items - stages of `value_stream_name-vsm.json`

Item	Query-able fields
issue	`count`, `status`, `labels`
issue.comments	`count`

Table 1163. Searchable items - stages of `value_stream_name-vsm.json` (continued)

Item	Query-able fields
issue.extended	<custom field>
issue.labels	`count`
issue.project	`id`, `key`, `name`. For example, `issue.project.name="my_project"`. Note: A project is a group of issues that include Jira: stories, bugs, tasks, and epics for a product, service, or activity.
issue.sprints	`active`, `count`
pr	`count`, `draft`, `labels`, `repositoryId`, `repositoryName`, `repositoryOwner`, `source`, `status`. For example, `pr.draft=true` will show only the issues that is having the draft pull requests in the value stream.
pr.approvals	`count`
pr.assignees	`count`
pr.comments	`count`
pr.labels	`count`
pr.reviewers	`count`
pr.reviews	`count`
commit	`count`, `repositoryId`, `repositoryName`, `repositoryOwner`, `source`
build	`count`, `status`, `type`
deployment	`count`, `env`, `environmentId`, `source`, `status`

The below table lists all the DevOps queries that you can use to search in **Value stream** view. Using the query, you can search in **search bar** to filter the required dots in **Value stream** view.

*Table 2. Searchable items - **Value stream** view search bar*

Table 1164. Searchable items - Value stream view search bar

Item	Query-able fields
build	`count`, `id`, `name`, `source`, `status`, `endTime`, `requestor`, `startTime`, `number`, `type`
build.application	`id`
commit	`name`, `repositoryId`, `repositoryName`, `repositoryOwner`, `source`

Table 1164. Searchable items - Value stream view search bar (continued)

Item	Query-able fields
deployment	`count`, `id`, `name`, `source`, `status`, `endTime`, `requestor`, `startTime`, `number`, `env`, `environmentId`, `versionName`
feature	`created`, `creator`, `id`, `name`, `status`, `url`
issue	`count`, `components`, `id`, `impact`, `name`, `storyPoints`, `source`, `status`, `owner`, `priority`, `type`, `created`, `lastUpdate`, `resolution`, `resolved`, `severity`, `labels`, `businessValue`
issue.comments	`count`, `comment`, `created`
issue.extended	<custom field>
issue.labels	`count`
issue.project	`id`, `key`, `name`. For example, `issue.project.name="my_project"`. Note: A project is a group of issues that include Jira: stories, bugs, tasks, and epics for a product, service, or activity.
issue.rawIssue	The `rawIssue` field contains non-normalized data from the external tool, such as Jira. For example, `issue.rawIssue.fields.custom_field`.
issue.releases	`id`, `name`, `description`, `archived`, `released`. Several typical examples include, `issue.releases.name="Version 1.1"`, `issue.releases.released = false` . Note: A release is a deployment to an environment.
issue.sprints	`active`, `count`, `id`, `name`, `previous`, `description`, `startTime`, `endTime`, `completeTime`, `url`
issues.comments	`updated`
issues.releases	`releaseDate`
pr	`count`, `draft`, `id`, `issueIds`, `labels`, `name`, `source`, `status`, `branch`, `baseBranch`, `commitId`, `merged`, `assignees`, `reviewers`, `created`, `lastUpdate`, `creator`, `number`, `repositoryId`, `repositoryName`. For example, `pr.draft=true` will filter only the issues that is having the draft pull requests in the value stream.
pr.approvals	`count`
pr.assignees	`count`

Table 1164. Searchable items - Value stream view search bar (continued)

Item	Query-able fields
pr.comments	`count`, `comment`, `created`, `updated`
pr.labels	`count`
pr.reviewers	`count`
pr.reviews	`count`, `status`

Note: A feature is a collection of stories and equivalent to an Epic in Jira.

The query operator tables displays search operators.

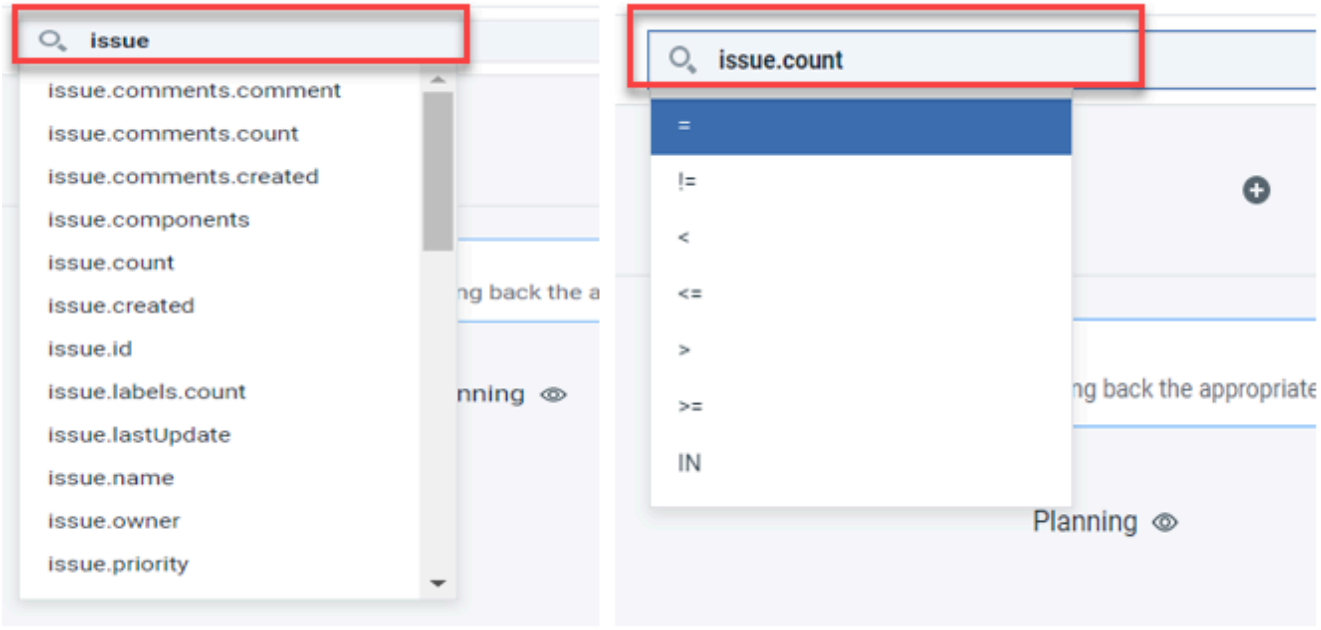
Table 1165. Query operators

Operator	Definition
=	equal
>	greater then
<	less than
>=	greater than or equal to
<=	less than or equal to
!=	not equal
""	required for exact phrase match with spaces
( )	order of operations grouping
`AND` or `and`	conjunction for searching both values
`OR` or `or`	disjunction for searching one value or another
`IN`	disjunction for searching one value or another.

Table 1165. Query operators (continued)

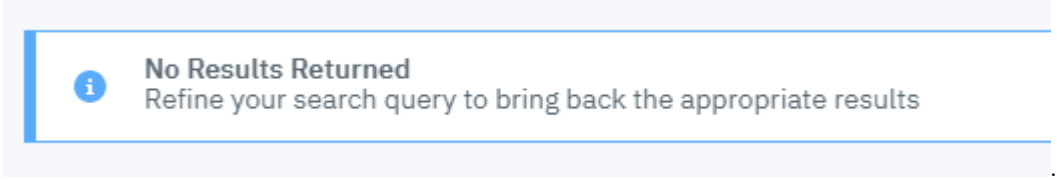
Operator	Definition
	Note: The `IN` operator is shorthand for the `OR` operator. Use the `IN` operator to avoid using multiple `OR` operators when you query in the same field.

Use **Search with DQL** field to search the dots with DQL queries on page 3118 and DQL operators on page 3121. The **Search with DQL** field displays all possible queries and operators for the typed



query.

Note: In case, no dots is available for the search data, value stream will display a error message.



.

The value types table describes the valid value types.

Table 1166. Value types

Value type	Definition
value	Supports any characters except whitespace or the following reserved characters : . = ! < > " ( )

Table 1166. Value types (continued)

Value type	Definition
quoted value	Characters are wrapped in double quotes. This type supports any character including those unsupported by value. For example: `“This is a quoted value”, “(This = valid input!)”`
time	Use to compare time fields. Valid input is a number followed by a measure of time, `(h = hours, d = days, w = weeks, y = years`. For example:`1w (one week), 10d (ten days), 3y (three years).`

External YAML configuration

You can create a minimal value realization of different DevOps tools into Measure quickly using external YAML configuration file.

You must define all your required configuration properties in `ucv.yaml` file, then you can import the `ucv.yaml` into Measure and apply the configurations defined in the YAML file.

You must perform the following steps to see the minimal value realization of DevOps tools into Measure:

Creating the YAML configuration file in GitHub repository

You can create YAML configuration with the properties of required DevOps tools.

The following table describes the properties required to define the configuration in the YAML file.

Property name	Type	Description	Required
version	String	The version number of the YAML file.	Yes
integrations	Array	List of integration configurations	Yes

Integrations

You must define the integration properties that include **type**, **attributes**, and **configs.** The following table describe the details of **type**, **attributes**, and **configs** properties:

Property name	Type	Description	Required
type	String	Type or category of the CI/CD tool.	Yes

Property name	Type	Description	Required
attributes	Object	Additional attributes specific to the integration.	Yes
configs	Object	Configuration object for the integration.	Yes

Configs

The following table describes the properties that you must define under the configs property:

Property name	Type	Description	Required
name	String	Name of the configuration.	Yes
loggingLevel	String	Logging level for the integration.	Yes
deltaTime	String	Time difference for the integration.	Yes

Depending on the integration type, additional configuration properties might be required. For more information about the additional configuration properties, see Measure plug-in configuration.

Sample YAML configuration file

The following sample shows a YAML configuration file with two integrations:

```
version: "8.0.0"
integrations:
  - type: ucv-ext-deploy
    attributes:
      auto-config: true
    configs:
      name: Deploy Integration
      loggingLevel: DEBUG
      deltaTime: '2023-05-15T18:30:00.000Z'
      # Additional integration-specific fields for Deploy Integration

  - type: another-integration
    attributes:
      auto-config: true
    configs:
      name: Another Integration
      loggingLevel: INFO
      # Additional integration-specific fields for Another Integration
```

Importing YAML configuration file to Measure

The YAML configuration file must be imported into Measure before you can apply the configurations defined in the YAML file.

You can import the YAML configuration file into Measure by any one of the following methods:

Importing YAML configuration file using GitHub plug-in integration

You can import the YAML configuration file into HCL DevOps Velocity (Velocity) by integrating GitHub repository that contains the ucv.yaml file.

1. Log in to Velocity.
2. Click **Settings > Integrations**.
3. In the Installed tab, click **Add Integration** for the installed GitHub plug-in.

   Note:
   - If the GitHub plug-in is not installed, go to Available tab and click Install for the GitHub plug-in.
   - Ensure that you add integration with GitHub plugin version 1.4.5 or later to sync the YAML configuration file.

4. Enter the details in the required fields to add the GitHub integration.
5. Click **Add** to save the details and enable the integration.

   Result

   After integration, the YAML configuration file from the GitHub repository is automatically synced to Velocity and displayed under **Settings > External config pipeline**.

   Note: If you want to make changes to YAML configuration file, you can update the file in GitHub repository and it is automatically synced to Velocity.

Results

You have successfully imported the YAML configuration file from the GitHub repository into Velocity.

Importing YAML configuration file using user interface

You can import the YAML configuration file into HCL DevOps Velocity (Velocity) using user interface if it is not hosted in a GitHub repository.

1. Log in to Velocity.
2. Click **Settings > External Config Pipeline**.
3. Click **Download sample yaml** to download the sample YAML file.

   Result

   The sampleYamlFile.yaml file is downloaded.
4. Edit the sample file with the actual values of your configuration.
5. Click **Add new config file**.

   Result

   Add New Config dialog opens.
6. Click **Choose file** to select the modified file.

7. Click **Confirm** to upload the file.
   Result
   The modified YAML configuration file is displayed in the configuration files list.
8. To modify the existing YAML configuration file, perform the following steps:

   a. Click the overflow menu for the required YAML configuration file and select **Edit**.

   Note: You cannot make changes to YAML configuration file that is imported through GitHub integration from UI, to make changes you can update the file in GitHub repository and it is automatically synced toVelocity.

   Result
   The existing YAML configuration file is downloaded.

   b. Edit the downloaded YAML configuration file.

   c. Click the overflow menu for the YAML configuration file which you have edited and then click **Update**.
   Result
   Update config dialog opens.

   d. Click **Choose file** to select the edited file.

   e. Click **Confirm** to upload the file.
   Result
   Yaml config added successfully message is displayed.

Results

You have successfully imported the YAML configuration file into Velocity form user interface.

Applying the YAML configuration file to Measure

You must apply the YAML configuration file to Measure for viewing the configuration defined in YAML file.

About this task

After you import the YAML configuration file, you can apply the configuration to Measure.

1. Log in to Measure.
2. Click **Settings > External Config file**.
3. Choose the required YAML configuration file in the list and click the right angle bracket to preview the configuration details.

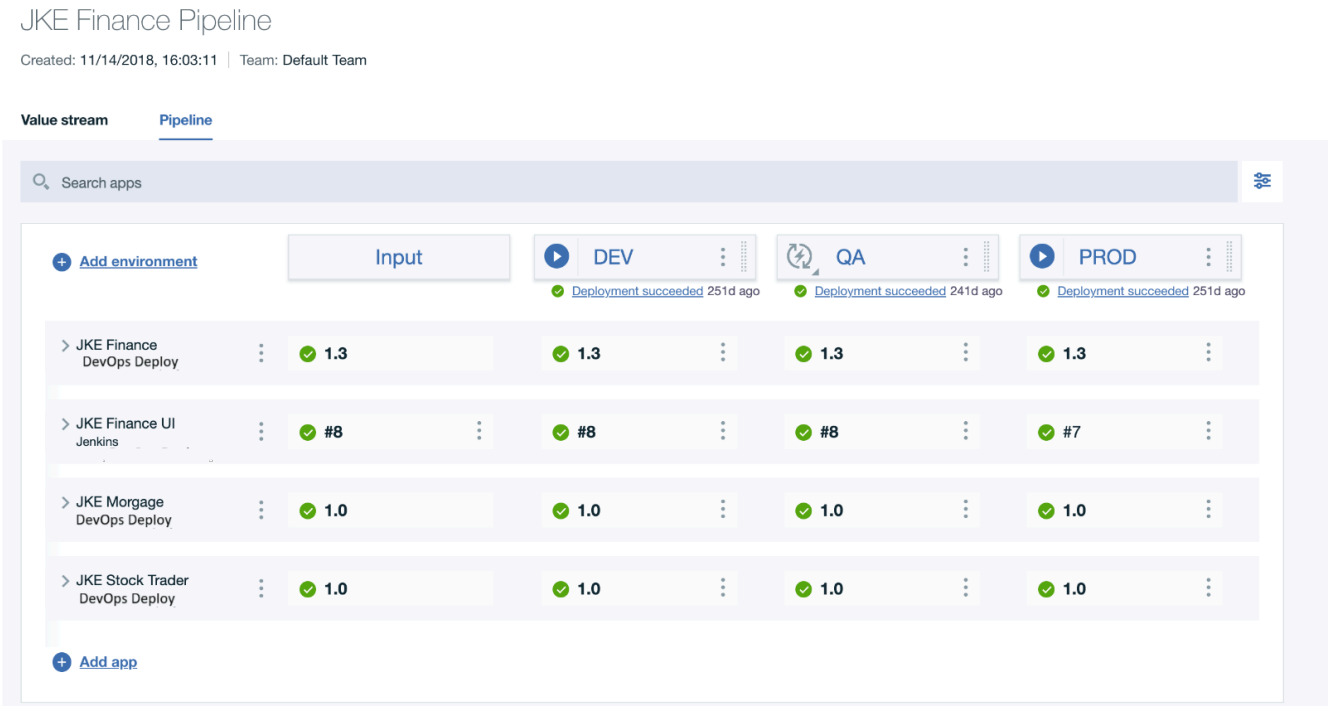
4. Click **Apply** to apply the required YAML configuration file to Velocity.
5. Click the overflow menu ⋮ for the required YAML configuration file and then click **View logs** to view logs for the integration.

Pipelines

Pipelines provide a streamlined method to manage the applications in your development lifecycle. With pipelines, you can auto-generate deployment plans and deploy applications versions to all environments.

A pipeline represents the environments and applications that you use to drive your development lifecycle. Environments are logical groupings for applications and tools. This process is intended to increase application quality before delivery to the target environment. A typical pipeline is shown in the following graphic:

Figure 23. Pipeline



Pipeline features include the following items:

- A pipeline represents the applications integrated into the value stream from Measure or Jenkins.
- The top row identifies the environments and provides tools to manage the environment.
- Each column represents a logical environment.
- The rows represent application versions. You can drill down to the underlying applications to view releases, history, or to troubleshoot.
- You can use the play button at the top of an environment to manually start a deployment. By default, this action deploys all changed applications in parallel.

- You can schedule deployments.
- You can add gates to environments that require approval before application versions can run in the environment.

Note: Ongoing active pipeline improvements are in process for robust performance capabilities including the following:

- Running deployments through the pipeline is documented here on page 3153 and there are gaps between the currently documented features and capabilities of these new plugins.
- Externalizing new deployment CI/CD plugins integrating with Measure.
- Performing deployments using the Deploy and Azure DevOps plugins and greater flexibility.

Pipelines accept input from either source control management (SCM) repositories or other external applications, such as Deploy. When you create an environment, some default settings are set for you on the **Input** environment.

You add applications to the pipeline from external tools that are integrated with the product, such as Jenkins™. Jobs run serially; they enable flow control for your work. For example, you might run a job in a test environment before deploying to the production environment. You can ensure that if the tests fail, the deployment job won't run.

You can add gates to environments. A gate is a condition that must be met before jobs can run in the environment. For example, you might add a gate that requires an approval before a job can start.

You can define environment properties that can be used in all jobs. For example, you might define a `TEST_URL` property that passes a single URL to deploy and test jobs in a single environment. The deploy job would deploy to that URL, and the test job would test the running app at the URL.

Each pipeline environment automatically has a release and deployment plan associated with it. You do not have to manually create a release beforehand. As you add applications to an environment, a task is automatically added to the default deployment plan.

When you run a pipeline application, a deployment starts that uses the associated deployment plan. You can monitor the progress of the deployment with links provided on the stage card.

Next to each pipeline, you can see a Value Stream icon. Click the icon to view the corresponding Value Stream page.

Managing pipelines

Add applications and jobs to your pipeline, and add or modify stages.

About this task

A pipeline is created when you create a value stream. If, for example, you create a value stream named "My Value Stream," a corresponding "My Value Stream" pipeline is also created. On the Home page, click Pipeline icon to go to the pipeline page.

You can add environments at any time and rearrange them as needed. Each application that you add to a pipeline is inserted onto a separate row below the last application. As you add apps and jobs to stages, tasks are added to the associated deployment plan in the order that they appear in the pipeline.

To modify a pipeline, complete the following steps:

1. **Optional:** On the **Pipeline** page, click **Add Environment** to create an environment, or stage.

    a. In the **Add environment** window, and in the **Environment name** field, enter the environment name.

    b. In the **Action** field, select the check boxes for the required deployment mode from the list of **Deploy**, **Join release**, and **Schedule deployment**.
    If more than one deployment mode is selected, both the default deployment mode play control and drop-down will be visible on the environment.

    The deployment mode play controls are as follows:

    - **Deploy**
    - **Join release**
    - **Schedule deployment**

    c. Based on the selected mode, in the **SET AS DEFAULT** field, select the default deployment mode.
    The deployment mode play control that is visible on the environment is the default.

    d. Click **Save**.

    e. Move the environment to the required location in the pipeline by hovering the mouse over the right-side of the environment, and then drag it to the required location in the pipeline.
    You can re-order the environments except for the first stage, **Input**.

    f. Click and select **Edit environment** to update the following parameters:

Parameter	Description
Environment name	The name of the environment.
Permitted actions	The actions to perform in environment. Possible actions are **Deploy**, **Join release**, and **Schedule deployment**.You can set any of these actions as **Default action**.
Groups and users allowed to perform actions	The group or user to perform the deployment in environment.

Parameter	Description
	Note: Only the selected group or user can perform the deployment in the environment.

In the **Edit environment** screen, select the groups or users who have permission to deploy in the selected environment.

Note: The group or user only can deploy to the selected environment.

g. Click ⋮ and select **Override inventory** to override the application in the deployment environment of pipeline. In the **Override inventory** screen, select the version for the application to override deployment in the selected environment. You can use **Override inventory** in all environments except **Input**.

2. **Optional:** To map an application environment to the pipeline, complete the following steps:

   a. For the environment where you want to add the application, click + **Add app**.

   b. On the **Add apps - Choose the apps** window, in the **Managed by** list, select the required application.

   c. Click **Save**.
   Result
   The application is added to the stage.

   d. To view the deployment template associated with the stage, click ⋮ and select **View deployment template**.
   Result
   The deployment plan detail page is displayed. As you add apps and jobs to the pipeline, associated tasks are inserted into the plan. You can also add tasks directly to the plan.

   e. To modify the mapped environment, click ⋮ and select **Edit application environments**.

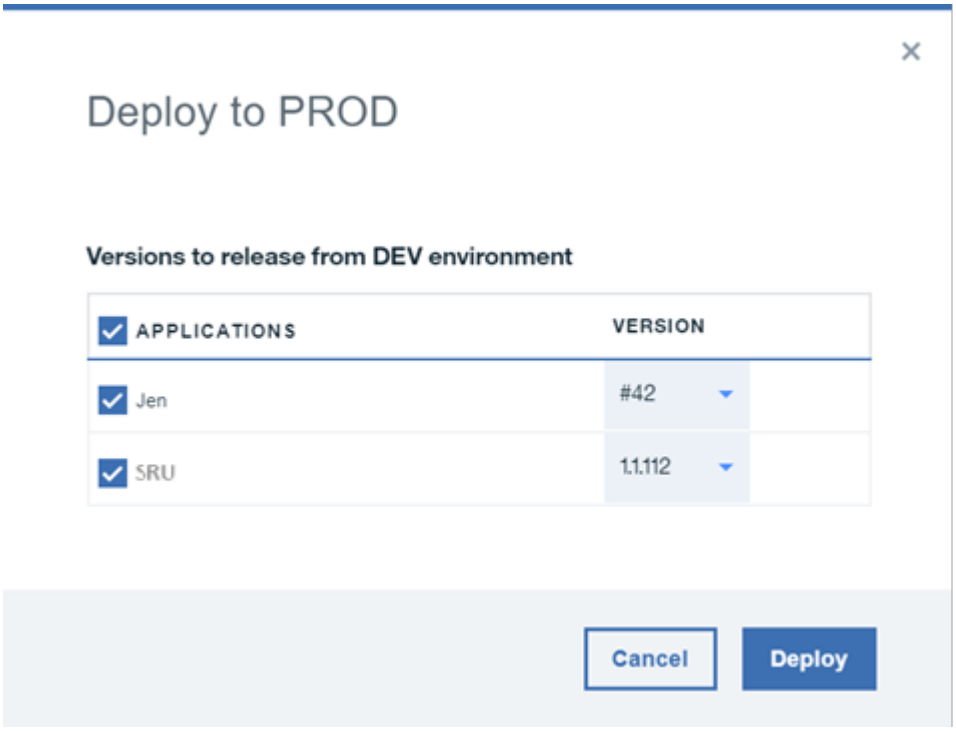
   f. To delete the environment, click ⋮ and select **Delete**.

3. **Optional:** To edit HCL DevOps Deploy (Deploy) application components already created on the pipeline, click ⋮ on the right side of the application and select **Manage components** to add and remove components of the application, **Edit description** to modify the description of the application in the selected pipeline, or **Delete application** to delete the application in the selected pipeline.
4. **Optional:** To add a gate on page 3145, click **Add gate** and then define the gate rule.
5. **Optional:** Click on the deployment mode play control to open the respective modal window.

The applications along with the versions deployed or joined releases in the previous environment will be available in the modal window dialogs shown in the figures below. The version to be deployed or joined releases for the selected application can be selected from the drop-down lists shown in the figures below.

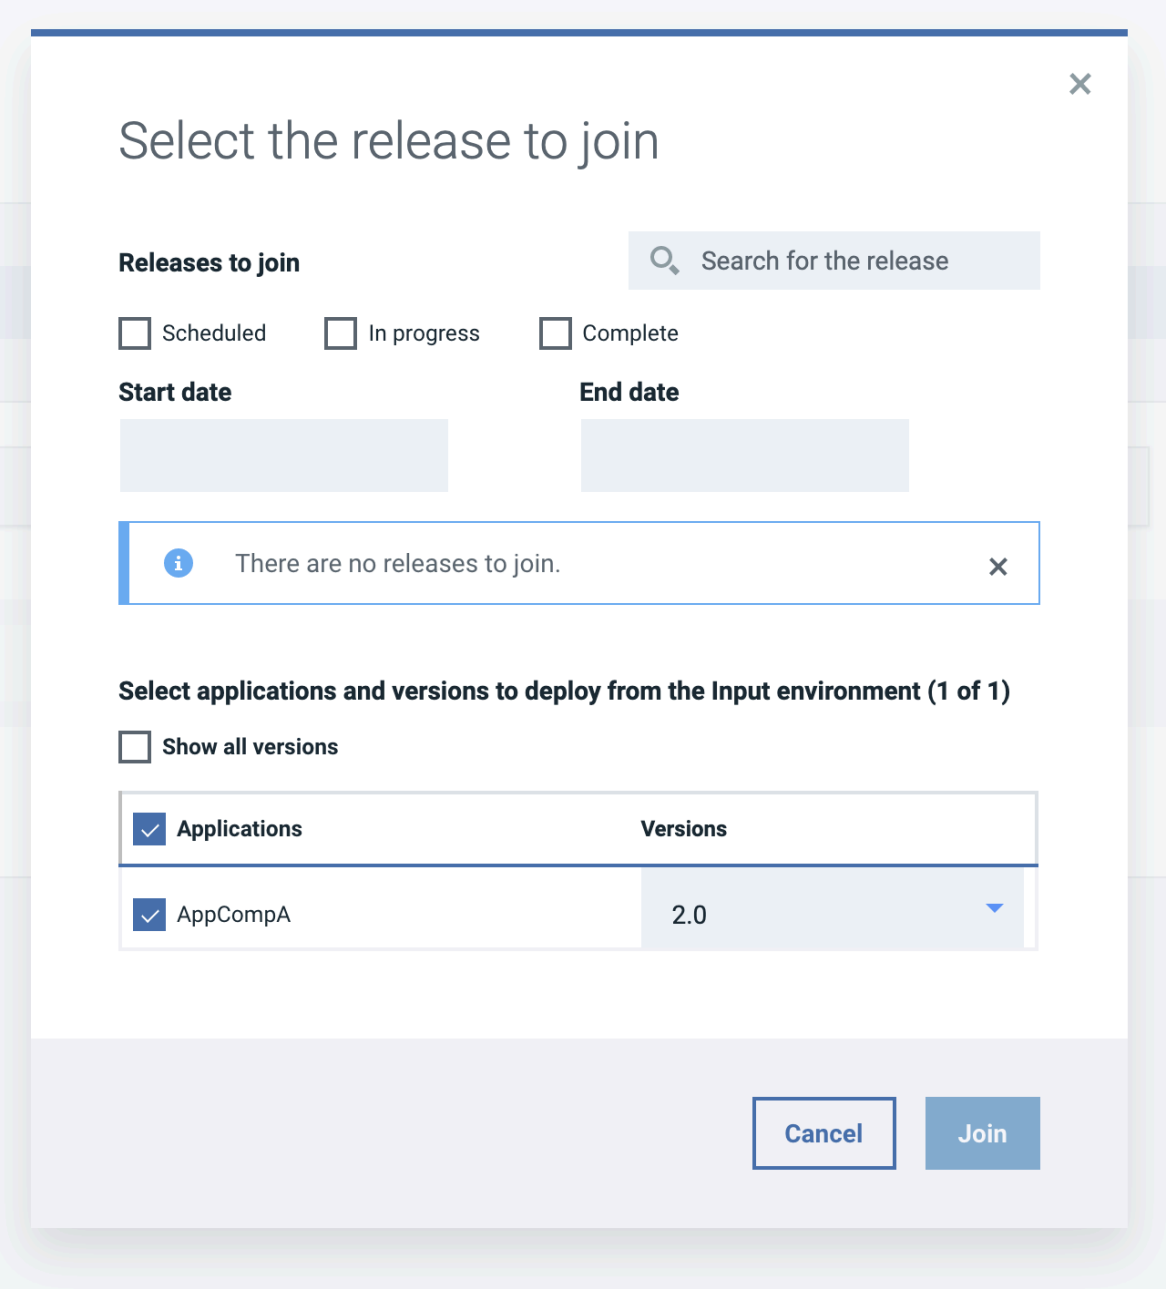
a. If **Deploy** is selected as the default deployment mode, the **Deploy** modal window is displayed.

Figure 24. Deploy modal window



b. If **Join release** is selected as the default deployment mode, the **Join release** modal window is displayed.

Figure 25. Join release modal window



Select the type of release from the below list to join,

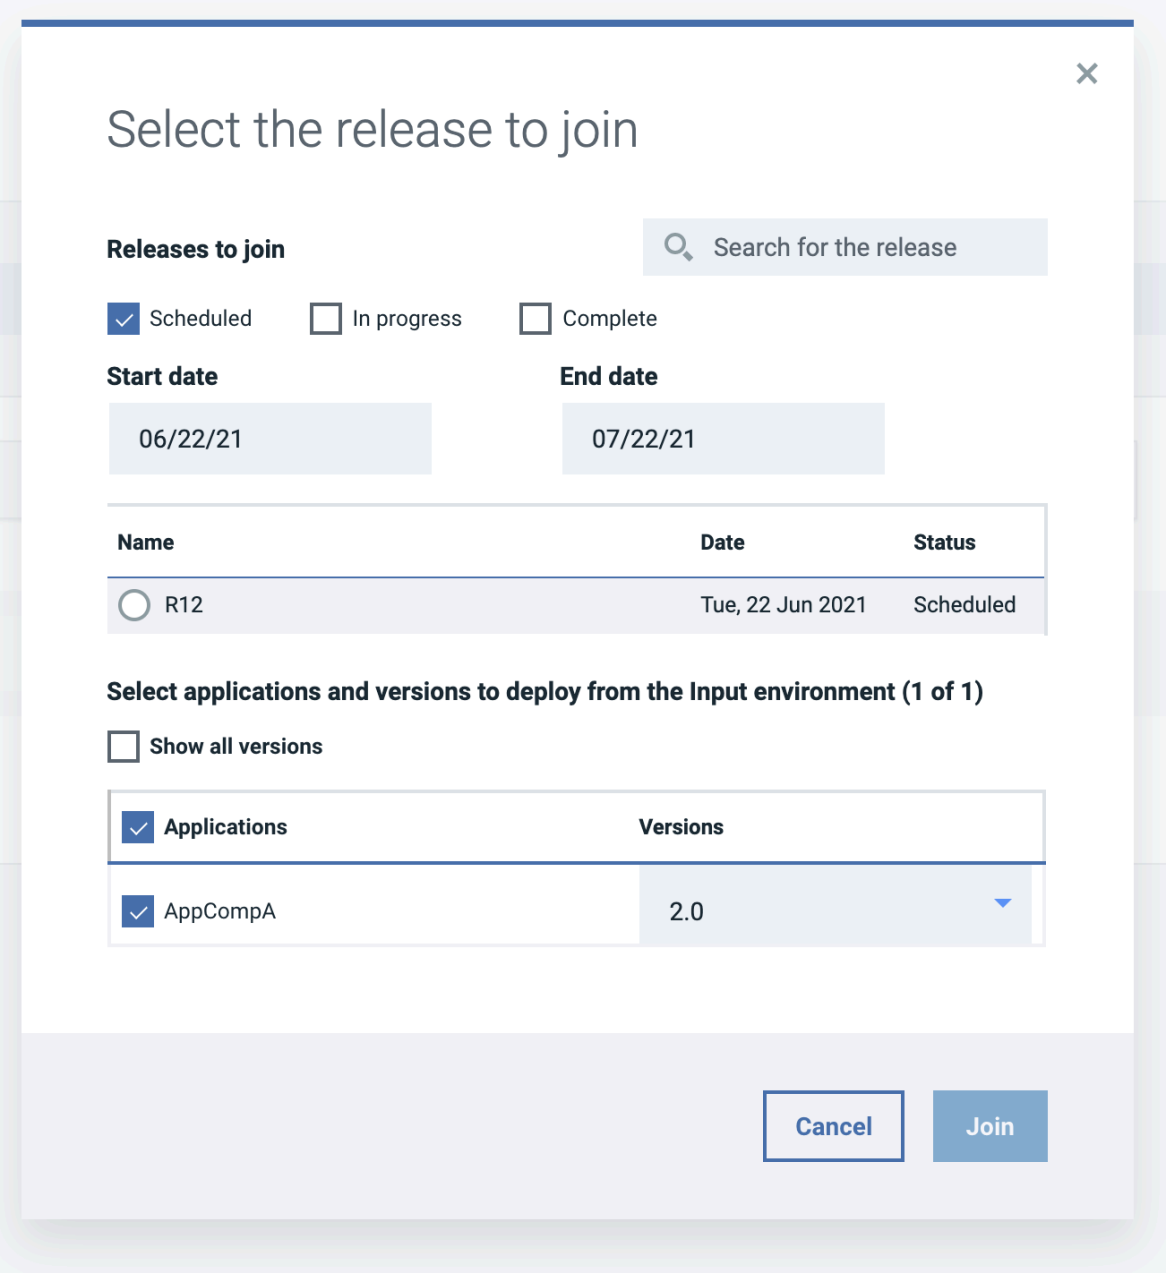
i. **Scheduled release**
ii. **In progress**
iii. **Completed**

With the release selected, select the date range to filter the available releases.

Select the required release **Name** from the list to join.

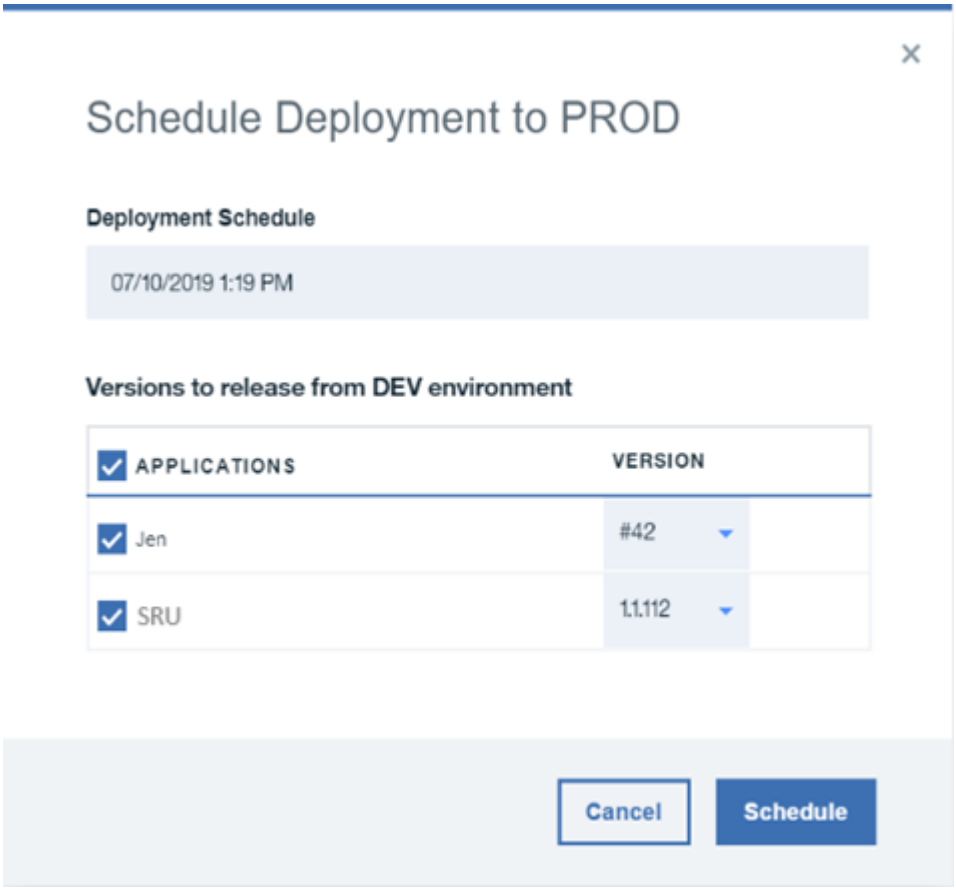
Select the **Application** and the required **Version** then click **Join** to join the release.

The below screen capture is an example for **Scheduled release** - **R12** in the date range of 06/22/2021 to 07/22/2021 for the version 2.0 of application **AppCompA**.



c. If **Schedule deployment** is selected as the default deployment mode, the **Schedule deployment** modal window is displayed.

Figure 26. Schedule deployment modal window



Example

After **Join release** is scheduled, the join release link appears below the **PROD** environment including the join release graphic and name. You can click the link to view the deployment plan page.

Figure 27. Join release link

You can use sort buttons for the alphabetical sorting of pipeline applications in ascending ( ) and descending order ( ).

What to do next

Run a deployment for a pipeline stage on page 3153.

Managing hybrid Continuous Integration (CI) and Continuous Deployment (CD) pipeline

You can create a hybrid CI and CD pipeline, add or modify the different applications and jobs to the pipeline.

About this task

Hybrid CI and CD pipeline enables you to integrate a combination of CI and CD applications to the associated deployment plan in the pipeline. Each application that you add to a pipeline is inserted onto a separate row below the last application. As you add apps and jobs to environments, tasks are added to the associated deployment plan in the order that they appear in the pipeline.

After you create the value stream, a pipeline is associated with your value stream by default. Each CI and CD application combination that you add to a pipeline is inserted onto a separate row below the last application. As you add apps and jobs to environments, tasks are added to the associated deployment plan in the order that they appear in the pipeline.

- The advanced features of hybrid CI and CD pipeline will work efficiently in Measure only when the hybrid CI/CD pipeline are not integrated with other applications.
- Whenever a user is migrating from a hybrid type environment to non-hybrid environment, ensure that all the CD physical environments that are deployed in the hybrid environment are removed. Otherwise, pipeline will not operate in the non-hybrid environment.

Limitations of hybrid CI and CD pipeline:

- The advanced features of the hybrid CI/CD pipeline will work efficiently in Measure only when the CD applications in the hybrid CI/CD pipeline are not part of any other pipeline.
- Migrating a CD application from the hybrid pipeline to the non-hybrid pipeline will not work without removing the CD application from all the logical environments in the hybrid CI/CD pipeline.

The following table provides the list of hybrid CI and CD applications currently supported in Measure:

CI application	CD application
• GitHub • Jenkins • DevOps Build	DevOps Deploy

Note: The **Full Resync** is not recommended for the applications which are part of hybrid CI and CD pipeline. You can remove the applications from the hybrid CI and CD pipeline to perform Full Resync.

1. **Optional:** On the **Pipeline** page, click **Add Environment** to create an environment.
    a. In the **Add environment** window, and in the **Environment name** field, enter the environment name.
    b. In the **Action** field, select the check boxes for the required deployment mode from the list of **Deploy**, **Join release**, and **Schedule deployment**.
    If more than one deployment mode is selected, both the default deployment mode play control and drop-down ▼ will be visible on the environment.
    The deployment mode play controls are as follows:
        - **Deploy**
        - **Join release**
        - **Schedule deployment**
    c. Based on the selected mode, in the **SET AS DEFAULT** field, select the default deployment mode.
    The deployment mode play control that is visible on the environment is the default.

d. Click **Save**.

e. Move the environment to the required location in the pipeline by hovering the mouse over the right-side of the environment, and then click and drag it to the required location in the pipeline.
You can re-order the environments except for the **Input**.

f. Click and select **Edit environment** to update the deployment mode.
In the **Edit environment** window, select the groups or users who have permission to deploy in the selected environment.

g. Click and select **Override inventory** to override the application in the deployment environment of pipeline.
In the **Override inventory** screen, select the version for the application to override deployment in the selected environment. You can use **Override inventory** in all environments except **Input**.

2. To add a CI application to the pipeline, perform the following steps:

a. To add the CI application, click **Add application**

b. On the **Add apps - Choose the apps** window, in the **Managed by** list, select a CI application.

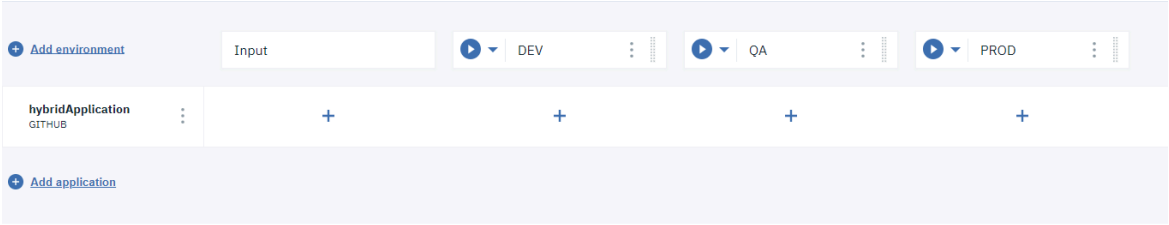
c. In the **Application name** field, enter a name for the application.

d. Click **Save**.

e. Under the **Input** environment, click to open the **Create version** window.

f. In the **Create version** window, select the required job from the list.

g. Click **Save**.



Result

You have successfully added a CI application to the pipeline.

h. In the CI application, run the build job selected in step 2.f on page 3137.

Result

You can see the build number under **INPUT**, after the build is successful in the CI application.

3. To add a CD application to the pipeline, perform the following steps:

a. Under the **Dev** environment associated with the application, click .

Note: The default environments are **DEV**, **QA**, and **PROD** environments. You can customize and create your own environments.

b. On the **Map a job to a logical environment (DEV)** window, in the **Managed by** list, select required CD application.

c. On the **Map app environments to logical environment (DEV)** window, click **Choose a different application...** > **Select your application,** choose the required application from the list, and then click **Continue**.

d. Select the process from the list, and then click **Continue**.

e. On the **Map app environments to logical environment (DEV)** window, select **dev** from the list, and then click **Save**.

Result

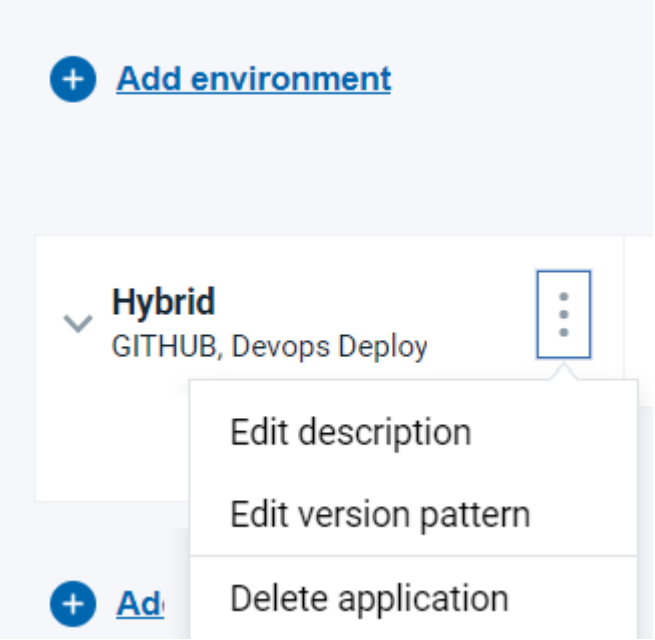
Similarly, you can map the app environments to any logical environment in the pipeline.

Result

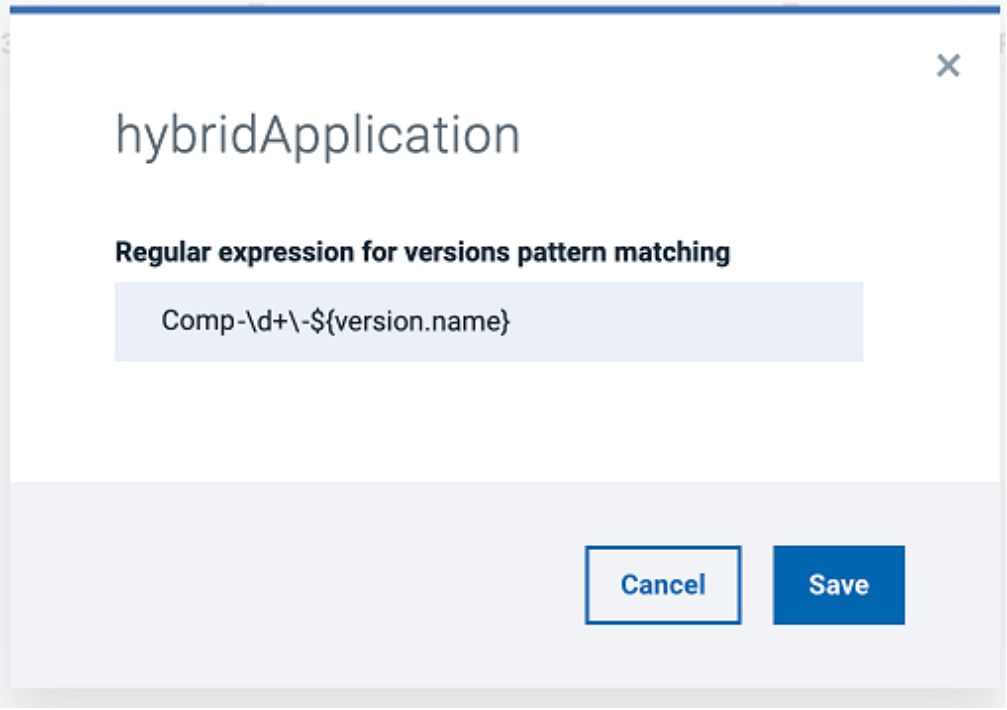
You have successfully added a CD application to the pipeline.

4. You have successfully created the hybrid CI and CD pipeline.
5. You can perform the CI and CD application versions matching by using any of the following methods:
   - **Strict matching**: To perform the strict matching of CI and CD application versions, ensure that the **snapshot name** in the CD application is same as the **build name** of the job in the CI application. Strict matching method is a default method for matching the CI and CD application versions.
   - **Regular expression matching**: To perform the regular expression matching of CI and CD application versions, perform the following steps:

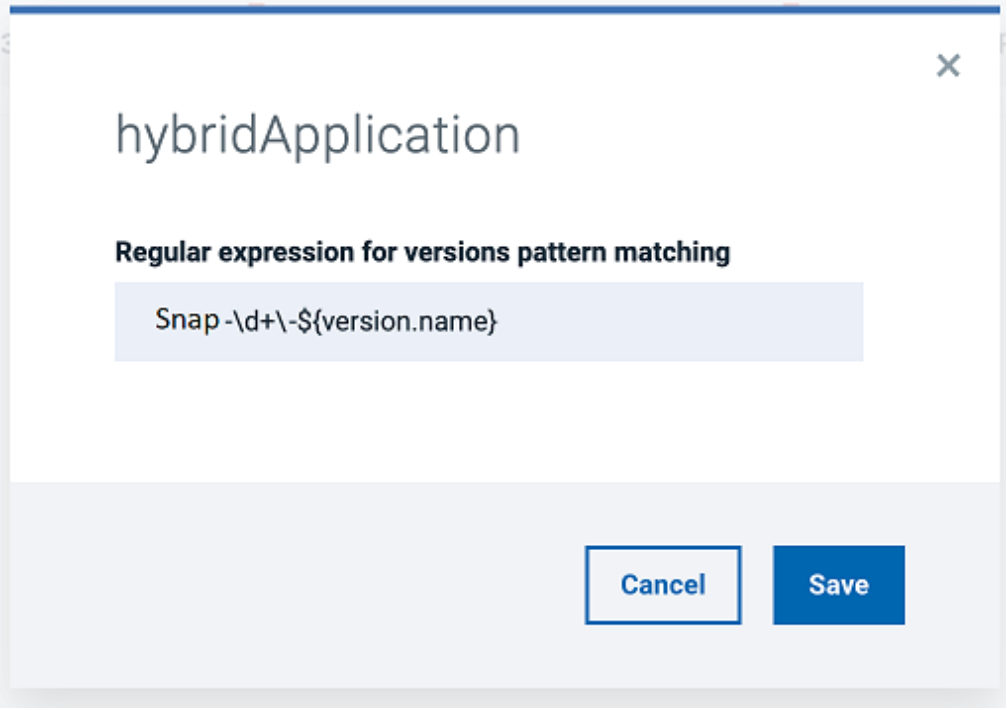
a. On the **Hybrid** CI and CD pipeline, click ⋮, and then select **Edit version pattern**.



b. On the **hybridApplication** window, perform any of the following actions to match the application versions in the CI application with the CD application.
   - **Component version pattern matching**: Add component version name for the CD application in the **Regular expression for versions pattern matching** field. Ensure that component version name of the CD application is same as the component version name of the job in the CI application.



- **Snapshot versions pattern matching**: Add snapshot version name for the CD application in the **Regular expression for versions pattern matching** field. Ensure that snapshot version name of the CD application is same as the snapshot version name of the job in the CI application.

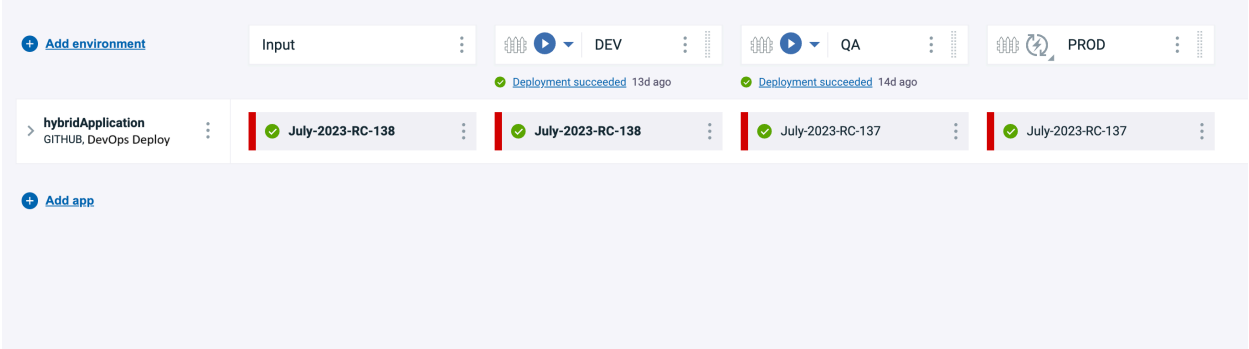


c. Click **Save**.

6. To view the deployment template associated with the environment, click ⋮ and select **View deployment template**.
   Result
   The deployment plan detail page is displayed. As you add apps and jobs to the pipeline, associated tasks are inserted into the plan. You can also add tasks directly to the plan.
7. To modify the mapped environment, click ⋮, and select **Edit application environments**.
8. To delete the environment, click ⋮ and select **Delete**.
9. **Optional:** To edit the hybrid CI and CD application components already created on the pipeline, click ⋮ on the right side of the application and select **Manage components** to add and remove components of the application, **Edit description** to modify the description of the application in the selected pipeline, or **Delete application** to delete the application in the selected pipeline.
10. **Optional:** To add a gate on page 3145, click **Add gate** and then define the gate rule.

Note: For **Automated** gates in the hybrid CI and CD pipeline, **application name** in metric input data should be **logical application name** which is defined in the hybrid CI and CD pipeline.

11. The following image is an example of the hybrid CI and CD pipeline with **DEV**, **QA**, and **PROD** environments.



What to do next

Run a deployment for a pipeline on page 3153.

Managing API-driven pipelines

API-driven pipeline applications

Before you begin

On the **Pipeline** page, you need to create a pipeline on page 3128 to incorporate API-driven applications.

About this task

API-driven pipeline applications enable you to effectively populate the pipeline and move dots through the system solely through build and deployment uploads. The create build and upload deployment API commands are displayed in the UI and can be executed in a command terminal. Advantages of using these build and deployment APIs are for providing simplified endpoints for loading data and allowing you to integrate the pipeline with unsupported tools. The relationship between the APIs and the pipeline phases that are populated are detailed in the following table.

API	Pipeline phases
builds/apiDriven	**Input**
deployments/apiDriven	**DEV**, **QA**, **PROD**, and any environments in the pipeline.

1. To map an application environment to the pipeline on the **Pipeline** page, complete the following steps:

    a. For the environment where you want to add the application, click **Add app**.

    b. On the **Add app - Choose the app** window, in the **Managed by** list, select **API-driven**.

c. Click either the **Create new application** or **Use existing appplication** radio button.

Note: The **Managed by** and **Description** fields are already populated with **API-driven**.

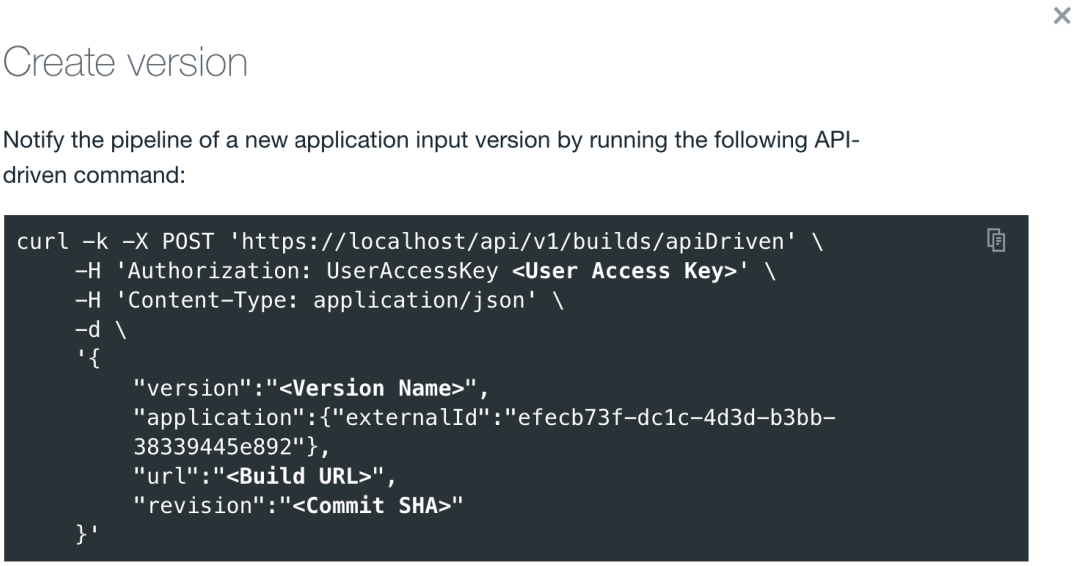
d. Based on the radio button you chose in the previous step, use the required procedure in the following table:

Create new application	Use existing application
In the **Application name** field, enter the name for the application.	This option links your pipeline application to an already existing application in Measure. You can use the API-driven REST API to create new versions and deployments for this application.
Click **Save** to add the application to the stage.	Click the **Existing application type** drop-down to list all the applications in your database and select the application. Note: If you want to use the API to create versions and run deployments for plugins without pipeline capabilities, select **Other**.
	Click the **Existing application name** drop-down to list and then select the application.
	Click **Save** to add the application to the stage.

2. To upload a build that will create a new version for the application, complete the following steps:

a. Click + under the **Input** stage of the pipeline for the **TEST API-driven Application** application, used as an example and shown in the figure below.

The **Create version** modal displays a curl command, shown in the figure below, to interact with the **TEST API-driven Application** REST API.



Note: The **Application name** entered previously in the **Add apps - Choose the apps** window is displayed in the **Create version** modal window above the `curl` command. Refer to this page on page 1891 for more details on the builds/apiDriven API.

b. Click to copy the curl command.

c. Paste the curl command in any text editor.

d. Edit the following user provided fields: `<User Access Key>`, `<Version Name>`, `<Build URL>`, and `<Commit SHA>`.

e. Copy the curl command.

f. Paste the curl command into a terminal or CI/CD automation scripts having network access to the Measure server.

Note: The displayed commands *only* work in the UNIX operating system. For MS-DOS operating systems, modifications will be required.

g. Run the curl command to update the new version of the application in **Input** environment.

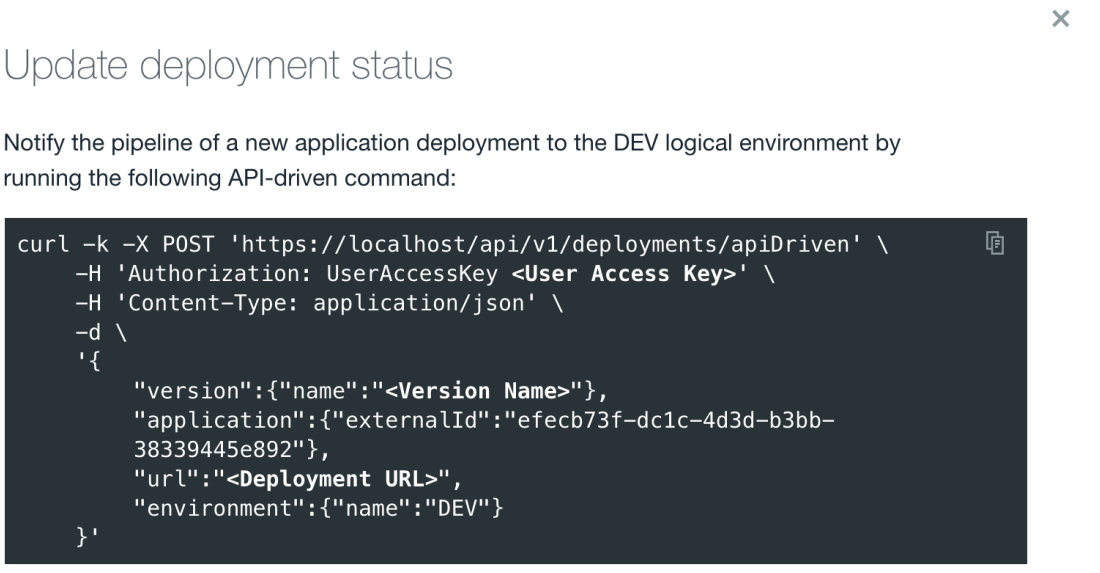
Note: Running these commands manually in a terminal are typically performed for several initial test runs. This method is *not* recommended for production use. For best practice, add the create build and upload deployment curl commands directly in the CI/CDs for automatic triggering.

Result

Succesfull run of the curl command updates the version of the application in all applicable pipelines.

3. Notify the pipeline of an **Input** version's deployment by completing the following steps:

a. Click + under the **DEV** stage of the pipeline for the **TEST API-driven Application** application, used as an example and shown in the figure of the previous step.
The **Create a deployment through the API (DEV)** modal window will display a curl command, shown in the figure below, to interact with the **TEST API-driven Application** REST API to upload a deployment to the aforementioned application.



Note: The **Application name** entered previously in the **Add apps - Choose the apps** window is displayed in the **Upload deployment status** modal window above the `curl` command. Refer to this page on page 1892 for more details on the deployments/apiDriven API.

b. Click to copy the curl command.

c. Paste the curl command in a text editor.

d. Edit the following user provided fields: `<User Access Key>`, `<Version Name>`, and `<Deployment URL>`.

e. Copy the curl command.

f. Paste the curl command into a terminal or CI/CD automation scripts having network access to the Measure server.

Note: The displayed commands *only* work in the UNIX operating system. For MS-DOS operating systems, modifications will be required.

g. Run the curl command to update the new version of the application in **DEV** environment.

Note: Running these commands manually in a terminal are typically performed for several initial test runs. This method is *not* recommended for production use. For best practice, add the create build and upload deployment curl commands directly in the CI/CDs for automatic triggering.

Result

Succesfull run of the curl command updates the version of the application in all applicable pipelines.

4. Perform the same for any required environments.

Managing pipeline gates

Gates ensure that orchestrations cannot be started in an environment until the gate rule is satisfied.

About this task

A gate is a condition that determines whether an application can run in the environment. A pipeline can have some environments with gates and some without gates. A gate condition is called a rule.

The **Gates readiness indicator** shows whether the gate rule is pass or fail for any environments in the pipeline.

In Measure 5.2.0, the gates readiness indicator verifies the status of gates rule of previous, current, and subsequent environments. There are three colors for gates readiness indicator such as Amber, Green, and Red. Each color represents the specific status of the gate rules.

Table 1167. Gates readiness indicator for 5.2.0

Gates readiness indicator	Gates rule for current and previous environment	Gates rule for subsequent environment
Amber	Fail	Pass
Green	Pass	Pass
Red	Fail or Pass	Fail

Note:

1. If there is no gates rule is set for subsequent environment, the gates readiness indicator is green for the current environment.
2. If there is no subsequent environment, the gate readiness indicator is green for the current environment.

In Measure 5.2.0, **Gates rule grouping** modal displays the gate rules and their status for each environment. There are four colors displayed for each environment based on the status of the gate rules. Each color denotes the specific status of the gate rules for each environment.

Table 1168. Gates rule status for 5.2.0

Gates rule status	Description
Amber with warning icon	Gate rules for current environment is pass but there is a gates rule failure in previous environment or approval is pending.
Green with check mark icon	Gate rules is pass for all current and previous environments.
Red with close icon	Gate rules is fail for current environment.
Gray with warning icon	Gate rules is applied but it is neither approved nor rejected.

In Measure 5.2.1 and later, the gates readiness indicator verifies the status of gates rule of the subsequent environment. There are three colors for gates readiness indicator such as Green, Grey, and Red. Each color represents the specific status of the gate rules.

Table 1169. Gates readiness indicator for 5.2.1 and later

Gates readiness indicator bar	Description
Green	Gate rules is passed or no gate rule set for subsequent environment.
Grey	Gate rule is set and it is neither approved nor rejected.
Red	Gate rule is failed in subsequent environment.

In addition to gates readiness indicator, there is an version name coloring which indicates that the previous environment failures. The version name get amber colored when there is failure in previous environment.

You can define a rule type based on the following criteria:

- **Approver** gate requires one or more responders to approve an application version before it can run in an environment. Approving a gate rule is considered passing the gate.

  Note: Anyone with access to the pipeline can create gates and be assigned as a responder. Scenarios detailing approval and rejection of application versions by responders are detailed below.
  - If a gate has multiple responders, one approval is sufficient for the application version to pass the gate.
  - If one responder rejects the application version, the application is rejected.
  - If responders both approve and reject the application version, the application is rejected.
  - When you add gates to an environment, all application versions in the affected environment must be approved before a deployment can be started. You can override a failed gate, that is, a rejected application version and you may want to do this when you run applications in a test environment.

- **Metric** gate leverages a metric-based system allowing you to automatically stop or advance application versions from being deployed into environments based on set conditions for the rule.

  Note: Using the metric rule type will provide you with visibility on the movement status of application versions and automated governance across your pipeline.

- **Compliance** gate enables you to control the deployment of application versions into different environments based on the conditions of the compliance rule.

  Note:
  - Currently under the Compliance gate, you can only create a rule for pull request approval.
  - Compliance rules are enabled only for the following type of applications:
    - Applications added by **Jenkins (Legacy)** plug-in.
    - Applications added by **Jenkins** plug-in.
    - Application added by external **HCL DevOps Deploy** and external **IBM DevOps Deploy** plug-ins and built using Jenkins. Ensure that the build details are pushed to Measure using the DevOps Deploy Jenkins publisher or pipeline plug-ins.

- **Status** gate allows you to define the statuses of a snapshot version in a Continuous Delivery (CD) application like DevOps Deploy and automatically stop or advance application versions from being deployed into different environments by matching the defined statuses with the actual statuses of the snapshot version.

  For example, when the two statuses **functional_testing** and **regression_testing** are added in the **Status** gate rule, the following scenarios illustrate when the gate will pass or fail:

Scenario 1: Status of a snapshot version in a CD application is empty.

In this scenario, the gate looks for both the **functional_testing** and **regression_testing** status in the snapshot version but the synced snapshot version will neither have **functional_testing** or **regression_testing**, so the gate will fail.

Scenario 2: Status of a snapshot version in a CD application is having one of the statuses added in the Status gate rule.

In this scenario, the gate looks for both the **functional_testing** and **regression_testing** status in the snapshot version, but the synced snapshot version will have either **functional_testing** or **regression_testing**, so the gate will fail.

Scenario 3: Status of a snapshot version in a CD application is having both the status added in the Status gate rule.

In this scenario, the gate looks for both the **functional_testing** and **regression_testing** status in the snapshot version, the synced snapshot version will have both **functional_testing** and **regression_testing**, so the gate will pass.

Scenario 4: Status of a snapshot version in a CD application is having both statuses and other additional status.

In this scenario, the gate looks for both the **functional_testing** and **regression_testing** status in the snapshot version, the synced snapshot version will have **functional_testing**, **regression_testing**, and other additional status so the gate will pass.

Scenario 5: Status of a snapshot version in a CD application is having one out of two statuses and other additional status.

In this scenario, the gate looks for both the **functional_testing** and **regression_testing** status in the snapshot version, but the synced snapshot version will have either **functional_testing** or **regression_testing**, and other additional status so the gate will fail.

Note:

- Currently the **Status** gate is not enabled for hybrid Continuous Integration/Continuous Deployment (CI/CD) pipelines. If you are using **Status** gates in hybrid CI/CD pipelines the gates will always fail.
- **Status** gate is enabled only for the applications added by the following **plug-in** versions of HCL DevOps Deploy and IBM DevOps Deploy:

- HCL DevOps Deploy 4.0.3 or later.
- IBM DevOps Deploy 4.0.3 or later.

1. For the environment where you want to add a gate, click ⋮ and select **Add gate**, and then perform the following steps.

   Note: For the environment where you want to modify a gate, click ⋮ and select **Edit gate**, and then complete the following steps.

   a. In the **Add gate** window, click **New Rule**.
   To use an existing rule, click **Existing Rules**.

   b. In the **Rule Type** field, select **Approver**, **Metric**, **Compliance**, or **Status**. Based on the **Rule Type** selected, use the following tables to add Approver, Metric, Compliance, or Status gates to environments.

Table 1170. Approver gate

"Approver" Add gate option	Value / action
Name your new rule	Enter a name for the rule.
Add Approver(s)	In the list, select responders.
Add Rule	Click to add gate to the environment, which is indicated by the **Gate** icon on the environment label. To view gate rules, click the **Gate** icon. A **Gate status** icon is added to the applications in the environment. **Note:** Initially, the **Gate status** is indicated by a vertical gray bar located to the left of the application version. If all application versions are approved, the gate is passed and the **Gate status** is a green bar. If application versions are rejected, the **Gate status** is a red bar.
Approver Rules statuses	Under the **Edit environment Gate Rules** on the right side of the **Add gate** window, you can view the statuses of the **Metric rules** and **Approver rules**. Under the **Approver rules**, select the **Send email alert to any user that requires manual approval** checkbox to receive email notification for approving the approver gates. The email notification is sent to all approver gate approvers. The approver gates approval email notification contains the **Stage Name**, **Approver Gate Name**, **Application Name**, and **Version Name** of the application for which the approval is requested.
Save	Click to populate the rule on the gate.

"Approver" Add gate option	Value / action
Send email notification to any user that requires manual approval	select the checkbox to send the e-mail notification for the designated approvers.

Table 1171. Metric gate

"Metric" Add gate option	Value / action
Name your new rule	Enter a name for the rule.
Description	Enter a description for the rule.
Metric Type	Select the required metric in the list from the following: **Coverage by Branch**, **Coverage by Function**, **Coverage by Line**, **Functional Tests**, **Static Code Analysis**, **Unit Tests**, **Container Vulnerabilities**, or **Application Vulnerabilities**. Descriptions for each **Metric Type** can be found here on page 3175.
Data Set	Select the required metric data set.
Field	Select the required field from the list. **Note:** The field is based on the **Metric Type** used for the metric rule and will be dynamically populated with selections associated with the metric. For example, if **Application Vulnerabilities** is selected, then **Blocker** will be the criteria measure for the gate.
Operator	Select the required operator from the list. **Note:** The operator is based on the **Field** that was selected and will be dynamically populated with selections suitable to the field. For example, if **Blocker** is the field, then the following list will be the available operators: **=**, **!=**, **>**, or **<**.
Value	Select the required value from the list.

"Metric" Add gate option	Value / action
	Note: The required value is entered based on the field and operator. For example, a value of zero indicating **Blocker** = 0 as the rule to pass the gate.
Occurrence period	Select the required occurrence period for the rule from the following list: **None**, **Minutes**, **Hours**, **Days**, **Weeks**, or **Months**.
Duration	Enter the duration for occurrence period of the rule.
Add Rule	Click to add gate to the environment, which is indicated by the **Gate** icon on the environment label. To view gate rules, click the **Gate** icon. A **Gate status** icon is added to the applications in the environment. **Note:** If all the application versions satisfies the added **Metric** rule, the gate is passed and the **Gate status** is a green bar. If application versions are rejected, the **Gate status** is a red bar.
Metric Rules statuses	Under the **Edit environment Gate Rules** on the right side of the **Add gate** window, you can view the statuses of the **Metric Rules**.
Save	Click to populate the rule on the gate. **Note:** For the above example of **Blocker** = 0, you may notice all the versions have a red bar indicating each had a blocker because of a failure with security scan.

Table 1172. Compliance gate

"Compliance" Add gate option	Value / action
Name your new rule	Enter a name for the rule.
Description	Enter a description for the rule.
Resource Type	Select the resource type from the list.
Field	Select the required field from the list.
Operator	Select the required operator from the list.

"Compliance" Add gate option	Value / action
	Note: The operator is based on the **Field** that was selected and will be dynamically populated with selections suitable to the field.
Value	Select the required value from the list. **Note:** The required value is entered based on the field and operator.
Add Rule	Click to add gate to the environment, which is indicated by the **Gate** icon on the environment label. To view gate rules, click the **Gate** icon. A **Gate status** icon is added to the applications in the environment. **Note:** If all the application versions satisfies the added **Compliance** rule, the gate is passed and the **Gate status** is a green bar. If application versions are rejected, the **Gate status** is a red bar.
Compliance Rules statuses	Under the **Edit environment Gate Rules** on the right side of the **Add gate** window, you can view the statuses of the **Compliance Rules**.
Save	Click to populate the rule on the gate.

Table 1173. Status gate

"Status" Add gate option	Value / action
Name your new rule	Enter a name for the rule.
Description	Enter a description for the rule.
Status (Comma Separated List)	Add the statuses which you want to match with the snapshot version in a CD application. You can add multiple statuses by separating them with a comma. Note: status names are case sensitive, enter the exact name in the snapshot version, if not the gates will fail.
Add Rule	Click to add gate to the environment, which is indicated by the **Gate** icon on the environment label. To view gate rules, click the **Gate** icon. A **Gate status** icon is added to the applications in the environment. **Note:** If all the status defined in the status rule matches the status added in the snapshot version, the gate is passed and

"Status" Add gate option	Value / action
	Gate status is a green bar. If the statuses does not match the gates are failed, the **Gate status** is a red bar.
Status Rules statuses	Under the **Edit environment Gate Rules** on the right side of the **Add gate** window, you can view the statuses of the **Status Rules**.
Save	Click to populate the rule on the gate.

c. In the **Add gate** window, on the right side, you can hover over a rule and click **Remove rule** to delete the individual rules.

2. In the **Environment** stage, click the **Gate** icon to view the gate rules.
   Result
   You can see the number of rules and approvers for each gate.
3. In the **Pipeline** window, click the **Gate status** icon for the application version with the gate to open **Version Rules** window.
   Result
   You can see the status of the gates and designated approvers can approve or reject the approver gate rule.
4. On the **Version Rules** window, click **Approve** or **Reject** and then click **Save** to approve or reject the approver gate rule.

   Note: If you are an approver for multiple rules, you can approve all or some of them and reject others. If you are not a designated responder, you can neither approve nor reject the gate rule.

5. For the environment where you want to delete a gate, click and select **Delete gate**.

What to do next

Run a deployment for a pipeline stage on page 3153.

Running pipeline applications

Run applications in a pipeline environment.

About this task

You can manually run an on-demand deployment, schedule a deployment for a later time, or join a deployment to a release. When you start a deployment, the deployment plan template associated with the environment is used. Tasks for applications in the environment are run in order starting with the first task defined in your deployment plan template. You can view the deployment's progress by using the supplied link.

1. To run a deployment, complete the following steps:

    a. On the **Pipeline detail** page, click the environment's **Deploy** button.
    The **Deploy** button is available if you have sufficient permissions to run applications in the environment.

    b. In the **Deploy to** window, select the applications that you want to run in the environment.
    By default, all applications are selected in which the latest version in the previous environment has not yet been deployed.

    c. In the **Version** column, select the version.
    If an environment has a gate rule assigned to it on page 3145, only application versions that pass the gate rule can deploy. Versions that have passed the gate rule have the status of **Passed**.

    Note: For hybrid CI/CD pipelines, only the matched versions will be available for deployment.

    d. If a gated environment has an unapproved application version, approve the version.
    Only users who are designated responders can approve or reject application versions.

    Note: You can override rejected application versions. To deploy a rejected version, confirm that you intend to override the gate and run the deployment anyway. To override a gate, you must be assigned the Lead Release Manager or Release Manager roles.

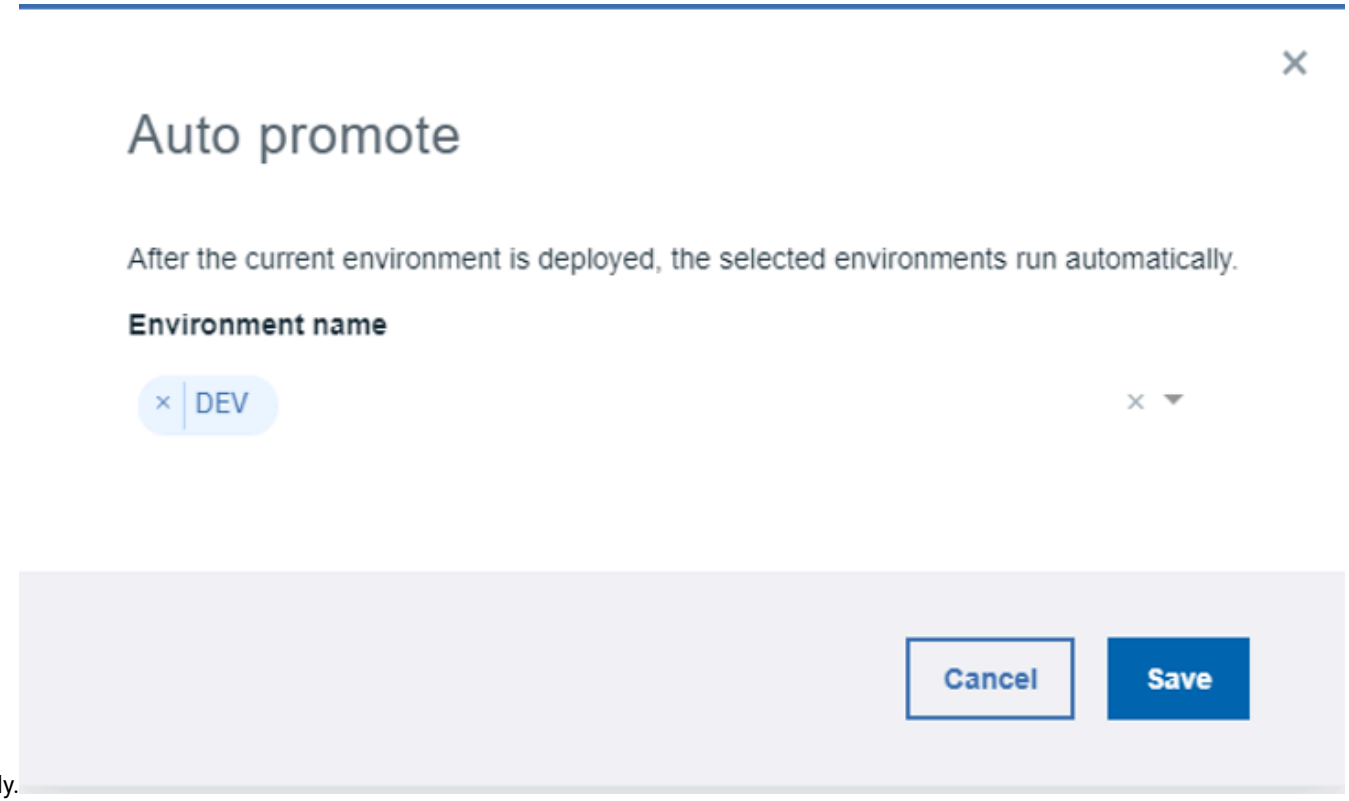
    e. Click **Deploy**, to run the selected application versions.
    Result
    A deployment starts with the deployment plan associated with the environment.

2. **Optional:** To schedule a deployment for a stage, click **Schedule deployment** on the context menu for the stage, and then select a future date and start time.
    A deployment for the stage deployment plan will start at the scheduled time. Pipeline scheduled deployments are displayed on the calendar.
3. **Optional:** To join a deployment to a release, click Join release on the context menu for the stage, select an associated release, and then a application version. The release must have been preemptively created. The deployment plan will start based on the scheduled start time of the selected release.
    If you would like to start it earlier, you can start the deployment by manually starting one of the eligible deployment plan tasks, or click **Edit this plan** on the deployment plan in the release. As with other deployment plans, you can add and delete tasks on the pipeline-generated plan at any time. On the release or plan page, use the **Go to pipeline...** link to open the associated pipeline or stage.

What to do next

You can auto-promote DevOps Deploy and Jenkins application from input stage to any other stage environments. To auto-promote, click ⋮ icon next to **Input** and then select **Auto promote**. In the following modal, select or deselect the environment(s) you wish to promote your version.

The auto-promote process will consider your gating criteria when determining whether to deploy the new version automatically.



Note: You can deploy the application manually in the auto-promotion environment. Click icon in stage and then select **Deploy** to deploy the application manually.

Running open pipeline deployment

You can run the deployment and release of the application using the Measure pipeline.

To run a deployment from Velocity pipeline perform the following steps,

1. Create a pipeline for the project in plugin.
2. Link the project to the repository in plugin.
3. Integrate the plugin by following the steps in integration section.
4. Add plugin project to the environment of Measure pipeline by following the steps in managing pipeline section on page 3128.
5. The latest build version of the plugin project gets populated in the **Input** stage of the Measure pipeline.

6. To deploy the application, click for the environment and select the required version of the project for deployment.
7. Click **Deployment from plan** to view the deployment task status. After the completion of deployment task, the status changes to **Complete**.
8. The result of the project deployment is updated in pipeline.

Solution versions

Solution version is a combination of different versions of one or more applications in a pipeline.

You can use a solution version to combine the required application versions from the pipeline and deploy them to different stages. A solution version includes the application versions that are tested and working in a stage and can be deployed into any stage in the pipeline. You can roll back or upgrade the version of applications in the solution version. You can add only the compatible combinations of application versions to the solution version.

The solution version is built incrementally to ensure that the tested combinations are included. You can create only one solution versions with a combination of deployed applications versions in a stage. You can deploy the solution version created in a stage into other stages in the pipeline.

During the build phase, a solution version is called a solution draft version. Any changes to the deployed application versions of a draft solution version in a stage are updated automatically in the solution version inventory. You can edit the combination of applications by editing the draft solution version. After the solution version is published, the version of the solution version is locked and its inventory cannot be updated.

When a new solution version is deployed in the stage where there is already a solution version is deployed, then the published solution version is either reverted to draft status or removed completely.

Enabling the solution version feature on Measure

When you want to use the solution version on Measure, you must enable it.

1. Log in to Measure.
2. Navigate to the following URL:

   `https://hostname:port/featureflags`

   Result

   The **Feature Flag** page is displayed.
3. In **Enter a feature name to enable it** field, enter `pipeline-solution-versions`.
4. Click **Enable**.

Results

You have enabled the solution version feature on Measure.

Adding an application to the pipeline

You can add an application to the pipeline in Measure.

Before you begin

You must have created a default or any customised value stream in Measure.

1. Perform the following steps to add an application to the pipeline:
    a. In the Measure home page, on the left navigational panel, click .
    Result
    The value streams that you created are displayed.
    b. Select the value stream that you created from the list.
    c. Click **Pipeline** on the panel.
    Result
    The **Pipeline** page is displayed for the value stream.
    d. Click **Add application**.
    Result
    The **Add app - Choose the app** window is displayed.
    e. In **Managed by** list, select application.
    f. In **Application name** field, enter a name for the application.
    g. Optional: In **Description** field, enter a description for the application.
    h. Click **Save**.
2. Perform the following steps to create a version for the application in the pipeline:
    a. Click **Create version** under the **Input** column.
    Result
    The **Create version** window is displayed.
    b. Select the required job from the list, and then click **Save**.
3. Perform the following steps to map the application to **DEV** environment:
    a. Click under the **DEV** column.
    Result
    The **Map a Jenkins job to a logical environment (DEV)** window is displayed.
    b. Select the required job from the list, and then click **Next**.

c. Specify a build number or select **${version.buildNumber}** from the **buildNumber** list. and the click **Next**.

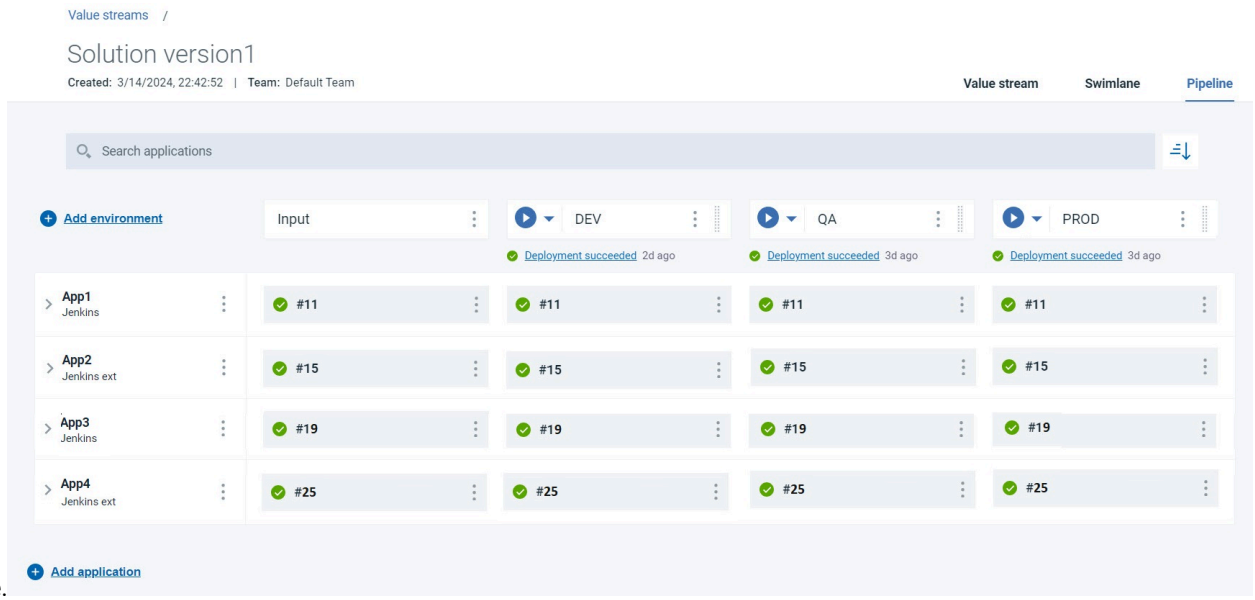
d. In **Select Version Parameter** list, select **buildNumber**.

e. Click **Save**.

Result

Similarly, you can map the app environments to any logical environment in the pipeline.

4. If required, do the above steps again to add the applications and map them to the pipeline.



Results

You have added an application to the pipeline.

Creating the solution version

You can create a solution version in the pipeline stage with combination of application versions.

Before you begin

You must have completed the following tasks:

- Enabled `pipeline-solution-versions` option in feature flags page.
- Created a pipeline with one or more applications.
- Deployed the applications in the pipeline.

About this task

You can create a solution version with a combination of the applications version in the pipeline.

1. Perform the following steps to navigate the required pipeline page:
    a. In Measure home page, on the left navigational panel, click .
    b. Select the required value stream from the list.
    c. Click **Pipeline**.

    Result

    The **Pipeline** page is displayed.
2. Perform the following steps to create a solution version:
    a. On the **DEV** environment, click , and then select **Solution Version > Create**.

    The **Create Solution Version** window is displayed.

    Note: An error message **At least one application version must be there to create solution version** will be displayed if application version is not created for the application.

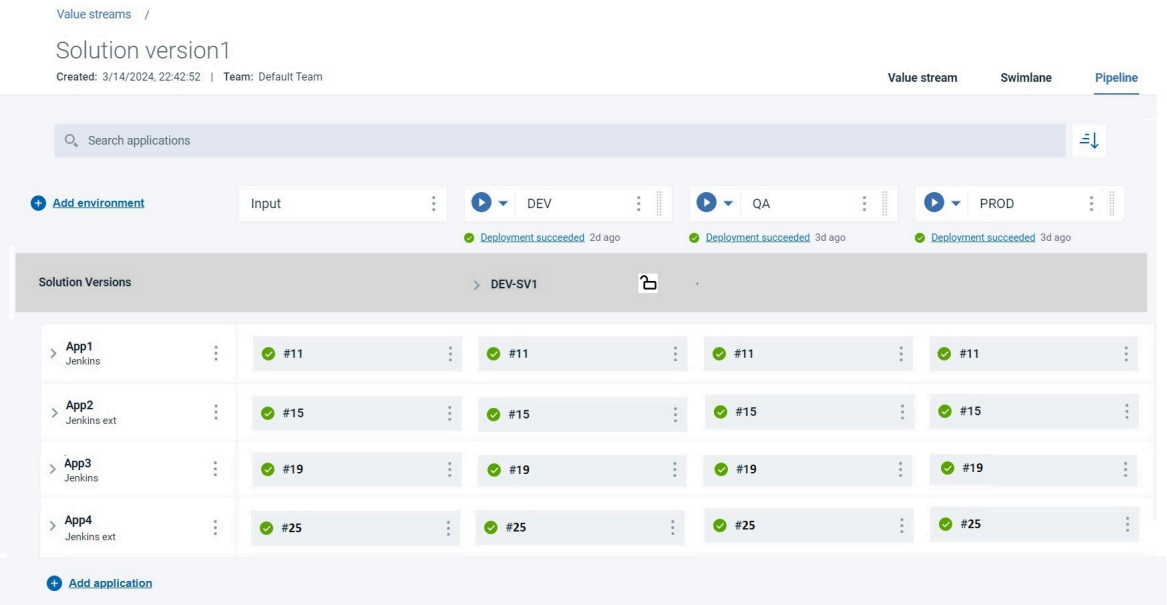
    b. In the **Name** field, enter a name for the solution version.
    c. Optional: In the **Description** field, enter a description for the solution version.
    d. In the **Versions** list, select the Application versions based on the requirement.

    For example, if you have added four applications such as **APP1**, **APP2**, **APP3**, and **APP4** to the pipeline, the **Versions** filter displays the **APP1**, **APP2**, **APP3**, and **APP4** with the version numbers.

    You can select the required applications version from the list when you create the solution version.
    e. Click **Create**.

    The **Solution Versions** row is displayed below the **Environment** column.

    The draft solution version is created for **DEV** environment. The draft solution version is indicated with icon.

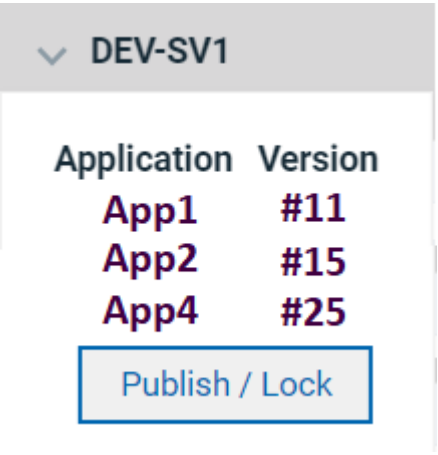


You can create the solution version for all the stages in the pipeline except for the **Input** phase.

Note: Only the deployed solution versions are displayed in the **Solution Versions** row in the pipeline page. You can create a solution version with different combination of application versions and deploy them in any stage. You can create one solution version It is not allowed to create multiple solution versions for a particular stage.

f. To view the application versions linked to solution version, click icon on the solution version .

A window is displayed with the application versions liked to the solution version.



The above example shows that the **App1**, **App2**, and **App4** were added to the solution version **DEV-S1**.

Results

You have created a draft solution version in the pipeline stage.

Related information

Managing pipeline gates on page 3145

Editing the draft solution version

You can edit the draft solution version to update name, description, and application version combinations.

About this task

You can edit the draft solution version at all the stages in the pipeline. It allows you to update the name and select the required application versions. The draft solution version is indicated by icon. It is not possible to edit the solution versions that are locked or published.

1. Click , and then select **Solution Version > Edit**.
   Result

   The **Edit Solution Version** is displayed.
2. You can perform the following actions:
   - Modify the name and description for the solution version.
   - Choose the application versions from **Versions** list.
3. Click **Save**.

Results

You have edited the draft solution version.

Publishing the draft solution version

You can publish the draft solution version in the pipeline stage to lock the application versions.

About this task

You can publish the draft solution version at all the stages in the pipeline to lock the application versions. The published solution version is indicated by icon. After publishing, you cannot make any changes to the solution version.

1. You can perform any of the following actions to **Publish** the draft Solution version:
   a. Click on the draft solution version, and then select **Publish / Lock**.
   b. Click on the environment, and then select **Solution Version > Publish**.

      The **Publish** window is displayed.

2. Click **Confirm**.
   Result
   The icon is suffixed to the published solution version on the **Solutions Versions** row.

Results
You have published the solution version in the pipeline.

Deploying the solution version

You can deploy the solution versions in the environments.

About this task
You can deploy the draft solution version and published solution version in the pipeline. When a new solution version is deployed to the environment where the published solution already exists, then the published solution version is either reverted to draft status or removed completely.

1. On the pipeline stage, you want to deploy the solution version, click , and then select **Deploy**.
   Result
   The **Deploy** window is displayed.
2. Select **Solution Version** tab.
3. Select the solution version from the list for deployment.

   Note: You can deploy all the **draft** and **published** solution version at all stages in the pipeline.

4. Click **Deploy**.

Results
You have deployed the solution version in the pipeline.

Unlinking the solution version

You can unlink the solution version from the pipeline stage.

About this task
You can unlink the draft and published solution versions in the pipeline. The unlinked solution versions are not deleted from the pipeline. You can also add the unlinked solution versions to the draft solution versions.

1. On the pipeline stage, click , and then select **Solution Version > Unlink Solution Version**.
2. Click **Confirm**.
   Result
   Solution version is unlinked from the environment.

The unlinked solution version are not permanently deleted from the stage. To reuse the unlinked solution version, .
You can find the unlinked solution versions under the **Solutions Version** tab.

3. To view the unlinked solution versions, click icon on the stage.
   Result
   The unlinked solution versions are listed under the **Solution Version** tab.

Results

You have unlinked the solution version from the pipeline.

Deleting the solution version

You can delete the solution version permanently from the pipeline stage when it is not required.

1. On the pipeline stage, click , and then select **Solution Version > Delete**.
   Result
   The **Confirm delete** is displayed
2. Enter the solution version number in the field, and then select **Delete**.
   Result
   The solution version is permanently deleted from the pipeline.

Results

You have deleted a solution version permanently from the pipeline stage.

Data Insights

The Insights feature provides DevOps metrics for your project data.

The Measure metric data tools enable you to assess your projects' efficiency and quality. You can measure every aspect of the development lifecycle with the supplied charts. You can create your own charts with metric definitions and upload custom data to Measure using the API endpoints on page 3091. Because Velocity data can come from plugins and API calls, project data can come from virtually anywhere, including planing and development tools, testing and build applications, and deployment processes.

The Insights feature consists of three focus areas:

Analyze project data with charts and graphs and then save the information in Insights dashboards on page 3165.

The HCL DevOps Deploy (Deploy) reports feature provides reports for data imported from Deploy.

Note: This feature will be deprecated in a future version.

The experimental Portfolio feature displays metric data for applications.

Managing Insights dashboards

Managing Insights dashboards

Managing Insights dashboards

Use the Insights dashboard feature to analyze project quality and efficiency.

Build dashboards by selecting from a large variety of charts. You can customize and annotate charts and download the data sets.

Dashboards are containers for customized metric data on page 3165. You select data by applying filters and queries to project areas, such as value streams. After you define data scope, attach charts and graphs to the dashboard. Measure provides a large variety of pre-defined charts, and you can create your own custom metric definitions on page 3091. Dashboards record your selections and automatically apply the same filters and graphs the next time you open them. You can create multiple dashboards, and each one can have unique criteria. If your organization has numerous teams, for example, you might create a separate dashboard for each one. The available charts are described later in this section on page 3175.

Additional managing Insights dashboards details are included in the following topics:

Creating dashboards

Create dashboards and favorites to manage metric data charts and graphs.

About this task

You create dashboards to by attaching charts to your project data that help you analyze your projects quality and efficiency.

Dashboards are created on the **Insights Dashboards** page. After you create a dashboard and customize it with charts and filter conditions, you can save and use for future sessions. The **Delivery Performance** dashboard is provided by default. It has several charts preconfigured, including the **Lead time**, **Cycle time**, and **Build count** charts. You can customize the **Delivery Performance** dashboard by adding new charts, and setting filters and data scope conditions.

To create a dashboard, complete the following steps:

1. On the Measure **Home** page, click **Insights > All Dashboards > Create dashboard**.
2. In the **Create dashboard** dialog, in the **Name** field, enter a dashboard name.
3. In the **Description** field, enter a distinctive description for the dashboard.
4. Click **Add**.

   Result

   Dashboards are also displayed either in card view by clicking or in list view by clicking on the **Insights All Dashboards** page. In the list view, you can sort fields in ascending or descending order by clicking on the following field names:

- **Name**
- **Description**
- **Creator**
- **Last Modified**
- **Modified By**

Each card or list view item contains status information about the dashboard, and provides a link to the dashboard details. In either list or card view, you can click and then select **Delete** to delete the dashboard.

Note: You can use Ctrl+P to generate the portable document format file of dashboard reports.

5. To add a created dashboard to your favorites, click the **All Dashboards** tab and then click to display the list view of dashboards. In the list, locate the **Name** of dashboard to be added to your favorites and then click in the left side of the field.
   The dashboard is listed on the **My Favorites** tab.
6. To remove a dashboard from your favorites, click and the dashboard is removed from the **My Favorites** tab.
7. To remove a dashboard from the **My Favorites** tab in card layout, click and then click for the dashboard to remove and select **Unfavorite**.
8. To remove a dashboard from the **My Favorites** tab in list layout, click and then click for the dashboard to remove and select **Unfavorite**.

What to do next

Customize the dashboard by filtering project data and applying charts to the data on page 3165.

Analyzing Insights data

Managing Insights dashboards.

About this task

With Insights dashboards, you measure your organization's progress and efficiency by applying analytic tools to your project data. Data comes from value streams, pipelines, HCL DevOps Deploy (Deploy) applications, and other project areas. By default, all data related to the teams to which you belong are available. You set data scope by selecting built-in filters. You can set the scope by application, team, value stream, or some combination.

You can add charts to the dashboard from a large collection of DevOps chart types. Chart data is determined by the metric definition associated with a chart on page 3170. When you add a chart to the dashboard, its graph area fills to reflect the filtered data. As you add multiple charts to a dashboard, the charts rearrange themselves to accommodate the new chart. When you save the dashboard, Measure saves the filter and the charts that you used.

The dashboard workflow follows these general steps:

1. Set the scope by defining a filter. You can scope data by teams, value streams, or applications.
2. Set the search limits.
3. Add a chart to the dashboard.
4. Customize the chart. You can change the chart style for all chart types. You can apply additional filters to some chart types, such as Deploy Count.

To manage a dashboard, complete the following steps:

1. On the Measure **Home** page, click **Insights > Dashboards**, and then select the dashboard.
   Result
   The dashboard page opens, which enables you to filter data, and apply charts.
2. In the **Dashboard** page, define the data scope by completing the following steps:

   a. In the **Filters** area, select one or more filters.
      By default, the data for all teams to which you belong populate the charts. You can restrict the data to a specific scope by selecting filters. Filters are available for teams, value streams, and applications. For example, you can restrict data to a specific team by selecting the team. Then the charts that you add will only contain data for the selected team. You can select more than one filter. Measure teams and teams integrated from Deploy are available.

   b. With the **Calendar** drop-down list to the right of the calendar, , set the search period.
      The default search boundary is **Last 90 days** or you can also select from one of the following: **Today**, **Last 24 hours**, **Last 7 days**, or **Last 30 days**.

   c. With the drop-down list to the right of **Group By**, set the x-axis coordinates for the charts.
      The default x-axis coordinate is **Day** or you can also select from one of the following: **Week**, **Month**, **Quarter**, or **Year**.

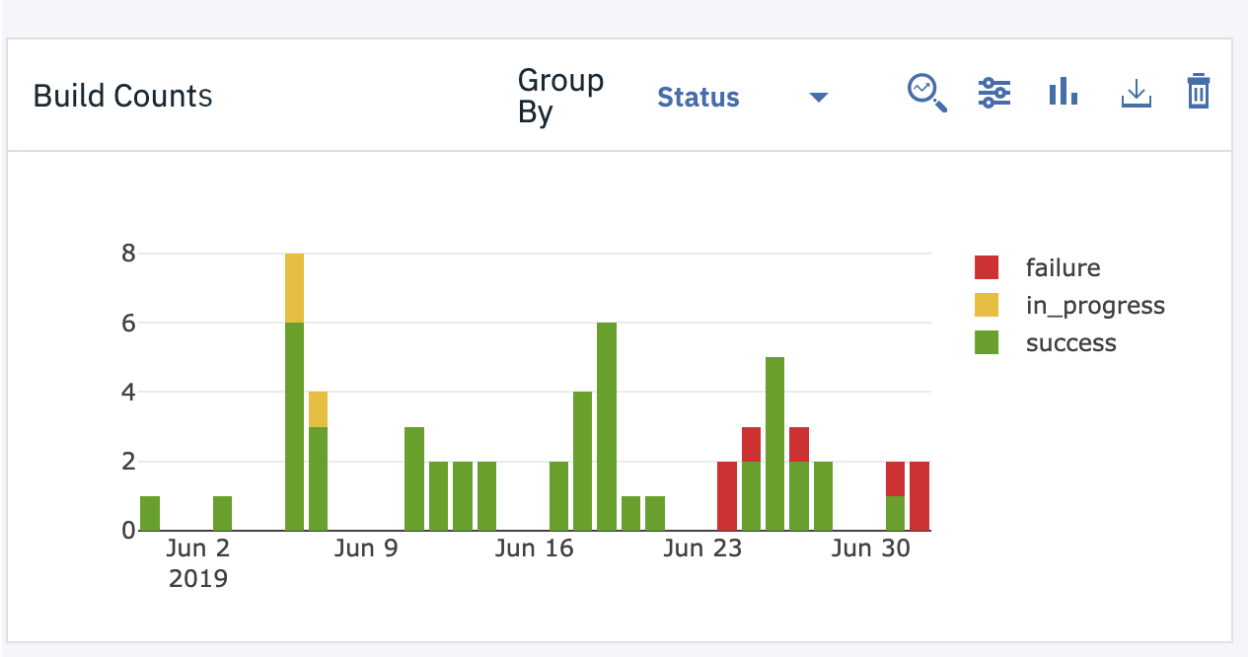
3. Click **Add charts** area and select a chart.
   The chart is displayed on the dashboard. If the dashboard already contains charts, the new one is inserted in the top row. Data that matches the filter condition populates the chart.

   Note: Depending on the filter and chart type, a chart might not contain significant data.

4. **Optional:** On the chart, use the **Group By** drop-down to set the data grouping.
   Result
   The **Group By** function modifies the data presentation without changing the data.

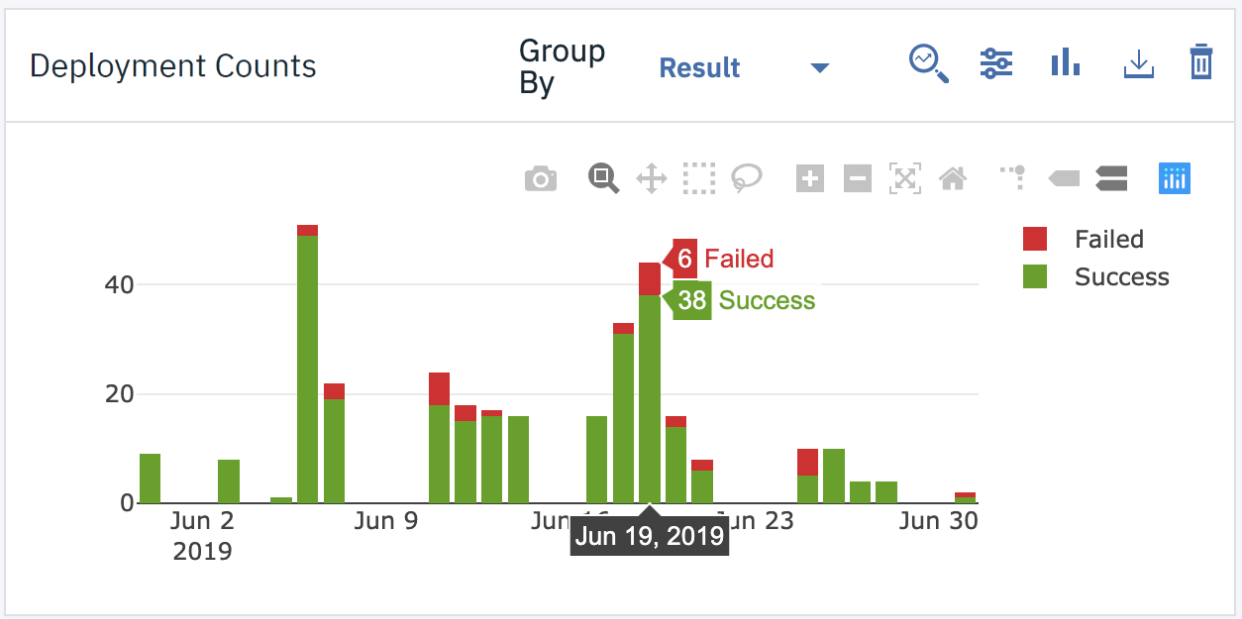
   The following illustration shows a delivery flow chart, **Build Counts**. Each bar in the graph represents the number of software builds for the specified coordinate, in this case days. The chart's **Group By** function is set to **Status**. A chart's **Group By** filter is determined by the metric definition assigned to the chart and might be unique to the chart. The chart's key displays the values for this grouping. This particular chart can also be grouped by **Name**, **Requestor**, **Application**, or **Tag**.

Note: Some chart types provide a default grouping that cannot be changed.



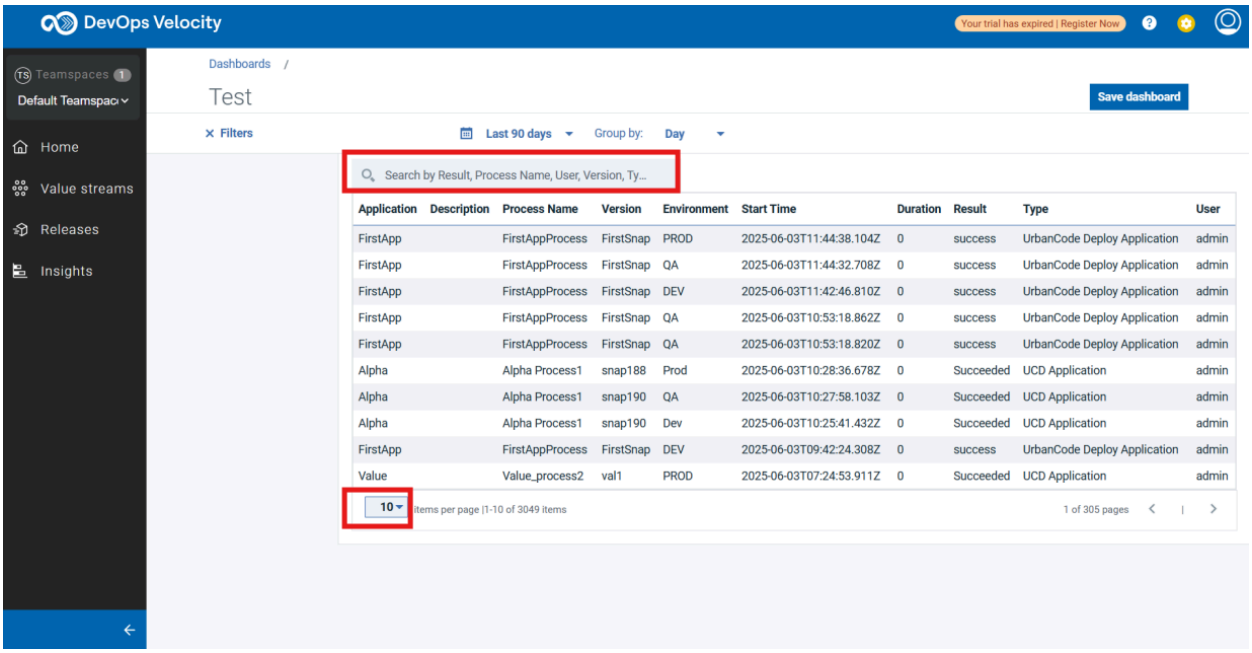
To see the breakdown of values for a grouping, hover the mouse over the interactive graph element. The following illustration shows another delivery flow chart, **Deploy Count**. This chart is grouped by result. Hovering the mouse over a bar shows the results for the selected coordinate.

Note: For the **Deployment Counts** chart only, the choices in the **Group By** list are: **Process name**, **Environment**, **Result**, **Type**, **User**, **Version**, **Application**, **Tag**, or **Team**.



5. **Optional:** On the chart, click icon to view the dataset grouping in table format.
   Result

   The following illustration shows a delivery performance chart, **Build Counts** in table format.

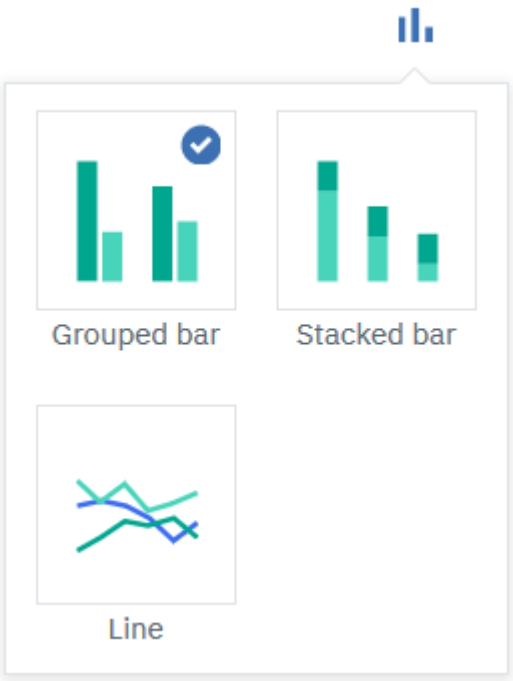


You can enter any keyword or phrase of the field listed in the **Search** bar to find the required data in the dataset table. You can use the pagination feature to define the number of items to display in the dataset table. The data in the table can be sorted in ascending and descending order.

6. **Optional:** On the chart, click the drop-down to refine the data filter.
   Result
   The chart is filtered, and the key is updated. The chart filter refines the data scope by applying additional filters to those you selected earlier.

   Note: Not all chart types provide a chart-specific filter. For the **Deployment Counts** chart only, the choices in the **Filter** list are: **Data set**, **Environment**, **Process name**, **Result**, **User**, or **Version**.

7. **Optional:** On the chart, click the drop-down to change the chart type.
   The types available are **Grouped bar**, **Stacked bar**, and **Line**, as shown in the following illustration. The default type is **Grouped bar**.



8. **Optional:** On the chart, click , to download a comma-separated-values file of the chart's data.
9. Click **Save Dashboard**.
   Result
   Measure saves your filters, charts, and chart customizations.
10. Use Ctrl+P to generate the portable document format file of dashboard report.

What to do next

You can create your own metric definitions and upload custom data on page 3091 to Measure. Custom charts are displayed in the **Add charts** area along with the pre-defined charts.

Metric chart reference

Metric charts can be attached to dashboards, value streams, and applications in the Portfolio view.

Measure provides metric definitions that you can apply to value streams, deployments, pipelines, and applications. Metric definitions describe expected data types and default chart settings. You can also send custom metric definitions to Measure from the external clients by using the API on page 1893.

Metric definitions, when applied to data, are represented by charts and graphs that can be attached to dashboards, value streams, and applications in the Portfolio view. Depending on how the data is collected, metric charts can be updated in near-real-time.

Measure provides many pre-defined metric definitions and their related charts. You can create your own custom metric definitions and use them wherever you would use a pre-defined one. on page 3091

Delivery flow charts

Table 1174. Delivery flow-type charts

Chart	Description
Lead Time	The time required for a dot to go from business acceptance to value realization. This includes both engineering time and non-value-added waiting time between sub-processes.
Lead Time Key Performance Indicator (KPI)	The Lead Time KPI measures the efficiency of a dot to reach the defined target. You can define the target using the status rule. To define target for lead time KPI, see here on page 3173.
Cycle Time	This is similar to lead time, except cycle time is measured from when the development team begins work to when that work reaches the customer.
Cycle Time Key Performance Indicator (KPI)	The Cycle Time KPI measures the efficiency of a dot to reach the defined target. You can define the target using the status rule. To define target for cycle time KPI, see here on page 3172.
Dev Cycle Time	This is similar to cycle time, except dev-cycle time is measured from when the development team begins work to when that work reaches end of the development (before the production stage).
Build Counts	Number of builds by type in a specified time period.
Deployment Counts	Number of deploys by status in a specified time period. The metric can be set to process names, environment, result, type, or application. The default metric is result. The data can scoped by data set, environment, process, result, or version.
Load	The number of work items active or waiting in a value stream at a given time. Load measures utilization capabilities of value streams related to productivity in the process flow. "Active" refers to the stages from the lead-time start until the lead-time end.
Throughput	The rate of work items completed during a period of time. Improving throughput can result in better responsiveness to customer requirements and may yield lead time reductions for value streams.

Table 1174. Delivery flow-type charts (continued)

Chart	Description
Agile Churn	The ratio of the sum of the values of story points added and removed to the value of the planned story points of a sprint. It calculates the percentage of the change in planned scope for any sprint.
Distribution	The proportion of different types of work items over time. This provides teams visibility into the type of work being completed (features, defects, tasks, and so forth.)
Flow Efficiency	The ratio of actual development time to cycle time. It is expressed as a percentage, which helps teams to understand their performance.
P.R.E Risk	Probabilistic Risk Estimator (P.R.E) Risk provides estimated probability to miss current sprint goal.
P.R.E Deadline	P.R.E Deadline provides estimated complete date for the current sprint.

DevOps Research and Assessment (DORA) metrics

Table 1175. DORA charts

Chart	Description
Deployment Frequency	The number deployments into production environment.
Lead Time to Change	The time required for a dot to go from commit to production deployment.
Time To Restore Service (MTTR)	The time taken to resolve the incident.
Change Failure Rate (CFR)	The ratio of the number of failed changes to the total number of changes deployed within a specified time period. It is expressed as a percentage, helping teams understand the rate at which their deployments are successful or failed.

Cycle Time KPI

To add **Cycle Time KPI** chart to dashboard, complete the following steps:

1. On the navigation bar, click **Insights**.
2. Select the required dashboard.
3. Under the dashboard, click **Add charts**.

4. Click right angle bracket to expand the **Delivery Flow** chart list.
5. Click **Add +** for **Cycle Time KPI** to add the chart to the dashboard.
6. The **Cycle Time KPI** chart is displayed with the following default status rule:

Table 1176. Cycle Time KPI

Status rule range	Color
0-5	Green
5-10	Yellow
10-30	Red

Note: The default status rule can be customized as required. See custom status rule for cycle time KPI on page 3173.

To set custom status rule for cycle time KPI, complete the following steps:

1. On the **Home** page, click **Settings** on upper-right corner of the page.
2. Click **Insights > KPIs**.
3. To set the status rule for Cycle Time KPI, click an overflow menu and select **Edit**. The **Edit KPI Definition - Cycle Time KPI.** window is displayed.
4. In **Edit KPI Definition - Cycle Time KPI.** window, click **Add status rule** to add a status rule.
5. In **Rule name** field, enter the name for the rule.
6. In **Rule** section in **Edit KPI Definition - Cycle Time KPI.**, select the range and color for the rule status.
7. Click **Add row** to add range for custom status rules. You can select the color for each range of custom status rule.

Note: You can add, edit, and delete status rules.

8. In **Scope > Teams** field, select the teams to apply the status rule.
9. In **Scope > Value streams** field, select the value stream to apply the status rule.
10. In **Scope > Applications** field, select the application to apply the status rule.
11. Click **Confirm**.
12. Click **Submit**.

Lead Time KPI

To add **Lead Time KPI** chart to dashboard, complete the following steps:

1. On the navigation bar, click **Insights**.
2. Select the required dashboard.

3. Under the dashboard, click **Add charts**.
4. Click right angle bracket to expand the **Delivery Flow** chart list.
5. Click **Add +** for **Lead Time KPI** to add the chart to dashboard.
6. The **Lead Time KPI** chart is displayed with the following default status rule:

Table 1177. Lead Time KPI

Status rule range	Color
0-5	Green
5-10	Yellow
10-30	Red

Note: The default status rule can be customized as required. See custom status rule for cycle time KPI on page 3174.

To set the status rule for lead time KPI, complete the following steps:

1. On the **Home** page, click **Settings** on upper-right corner of the page.
2. Click **Insights > KPIs**.
3. To set the status rule for Lead Time KPI, click an overflow menu and select **Edit**. The **Edit KPI Definition - Lead Time KPI.** window is displayed.
4. In **Edit KPI Definition - Lead Time KPI.** window, click **Add status rule** to add a status rule.
5. In **Rule name** field, enter the name for the rule.
6. In **Rule** section in **Edit KPI Definition - Lead Time KPI.**, select the range and colour for the rule status.
7. Click **Add row** to add range for custom status rules. You can select the color for each range of custom status rule.

Note: You can add, edit, and delete status rule.

8. In **Scope > Teams** field, select the teams to apply the status rule.
9. In **Scope > Value streams** field, select the value stream to apply the status rule.
10. In **Scope > Applications** field, select the application to apply the status rule.
11. Click **Confirm**.
12. Click **Submit**.

Quality charts

Table 1178. Quality-type charts

Chart	Description
Coverage By Branch	Percent of branches with associated tests executed during testing.
Coverage By Function	Percent of program functions executed during testing.
Coverage By Line	Percent of lines of code executed during testing.
Functional Tests	Number of functional tests by status in a specified period of time.
Static Code Analysis	Number of issues by severity in a specified period of time.
Unit Tests	Number of tests by status in a specified period of time.
API Tests	Number of tests by status in a specified period of time.

Risk charts

Table 1179. Risk-type charts

Chart	Description
Container Vulnerabilities	Number of container vulnerabilities by severity in a specified period of time. The metric can be set to process names, environment, result, type, application, tag, or team. The default metric is result. The data can scoped by data set, process, or version.
Application Vulnerabilities	Number of application vulnerabilities by severity in a specified period of time.

Lead time, cycle time and dev-cycle time table metrics

Lead time, cycle time and dev-cycle time table metrics provide refined granularity for issues.

Lead time, cycle time and dev-cycle time

To effectively manage and improve the delivery process, it is critical to understand the metrics that reflect the different phases of the workflow: Lead time, Cycle time, and Dev cycle time. These metrics provide deeper insights at the issue level for pinpointing to identify the delays and measure efficiency. Each metric provides a different perspective, helping both technical and business teams align performance and delivery expectations.

Name	Description
Lead Time	The total time from initial request or planning of the work to its completion. This includes all stages—waiting, development, testing, and delivery.
Cycle Time	The time from the start of actual work to the delivery of the final output to the customer. It focuses only on the active execution phase.
Dev Cycle Time	The time from the start of the development team work on a task to the end of the development phase, just before it is released to production.

Viewing the Lead time, Cycle time and Dev-cycle time metrics

You can view the Lead time, Cycle time and Dev-cycle time in the **Insights** page on Measure dashboard.

1. Click **Insights > All Dashboards**.
2. Click to display the dashboard card layout view. Alternatively, you can click to display the dashboard list layout view.
3. Click on the name of required dashboard on the **Insights** page.
4. Click

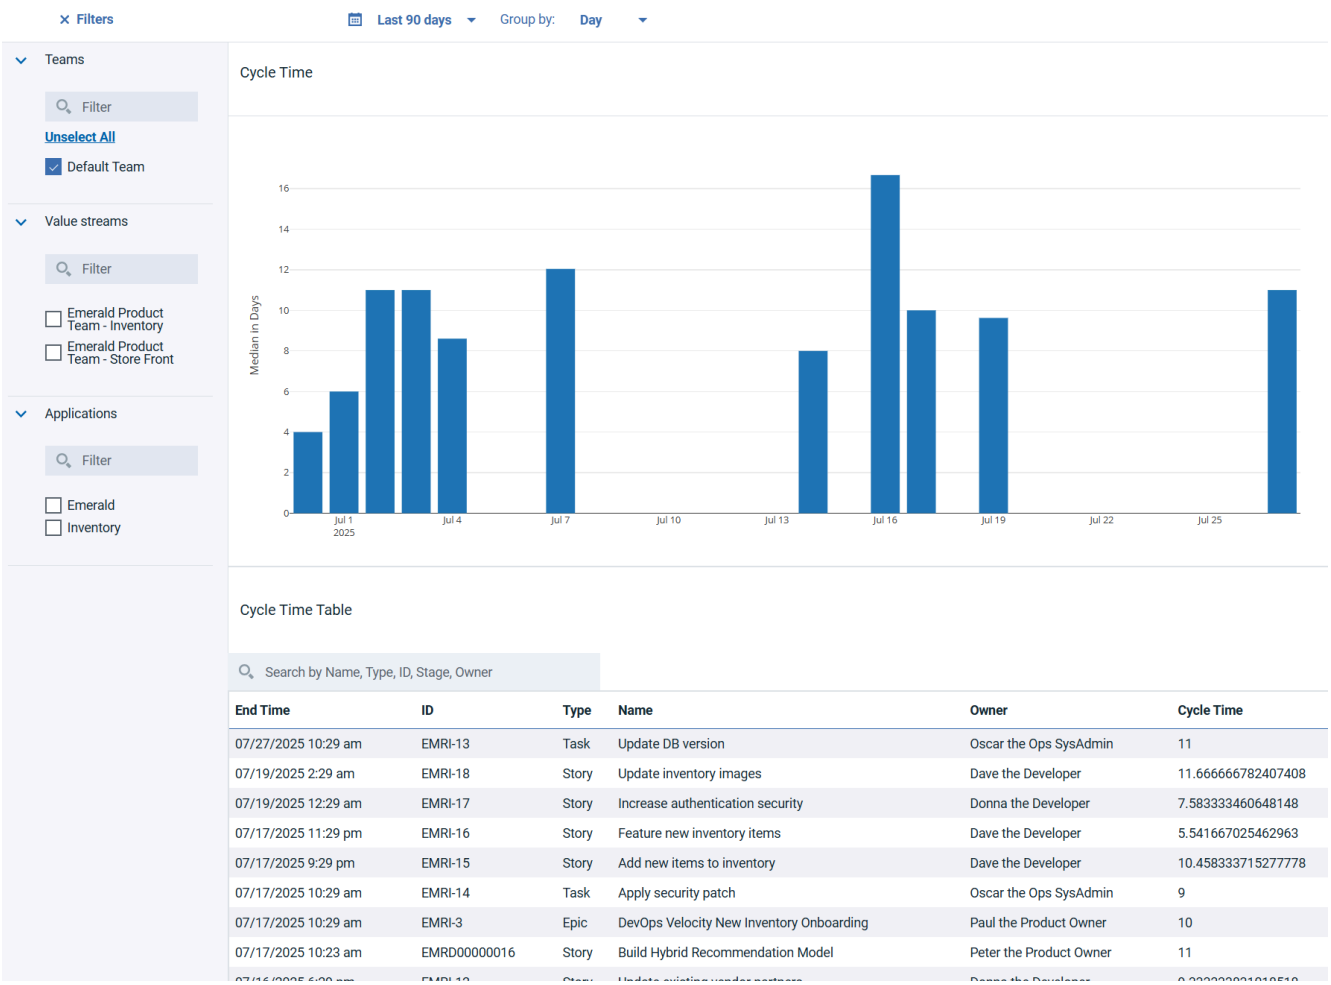
, and expand **Delivery Flow** option.
5. Click

for **Lead Time**, **Cycle Time**, and **Dev Cycle Time**.
6. Click **Save Dashboard**.

   The **Lead Time**, **Cycle Time**, and **Dev Cycle Time** are added to the dashboard. You can view the metric table with graphical representation of the **Lead Time**, **Cycle Time**, and **Dev Cycle Time**

Analyzing the Lead Time, Cycle Time, and Dev Cycle Time in the dashboard

The following example shows the Cycle time in the graphical presentation for the selected Teams, Value streams, and Applications.



The **Lead Time Table**, **Cycle Time Table**, and **Dev Cycle Time Table** display the fields detailed in the following table:

Field	Description
End Time	Date and time completed
Id	Issue number
Type	Issue type including task, story, bug, and so forth
Name	Issue descriptive name
Owner	Owner name
Lead Time	Lead time metric in days. Note: The lead time only appears in the **Lead Time Table**.
Cycle Time	Cycle time metric in days. Note: The cycle time only appears in the **Cycle Time Table**.

Field	Description
Dev Cycle Time	Cycle time metric in days. Note: The dev-cycle time only appears in the **Dev Cycle Time Table**.

Agile Churn metric

The Agile Churn metric is the ratio of the sum of the values of story points added and removed to the value of the planned story points of a sprint. It calculates the percentage of the change in planned scope for any sprint. By using this metric, you can learn how the change in planned scope impacts the progress and completion of the sprint.

Based on the Agile Churn metric data of any sprint, you can plan or organize the planned scope for any future sprints. You can learn the issue details of the story points that are added and removed to the active sprint in the metrics data table.

Note: Currently, Measure supports Agile Churn metric calculation only for the Jira integration. You must integrate or upgrade your Jira integration with plugin 2.3.24 or later for the accuracy of Agile Churn metric calculation.

Measure calculates the Agile Churn metric by using the following formula:

$$\text{Agile Churn} = \frac{\text{Story points added} + \text{Story points removed}}{\text{Planned story points}} \times 100$$

Where:

- **Story points added:** The total value of the story points of the issues that are added to the sprint.
- **Story points removed:** The total value of the story points of the issues that are removed from the sprint.
- **Planned story points:** The total value of the story points of the issues of the sprint that are present at 24 hours of offset time after sprint start time.

Note: Agile Churn metric is calculated after the completion of 24 hours of offset time from the sprint start time. Any story points that are added or removed within 24 hours of offset time is not be considered for Agile Churn metric calculation.

Here is an example of the calculation:

Consider a sprint had a total planned story points of 50 at the end of 24 hours of offset time completion after sprint start time.

An issue with story point of 5 is added to the sprint after completion of 24 hours of offset time from the sprint start time.

An issue with story point of 7 is removed from the sprint after the completion of 24 hours of offset time from the sprint start time.

Therefore, Measure calculates the Agile Churn metric as follows:

$$\text{Agile churn} = \frac{5+7}{50} \times 100 = \frac{12}{50} \times 100 = 24\%$$

Display of the Agile Churn metric in Measure

In Measure, the Agile Churn metric is displayed on the Dashboards and Value Streams pages:

- **Dashboards page:** Agile Churn is displayed in the Dashboards by using a graph, which dynamically shows the average churn percentage over time. You can group by days, month, week, quarter, year or with custom dates.
- **Value Streams page:** The **Value Streams** page shows the Agile Churn for changes in a specific value stream. It shows the percentage of churns in the value stream over the last 90 days.

  The result is presented on the Value Streams page, which helps stakeholders to view the overall stability and reliability of the deployment process for the value stream.

Adding the Agile Churn metric chart to Measure Dashboard

Perform the following steps to add the Agile Churn metric chart to the dashboard:

1. Click **Insights > All Dashboards**.
2. Perform any of the following steps:
   - Click any existing dashboard to open the dashboard.
   - Click **Add new dashboard**, provide the name and description for the dashboard, and then click **Add**.

   The dashboard is displayed.
3. Click **Add charts** and in the **Delivery Flow** category, click **Add** for the **Agile Churn** metric.

   The chart is displayed on the dashboard.

   If the dashboard already contains charts, the new one is inserted in the top row. Data that matches the filter condition populates the chart.

Adding the Agile Churn metric in the value stream

Perform the following steps to add Agile Churn metric in the value stream:

1. On the Home page, click **Value streams**.

   The **Value Streams** page is displayed.
2. Click 
to display the metric bar.
3. Click to display the **Add Metrics** window.

4. In the **Delivery Flow** category, click **Add** for the **Agile Churn** metric.

   The Agile Churn metric is displayed in the value stream.

Change Failure Rate metric

The Change Failure Rate (CFR) is the ratio of the number of failed changes to the total number of changes deployed within a specified time. It is expressed as a percentage, which helps teams to understand the rate at which their deployments are successful or failed.

The CFR is a key metric used to understand how the changes introduced in software are reliable. It calculates the percentage of changes that fail, which requires rollbacks, hotfixes, or other actions. As part of the DORA metrics, CFR measures the percentage of changes that need to be rolled back, fixed with a hotfix, or require other actions. This metric helps organizations to evaluate the stability of their deployment process.

Note: Currently, Measure supports CFR metric calculation only for the ServiceNow integration. You must integrate or upgrade your ServiceNow integration with plugin version 1.1.13 or later with custom field mapping for CFR metric calculation.

Measure calculates the CFR metric by using the following formula:

$$\text{Change Failure Rate (CFR)} = \frac{\text{Number of failed changes}}{\text{Total number of changes}} \times 100$$

Where:

- **Number of failed changes:** The total number of failed changes such as rollbacks or incidents triggered by those changes.
- **Total number of changes:** The total number of changes made during the given time, such as code deployments, updates, rollbacks, incidents, or releases.

Here is an example of the calculation

A project had a total of 50 changes deployed, out of which 5 resulted in failures.

Therefore, Velocity calculates CFR as follows:

$$\frac{5}{50} \times 100 = 10\%$$

Display of the CFR metric in Measure

In Measure, the CFR metric is displayed on the Dashboards and Value Streams pages:

- **Dashboards page:** CFR is displayed in the Dashboards by using a graph, which dynamically shows changes in the failure rate over time. You can group by days, month, week, quarter, year or with custom dates.
- **Value Streams page:** The **Value Streams** page shows the CFR for changes in a specific value stream. It shows the percentage of failed changes in the value stream over the last 90 days.

  The result is presented on the Value Streams page, which helps stakeholders to view the overall stability and reliability of the deployment process for the value stream.

Adding the CFR metric chart to Measure Dashboard

Perform the following steps to add the CFR metric chart to Dashboards:

1. Click **Insights > All Dashboards**.
2. Perform any of the following steps:
   - Click any existing dashboard to open the dashboard.
   - Click **Add new dashboard**, provide the name and description for the dashboard, and then click **Add**.

   The dashboard is displayed.
3. Click **Add charts** and in the DORA category, click **Add** for the CFR metric.

   The chart is displayed on the dashboard.

   If the dashboard already contains charts, the new one is inserted in the top row. Data that matches the filter condition populates the chart.

Adding the CFR metric in the value stream

Perform the following steps to add CFR metric in the value stream:

1. On the Home page, click **Value streams**.

   The **Value Streams** page is displayed.
2. Click 
to display the metric bar.
3. Click to display the **Add Metrics** window.
4. In the DORA category, click **Add** for the CFR metric.

   The CFR metric is displayed in the value stream.

Flow Efficiency metric

The Flow Efficiency metric is the ratio of actual development time to cycle time. It is expressed as a percentage, which helps teams to understand their performance. A higher flow efficiency indicates a smoother process with fewer delays, while lower values indicate inefficiencies that might require attention to identify and eliminate bottlenecks in the workflow.

The Flow Efficiency metric is a key metric used to assess the reliability and success of the changes deployed within a system. This metric provides insight into the efficiency of work in the development pipeline. By using the Flow Efficiency metric, teams can create a more predictable and effective delivery process. Therefore, you can get better-quality results and increased delivery efficiency.

Measure calculates the Flow Efficiency metric by using the following formula:

$$\text{Flow Efficiency} = \frac{\text{Story points x 7.5}}{\text{Cycle time}} \text{ x 100}$$

Where:

Story points: The total value of the story points of the issues.

Cycle time: The total time taken for each issue to progress from start to completion.

Here is an example of the calculation:

A work item had 6 story points, and the cycle time was 18.5.

Therefore, the Flow Efficiency metric is calculated as follows:

$$\frac{6 \text{ x } 7.5}{18.5} \text{x } 100 = 243.24\%$$

Display of the Flow Efficiency metric in Measure

In Measure, the Flow Efficiency metric is displayed on the **Dashboards** and **Value Streams** pages:

- **Dashboards** page: The Flow Efficiency metric is displayed in the **Dashboards** by using a graph, which dynamically shows flow efficiency data in percentage over time. You can group by days, month, week, quarter, year, or with custom dates.
- **Value Streams** page: The **Value Streams** page shows the Flow Efficiency metric in a specific value stream. It shows the ratio of actual development time over the cycle time in percentage by taking the number of overall work items in the value stream in the last 30 days.

  The result is presented on the **Value Streams** page, which enables stakeholders to view the overall stability and reliability of the deployment process for that specific value stream.

Adding the Flow Efficiency metric in the value stream

Perform the following steps to add the Flow Efficiency metric for a value stream:

1. On the Home page, click **Value streams**.

   The value stream page is displayed.

2. On the **Value Streams** page, click 
to display the metric bar.
3. Click to display the **Add Metrics** window.
4. In the **Delivery Flow** category, click for the **Flow Efficiency** metric.

   The Flow Efficiency metric is displayed in the **Metrics** bar on the value stream page.

Adding the Flow Efficiency metric chart to the Dashboard

Perform the following steps to add the Flow Efficiency metric chart on **Dashboards**:

1. Click **Insights > All Dashboards**.
2. Perform any of the following steps:
   - Click any existing dashboard to open the dashboard.
   - Click **Add new dashboard**, provide the name and description for the dashboard, and then click **Add**.

   The Dashboard is opened.

3. Click **Add charts** and in the **Delivery Flow** category, click **Add** for the **Flow Efficiency** metric.

   The chart is displayed on the dashboard.

GenAI metrics - Tech Preview

Overview

Disclaimer:

This release contains access to the GenAI metrics feature in Measure as a Tech Preview. The Tech Preview is intended for you to view the capabilities of GenAI metrics offered by Measure, and to provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL® provides the information without obligation of support and "as is" without warranty of any kind.

The GenAI metrics provides you the insights about GitHub Copilot usage within an organization. This feature retrieves user activity, engagement levels, language-specific completions, and other Copilot adoption metrics directly from the GitHub API and syncs them into Measure

The Gen AI metrics helps organizations track how developers are using AI-assisted coding and measure productivity impact through structured metrics.

The following GenAI metrics can be added and displayed within the Measure insights section.

- **GenAI Line Acceptance**
- **GenAI User Adoption**
- **GenAI Chat Events**
- **GenAI Code Acceptance**
- **GenAI PR Events**

Prerequisites

You must integrate or upgrade your Github integration with plugin version 1.5.4 or later with Copilot metrics collection enabled during integration. For more information, refer to Github plugin documentation.

Display of the GenAI metrics in Measure

In Measure, the GenAI metrics are displayed on the **Dashboards** page under **GenAI** category:

Adding the GenAI metric chart to the Dashboard

Perform the following steps to add the GenAI metric charts on **Dashboards**:

1. Click **Insights > All Dashboards**.
2. Perform any of the following steps:
    - Click any existing dashboard to open the dashboard.
    - Click **Add new dashboard**, provide the name and description for the dashboard, and then click **Add**.

   The Dashboard is opened.
3. Click **Add charts** and in the **GenAI** category, click **Add** for the available GenAI metrics collected from GitHub Copilot.

   The chart is displayed on the dashboard.

Insights reports

Insights reports are generated for the data that is aggregated in the **Value streams**, **Pipelines**, and **Release** categories. You can generate reports by clicking a button and then shared with the required stakeholders. You can run the following insights reports in Measure.

Running insights reports

The insights reports generate reports for the data aggregated into Measure.

To run an insights report, perform the following steps:

1. Click **Insights > Reports**.
2. Click **Add report** to add the required report from the report templates.
3. After adding the report, click **Run Report** to open the **RUN REPORT** window.
4. Select the required property for running the report.

   Note: You can set the property as default by clicking **Set as Default**.

5. Click **Confirm** to run the report.

The insights report page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.
- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the insights report page is displayed.

Downloading sample report

You can download the sample insights report by performing the following steps:

1. Click **Insights > Reports**.
2. Click **Download sample report** to download sample report.

The downloaded sample report folder contains `report.json` file with sample properties to generate custom reports. You must read the instructions available in README file for generating custom reports.

AppScan Enterprise scan report

The AppScan Enterprise (ASE) scan report displays a summary of vulnerabilities identified in the scans conducted by an AppScan Enterprise instance for which an Measure integration has been configured.

The AppScan Enterprise report provides the information about the quality and severity of security issues. The report displays common issue types, issue type by application, and scans by application for the selected duration of time.

To run the **AppScan Enterprise scan** report, perform the following steps:

1. Click **Insights > Reports**.
2. Select the **AppScan Enterprise scan report** field under the **Report Templates** heading on the left side of the page.

Note: When the **AppScan Enterprise scan report** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click **Run Report** to open the **RUN REPORT** window.
4. Enter the following information:
    - **Start date** - Select the start date for the scan report
    - **End Date** - Select the end date for the scan report
5. Click **Confirm** to run the report.

The **AppScan Enterprise scan report** page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.
- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the **ASE scan report** page is displayed.

Release readiness report

The **Release readiness** report details criteria based on internal standards and compliance requirements.

The **Release readiness** report page provides comprehensive details for assessing risk of a specific version prior to its release into the production environment. In order to evaluate release readiness for a new version candidate, the report assists in evaluating the following areas:

- Are release preparations final and is the version meeting all quality criteria?
- Did the reviewers submit the required approvals?
- Is the version thoroughly and properly tested against the quality criteria?
- Do specific issues exist for this version now that require additional attention?

To run the **Release readiness** report, perform the following steps:

1. Click **Insights**, and then select **Reports**.
2. Select the **Release readiness** field under the **Templates** heading on the left side of the page.

Note: When the **Release readiness** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click the **Run report** button to display the **RUN REPORT** window.
4. In the **Pipeline / value stream** drop-down, select the required value stream and pipeline from the list.
5. In the **Stage containing release candidates (optional)** field, enter the pipeline environment containing the release candidates.
6. In the **Targeted release stage (optional)** field, enter the environment.

Note: To set the report inputs as default, click the **Set as Default** button.

7. Click the **Confirm** button to run the report.
8. If the report ran successfully, in the **Status** field of the table below the **Run report** button, a green circle and **Complete** is displayed.

Note: If a red circle and **Failed** is displayed, run the report again.

9. After the report runs successfully, in the line item for the report in the table, click **Results** to view the **Release readiness** report.

A sample **Release Readiness Report** page is shown below.

Release readiness report

Aug 7th 2024, 2:06:24 pm UTC

Value stream: Ai

This report collects and analyzes data from Ai value stream and related delivery pipeline including Insights quality data to assess the current release readiness for : Ai | DEV release.

Release: Ai | DEV release

Scheduled date: Aug 7th, 2024

Application: Jenkins

CANDIDATE	CURRENT VERSION

Release summary

Release summary

Summary of the release

✓ **Improved User Experience:** The release focused on enhancing the user interface and experience by redesigning interactive elements and refreshing the global design. This included modifications to the web client interface for better usability (VEL-247).

✓ **Performance Optimization:** Several tasks were completed to optimize database queries and implement caching mechanisms to improve system performance and scalability (issues_id).

✓ **Bug Fixes and Quality Assurance:** The release included a thorough review of documentation and addressed issues related to the user interface, image display problems, and container start-up errors (issues_id).

✓ **New Feature Development:** The release also included the development of new features and functionality to enhance the overall user experience, such as integrating with third-party services and adding support for mobile devices (issues_id).

Warning: 2 out of 2 issues have no description. The summary may not be accurate.

Release process

The main sections of the Release readiness report include the following:

- **Report header**
- **Release summary**
- **Release content**
- **Release quality & security**
- **Release process**

Subdivisions of the main sections listed above are detailed in the table below.

Table 1180. Report sections details

Main section	Subdivision
Report header	**Value stream** name, **Release** name with **Scheduled date**, **Application** name with **CANDIDATE** and **CURRENT VERSION** details, **Readiness score**, **Time in stage**, **Deployment success rate**
Release summary	**Release summary**
Release content	**Candidate version**, **Changes introduced since version (number)**, **Contributors**, and **Individual Measures**.
Release quality & security	**Approvals**, **Current version quality & security metrics**, **Current application quality & security metrics**, **Pipeline gates**
Release process	**Release activites**, **Value stream - highest priority items opened**

Report header

Under the **Application** name in the report header, the **CANDIDATE** and **CURRENT VERSION** details including environment, version, and date are displayed for each. These two versions are compared with one another with the results listed in the report sections contained in the table above. The **Readiness score**, **Time in stage**, and **Deployment success rate** details are also displayed in the report header.

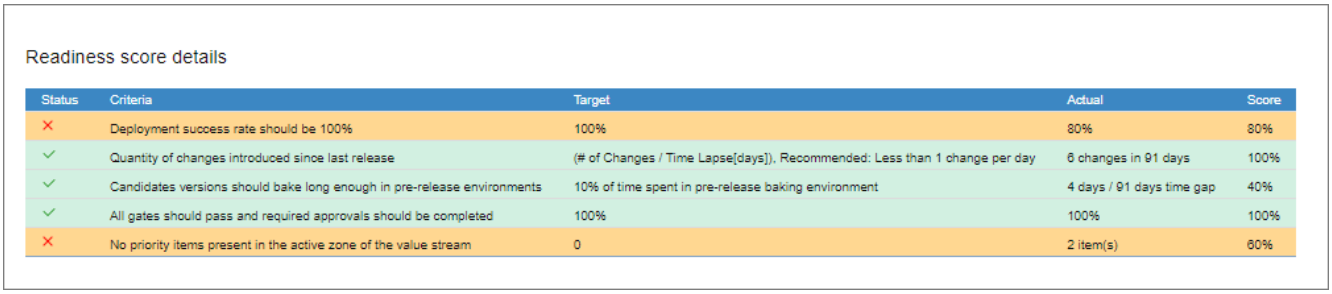
Readiness score

The **Readiness score** view provides a detailed readiness score breakdown for the candidate version and is viewed by hovering over the icon in the bottom right hand corner of the section. The **Readiness score details** are listed in tabular form with the fields detailed and shown in the following table and figure respectively.

Table 1181. Readiness score details

Field	Description
Status	Indicates the state of the specific criteria as success or fail with the green ⎫ or red ⎭ symbols respectively.
Criteria	Specific area of focus for this release candidate.
Target	Based on the criteria, what is the optimal value for success?
Actual	Based on the criteria, what actual value was achieved?
Score	The percentage of success between the **Score** and **Actual** values.

Figure 28. Readiness score details



Release summary

In the **Release summary** section, you can view the composite summary of the works items associated with the release. This section provides insights on the features, enhancements, defects, and the overall status of release activities.

Note: You must install the GenAI Summary Release plug-in to view the **Release summary**.

Release content

The **Candidate version** section identifies details for the specific build including names, issues, PR and commits. The **Changes introduced since version (number)** section lists the items that are added to the **CURRENT VERSION** to represent the **CANDIDATE** version including issues, PR and commits. The names and number of owners providing changes for the aforementioned items in the new version are listed in the **Contributors** section. Links are provided in each of the aforementioned sections to view information for specific items. You can also see the individual measures for the contributors of the release. See the **Individual Measures** on page 3190 section for more details.

Individual Measures

The **Individual Metrics** section, available in the **Release Readiness Report**, provides detailed insights into the performance and involvement of each contributor in the release. This data is essential for engineering managers, product owners, and team leads to assess individual efficiency, promote accountability, and drive continuous improvement.

For every contributor who has participated in the release, the following metrics are displayed:

- **Number of Issues Completed**

  Tracks the number of tasks (stories, bugs, or technical items) a contributor has completed. This metric helps evaluate task throughput and individual contribution levels.

- **Total Story Points Completed**

  Measures the total effort delivered by a contributor based on the story points assigned to completed work items. This metric supports capacity planning and performance evaluation.

- **Number of Pull Requests Created**

  Indicates the frequency at which a contributor submits the code changes for review. This metric provides insight into coding activity and collaboration with peers.

- **Total Number of Commits**

  Shows the number of code commits made by a contributor, reflecting consistency, development cadence, and active involvement in coding tasks.

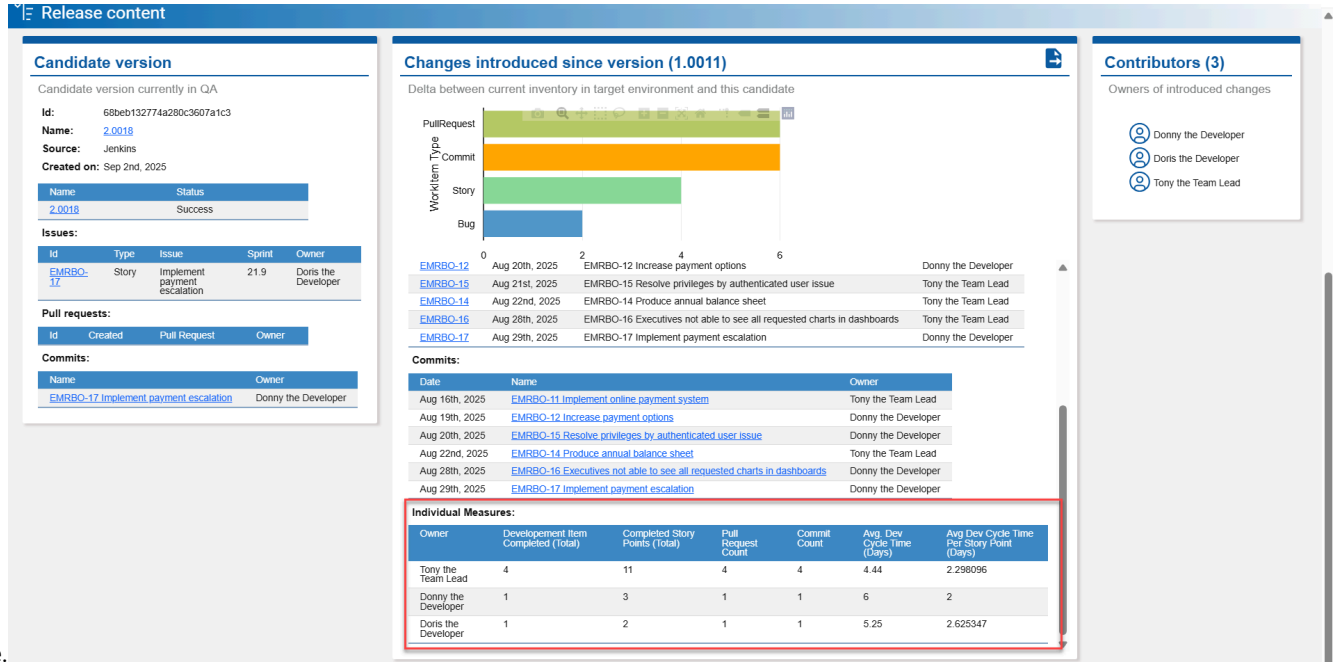
- **Dev Cycle Time**

  Measures the duration a contributor takes to complete a work item, calculated based on the specific stages configured for Dev Cycle Time within your value stream. This metric is useful for identifying delays, inefficiencies, or areas needing support or process improvement.

- **Dev Cycle Time per Story Point**

  Normalizes Dev Cycle Time by story point size, allowing teams to evaluate individual efficiency relative to task complexity. This metric helps in identifying high-performing contributors or highlighting potential mismatches between estimated and actual effort.

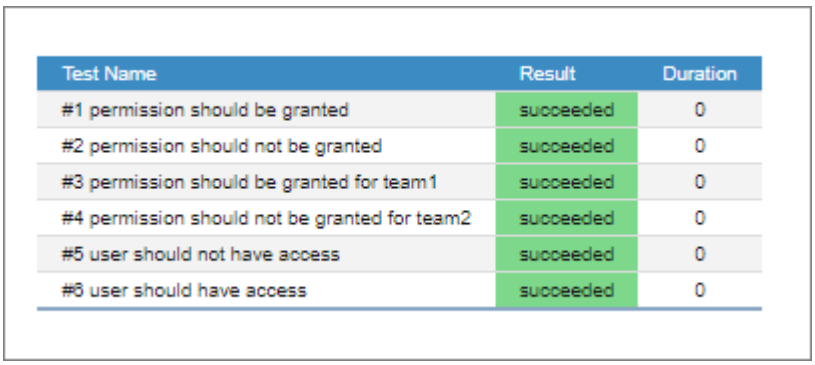
Individual Measures are displayed in a tabular format within the **Release Readiness Report**, as shown in the following example, offering a clear overview of the contributions and performance metrics of each contributor for the release.



Release quality & security

This section focuses on how extensively the candidate version was tested along with the test results. The unique test results for the **CANDIDATE** version are found in the **Current version quality & security metrics** section. Recent Appscans affecting the application are viewed in the **Current application quality & security metrics** section and may not be directly tied to the candidate version. Links to specific metric pages are provided on the right side of the metrics for each of the aforementioned sections. You can also hover over the test results blocks to display a test results table including **Test Name**, **Result**, and **Duration** as shown in the following figure.

Figure 29. Test results table



Note: Only test blocks containing data will display the tabular pop-up shown in the above figure.

In the **Pipeline gates** section, you can view approvals and quality checks across the pipeline phases.

Release activities

In this section, you can view scheduled or releases in progress and any prerelease activities necessary prior to moving into the production environment. Links to specific release activities are provided in this section.

Value stream - highest priority items opened

This section monitors specific issues in the value stream for the candidate version that require attention and resolve prior to release. Links to specific work items are provided in this section.

Reporting on security

The **Security Report** displays roles of all users based on the teams or groups they belongs to.

The **Security Report** provides a comprehensive list of all users with the teams they belong to, the roles they are assigned to, and the groups they associated with. Users can be filtered by categories such as, **By Users** , **By Teams** , **By Roles**, and **By Groups**. With the security report, you can view users based on their roles, teams, and groups.

To run the **Security Report**, perform the following steps:

1. Click **Insights > Reports**.
2. Select the **Security Report** field under the **Report Templates** heading on the left side of the page.

   Note: When the **Security Report** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click **Run Report** to open the **RUN REPORT** window.
4. Enter the security report title in the **Report Title** field.

   Note: To set a report title as default, click **Set as Default**.

5. Click **Confirm** to run the report.

The **Security Report** page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

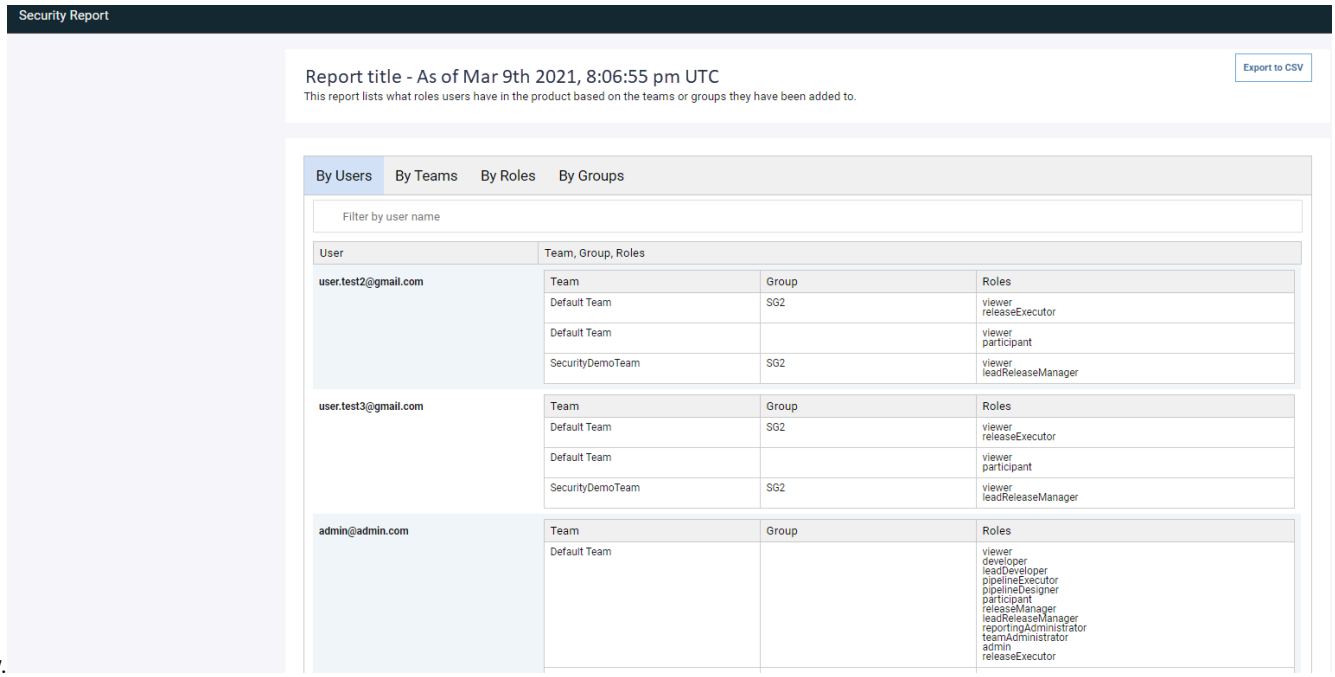
- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.

- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the **Security Report** page is displayed. You must then click **Export to CSV** to export the deployment audit report.

The security report is displayed with four categories:

1. **By Users:** Type the user name in **Filter by user name** to filter users by user name.
2. **By Teams:** Type the team name in **Filter by team name** to filter users by team name.
3. **By Roles:** Type the role name in **Filter by role name** to filter users by role name.
4. **By Groups:** Type the user name in **Filter by group name** to filter users by group name.

A sample **Security Report** page is shown below.



State of the sprint report

The **State of the Sprint Report** page displays all the sprints with related work items for a value stream selected as the output for the report execution.

The **State of the Sprint Report** page provides comprehensive details of all active and inactive sprints for a selected value stream. All of the issues are aggregated by each sprint and grouped according to the stage position of the items in the value stream. Current sprints are identified as **Active** while past and future sprints are identified as **Inactive** on the **State of the Sprint Report** page. For a given sprint in a value stream, data represented in the report includes the following:

- Start, end, and completed dates
- Total issues number
- Percentage issues done
- Story points planned number

- Story points done number
- Issues not pointed number
- Contributors number
- Sprint Burndown chart
- Individual Measures

Additionally, **Pointed vs Not Pointed** and **Planned vs Done (Release)** bar chart graphs for all the sprints in the value stream are displayed at the top of the **State of the Sprint Report** page.

Notes:

- Before you generate **State of the sprint** report, you must install and integrate **Handlebars Reporter** plugin with Measure. For more information, see **Handlebars Reporter** plugin documentation.
- You must use Handlebars Reporter plugin version 2.0.5 or later to get accurate metrics in **Individual Measures** section.

To run the **State of the Sprint** report, perform the following procedure:

1. Click **Insights > Reports**.
2. Select the **State of the Sprint** field under the **Report Templates** heading on the left side of the page.

   Note: When the **State of the Sprint** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click **Run Report** to open the **RUN REPORT** window.
4. Select the required **Value Stream** from the list.

   Note: To set a value stream as default, click **Set as Default**.

5. Based on the **Value Stream** selected, the **Sprints** field selects the latest 10 sprints by default. You can add or remove sprints in the **Sprints** field to generate the report.

   Sprints field value is mandatory to generate the report. You must select minimum one sprint to generate the report.

6. Click **Confirm** to run the report.

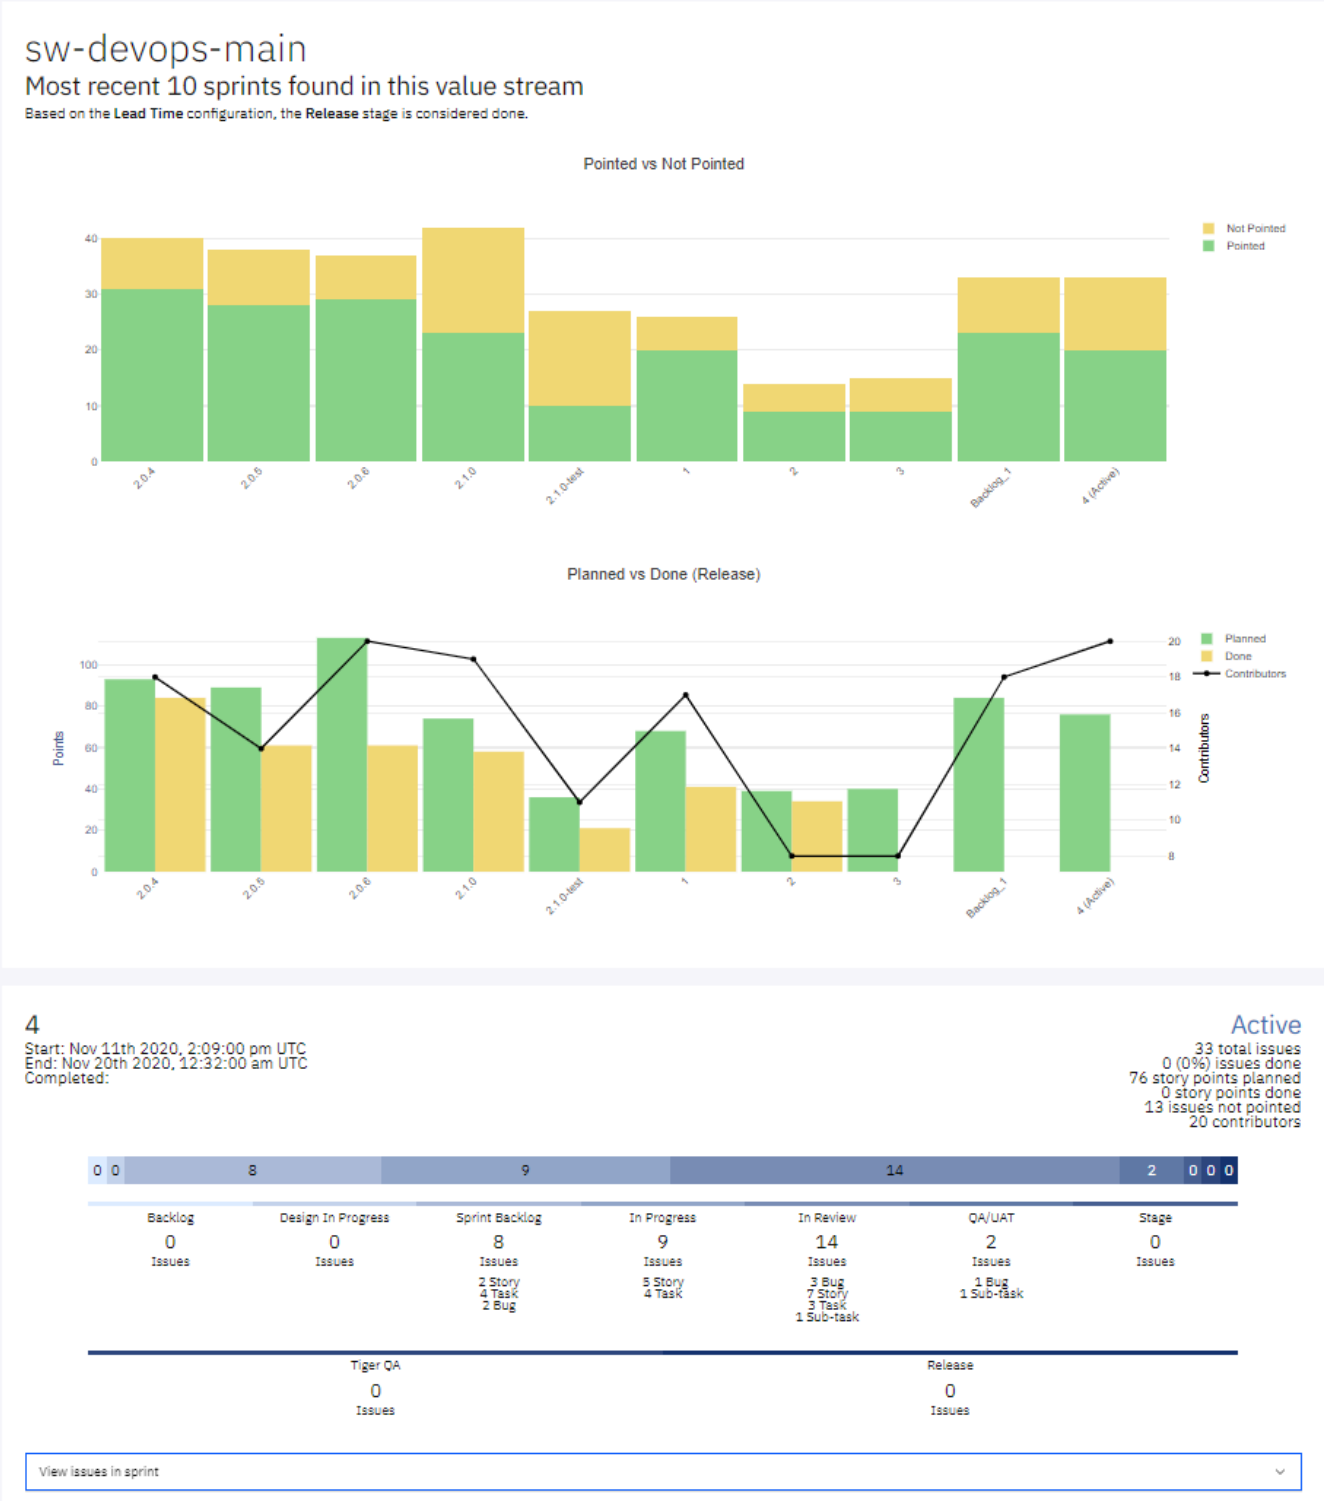
The **State of the Sprint Report** page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

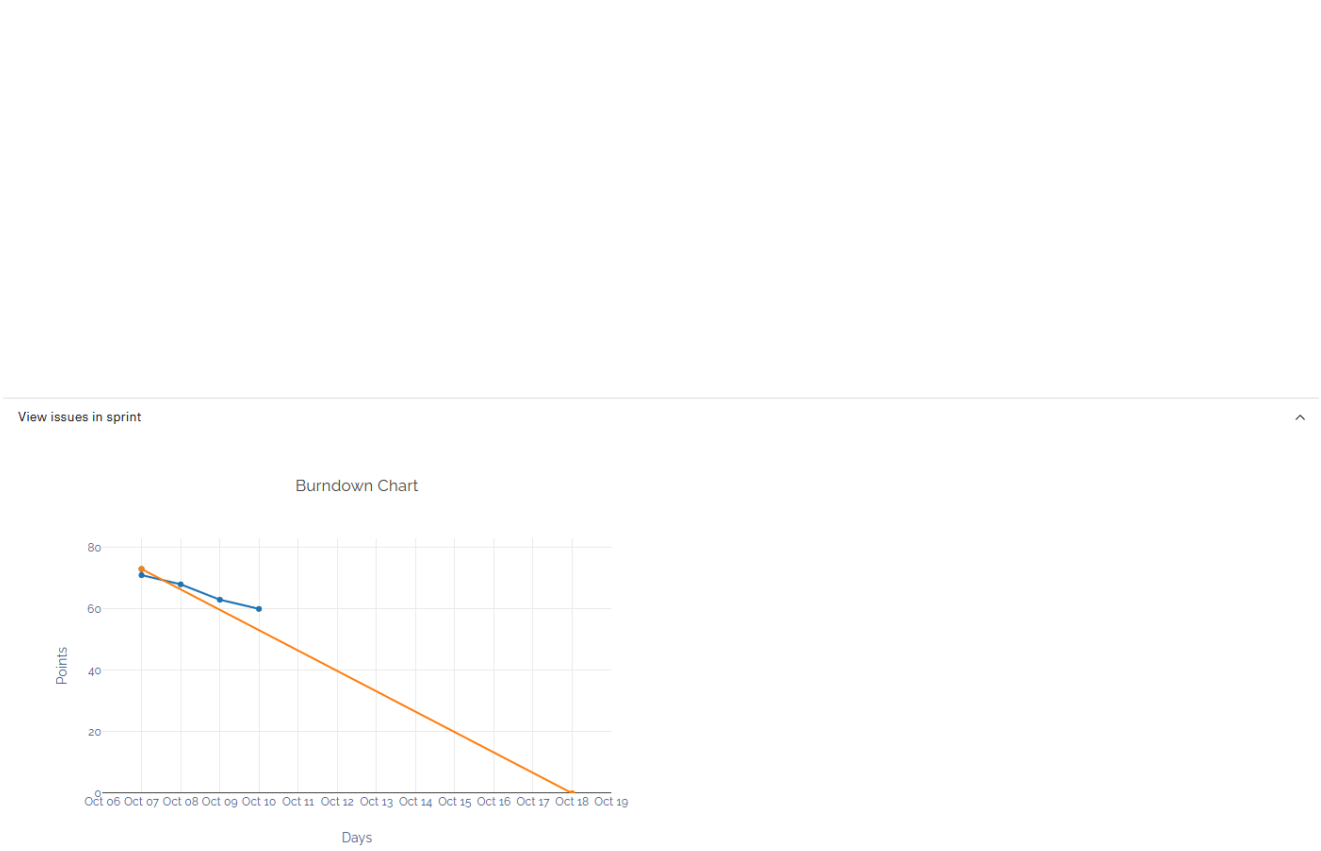
- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.
- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the **State of the Sprint Report** page is displayed.

A sample **State of the Sprint Report** page is shown below.



The **Pointed vs Not Pointed** and **Planned vs Done** bar charts are both interactive and you can hover over any areas of the chart to dynamically display values and plot tool icons providing extended functionality. You can click on different areas of the blue shaded bar chart above to display the stage name with number of related issues.

Click **View issues in sprint** bar to extend and display the burndown chart, related issues for each stage of the value stream and the individual measures for the developers who has contributed to the sprint.



The red vertical bar indicates alerts for issues such as over median time, no owner, and so on. You can click the issue link to open the ticket in a browser window to view detailed information for that item.

Individual Measures

The **Individual Metrics** section, available for each sprint, provides detailed insights into the contributions and performance of each contributor. This data is critical for engineering managers, product owners, and team leads to assess individual efficiency, promote accountability, and guide continuous improvement initiatives.

For every contributor who has participated during a sprint, the following metrics are displayed:

- **Number of Issues Completed**

  Tracks the number of tasks (stories, bugs, or technical items) a contributor has completed. This metric helps evaluate task throughput and individual contribution levels.

- **Total Story Points Completed**

  Measures the total effort delivered by a contributor based on the story points assigned to completed work items. This metric supports capacity planning and performance evaluation.

- **Number of Pull Requests Created**

  Indicates the frequency at which a contributor submits the code changes for review. This metric provides insight into coding activity and collaboration with peers.

- **Total Number of Commits**

  Shows the number of code commits made by a contributor, reflecting consistency, development cadence, and active involvement in coding tasks.

- **Dev Cycle Time**

  Measures the duration a contributor takes to complete a work item, calculated based on the specific stages you've configured for Dev Cycle Time within your value stream. This metric is useful for identifying delays, inefficiencies, or areas requiring support or process refinement.

- **Dev Cycle Time per Story Point**

  Normalizes Dev Cycle Time by story point size, allowing teams to evaluate individual efficiency relative to task complexity. This metric helps in identifying high-performing contributors or flag potential mismatches between estimated and actual effort.

Individual Measures are displayed in a tabular format within the **State of the Sprint** report, as shown in the following example, offering a clear overview of the contributions and performance metrics of each contributor for a given sprint.

Deployment audit report

The Deployment audit report displays a summary of the deployments.

The **Deployment audit** report page provides comprehensive details about the deployment frequency, success rate, deployment by application type, environment, and process.

To run the **Deployment audit** report, you must perform the following steps:

1. Click **Insights > Reports**.
2. Select the **Deployment audit** field under the **Report Templates** heading on the left side of the page.

   Note: When the **Deployment audit** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click **Run Report** to open the **RUN REPORT** window.
4. Enter the following information:
   - **Start date** - Start date and time for the report
   - **End date** - End date and time for the report

- **Pipelines** - Select the pipeline
- **And / or pick applications** - Select the application you want to include in report
- **Timezone** - Select the time zone

5. Click **Confirm** to run the report.

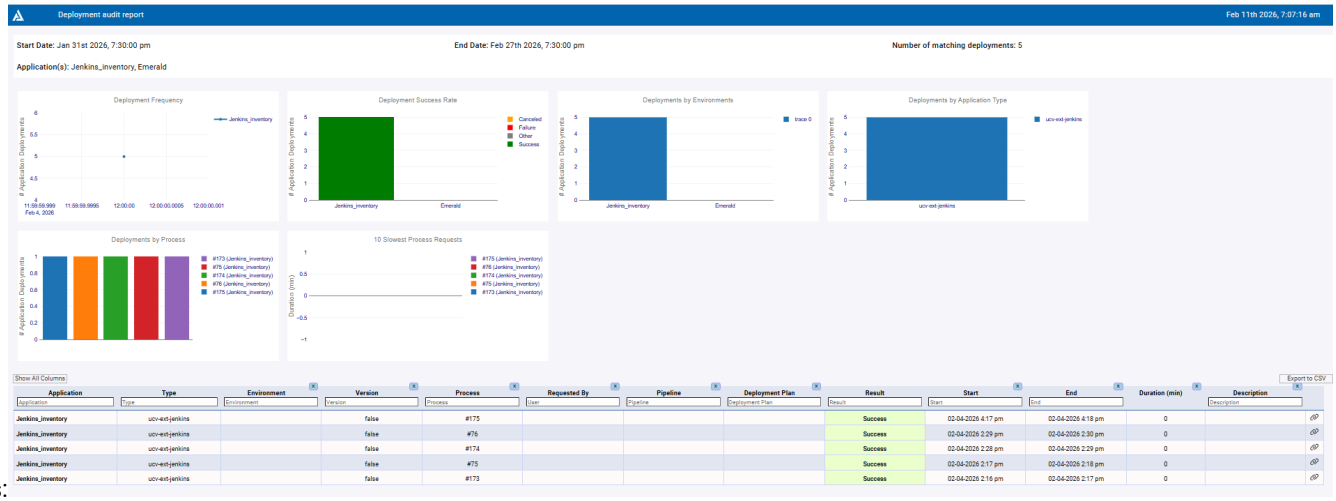
The **Deployment audit report** page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.
- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the **Deployment audit report** page is displayed. You must then click **Export to CSV** to export the deployment audit report.

A sample deployment audit report page is shown as follows:



Pipeline snapshot report

The Pipeline snapshot report displays the snapshot of the pipeline for a specific value stream.

The **Pipeline snapshot** report page provides the details about the pipeline view for a value stream for a particular date.

To run the **Pipeline snapshot** report, you must perform the following steps:

1. Click **Insights > Reports**.
2. Select the **Pipeline snapshot** field under the **Report Templates** heading on the left side of the page.

Note: When the **Pipeline snapshot** field is selected, a vertical blue bar is displayed on the left side of the field to indicate it as the report to run.

3. Click **Run Report** to open the **RUN REPORT** window.
4. Enter the following information:
   - **Value Stream** - Select the value stream from the drop-down list
   - **Snapshot Date** - Select the date for the pipeline snapshot
5. Click **Confirm** to run the report.

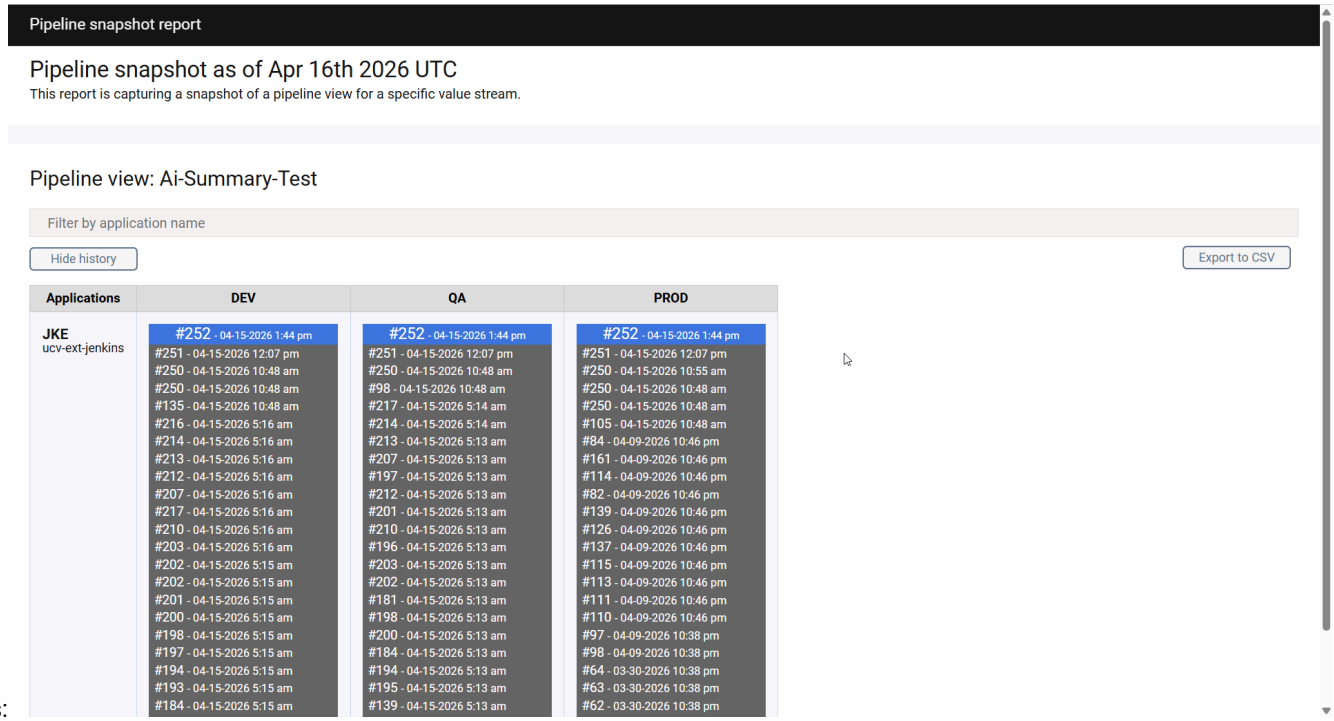
The **Pipeline snapshot** page displays the following information about the report:

- **Date**: Shows the date, time, and email address of the user who ran the report.
- **Status**: Shows the color-coded status: Orange = **STARTED**, green = **COMPLETE**, and red = **FAILED**.

The following elements provide detailed information about the report:

- **View log**: When you click **View log**, the log details of the report are displayed.
- **View parameters**: When you click **View parameters**, the **VIEW PARAMETERS OF EXECUTION** window opens and displays the details used to run the report.
- **Share**: When you click **Share**, the URL is copied so you can share the report.
- **Results**: When you click **Results**, the **Pipeline snapshot report** page is displayed. You must then click **Export to CSV** to export the pipeline snapshot report.

A sample pipeline snapshot report page is shown as follows:



Releasing Software

A release is a repeatable plan that is used to drive deployments.

Releases are the organizing focus of software deliveries. Releases can represent any software-development-related event, from major milestones in the life of the company to comparatively minor events, like recurring maintenance. You can schedule a release at any point in your development-operations lifecycle. You can automate release schedules or manually run deployments.

A release contains deployment plans and events that are related in some business-meaningful way. For example, the deployment plans might represent the phases in a software development lifecycle, such as development, QA, and production. An event might represent a blackout that affects the release.

Every value stream has a corresponding pipeline generated for it, and every pipeline has deployment plan templates. The tight relationship between pipelines and deployments makes it easy to use pipelines to drive deployments. You can start by creating a release and adding deployment plans and events to it. Or you can start with value streams and pipelines and then join them to a release. You can run deployments directly from a pipeline or from a deployment plan.

You can coordinate several releases into a single event, which ensures that all release stakeholders can participate. If you add events to a release, you can use the calendar to organize releases and deployment plans.

Managing a release

Use the release details page to view details about a specific release.

This page contains the calendar and list of tasks. When viewing tasks you can select to view only your tasks or all tasks.

You can also use this page to access and work with release templates.

Use this page to view and work with archived releases removed from the calendar and list of tasks.

When you access a release from the **Releases** page, you can create a deployment plan and display overview details about the release, such as the deployment plans associated with the release with related details. From the **Overview** section of the **Releases** page, you can view the following release details for specific releases:

- **Plans** displays the plans associated with the release and task status, team, and date that the task is scheduled. You can access additional details for specific plans.
- **Task progress** displays the associated tasks that are not completed and contains information such as type of task, task owner, start and end time, duration, and task dependencies.
- **Approvals** list the approvals with the status of the approval and approver.
- **Change requests** displays a list of ServiceNow™ change requests.

The **Properties** section displays properties defined in the plan and property value.

Managing releases

Release management is the process of planning, scheduling, and controlling software deliveries.

About this task

The **Releases** page displays information about releases. This page provides access to the calendar, tasks, events, release activities, and related details.

The page contains the calendar or list of tasks. Click **Calendar** to view the calendar. To hide the calender and task bar, click . To view tasks, click **Tasks**. When viewing tasks, you can select to view only your tasks or all tasks. To view events, click **Events**. To create an event, click .

Release activities are displayed in a tile or list () format. Using the search bar on the top of the page, you can limit the amount of information displayed by typing a filter to narrow the search results. Additionally, click the filter ( ) to limit the list of displayed release activities to: **Complete**, **In progress**, or **Scheduled**. Click an item in the **Release activities** list to view specific release details.

Click the tag ( ) to toggle on or off the display of tags associated with the release activity.

To create a new release, click **Create release**.

To import the releases and events, click **Import Release**.

You can also use this page to access and work with release templates by clicking **Templates** on the page.

Click **Archived** to view and work with releases removed from the **Releases** page and the calendar.

You can view release details, such as deployment plans associated with the release, by clicking **Overview**. This page will display headings that include: **Plans**, **Task progress**, **Approvals**, and **Change requests**.

- Plans associated with the release an be viewed by clicking **Plans**. The number above the **Plans** heading is the total number deployment plans related to this release.
- Tasks details can be viewed by clicking **Task progress**. The number above the **Task progress** heading displays the number of associated tasks not completed and total number of tasks. Click the task for additional task information.
- Click **Approvals** to display approvals details. The number above the **Approvals** heading is the total number of approvals. Click the approval name for details about a specific approval.
- Click **Change requests** to display a list of ServiceNow™ change requests. The number above the Change requests heading is the total number of ServiceNow™ change requests.

Click **Properties** to display a properties defined in the plan and property value. You can add or change the property value by double-clicking the **VALUE** property field. Click the check mark to save the value.

To create a new deployment plan, click **Create deployment plan**.

Creating releases

1. On the **Releases** page, click **Create release**
2. In the **Create release** window, type a name for the release in the **Name** field.
   This field can be referenced with the `${sys:release.name}` system property. A name is required.
3. In the **Tags** list, select one or more events or tags. You can also create a tag by typing the name of the new tag in the field.
   If you want the event to appear on the calendar, select an event that is created on the **Configure Calendar** page. Tags that you create with the **Create release** window are not displayed on the calendar, which can prevent calendar clutter.
4. In the **Description** field, type a description of the release. This field can be referenced with the `${sys:release.description}` system property.
5. In the **Deployment plan templates** field, select one or more templates to add to the release.
   Each template that you select, adds a deployment plan to the release with the name **Copy of *template_name***. You can convert any deployment plan into a template. If the selected templates have user-defined properties, you are prompted to provide values for them when you save the release.
6. In the **Start Time** field, select a starting date and time. This field can be referenced with the `${sys:release.start}` system property. Starting times are required for all releases.
7. In the **End Time** field, select the ending date and time. This field can be referenced with the `${sys:release.end}` system property.
8. In the **Team** list, select a team to manage the release. You can add deployment plans from other teams to the release event, not just the team that manages the release. All the teams that you belong to are available. A team is required.
9. If the selected templates have properties, click **Next**, and then provide values for the properties. Otherwise, click **Save** and view details to save the release and open the **Releases** details page. If you added templates to the release, a deployment plan for each template is created and displayed. If you didn't select any templates, an empty deployment plan is added to the release with the name **Plan: *release_name***.

   To display the release in the **Activities** list, ensure that the date range includes dates within the release's start or end times.

What to do next

After the release is created, you can add deployment plans, events, and tags to it.

Archiving releases

You can archive a release to remove it from the list of releases.

About this task

Although you cannot delete a release, you can store it in the archives. Archived releases are not displayed on the **Releases** page.

To archive a release, click the overflow ( ) and then select **Archive**.

Repeat this action for each release to be archived.

You can view archived releases and restore them by clicking **Archived** on the **Releases** page.

Events and tags

An event represents a release-related activity that you manage with the calendar. A tag is a label that you can add to a release or an event. You can use tags to filter the `Activities` list on the **Releases** page. Tags do not appear on the calendar.

Events are organized into general categories that include releases, holidays, and maintenance windows. You can add events to releases or use them independent of releases. When an event is assigned, it is represented on the calendar by an icon appropriate for the event category. You can use the icons to filter the **Releases** page and select releases for any affected date or range of dates.

Tags are assigned to releases and can be used to filter the **Releases** page. Assigned tags appear in Releases page but they do not appear on the calendar. You can use tags to avoid calendar clutter.

Restoring archived releases, plans, and templates

You can restore archived releases, deployment plans, and templates.

About this task

A restored release retains all of its original deployment plans.

1. On the **Releases** page, click **Archived**.
   The **Archive** page lists all archived items. The **TYPE** column displays whether the item is a release, plan, or template.
2. Locate the item to be archived.
   Using the search bar, you can limit the amount of information displayed by typing a filter to narrow the archive search results. Filters can contain keywords, teams, tags, or name. You can also click on some of the table headers to sort the table in ascending or descending order based on the heading selected. For example, clicking **ARCHIVED DATE**, list the items from earliest archive date to current. Click the tag ( ) to toggle on or off the displaying of tags associated with the release activity.
3. If an item needs to be restored, click the overflow ( ) and then select **Restore**.
   Repeat this step for each release to be restored.
4. Click **Releases** to return to the **Releases** page.

Results

- Restored releases are displayed in the list of releases.
- Restored releases retains all of its original deployment plans.
- Restored deployment plans have a status of **draft**.

Deployment plans

A deployment plan is a container for tasks. Tasks define the activities that your team runs to complete a software deployment.

You create a deployment plan by assigning a team to manage it and then adding tasks to the plan. Team members add tasks to the plan and run the tasks during deployments. The managing team also determines which HCL DevOps Deploy (Deploy) applications are available. After an integration is configured, all applications that are managed by the team in Deploy are available.

When you use the Pipeline feature, releases and deployment plans are automatically generated as you add stages and applications to the pipeline. You can start deployments directly from the pipeline, or open the deployment plan and start the deployment by running an eligible task.

The tasks define the activities that the team performs to complete a deployment. You can create new tasks, copy tasks from other deployment plans or import tasks from CSV files. When you are satisfied with the plan, you can schedule a deployment. You can also run a deployment at any time by starting one of the plan's tasks.

Tasks are displayed on individual rows in deployment plans. Each row contains information that identifies the task and provides its status. Each row also contains action icons that are used during deployments, such as **Start** task or **Skip**.

You can run the tasks sequentially or parallely beginning with the first task, or topmost task, in the plan. After the first task finishes, the second task is eligible to run, and so forth. The order in which tasks are eligible to run is called the execution order.

The execution order can be modified by combining tasks into groups. When you create a group on page 1849, you set the group's execution pattern, which can be sequential or parallel. If a group has a sequential execution pattern, its tasks run sequentially starting with the first task. If a group has a parallel execution pattern, tasks in the group can be started in any order and they can run simultaneously. If a plan consists entirely of parallel tasks, you can start any task regardless of its position in the list.

Task eligibility can also be effected by task dependencies. If a task has any prerequisites on page 1848, it cannot start, even if it is otherwise eligible, until all prerequisite tasks are resolved.

Some tasks start automatically as soon as they are eligible to run, while other tasks are started manually. Whether a task starts automatically or not depends on its type. Manual tasks, as the name implies, are started manually. Deploy and Delayed-type tasks automatically start as soon as they are eligible.

Eligible tasks display a **Start Task** button. To start a deployment, you start one of a plan's eligible tasks. Scheduled deployments start automatically at the scheduled time if an eligible task is of a type that can start automatically, such as Deploy.

Managing deployment plans

You can change existing deployment plans and view current status from the **Deployment Plan** details page.

About this task

The **Deployment Plan** details page displays a list of tasks, properties, versions, and the change history associated with the plan.

- Click **Tasks** to work with the tasks in the plan. You can add tasks, schedule tasks, skip a task, and reopen a completed task.
- Click the **Properties** to view properties and their value.
- Click the **Versions** to view versions.
- Click the **Change history** to view a list of the changes, revision number, user who made the revision, and date. You can also restore a plan to a specific version by clicking restore ( ).

From this page you can modify and archive the plan, change the name of the plan, make a copy of the plan, and create a template from the plan. Access these features from the overflow menu ( ) at the top right corner of the page.

- Click **Import tasks** to incorporate tasks into the deployment plan from various file sources including spreadsheets, project management tools, or IBM® DevOps Release.
- Click **Estimate task times** for approximating task durations.
- Click **Edit** to modify the deployment plan. With this option, you can add events and tags to the release event.
- Click **Copy** to copy a deployment plan. A copy of the selected plan is added to the release.
- Click **Copy as template** to create a template based on this plan.
- Click **Archive plan** to remove the deployment plan from the release. Removed plans are not permanently deleted and can be added to another release.

Creating deployment plans

You can start with a blank plan that has no defined tasks, copy an existing plan, or start with a plan template. You can also auto-create them by assigning applications to pipelines. When you copy a plan or use a template, many tasks are already defined.

About this task

Complete the following steps to create a deployment plan:

1. On the **Releases** details page, click **Create Deployment Plan**.
2. On the Create Deployment Plan window, in the **Deployment plan template** list, specify the template that you want to base the plan on. The default value is **None**.
3. In the **Plan name** field, enter the plan name.
4. In the **Description** field, enter the description.
5. In the **Team** list, select a team to manage the plan. All teams that you are a member of are available. Team members can modify the plan and manage tasks. The HCL DevOps Deploy applications that are managed by the team in Deploy are available to assign to Deploy type tasks.

6. To schedule a deployment for the plan, click **Start time**, and then select a date and time for the deployment. Scheduled deployments automatically start at the scheduled time if the plan contains eligible auto tasks. You can schedule a deployment for any future time.
7. In the **Tags** list, select tags that you want to add to the plan.
8. Click **Save**. If you created the plan on a **Releases** details page, the plan is part of the selected release. After you save the plan, click **Edit** to modify plan details.

Note: You can create one deployment plan as a primary linked to many secondary deployment plans. Deployment is executed only from primary deployment plan.

Importing tasks into deployment plans

You can import tasks that are defined in comma-separated values (CSV) files into a deployment plan.

About this task

You can import tasks from CSV files that are exported from IBM® DevOps Release or another application capable of creating CSV files. When you import a deployment plan from Release, segments are converted into groups with the same execution pattern as the original segments. Segment tasks are bracketed by note-type Start Segment and End Segment tasks. Task dependencies are preserved during import. Segment dependencies are represented by dependencies to End Segment tasks.

To learn about deployment plans exported from Release, download the `SamplePlan.csv` file from the Import Tasks dialog.

Note: When you import tasks, tasks that are already defined in the deployment plan are overwritten and replaced by the tasks in the CSV file.

The following table contains the fields that define a task in an Release deployment plan. The first row in the CSV file contains the column headers, which correspond to the table's Field column. The rows after the first row contain task data, one task per row. The order of the columns does not matter.

Note: If you are creating tasks in a CSV file, you must include the required fields that are identified by the asterisk character (*) in the following table.

Table 1182. Release deployment plan fields

Field	Description
segmentName*	The name segment. Required field.
name*	The name of the deployment task. Required field.
type*	Task type. Possible values are note, waitfortimetask, ucdtask, or manual. During import, if the field contains an unrecognized value, the task is assigned the manual type.
description	Description of the deployment plan.

Table 1182. Release deployment plan fields (continued)

Field	Description
property:processId	The process ID in HCL DevOps Deploy (Deploy) that corresponds to the task.
property:task-environments	Application environments available to the task.
property:mailRecipients	Email addresses of users who receive email messages when notifications are sent.
taskTagNames	The names of the tags that are associated with the task.
taskPrequisiteIds	A comma-separated list of IDs for tasks that must complete before this task can start.
segmentPrerequisiteIds	A comma-separated list of IDs for segments with which the current segment has dependencies.
taskPrequisiteNames	A comma-separated list of names for tasks that must complete before this task can start.
segmentPrerequisiteNames	A comma-separated list of names for segments with which the current segment has dependencies.
assignedUserEmail	Email address of the user who is assigned to the current task.
executorGroup	User group assigned to the current task.
segmentPattern	Execution pattern of the selected segment.

Complete the following steps to import tasks into a deployment plan:

1. On the **Deployment Plan** details page, click **Import Tasks**.
2. In the Import Tasks dialog, click **Choose File**, and then select the CSV file in addition to confirming the choice in the dialog box. You can also drag a file onto the field.
3. Click **Import**. The tasks are added to the deployment plan. If the import process is unsuccessful, click **View Report** to display the error log.

Copying deployment plans

You can duplicate deployment plans by copying them.

About this task

The status of a copied or promoted plan is `draft` even if the original plan has a status of `done` or `in progress`.

1. **Optional:** To copy a plan, click the overflow icon ( ) and select **Copy plan** from the drop-down on the **Releases** details page. When you copy a plan, a new plan with the name "Copy of `plan_name`" is inserted into the **Releases** details page. The copied plan contains all the tasks that are defined in the original plan. If HCL DevOps Deploy (Deploy) tasks are in the plan, the applications, versions, and environments that are selected in the original are also selected in the copied plan. Applications, versions, and environments are displayed on the **Versions** tab on the Deployment Plan Detail page.
2. **Optional:** To create a template from a plan, click the overflow icon ( ) and select **Copy as template** from the drop-down on the **Releases** details page. When you copy a plan as a template, a new plan with the name "Copy of `plan_name`" is inserted into the **Templates** page. The copied plan contains all the tasks that are defined in the original plan. If Deploy tasks are in the plan, the applications, versions, and environments that are selected in the original are also selected in the template.

Managing deployment plan templates

You can convert deployment plans to create deployment plan templates.

About this task

To create a template, click the overflow icon ( ) and select **Copy as template** from the drop-down on the **Releases** details page. When you create a template, a new plan with the name "Copy of plan_name" is inserted into the **Templates** page. The status of a template is `template` even if the original plan has a status of `done` or `in progress`. The template contains all the tasks that are defined in the original plan. If HCL DevOps Deploy (Deploy) tasks are in the plan, the applications selected in the original are also selected in the template.

You cannot run deployments with templates. To use a template for a deployment, first copy or promote it and then use the copied or promoted plan.

Archiving deployment plans

You can remove deployment plans from releases by archiving them.

About this task

Deployment plans cannot be permanently deleted, but can be archived. When you archive a deployment plan, it has a status of **Archived** and is not displayed in the list of plans on a **Releases** details page.

You can view archived deployment plans and restore them by clicking **Archived** on the **Releases** page.

1. Click **Plan** for a release to view a list of associated deployment plans.
2. On the line of the plan to be archived, click the overflow menu icon ( ) and select **Archive this plan**.
   Repeat this step for each plan to be archived.

Running deployments

Complete deployments by resolving the tasks in a deployment plan.

A deployment starts when one of the plan's eligible tasks starts. A scheduled deployment starts automatically at the scheduled time if one of its eligible tasks is an auto task, such as HCL DevOps Deploy (Deploy) tasks. Otherwise, begin a deployment by starting one of the plan's eligible tasks. If the plan contains several eligible tasks, you can start any of them. You can manually start a deployment at any time. You can manually start a scheduled deployment before its scheduled time.

The deployment plan's execution pattern determines when tasks are eligible to start. If the plan has the sequential execution pattern, which is the default pattern, tasks become eligible in the order in which they are listed in the plan, starting with the first task. After the first task resolves, the second task becomes eligible. Start eligible manual tasks by clicking the task's **Start** button. Auto tasks, such as Deploy tasks, start automatically as soon as they become eligible.

The tasks in a group with a parallel execution pattern become eligible simultaneously. Tasks in parallel groups can be started in any order. Nested groups and tasks with ad hoc dependencies can affect the execution pattern.

You can modify a deployment plan after you start a deployment. You can add, delete, and modify tasks.

After all tasks are resolved, the deployment is complete. A task is resolved if it has a status of `Complete`, `Failed`, or `Skipped`. If you reopen a task or add a task after the deployment is complete, the deployment's status changes to `In Progress`.

Starting deployments manually

Starting deployments manually

About this task

You can start a deployment manually at any time, including deployments that are scheduled to start later.

Tasks in a deployment plan might be inapplicable for deployment. HCL DevOps Deploy (Deploy) tasks are inapplicable if no version or environment is specified for the tasks. When you create Deploy tasks, you can delay selecting the environment and version by using the **Use Version** option. Before the deployment starts, ensure that all Deploy tasks are applicable for the upcoming deployment.

You can deliberately exclude tasks from a deployment. You can make tagged tasks inapplicable by excluding their tags from the deployment. Tasks with excluded tags are inapplicable for deployment.

Inapplicable tasks have the status of `Not Applicable`. Tasks with the `Not Applicable` status cannot be started. If an inapplicable task is a prerequisite for an active task, the dependency is ignored.

To start a deployment, complete the following steps:

1. On the **Releases** details page, click the deployment plan that you want to use for the deployment. The **Deployment Plan** details page is displayed.
2. **Optional:** To make tagged tasks inapplicable for the current deployment, click **Versions**, and then in the **Tags** area, clear the tags. If a task has more than one tag, clear all of them.

3. To select the version or environment for any inapplicable Deploy tasks, click **Versions**, and then select the environment and version. You can also change your choices for tasks that have their environments and versions already selected.
4. **Optional:** Click **Hide Not Applicable Tasks** to remove inapplicable tasks from the displayed task list. Hidden tasks are not removed from the deployment plan.
5. Click the **Start** action for one of the plan's eligible tasks. If more than one task is eligible, you can start any of them. Only eligible tasks display the start button. A started task has the status of `In Progress` until it is resolved.
   Result
   After a deployment starts, the plan's status changes to `In Progress`. The status remains `In Progress` until all tasks are resolved. When all tasks are resolved, the plan's status changes to `Done`.

Resolving tasks

Complete a deployment by resolving the tasks in the deployment plan.

About this task

A started task is resolved when its status changes to `Complete`, `Failed`, or `Skipped`.

You resolve manual tasks by using the appropriate status action. Auto tasks, such as HCL DevOps Deploy (Deploy) tasks or Jenkins®, change status automatically as conditions change. However, you can manually resolve auto tasks. For example, you might manually fail an Deploy task that is taking too long to complete.

To resolve a started task, apply one of the following statuses:

- Click **Complete** to finish the task. `Complete` means that the task finished with the expected results.
- Click Skip to skip the task for the current deployment.
- Click **Fail** to end the task. `Fail` means that the task did not finish or finished with unexpected results.
- Click **Task Reopen** to open a resolved a task. If all tasks are completed, reopening a task reopens the deployment.

Importing tasks into deployment plans

You can import tasks that are defined in comma-separated values (CSV) files into a deployment plan.

About this task

You can import tasks from CSV files that are exported from IBM® DevOps Release or another application capable of creating CSV files. When you import a deployment plan from Release, segments are converted into groups with the same execution pattern as the original segments. Segment tasks are bracketed by note-type Start Segment and End Segment tasks. Task dependencies are preserved during import. Segment dependencies are represented by dependencies to End Segment tasks.

To learn about deployment plans exported from Release, download the `SamplePlan.csv` file from the Import Tasks dialog.

Note: When you import tasks, tasks that are already defined in the deployment plan are overwritten and replaced by the tasks in the CSV file.

The following table contains the fields that define a task in an Release deployment plan. The first row in the CSV file contains the column headers, which correspond to the table's Field column. The rows after the first row contain task data, one task per row. The order of the columns does not matter.

Note: If you are creating tasks in a CSV file, you must include the required fields that are identified by the asterisk character (*) in the following table.

Table 1183. Release deployment plan fields

Field	Description
segmentName*	The name segment. Required field.
name*	The name of the deployment task. Required field.
type*	Task type. Possible values are note, waitfortimetask, ucdtask, or manual. During import, if the field contains an unrecognized value, the task is assigned the manual type.
description	Description of the deployment plan.
property:processId	The process ID in HCL DevOps Deploy (Deploy) that corresponds to the task.
property:task-environments	Application environments available to the task.
property:mailRecipients	Email addresses of users who receive email messages when notifications are sent.
taskTagNames	The names of the tags that are associated with the task.
taskPrequisiteIds	A comma-separated list of IDs for tasks that must complete before this task can start.
segmentPrerequisiteIds	A comma-separated list of IDs for segments with which the current segment has dependencies.
taskPrequisiteNames	A comma-separated list of names for tasks that must complete before this task can start.
segmentPrerequisiteNames	A comma-separated list of names for segments with which the current segment has dependencies.
assignedUserEmail	Email address of the user who is assigned to the current task.
executorGroup	User group assigned to the current task.

Table 1183. Release deployment plan fields (continued)

Field	Description
segmentPattern	Execution pattern of the selected segment.

Complete the following steps to import tasks into a deployment plan:

1. On the **Deployment Plan** details page, click **Import Tasks**.
2. In the Import Tasks dialog, click **Choose File**, and then select the CSV file in addition to confirming the choice in the dialog box. You can also drag a file onto the field.
3. Click **Import**. The tasks are added to the deployment plan. If the import process is unsuccessful, click **View Report** to display the error log.

Running scheduled deployments

A scheduled deployment starts automatically at its scheduled time if any of its auto tasks are eligible to start.

About this task

If a deployment plan does not contain any eligible auto tasks, start the deployment by manually starting one of the eligible tasks. If the deployment plan belongs to a pipeline-generated release, you can start the deployment directly from the pipeline.

You can manually start a scheduled deployment at any time even if the plan has eligible auto tasks.

Tasks

A task represents a business-meaningful activity that is associated with a software deployment. Each task is defined on a separate row in a deployment plan. During a deployment, you run tasks defined in the deployment plan to complete the deployment.

Most tasks have a starting and ending point, and a measurable duration. A task can have other attributes depending on its type. A task can be of one of following types:

Ansible

Automation tool used for configuration management, application deployment, intraservice orchestration, and provisioning tasks.

Delayed

Represents a critical event that happens at a specific time.

Email

Sends an email message.

Header/Note

an organizational element. For example, you might use a header task to identify a task group.

Jenkins®

Runs a Jenkins® job or pipeline.

Manual

Represents any activity that is associated with a software deployment, such as taking a server offline or updating a database. Users assigned manual tasks can be sent email notifications when their tasks start or fail.

Run a Shell Script

Shell script tasks are used to execute a sequence of commands. The shell is the command line interface (CLI) for the operating system (OS) used to interpret the sequence of commands communicating with the software interface.

Run another plan

Runs deployments for other deployment plans participating in the same release event. This is an experimental task type.

ServiceNow™

Creates and manages ServiceNow tickets.

HCL DevOps Deploy (Deploy) (requires Deploy integration)

Use this task to run an Deploy application process.

Deploy Status (requires Deploy integration)

Use this task to add a status to all component versions contained within an Deploy snapshot.

Wait for approval

Pauses a deployment until the designated users approve the task.

You can add tasks to deployment plans by one of the following methods:

- Create a new task
- Import from CSV files that are created by Deploy or another application
- Copy tasks from other deployment plans

Additionally, tasks are auto-created when you add an application to a pipeline on page 3127.

Managing tasks

A list of associated tasks can be viewed from a **Deployment Plan** details page. The list of tasks include details about the task. You use action icons to change the task's status during a deployment, such as start or skip a task.

About this task

Each task in a deployment plan is contained in a separate row. Click ( ) to show or hide associated tasks from the list.

Click ( ) show or hide tags.

The information that is displayed for each task is described in the following table.

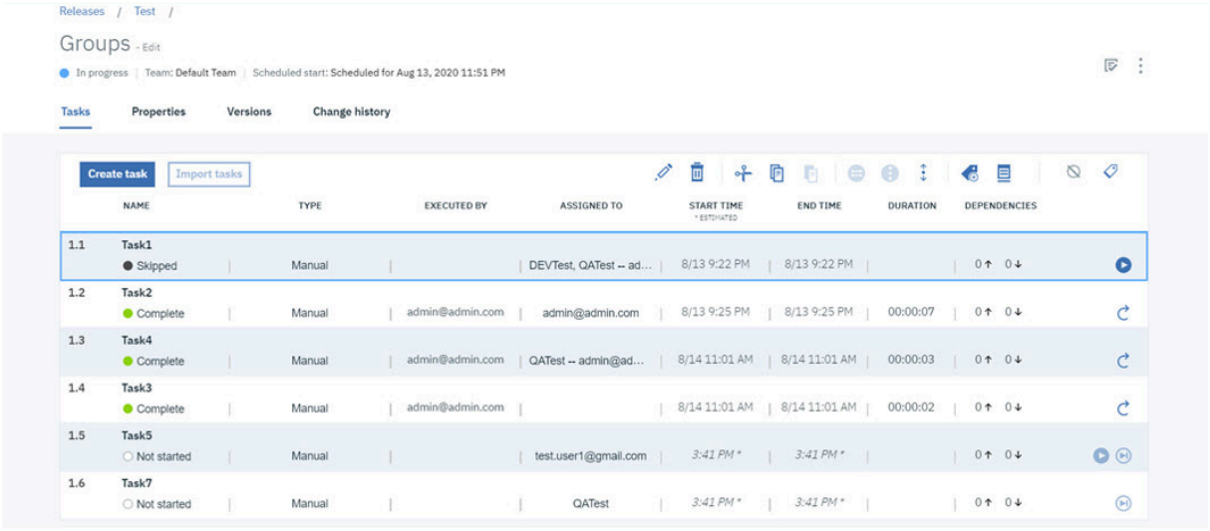


Table 1184. Task properties

Property	Description
Name	Task name
Status	Task status: Not started, complete, failed, skipped, not applicable
Type	Type of task: Delayed, Deployment Risk Analysis, Email, Header/Note, Jenkins®, Manual, Run another plan, ServiceNow™, HCL DevOps Deploy, and Wait for approval.
Executed by	Person who executes the manual task
Assigned to	Groups and users designated as the task owner
Start time	Start time or expected start time based on scheduled start, or estimated duration of other tasks
End time	Time that the task resolved
Duration	Length of time in minutes from task start to task resolution.

Table 1184. Task properties (continued)

Property	Description
Dependencies	Indicates the number of tasks that are prerequisites for the task, and dependent on the task
Action icons	One or more actions used to change the status of the task during a deployment

Tasks are listed in the order that they run. The order of the tasks can be changed by selecting one or more tasks and dragging to the new location.

At the end of each row are applicable actions associated with the task. Depending on the task you can perform one or more of the following actions.

- Start task ( )
- Skip task ( )
- Re-run task ( )
- Complete task ( )
- Fail task ( )

You can manage the tasks in a deployment plan from the task bar above the table. When a task is selected, the task bar displays and you can perform the following actions:

- Click ( ) to edit the task.
- To copy a task or group, select one or more tasks and click , and then place the cursor where you want to insert the copied task and click to paste the selection.
- To cut a task or group from a deployment plan, select the task and click .
- To delete a task, select the task and click . The task is removed from the deployment plan.

- To create a group of tasks that can run simultaneously, select the tasks and click . The group must consist of at least two tasks.
- To create a group of tasks that are to consecutively run, select the tasks and click . This is the default execution pattern.
- To add or remove tasks that must complete first, select the task and click . In the dialog box, select or type the prerequisite task to be added. Click **X** next to the prerequisite to be removed. When finished, click **Save**.
- To add or remove tags, select the task and click . In the dialog box, type or select tags to add. To remove a tag, click **X** next to the tag to be removed. When finished, click **Save**.
- To view information about when the task started, completed, and errors, click .

Creating tasks

By default, new tasks are inserted at the bottom of the deployment plan. After a task is created, you can move it, or copy it and paste it into another deployment plan. You can also create dependencies with other tasks on page 1848.

About this task

Tasks can be added to a deployment by creating a new task or importing an existing task.

After you save a task, actions are displayed for the task. You use actions to change the task's status during a deployment.

All tasks have the skip action. Other actions, such as the start action, are displayed when the context is appropriate for them.

1. From the **Deployment Plan** details page, click **Create task** to create one or more tasks.
2. Select a task type.

   Note: The availability of task types will depend on your version of HCL DevOps Deploy (Deploy) and integrations.

   Possible task types include:
   - Ansible
   - Delayed
   - Deployment Risk Analysis
   - Email
   - Header / Note
   - Jenkins

- Manual
- Run a Shell Script (requires shell script plugin)
- Run another plan
- ServiceNow™
- Deploy (requires Deploy integration)
- Deploy Status (requires Deploy integration)
- Wait for approval

3. Provide information in required and optional fields displayed according to the task type selected.
4. Click **Save and create another** to create additional tasks. Click **Save** when finished.

Managing task dependencies

You can make a task a prerequisite for other tasks. If a task is a prerequisite, dependent tasks cannot start, even if they are otherwise eligible, until the prerequisite task is resolved.

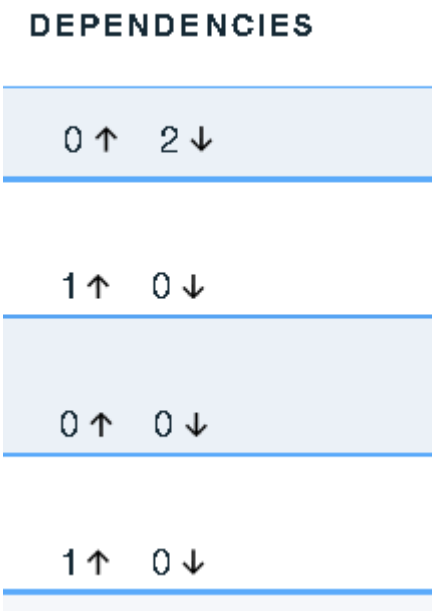
About this task

A task can have multiple dependent tasks and multiple prerequisite tasks. You can define dependencies for a task with any other task in the deployment plan. However, you cannot create circular dependencies. You cannot, for example, make a task dependent on a task that itself depends on the first task. By controlling task dependencies, you can ensure that events occur in their expected order.

To make a task a prerequisite for other tasks, complete the following steps:

1. On the **Deployment Plan** details page, select a task or task group, and then click . You can select multiple tasks and groups.
2. In the **Manage prerequisites for selected tasks** dialog box, in the **Prerequisite tasks for selected tasks** drop-down list, select the prerequisite task.
3. Click **Save**.
   Result
   Task dependencies are shown in the **DEPENDENCIES** column on the **Deployment Plan** details page. Up arrows indicate task prerequisites; down arrows indicate task dependencies. In the following figure, the first task does not

have any prerequisites and has two tasks dependent on it. The second task has one prerequisite task and there are no tasks dependent on it.



What to do next

To review or modify dependencies, select the task and then click . Use the **Manage prerequisites for selected tasks** dialog box to modify or remove dependencies.

Creating task groups

You can combine two or more tasks into a task group. When you create a group, you define the whether the group task are executed sequentially or in parallel.

About this task

Tasks can run in a parallel or sequential pattern. When you create the task, you decide the execution pattern. Tasks without dependencies can execute in any order or simultaneously which is *parallel* execution. Tasks that must execute in specific order are *sequential* execution. Tasks are done in list-order starting with the first or top-most task.

You can embed groups within other groups. A sequential-pattern group can be embedded within a parallel-pattern group, and vice versa; however, you cannot embed a sequential-pattern group within another sequential group, or a parallel-pattern group within another parallel group.

1. On the **Deployment Plan** details page, select two or more tasks.
2. Depending on the type of group you want to create, complete one of the following.
   Choose from:

- To create a parallel group, click the Parallel icon)). If you cannot create a parallel group with the selected tasks, the icon is disabled. For example, you cannot create a parallel group if all the selected tasks are already in a parallel group.
- To create a sequential group, click the Sequential icon ( ).

Result

The group is formed and a group select bar is added to the deployment plan. If you selected discontiguous tasks, the tasks form a contiguous list starting with the topmost selected task.

Managing task groups

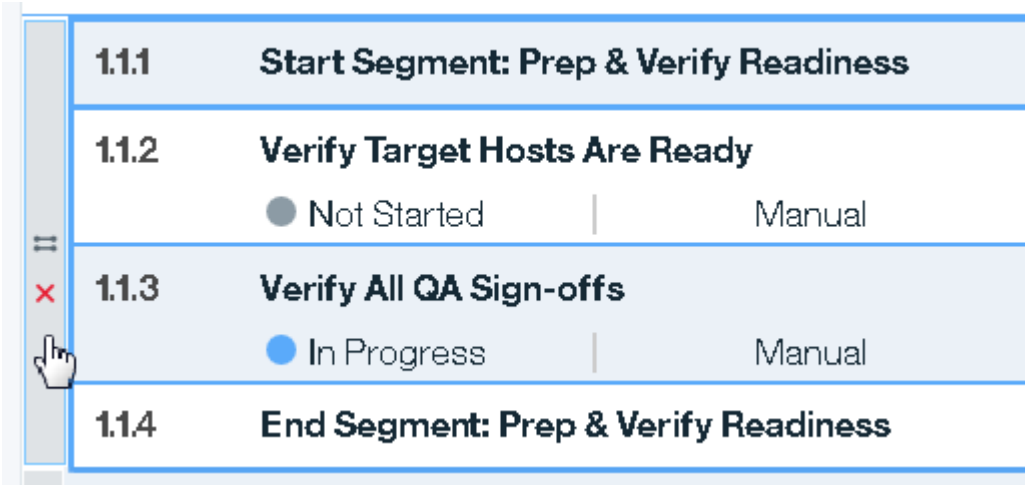
You can combine two or more tasks into a task group. When you create a group, you define the whether the group task are executed sequentially or in parallel.

About this task

You can recognize task groups in the list of task, there is a bar connects the grouped tasks and contains an icon to identify if it is a parallel or sequential group.

- parallel
- sequential

The following image shows a parallel group.



You can manage task groups in several ways:

- To move a group, select the group select bar or click anywhere on the group, and then drag it to a new location.
- To copy a group, select the group and click , and then place the cursor where you want to insert the copied group and click .
- To cut a group, select the group and click .
- To ungroup a group, select the group and click the **Ungroup** icon on the group select bar.
- To delete the tasks in a group, select the group and click . The tasks are removed from the deployment plan.

Managing task tags

Tags are organizing elements that you can add to tasks. You can filter deployment plans by tag. For example, during a deployment to a production environment, you might disable tasks with the `DEV_only` tag, which is intended to be used only in development environments.

About this task

To add a tag to a task, complete the following steps:

1. On the **Deployment Plan** details page, select a task or task group, and then click . You can select multiple tasks and groups.
2. In the **Manage Tags for Selected Tasks** dialog box, in the **Tags** drop-down list, select tags. You can create a new tag by typing a name in the list's text box.
3. Click **Save**.
   Tags are displayed on the task rows in the **Deployment Plan** details page. In the following figure, the Deploy WAR task has two tags assigned to it, `Deployment`, and `Critical`.

   The tags used by a deployment plan are displayed on the **Deployment Plan** details page by clicking **Versions**. To render tasks with a specific tag `Not Applicable` for a deployment, clear the tag. Tasks with the `Not Applicable` status cannot be started.

Creating run another plan tasks

A run another plan task runs a deployment for another deployment plan.

About this task

The targeted plan can be created from a template or a tag. If you use a template, the template and the targeted plan must be in the same release as the run another plan task.

To create a run another plan task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create task**. If you want to insert a task at a specific position in the plan, select a task before you use the **Create task** action. The new task is inserted before the selected task.
2. In the **Create task** dialog box, in the **Type** drop-down list, select **Run another plan**.
3. In the **Name** field, enter a name for the task.
4. In the **How do you want to choose another plan** area, select an option.
   If you choose, **By template**, the template and associated deployment plan must be in the same release as the task's parent plan. If you choose, **By tag**, the tagged deployment plan must be in the same release as the task's parent plan as demonstrated in this example on page 1852 of creating a primary and secondary template.
5. In the **Run plans created from this template** list, select a deployment plan template. The template and associated deployment plan must be in the same release as the task's parent plan.
6. In the **Run plans with this tag** list, select the tag associated with the template to the task.
   You can select multiple tags. To create a tag, type the tag name in text box.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When the task runs, a deployment starts for the deployment plan that was created from the selected template or tagged plan. If multiple plans in the release event are eligible, deployments start for all of them. While the other deployments run, status information is provided by the run another plan task. Expand the task to see the status information. You can open the other deployments by using links on the task. While the other deployments run, the run another plan task has a status of **In Progress**.

Creating run another plan tasks: Example

A run another plan task runs a deployment for another deployment plan.

About this task

This example is a targeted plan that is created from a tag. The tagged deployment plan must be in the same release as the task's parent plan.

To create a targeted plan that is created from a tag, complete the following steps:

1. Create the primary template.
    a. On the **Releases** page, click **Templates > Create template**.
    b. In the **Plan template name** field, enter the name for the primary template.
    Accept the default values for the remaining fields.
    c. Click **Save**.
    d. Click the name of the primary template.
2. Referring to the Creating tasks on page 1847 page, create independent and dependent tasks for the primary template by using field values that are detailed in the following tables for each task:

Table 1185. Manual task

Create task field	Value
Type	Select **Manual**.
Name	Enter the name for the manual task.
Description	Default value.
Duration (minutes)	Default value.
Tags	Default value.
Assigned groups and users	Default value.

Table 1186. Run another plan task

Create task field	Value
Type	Select **Run another plan**.
Name	Enter the name for the secondary task.
How do you want to choose another plan?	**By tag**
Run plans with this tag	Select a tag or create a new tag by typing a name in the field. The primary deployment plan will find any other plan with this tag name when it runs.
Tags	Default value.

3. Create the secondary template.
    a. On the **Releases** page, click **Templates > Create template**.
    b. In the **Plan template name** field, enter the name for the secondary template.
    Accept the default values for the remaining fields.

c. Click **Save**.

d. Click the name of the secondary template.

4. Referring to the Creating tasks on page 1847 page, create independent and dependent tasks for the secondary template by using field values that are detailed in the following tables for each task:

Table 1187. Wait for approval task

Create task field	Value
Type	**Wait for approval** or any task that starts automatically.
Name	Enter the name for the task.
Approval prompt	Default value or enter a prompt message.
Approvers	Select the name of the approver. You can select multiple approvers.
Required Approver	Select **Any approver can approve** or **All approvers must approve**

Table 1188. Manual task

Create task field	Value
Type	**Manual**
Name	Enter the name for the task.
Description	Default value.
Duration (minutes)	Default value.
Tags	Default value.
Assigned groups and users	Default value.

5. Referring to the Creating releases on page 1833 page, create a release with the primary and secondary templates by using field values that are detailed in the following table:

Table 1189. Create release

Create release field	Value
Name	Enter the name for the release.
Tags	Select the name for the required tag.
Description	Default value.
Deployment plan templates	Select the name of the primary template that you created.

Create release field	Value
Start time	Default value.
End time	Default value.
Team	Default value.

6. On the **Releases** page, click the name of the release.
7. Click the primary plan to display the independent task and dependent task with a tag in the template.
8. At the top of the page, click the link to go back to the release.
9. Create the deployment plan.
    a. Click **Create deployment plan**.
    b. In the **Deployment plan template** list, select the name of the secondary template that you created.
    c. In the **Tags** field, select the name for the required tag.
    d. Click **Save**.

    Note: You can create one deployment plan as a primary linked to many secondary deployment plans. Deployment is executed only from primary deployment plan.

10. Click the primary plan to display the independent and dependent tasks.
    The dependent task is now ready to run with the independent task being a manual type.

    a. On the manual task, click **Start task** to start the task.

    b. On the manual task, click **Approve task** to complete the task.
    The manual task displays the status as `Complete`, and the dependent task displays `In progress`.

    c. On the dependent task, click the arrow to the left of **In progress**.

    d. Click **Go to** to go to the dependent task.

    e. On the "Wait for approval" task, click **Approve task** to approve the task.

    f. On the "Manual" task, click **Start task** to start the task.

    g. On the "Manual" task, click **Complete task** to complete the task.

    h. At the top of the page, click the link to go back to the release.

The **Manual** and **Run another plan** tasks are both displayed as completed in the secondary plan.

i. At the top of the page, click the link to go back to the primary plan to display the plans in the release that are completed.

Creating delay tasks

Delayed-type tasks represent milestones or critical events during a deployment. With delayed tasks, you can ensure that important tasks start at the expected time. Typically, delayed tasks are prerequisites for other important tasks.

About this task

A delayed task starts as soon as it is eligible to run, and it finishes at a user-specified time. A started delayed-type task has a status of `In Progress` until it reaches its planned-for time, when it then changes its status to `Complete`. When a delayed tasks completes, auto tasks that are dependent on it start running.

Complete the following tasks to create a delayed task:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Delayed**.
3. In the **Name** field, enter a name for the task.
4. In the **Delay type** field, select the method used to determine the length of the delay.
   If you select **Delay by selecting a time and time zone**, use the **Delay until time** and **Time zone** fields to specify when the task will complete. If you select **Delay by using a date and time property**, use the **Delay property** field to enter a property name. The property value can be set at run-time when the deployment starts. Refer to the Properties reference for information about properties:

   ```
   /docs/services/UCCR/UCCR_property_ref.html#property_overview
   ```

   Otherwise, if you select **Delay by selecting a number of minutes**, use the **Minutes** field and enter the number of minutes between tasks.
5. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating email tasks

An email task sends an email message when the task runs. You specify the email's recipients and message when you create the task. Email tasks are auto tasks and run as soon as they are eligible.

Before you begin

Before using email tasks in your deployments, setup an email server. on page 1800

About this task

To create an email task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Email**.
3. In the **Name** field, enter a name for the task.
4. In the **Recipients** field, enter or select the email's recipient.
   The list of available recipients includes the users and groups who are members the team that manages the task. You can also type the email addresses of non-team members. You can specify multiple recipients.
5. In the **Email subject** field, enter the email topic.
   You can use properties in this field.
6. In the **Email message** field, enter or paste the email message.
   You can use properties in this field. For example, you might notify email recipients that a release is started by using a message similar to this one, "The `` `${sys:release.name}` `` release has started." See the Properties reference for information about properties on page 1871.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When the task runs, the recipients receive an email with the subject you specified when you created the task.

Creating header/note tasks

Header tasks represent organization elements that you can add to deployment plans. If you create a task group, you might identify the group with a header task. Header tasks can have dependencies like any other task.

About this task

You can organize task groups with header/note tasks. You can create a note by adding information about a group or task. When you import a deployment plan from IBM® DevOps Release, segment tasks are bracketed by note-type Start Segment and End Segment tasks. Segment dependencies are represented by dependencies to End Segment tasks.

To create a header task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Header / Note**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter or paste a description.
   You might enter a note, a reminder, or other instructions in the field.
5. Click **Save**.

Result

The task is inserted into the deployment plan.

Creating Jenkins (Legacy) tasks

A Jenkins (Legacy) task runs a job in your integrated Jenkins instance.

Before you begin

Before using Jenkins (Legacy) tasks in your deployments, add the plugin to your Jenkins instance and configure an integration. on page 1886 After integrating Measure to Jenkins, you can add Jenkins jobs to you pipelines and releases.

About this task

To create a Jenkins (Legacy) task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Jenkins (Legacy)**.
3. In the **Name** field, enter a name for the task.
4. In the **Jenkins Job or Pipeline** field, select a job or pipeline.
5. In the **Duration (minutes)** field, enter an estimate for the length of the task.
6. In the **Tags** list, select an item to attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating manual tasks

Manual tasks represent some activity that is associated with a software release. Manual tasks have a start point, end point, and a measurable duration.

About this task

To create a manual task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Manual**.
3. In the **Name** field, enter a name for the task.
4. In the **Duration (minutes)** field, enter the number of minutes that you expect the task to run until it is completed.
   The estimated duration is used to calculate expected deployment times.
5. In the **Tags** list, select an item to attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.

6. In the **Assigned groups and users** list, select the task owner.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

Once the manual task is executed, you can select the task on the deployment plan details page on page 1845, click to display the **Edit task** window, and view who executed the task in the **Executed By** field.

Creating run shell script tasks

Shell script tasks are used to execute a sequence of commands.

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create task** dialog box, in the **Type** list, select **Run a Shell Script Task**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter or paste a description.
   You might enter a note, a reminder, or other instructions in the field.
5. In the **Shell Script** field, enter or paste the shell script code. An example shell script code is the following:

```
echo "Hello World"
sleep 2
"Do some stuff..."
sleep 2
echo "Task finished"
```

6. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating ServiceNow tasks

A ServiceNow™ task can create and update ServiceNow™ change requests.

Before you begin

ServiceNow task prerequisites:

- ServiceNow tasks work with Internet-accessible instances of ServiceNow, such as `my_instance.service-now.com`.
- ServiceNow tasks work with the Jakarta® release of ServiceNow, and references the current API version.
- The user supplying credentials for the task must have access to the ServiceNow API, and permission to see and modify all change request fields. At a minimum, the user must be in a ServiceNow role that has the Create Change permission.

About this task

A ServiceNow task can perform one of the following actions:

- **Create** creates a ServiceNow change request. You can set the values for all request fields, and pass the request ID to update, and wait tasks.
- **Update** can update the values for any request field.
- **Wait** waits for a particular value in a specific field. The field can be any field on the change request.

A ServiceNow task can include ServiceNow properties and Measure properties. ServiceNow properties have the following syntax: `propertyName=value`.

This short video describes how to use ServiceNow with Measure.

To create a ServiceNow task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **ServiceNow**.
3. In the **Name** field, enter a name for the task.
4. In the **Tags** list, attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.
5. In the **Connection settings** area, enter the URL of the ServiceNow instance, and the user ID, and password of the ServiceNow user.
6. In the **Action** list, select the action type for the task.
   The action types are defined in this list:
   - The **create** action creates a ServiceNow change request with the properties defined in the task.
   - The **update** action modifies properties in change request.
   - The **wait** action waits for a specific value in a change request field.
7. Complete the action-specific parameters, as described in the following tables:

Table 1190. Create action

Create action	Description
Request type	You can use the ServiceNow default types or a user-created type. Default types are normal, emergency, and standard. Normal requests pass through all stages

Create action	Description
	of the ServiceNow state model. Standard types are pre-authorized and skip the Assess and Authorize states. Emergency types skip the Assess state.
Short description	The text you enter is displayed in the Short description field of the ServiceNow change request.
Assignment group	The ServiceNow agent or group responsible for resolving the change request. Possible assignees include agents and groups available to the ServiceNow instance.
Additional properties	The ServiceNow properties set by this task. Each property must be on its own line. For example, a simple request might include the following fragments: `approval=requested`.
Output property	Measure property that contains the change request ID. For example, if you specify `service_now_stage_ticket_id`, you can use the property with update and wait actions to identify the ticket.

Table 1191. Update actions

Update action	Description
System ID	The ID of the ServiceNow change request. If you capture the ID with a create action **Output property** field, you can use it here. For example, if you specify `service_now_stage_ticket_id` in the **Output property** field of a create action, you can use the ID by specifying `${service_now_stage_ticket_id}`. See the Properties reference for information about properties on page 1871.
Additional properties	The ServiceNow properties set by this task. Each property must be on its own line. For example, to update the state of the change request, you can specify or `state=-1`.

Table 1192. Wait actions

Wait action	Description
System ID	The ID of the ServiceNow change request. If you capture the ID with a create action **Output property**

Wait action	Description
	field, you can use it here. For example, if you specify `` `service_now_stage_ticket_id` `` in the **Output property** field of a create action, you can use the ID by specifying `` `${service_now_stage_ticket_id}` ``.
Field	The name of the affected field in the ServiceNow change request. The value in the field is checked for updates by the interval defined by the Check request interval field. For example, if you are checking the **approval** field, you might specify `` `approval` ``.
Value	The value expected in the ServiceNow field as defined by the **Field** property. For example, if you are checking the **approval** field, you might specify `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` ``, the task completes successfully.
Check request interval	The value defines how frequently ServiceNow is checked for updates. The value represents minutes. The default value is `1`, which mean ServiceNow is polled every minute.

Result

When the task starts, it has the status of **In progress**. The status changes to **Complete** when the related ServiceNow action is resolved.

What to do next

The ServiceNow change request life cycle is referred to as the state model. As a change request is used, it progresses through the various states of model. The state of a closed request is 'closed', for example.

In Measure, ServiceNow tasks are frequently used to change the state of a request. To modify a request state, you use the ServiceNow `state` property. For example, to change the state of a request to Review, you can specify **`state=0`** in the **Additional properties** field of an Update action.

The following table provides the values for the default states for the normal request type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 1193. ServiceNow normal request state model

State	Value
New	-5
Assess	-4
Authorize	-3

Table 1193. ServiceNow normal request state model (continued)

State	Value
Scheduled	-2
Implement	-1
Review	0
Closed	3
Canceled	4

Creating ServiceNow task using Service Now plug-in

A ServiceNow™ task can create and update ServiceNow change requests and the change tasks within the change request. You can also create a ServiceNow - Wait Change Request task which will wait for the specified value to appear in a specific field of a change request in ServiceNow.

Before you begin

You must have completed the following tasks:

- Ensured that you have internet-accessible instances of ServiceNow, such as `my_instance.service-now.com`.
- Created an integration with ServiceNow plug-in. For more information, refer to ServiceNow plug-in documentation.

Note: Ensure that the credentials used for the plug-in integration must have access to the ServiceNow API and permission to see and modify all change request fields. At a minimum, the user must be in a ServiceNow role that has the Create Change permission.

About this task

You can create the following automation tasks with which you can perform the actions in ServiceNow directly from Measure:

- **ServiceNow - Create Change Request and Change Task**

  This task creates a change request, change task or both in ServiceNow.

- **ServiceNow - Update Change Request and Change Task**

  This task updates the value in any change request, change task, or both in ServiceNow.

- **ServiceNow - Wait Change Request**

  This task waits for specified value to appear in a specified field of a change request in ServiceNow. The task will be completed when the provided value appears in the ServiceNow change request. The field can be any field of a change request.

- **ServiceNow - Wait Change Task**

  This task waits for specified value to appear in a specified field of a change task in ServiceNow. The task will be completed when the provided value appears in the ServiceNow change task. The field can be any field of a change task.

1. Click **Releases** on the left navigation pane.
   Result
   The **Releases** page is displayed.
2. Click any deployment plan.
   Result
   The **Deployment Plan** details page is displayed.
3. Click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
   Result
   The **Create Task** dialog is displayed.
4. In the **Type** list, select any one of the following options based on the action that you want to perform in ServiceNow:
   - **ServiceNow - Create Change Request and Change Task**
   - **ServiceNow - Update Change Request and Change Task**
   - **ServiceNow - Wait Change Request**
   - **ServiceNow - Wait Change Task**
5. In the **Name** field, enter a name for the task.
6. In the **Description** field, enter the description for the task.
7. In the **Integration** field, select the integration which you have created for ServiceNow.
8. Based on the task type you selected, enter the details in the task specific parameters, as described in the following tables:

Table 1194. ServiceNow - Create Change Request and Change Task

ServiceNow - Create Change Request and Change Task type	Description
Short description for change request	Enter the text that you want to display in the Short description field of the ServiceNow change request.
Request type	Enter the ServiceNow request type. you can use the ServiceNow default types or a user-created type. Default types are normal, emergency, and standard. Normal requests pass through all stages of the ServiceNow state model. Standard types are pre-authorized and skip the **Assess** and **Authorize** states. Emergency types skip the **Assess** state.

ServiceNow - Create Change Request and Change Task type	Description
Assignment group for change request	Enter the ServiceNow agent or group responsible for resolving the change request. Possible assignees include agents and groups available to the ServiceNow instance.
Additional properties for change request	Enter the ServiceNow properties that you want to update by this task while creating the change request. For example, a simple create change request might include the following fragments: {"approval:requested"}.
Create change task	Enter the ServiceNow properties that you want to update by this task while creating the change task within the change request. You can create multiple change task by separating each change task properties object by a comma. For example, a simple create change task might include the following fragments:[{"short_description":"createtask","change_task_type":"planning","description":"changetask"}]
Output property	Enter the system ID of the created change request.

Table 1195. ServiceNow - Update Change Request and Change Task

ServiceNow - Update Change Request and Change Task type	Description
Change Request Number	Select the Change Request Number of the ServiceNow change request that you want to update. See the Properties reference for information about properties on page 1871.
Change request properties	Enter the ServiceNow properties that you want to update by this task while updating the change request. For example, to update the state of the change request, you can specify or `{"state:-1"}`.
Update change task	Enter the ServiceNow properties that you want to update by this task while updating the change task within the change request. You can update multiple change task by separating each change task properties object by a comma. For example, to update the state of the change task, you can specify or `[{"state:3"}]`.

Table 1196. ServiceNow - Wait Change Request

ServiceNow - Wait Change Request type	Description
Change Request Number	Select the Change Request Number of the ServiceNow change request. See the Properties reference for information about properties on page 1871.
Field	Enter the name of the field for which the task should check for a match in the ServiceNow change request. The value in the field is checked for updates in a regular interval. For example, if you want to check for a match in the **approval** field, you might specify `` `approval` ``.
Value	Enter the value expected in the ServiceNow field defined in the **Field** property. For example, if you are checking the **approval** field, you can specify a value `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` `` in ServiceNow, the task completes successfully.

Table 1197. ServiceNow - Wait Change Task

ServiceNow - Wait Change task type	Description
Change task system id from property reference.	Enter the system ID of the change task.
Change Request Number	Select the Change Request Number of the ServiceNow change request. See the Properties reference for information about properties on page 1871.
Change request system id from property reference.	Enter the system ID of the change request.
Field	Enter the name of the field for which the task should check for a match in the ServiceNow change request. The value in the field is checked for updates in a regular interval. For example, if you want to check for a match in the **approval** field, you might specify `` `approval` ``.
Value	Enter the value expected in the ServiceNow field defined in the **Field** property. For example, if you are checking the **approval** field, you can specify a value `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` `` in ServiceNow, the task completes successfully.

9. Click **Save** or **Save and create another** to add the task or add the task and create another task respectively.

Result

When the task starts, it will have the status of **In progress**. The status changes to **Complete** when the action mentioned in the task is performed in ServiceNow.

Example

Additional Information

The ServiceNow change request life cycle is referred to as the state model. As a change request is used, it progresses through the various states of model. For example, the state of a closed request is 'closed'.

In Measure, ServiceNow tasks are frequently used to change the state of a change request and change task.

To modify a request state, you use the ServiceNow `state` property. For example, to change the state of a change request to **Review**, you can specify "state:0" in the **Change request properties field** of a **ServiceNow - Update Change Request and Change Task** type and to change the state of a change task to **In progress**, you can specify "state:2" in the **Update change task** field of a **ServiceNow - Update Change Request and Change Task** type.

The following table provides the values for the default states for the normal change request type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 1198. ServiceNow normal change request state model

State	Value
New	-5
Assess	-4
Authorize	-3
Scheduled	-2
Implement	-1
Review	0
Closed	3
Canceled	4

The following table provides the values for the default states for the normal change task type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 1199. ServiceNow normal change task state model

State	Value
pending	-5
open	1
in progress	2
closed	3
canceled	4

Creating DevOps Deploy tasks

Use DevOps Deploy tasks to run DevOps Deploy applications.

Before you begin

Before you can use DevOps Deploy tasks in pipelines and deployment plans, you must first configure DevOps Deploy integration on page 1885.

The applications that are available to a deployment plan depend on the team that is assigned to the plan. The applications that are managed by the team in DevOps Deploy are also available in Measure.

About this task

To create this task type, specify the application's process, version, and environment. You can set the version and environment at design time or select them at run time. When you run this task, the application runs in the integrated DevOps Deploy instance. During deployments, DevOps Deploy tasks start automatically when they become eligible to run.

To create a DevOps Deploy task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **DevOps Deploy**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, provide the description of the task.
5. In the **Integration** drop-down list, select the plugin integration.
6. Select the **Assigned group or user** from the drop-down list.
7. In the **Application** drop-down list, select an application.
8. In the **Process** drop-down list, select or enter an application process.

Processes that belong to the selected DevOps Deploy application are available.

9. In the **Version** drop-down list, select an application version.
   Versions refer to DevOps Deploy application snapshots. Versions that belong to the selected application are available. To postpone selecting a version, select **Use Version Tab**. If the application process does not require a version, select **No version items exist**. You might select this last option if you are running a configuration-type process that does not require components.
10. In the **Environment** drop-down list, select or enter an application environment.
    Environments that belong to the selected DevOps Deploy application are available. To postpone selecting an environment until you are ready to run the deployment, click **Versions** on the **Deployment plan** details page.
11. In the **Deploy Request Properties** box, enter the properties that you want to pass to the IBM DevOps Deploy (Legacy) application.
    Properties are name-value pairs. You can enter multiple properties. Put each property on a separate line. The following graphic provides an example of property definitions:
    Figure 30. property definitions

12. Select the snapshot display from the **On Failure** and **On Success** drop-down list.
13. Click **Save**.
    Result
    The task is inserted into the deployment plan.

Results

After the task is created, the plan's **Versions** page is updated with information about the application. If you selected **Only Changed Versions** for the application environment and version on the **Create Task** dialog box, use the **Versions** page to set those options before running the deployment.

Creating Ansible tasks

Create an Ansible® task.

Before you begin

In your Ansible® instance, create a user token. You use the token to authenticate your Measure user to Ansible®.

About this task

Create an Ansible® task to manage Ansible® jobs.

To create an Ansible® task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Ansible**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter a name for the task.
5. In the **Instance URL** field, enter the location of your Ansible® installation..
6. In the **Access Token** field, paste the token that you generated in your Ansible® instance.
7. In the **Job ID** field, enter the Ansible® job identification number..
8. **Optional:** In the **Extra Variables** box, enter any parameters that you want to pass to the Ansible® job.
   The parameter format is JSON. For example:

   ```
   {
    "environment": "DEV"
   }
   ```

   example,
9. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When you run the task, a webhook is created that uses the Ansible® API to run the job. While the job is running, you can accesses Ansible® logs by using a link in the deployment plan. When the Ansible® job is finished, the Measure task status is updated.

Creating wait for approval tasks

A Wait for approval task pauses a deployment until a designated user provides approval. Email notifications are sent to users when the task starts.

Before you begin

Before using email tasks in your deployments, setup an email server. on page 1800

About this task

To create a wait for approval task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Wait for approval**.
3. In the **Name** field, enter a name for the task.
4. In the **Approval prompt** field, enter the text that you want to include in the email message.

The text is displayed in the **Task Details** section of the email.

5. In the **Approvers** list, select the users or groups designated to approve the task.
   Team members and groups are available to choose.
6. In the **Required approver** area, specify whether all the approvers must approve the task, or a single approver is sufficient.
7. Click **Save**.
   The task is inserted into the deployment plan.

Results

When the task runs, email notifications are sent to the selected approvers. The deployment plan cannot progress until the task is approved or skipped. Approval is granted by completing the task in the deployment plan.

Note: For information on pipeline notifications, see this page on page 3149.

Approving wait for approval task

You can approve the wait for approval task using the received email notifications.

About this task

Designated approval user receives the email notification for approving the wait for approval tasks. The email notification contains the task information for which the wait for approval task needs to be approved.

You can click **Approve** or **Reject** for approving or rejecting the wait for approval task.

By default, designated users can approve the task or share the email notification to any user for approving. You can prevent the latter functionality by enabling the `authorized-approval` feature flag.

To activate this security feature, enter the feature name `authorized-approval` under `featureFlags` . After enabling `authorized-approval` feature flag , only designated users can approve or reject the wait for the approval task. To approve or reject, the user must login Measure. Not designated users are not authorized to approve or reject the wait for approval task using the email notification.

Using properties

A deployment plan can contain user-defined properties. Properties values can be defined at design- or run-time.

Tasks can reference properties defined in their parent deployment plan. In addition to the properties that you create, system properties are available to all plans.

Creating properties

Creating properties

About this task

You define properties with the **Deployment Plan** details page by clicking **Properties**. You can create a property before you use it, or you can create a property by first referencing it in a task, and then later defining its attributes. If you create a property by reference, it appears as text-type property on the **Properties** tab.

To create a property, complete the following steps:

1. On the **Deployment Plan** details page, click **Properties**, and then click **Add**.
2. On the **Add property** window, in the **Name** field, enter the name. Property names cannot contain white spaces, `{}`, or `:`.
3. In the **Label** field, enter the label that appears in the user interface.
4. In the **Type** list, select the property type.
   The available types are described in this list:
   - `Text`
   - `Textarea`
   - `Password`
   - `Select`
   - `Boolean`
   - `Date and time`. Values are replaced by a string with the following format `day, month, year, time`. For example, `Thursday, January 1st 1970, 12:00 am UTC`.

     Note: When a date and time property is used in a ServiceNow® task, the value is replaced with the date and time format expected by ServiceNow®.

5. In the **Value** field, you can enter an initial value for the property.
6. In the **Default Value** field, enter a value for the property.
   This value is used unless the user sets the value. You can leave this field blank.
7. If you want users to supply a value for the property when they create a release, check **Prompt for this property at release creation at the specified sequence position**.
8. In the **Display sequence position** list, select a position for the property.
   This selected value affects the property's position on the **Properties** tab
9. Click **Save**.
   Result
   The property is displayed on the deployment plan **Properties** page.

What to do next

After the release is created, you can add deployment plans, events, and tags to it.

Using properties

You can use properties in deployment plans, REST API endpoints, and external systems, such as ServiceNow®.

Property examples

Use the following syntax to reference a property: `` `${propertyName}` ``. To escape the syntax pattern, use two dollar-sign symbols, `$${...}`. You set property values with the deployment plan's **Properties** page, REST API endpoints, or external systems, such as ServiceNow®.

The following table describes how to properties with task types.

Task type	Usage
ServiceNow	You can use the ServiceNow on page 1863 **Output property** field in a create change request action to store the change request ID in a property, for example, `'service_now_prod_ticket_id'`. Then, with another task, update the change request by referencing the property in the **System ID** field like this, `'${service_now_prod_ticket_id}'`.
Email	You can reference a system property in the email task on page 1856 **Subject** field, for example, `'${sys:release.name}' is complete!`.
Delayed	You can reference a delay task on page 1856 property in the **Delay property** field, for example, `'${prodTarget}'`. In this example, the task delays until the value in the `'${prodTarget}'` property is reached.

System properties

System properties enable you to access information about the parent release of a deployment plan. System properties can be referenced by any property-enabled task that is part of a release.

The following table contains the available system properties:

Table 1200.

Property	Description
`${sys:release.name}`	The value in the release's **Name** field.
`${sys:release.description}`	Contains the content of the release's **Description** field.
`${sys:release.start}`	Release's **Start time**.
`$${sys:release.end}`	Contains the content of the release's **End time** field.

In the **Email message** field of an email-type task, you can reference system properties like this example:

```
Deployment for release `${sys:release.name}` - `${sys:release.description}` is complete.
```

You can reference a system property in a ServiceNow task's **Short description** field like this example:

`Staging deployment `${sys:release.name}``.

Extending Product Functions

Learn how to extend the function of Velocity Measure

Measure is designed to be easily extended. You can enhance existing functions or add entirely new ones by configuring plugin integrations. Plugins are software add-ons that extend Measure functionality by integrating with external tools. In general, each plugin manages one external application. The HCL DevOps Deploy (Deploy) plugin, for example, enables you to run Deploy applications.

If you cannot find a plugin for your environment, you can create plugins by using the plugin software development kit (SDK) on page 1884.

Measure supports several plugin types:

- Value stream plugins are supported by default. To create an integration with these plugins, you simply configure an integration in the value stream JSON file.
- Quality data plugins integrate test and metrics data into reports and value streams on page 1893. To create an integration with these plugins, you use external clients to post data to Measure API endpoints.
- Dedicated plugins provide external data to value streams, pipelines, and releases. Plugins of this type include: Deploy on page 1885, and Jenkins on page 1886. Use the Integrations page to configure integrations for these plugins.
- Task-based integrations provide external data to deployment plans. Use ServiceNow tasks to manage ServiceNow change requests on page 1887.

Introducing plugins

Extend Measure by configuring plugin integrations to external tools.

Measure uses a containerized microservices architecture. This means that plugins are not run directly from Measure but from containerized instances managed by a containerization platform. Runtime instances are created from images on the Docker Hub™ repository. Measure retrieves images from this repository and creates instances as needed.

For Kubernetes-based installations such as OpenShift™, Measure uses Kubernetes™ as its containerization platform. An Argo Workflow Engine manages plugin workflow. A Kubernetes pod starts when a plugin task is requested and sends the results to Measure. When complete, the container containing the plugin ends.

Plugins are categorized by data collection and communication methods. Generally, plugins are designed to use one of the following communication methods.

- **Webhook**. These plugins use webhooks to communicate with a defined Measure API endpoint. The webhook is used to trigger data collection events. Examples include the AppScan™, and SonarQube plugins.
- **Poller**. These plugins are based on an event defined by the plugin. Queries are performed to determine when to send and update data from the external service. Examples include the GitHub™, and Rally plugins.
- **Parser**. These plugins integrate functions to parse a specific file type and create a metric document that Measure can display with other value stream management and portfolio views. Examples include the JUnit, and OneTest plugins.

Available plugins are stored at HCL plugin database.

If you cannot find a plugin for your environment, you can create plugins by using the plugin software development kit (SDK) on page 1884.

If a metrics plugin is not available for your tool, you can upload custom metrics using Measure API endpoints.

To use a plugin, you configure an integration. "Integration" refers to a user-configured instance. You might use the GitHub plugin to configure an integration with the Service A repository, and then configure another integration with your Service B repository. Although both integrations use the GitHub plugin, each integration provides a unique set of data to Measure. You manage each integration separately.

Some integrations are termed "native integrations," and are not technically plugin derived. Native integrations are used with deployment plans by defining tasks of a specific type on page 1885. You can use DevOps Deploy data with your deployments and pipelines, for example, by defining DevOps Deploy-type tasks.

Some plugins might have a corresponding plugin in the external tool. To integrate Jenkins, for example, you install the " Measure" plugin into Jenkins™ using the Jenkins plugin manager. Then you configure a corresponding Jenkins integration in Measures. The two integrations operate in tandem.

Preventing plugins installs in unsupported server versions

Plugin versions incompatible with Measure are prevented from installing.

About this task

Based on the your installed version of Measure, plugins not compatible with that version are prevented from installing in the product. If the installed version of Measure is equal or greater than the product version that the plugin supports, the installation of the plugin is possible.

Notifications for incompatible plugins versions prevented from installation are displayed in each of the following three scenarios:

Scenario 1: Installing plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Plugins** tab.

3. Locate the required plugin in the list and click **Install**.
4. The error **Plugin <name> is only supported on** Velocity **versions equal to or greater than x.x.x** is displayed on the right side of the **Status** field for that plugin.

Scenario 2: Loading plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Plugins** tab.
3. Click **Load plugin**.
4. In the **Load a custom plugin** window, click in the **Plugin Image** field and enter the required plugin.
5. Click **Submit**.
6. The error **Plugin <name> is only supported on** Velocity **versions equal to or greater than x.x.x** is displayed in the **Load a custom plugin** window.

Scenario 3: Upgrading plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Integrations** tab.
3. Locate the required plugin and then click on the overflow menu and select **Upgrade**.
4. In the **Status** field for the plugin, **Upgrade failed** is displayed.

Creating plugin integrations

Defining integration allows you to communicate with external tools.

Before you can create an integration, ensure you have the user credentials and connection information required by the external tool, such as URLs, and API endpoints. To create an integration with HCL DevOps Deploy (Deploy), for example, you need a user token generated by Deploy, and the URL where the server is located. Ensure that you have all the necessary connection information before starting.

Credentials and other connection properties vary among individual plugins. You can find property descriptions and use cases for all plugins on the product website.

A plugin is a software add-on designed to communicate with external services and applications. Each plugin defines an expected record type and communication method. Communication can be uni-directional or bi-directional. To use a plugin, you must install and configure an integration.

To view the plugin in Measure, on the **Home** page, click **Settings > Integrations**.

The **Integrations** page has three tabs:

1. Integrations on page 3249
2. Installed Plugins on page 3249
3. Available Plugins on page 3250

Integrations

The **Integrations** tab lists all plugins that are configured for integration. Click the right-angle bracket to view the details of the configured plugin. All integrations are listed regardless of how they are created.

You can use search to find configured plugin integrations. The search query finds matches in the **Name** and **Type** fields. On the **Integrations** tab, you can sort by the **Name**, **Status**, **Type**, and **Last sync** fields in ascending or descending order by clicking a table header.

Click **Show Archived** to see the archived plugin integrations. The following table details the fields on the **Integrations** tab:

Field	Description
Name	The name of the plugin. Click the right-angle bracket to view details of the plugin integration. Click to view plugin documentation.
Status	The working status of the configured plugin integration. Possible values are **Online** and **Failed**. The **Online** status is displayed for working plugin integrations. The **Failed** status is displayed for plugin integrations that are not working. Disrupted communications or inaccurate integration configurations can cause the integration to fail.
Type	The type of the plugin.
Last sync	The last plugin synchronization time.
Disable/Enable	Set to disable or enable the plugin integration.
	Click to **Edit**, **Upgrade/Downgrade**, **View logs**, and **Archive/Delete** plugin integrations.

Installed Plugins

The **Installed Plugins** tab displays all plugins that are installed by default with the Measure installation. The installed plugins are ready to configure for integration.

You can search for installed plugins. The search query finds the matches in the **Name** field. On the **Installed Plugins** tab, you can sort the **Name** field in ascending or descending order by clicking the header.

The following table details the fields on the **Installed Plugins** tab:

Field	Description
Name	The name of the plugin. Click to view all installed versions of the plugin. Click to view plugin documentation.
Version	The version of the installed plugin.
Image	The image of the plugin.
Release Date	The release date of the installed plugin.
Actions	Click **Add integration** and provide details to configure the integration. All the integrations are enabled by default. To create a disabled plugin integration perform the following the steps: • In the **Add integration** window, click **Show hidden properties**, and then clear **Enabled** to create a disabled plugin integration. Click and select **Delete** to delete the installed plugin.

The latest version for Parser plugins are installed with the **Non-Configurable** status.

Available Plugins

The **Available Plugins** tab displays all supported plugins for Measure.

You can search for the supported plugins. The search query finds matches in the **Name** field. On the **Available Plugins** tab, you can sort the **Name** field in ascending or descending order by clicking on the header.

The following table details the fields on the **Available Plugins** tab:

Field	Description
Name	The name of the plugin. Click to view all versions of the plugin. Click to view plugin documentation.
Version	The version of the available plugin.
Image	The image of the plugin.
Release Date	The release date of the available plugin.

Field	Description
Actions	Click **Install** to install the required version of the plugin.

Advanced usage

You can configure integrations for some plugin types by adding an integration definition to a value stream JSON file on page 3078. Using a text editor, define an integration object in the `integrations` array of the `value_stream_name-vsm.json` file. The following code example illustrates a Jira integration.

```
{
     "_id": "velocity-generated-id",
     "type": "ucv-ext-jira",
     "tenant_id": "velocity-generated-id",
     "name": "my-JIRA",
     "disabled": false,
     "properties": {
       "baseUrl": "http://my-jira-url",
       "username": "admin",
       "password": "****",
       "jiraProjects": [
         "My-Project"
       ]
     }
   },
```

Integrations created by the value stream method are displayed on the **Integrations** page along with integrations created by the other methods.

Additional Measure product features requiring you to perform plugin installation before use include the following:

1. Handlebars Reporter
2. Bottleneck detection
3. Parser

The integration is listed on the **Integrations** page. The **Integrations** page is where you manage integrations. on page 1881

Integrations start providing data when successfully configured. For some integration types, such as quality-data types on page 3165, you can start using their data without additional configuration. For example, you can create dashboard charts that contain quality data when the integration is added. For example, JUnit is a quality-type plugin.

Other integration types require additional configuration before you can start using the associated data. Native integrations require that tasks are added to deployment plans. on page 1885 Value stream integrations, such as GitHub™, require a reference in the value stream JSON file. If you define an integration on the **Plugins** tab, add a reference to the integration name in the JSON file. If you define an integration directly in a JSON file described in Step 3, no additional configuration is required.

Github plugin integration example

Github plugin integration example

About this task

To configure the Github plugin integration, complete the following steps:

1. In the **Integration Name** field, enter a name for the integration, such as "Git tutorial."
   Such as GitHub tutorial. Later, we use this name to associate the integration to our value stream.
2. In the **Url** field, enter the URL for the GitHub project that you configured earlier .
   The URL is similar to this example, `https://github.com/myGitHubID/myGitHubProject`.
3. In the **Name** field, enter the name of the GitHub repository.
   Using the example URL from the preceding step, the name is `myGitHubProject`.
4. In the **Owner** field, enter the GitHub account that owns the repository.
   Using the example URL, the owner is `myGitHubID`.
5. In the **Token** field, enter your Github personal access token to authenticate with the Github repository.
   In GitHub, to generate a personal access token, go to **Settings**>**Developer settings**>**Personal access tokens** then click **Generate new token** and select the scope **repo** which allows to access repositories.
6. In the **API URL** field, enter the GitHub API URL.
   For enterprise Github account, use GitHub API URL `https://example.com/api/v3`.
   For public Github account, use GitHub API URL `https://api.github.com`.
7. Select the **Show Hidden Properties** check box.
   Result
   The hidden fields are displayed.
8. Enter the custom time for the plugin job in the **Plugin Job Timeout** field.

   Note: The default time is 1h, you can specify the maximum time a plugin job should be allowed to run before being automatically canceled in the following format:
   - 30m for 30 minutes
   - 1h for one hour
   - 1d for one day

9. **Optional:** Select the **Interval** time to set the frequency to run the schedule event.

   Note: If you do not want to change the interval time of the schedule event while creating the integration, the default sync intervals defined in the plugin are applied.

10. Click **Add**.

Results

The integration is listed on the **Integrations** page. If the integration is successful, the **Status** field displays `Online`. If the status is not `Online`, use the **View log** option to troubleshoot the integration. You can increase the logging level in the integration configuration if you need more troubleshooting information.

Managing integrations

You can manage the existing configured integrations.

About this task

After an integration is successfully configured, it periodically communicates with the external tool to synchronize the data flow.

The default communication interval when scheduled event integrations run can be configured by the `PLUGIN_INTEGRATION_RUN_INTERVAL` environment variable on the reporting-consumer service to a valid integer for the minutes between each run.

To manage an integration, perform the following steps:

1. On the Measure **Home** page, click **Settings > Integrations**.
   Result

   The **Integrations** page lists all configured integrations. All integrations are listed regardless of how they are created. You can use search functionality for searching the integration in the **Integrations** tab. The search query finds the matches in **Name** and **Type** fields. On the **Integrations** tab, you can sort the **Name**, **Status**, **Type**, and **Last sync** fields in ascending or descending order by clicking on the required table header field.
2. **Optional:** To modify an integration definition, click overflow menu ⋮ **> Edit**, and then modify the integration definition properties.
3. **Optional:** To view the integration log file, click overflow menu ⋮ **> View logs**.
   This action displays the integration's last execution log.
4. **Optional:** To upgrade or downgrade the plugin used by the integration, click overflow menu ⋮ **> Upgrade/ Downgrade**.
5. **Optional:** To sync with the external tool, click overflow menu ⋮ **> Resync**.
   This action attempts to communicate with the external tool immediately. You might do this when you want to run tests before the next communication interval. You can also select the time line from when you want to resync the data from the external tool.

   Note:

Not all integration types support this action. All scheduled event plugins such as Jira, GitHub, GitLab, Azure DevOps, and HCL DevOps Deploy are supported with the resync functionality.

6. **Optional:** To archive an integration, click overflow menu **> Archive/Delete**.

   Note: Select the **Delete the integration data** checkbox to delete the integration data.

7. **Optional:** To disable or enable an integration, click the **Disable/Enable** field of the integration.
   Result
   Communication with the external tool stops until re-enabled. You might do this if you want to stop data delivery during testing.
8. **Optional:** To disable or enable multiple integrations, select the required integrations and then **Select Actions** appears. Click the drop-down list of **Select Actions** and select **Disable** or **Enable**.

Defining an initial sync date for plugins

For scheduled events plugins, you can specify an initial sync date.

About this task

For scheduled events plugins, you can specify an initial sync date by performing the following steps:

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click **Plugins** tab.
3. Locate the required plugin and then click **Add integration**.
4. In the **Add Integration** window, click the **Show hidden properties** check box.
5. Click **Initial Sync Date** field to specify the date to pull data for initial run.
6. Fill the remaining required fields in the **Add Integration** window.
7. Click **Add**.

Note: If the plugin does not support the sync feature, the **Initial Sync Date** field is not displayed when you click the **Show hidden properties** check box in the **Add Integration** window.

Archiving integrations

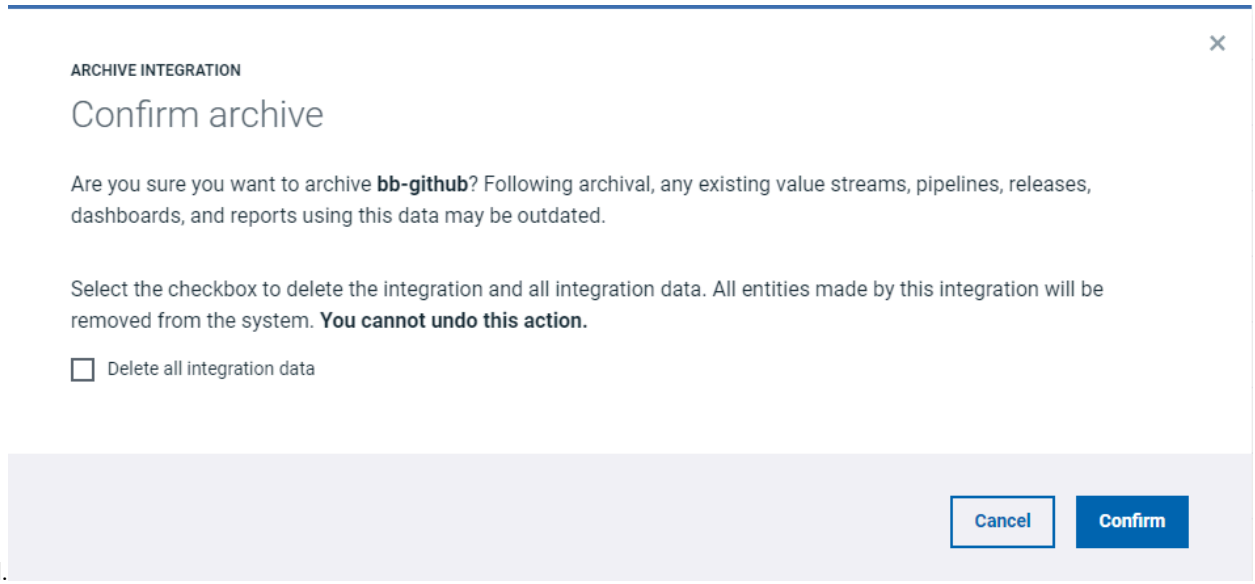
Archive the no longer needed integrations.

About this task

This topic describes the procedure for archiving integrations.

To archive integration, complete the following steps:

1. On the **Home** page, click **Settings > Integrations > Configured**.
   Result
2. Select **Archive/Delete** from the overflow menu (⋮) of the plugin integration which you want to archive.
3. The archive confirmation modal window is displayed.



4. Select **Delete all integration data** checkbox to delete all integration data and click **Confirm**.
   You can view all archived integrations by clicking **Show Archived**.

Note: You can restore the archived integrations by clicking the overflow menu and select the **Restore**.

Upgrading and downgrading integrations

You can upgrade or downgrade the integration versions based on the plugin's compatibility with Measure.

Before you begin

You must have installed the required plugin. See Creating plugin integrations on page 1876.

1. On the **Home** page, click **Settings > Integrations**.
   The **Plugin and Integrations** page is displayed.
2. Click **Integrations**.
3. Select the toggle button under the **Disable/Enable** field to disable the plugin integration for which you want to upgrade or downgrade the version.
   You can avoid a partial data synchronization issue by disabling the integration before the upgrade.
4. Select **Upgrade/Downgrade** from the overflow menu (⋮) .

Note: The plugin version must be compatible with the Velocity version. For more details about the compatibility matrix, see the specific plugin documentation.

5. Select the version from the drop-down list.
6. Click **Upgrade**.

Note: If you select a lower version of the plugin from the drop-down list, the integration downgrades to the lower version.

7. Select the toggle button under the **Disable/Enable** field to enable the plugin integration.

Results

You have upgraded or downgraded the integrations.

Creating plugins with the plugins SDK

You can create your own plugins and install them in Measure. After installing custom plugins, you can integrate them in your releases, reports, and value streams.

Measure provides a SDK that contains the tools, including local dependencies and wrappers, that you need to create your own plugins. The plugin SDK provides a sample plugin that you can use to get started, and JavaScript templates that you can customize for your own plugins.

To create a plugin, your development environment must include the following items:

- Node.js version 12 or later
- NPM version 6 or later
- Docker
- Measure version 2.0 or later

To get started with the plugin SDK, complete the following steps:

1. Download the plugin SDK. On the Measure **Plugins** tab, click **Download plugin sample**. After the download is finished, extract the compressed file.
2. Build the sample plugin. In the `ucv-ext-sdk-template` folder, run the following commands. Additional instructions are provided in the SDK `Readme.md` file.

```
 npm install
npm run dist-runnable
docker build . -t name:tag
```

The `name` value can be any value that you want. The `tag` value must represent the latest image version, or some other valid semantic version. For example, `docker build . -t testplugin:0.1`.

3. Upload the sample plugin. On the Velocity **Plugins** tab, click **Load plugin**, and then select the Docker image that contains your plugin. To upload the image from the previous step, you specify `testplugin:0.1`.
4. Create an integration by using the sample plugin. On the **Plugins** tab, click **Add integration**.

Plugins are categorized by data collection and communication methods. Generally, plugins are designed to use one of the following communication methods.

- **Webhook**. These plugins use webhooks to communicate with a defined Measure API endpoint. The webhook is used to trigger data collection events. Examples include the AppScan™, and SonarCube plugins.
- **Poller**. These plugins are based on an event defined by the plugin. Queries are performed to determine when to send and update data from the external service. Examples include the GitHub™, and Rally plugins.
- **Parser**. These plugins integrate functions to parse a specific file type and create a metric document that Measure can display with other value stream management and portfolio views. Examples include the JUnit, and OneTest plugins.

The plugin SDK provides JavaScript templates for each type. For example, the template `ucv-ext-sdk-templates/src/endpoints/SampleEdnpoint.js` defines the properties that you need to create an endpoint-type plugin.

Managing native integrations

Native integrations add external functionality to releases, deployment plans, and pipelines.

Native integrations are available for the following applications or services:

- IBM DevOps Deploy
- Jenkins™
- ServiceNow™
- Ansible™

Configuring DevOps Deploy integrations

Use DevOps Deploy applications in your deployments and pipelines.

Before you begin

- Obtain a token from your DevOps Deploy server. When you create the DevOps Deploy token, specify **admin** as the user.

  This task requires that you are an Measure administrator.
- You must install the DevOps Deploy plugin, see Github plugin integration example on page 1880.

Note:

You must not integrate the same instance of Deploy using UrbanCode Deploy (Legacy) and Deploy (ucv-ext-ucd) plug-in in Measure. Integrating the same Deploy instance using UrbanCode Deploy (Legacy) and Deploy plug-in in Velocity can result in data corruption.

About this task

After you configure an integration, create tasks to run DevOps Deploy applications during your deployments on page 1868. You can also add applications to your pipeline stages and run them that way.

1. Click **Settings > Integrations**.
   The **Plugin and Integrations** page is displayed.
2. Click **Installed Plugins**, and click **Add Integration** for **DevOps Deploy**.
3. In the **Add DevOps Deploy Integration** window, enter a name for the integration, and in the **URL** field, specify the URL. The format is `HTTPS://hostname:port`. For example, `HTTPS://sampleUCD:8443`.

   Note: If you are running DevOps Deploy locally, you can substitute `HTTPS://host.docker.internal:port` in place of `localhost`.

4. In the **Access Token** field, paste the token from DevOps Deploy.
5. Click **Add**.

   Note: The initial synchronization includes four months of data. Depending on the amount of data, the synchronization process can take some time.

What to do next

Synchronization occurs every fifteen minutes but you can synchronize any time by clicking **Actions > Resync** on the **Integrations** page. To prevent synchronization, select the toggle button under **Disable/Enable** field on the **Integrations** page.

Configuring Jenkins integrations

Manage Jenkins™ jobs with your deployments and pipelines.

Before you begin

Obtain the Measure plugin and install it in your Jenkins instance. On the Jenkins Plugin page search for `velocity`. Complete the integration by pasting the Measure credentials into Jenkins.

Note: Ensure the following requirements are met prior to installation of the plugin.

- You must have admin privileges in Jenkins.
- Upgrade the Jenkins plugin version to 2.1.0 in order to upgrade the Velocity version to 2.1.0 and later. Velocity version 2.0.6 will be the last version to support the previous Jenkins plugin version of 2.0.6 and earlier.

Note:

You must not integrate the same instance of Jenkins using Jenkins (Legacy) and Jenkins (ucv-ext-jenkins) plug-in in Measure. Integrating the same Jenkins instance using Jenkins (Legacy) and Jenkins plug-in in Velocity can result in data corruption.

About this task

This configuration makes Jenkins jobs available to pipelines and deployment plans. You can run Jenkins jobs with Measure and use the output in later tasks. After you configure an integration, add Jenkins tasks to deployment plans on page 1858 and pipeline stages.

1. Click **Settings > Integrations > Plugins**.
   A list of defined integrations with current information about each integration is displayed in a table.
2. Click **Add Integration** for **Jenkins**.
3. In the **Add Jenkins Integration** window, in the **Name** field, enter a name for the integration and click **Create**.
4. In the **Integration ID** field, click to copy the ID and then paste it into the corresponding field in your Jenkins instance, **Manage Jenkins > Configure System > DevOps Velocity**.
5. In the **Integration token** field, click to copy the token and then paste it into the corresponding field in Jenkins.
6. Click **Save**.
   Depending on the amount of data,the initial integration can take some time.
   Result
   Synchronization occurs every minute. To prevent synchronization, click the **Disable/Enable** field on the **Integrations** page.

What to do next

After the initial integration, you can add Jenkins tasks to deployment plans and select any of the integrated jobs. Similarly, you can add Jenkins jobs to pipeline stages.

Integrating with ServiceNow

Create and manage ServiceNow™ change requests with Measure. Update change requests with Measure tasks and then react to status changes. Control deployment progress with change request updates.

ServiceNow integrations are managed on the task level. You configure an integration when you add a ServiceNow task to a deployment plan on page 1859. After an integration is configured, other ServiceNow tasks can use the same instance.

Migrating integrations

Migrate the legacy plug-in integrations to external plug-in integrations.

You can migrate the following (Legacy) plug-in integration to external plug-in integrations:

Migrating integration of Jenkins (Legacy) to Jenkins

Migrating integration of Jenkins (Legacy) to Jenkins.

Before you begin

You must have completed the following tasks:

- Back up the database, see instructions in this page.
- Ensure that you have added the version parameter to all applicable jobs in Jenkins server. The Jenkins plugin search for jobs with version parameter as reference.

About this task

To migrate the integrations of Jenkins (Legacy) to Jenkins, complete the following steps:

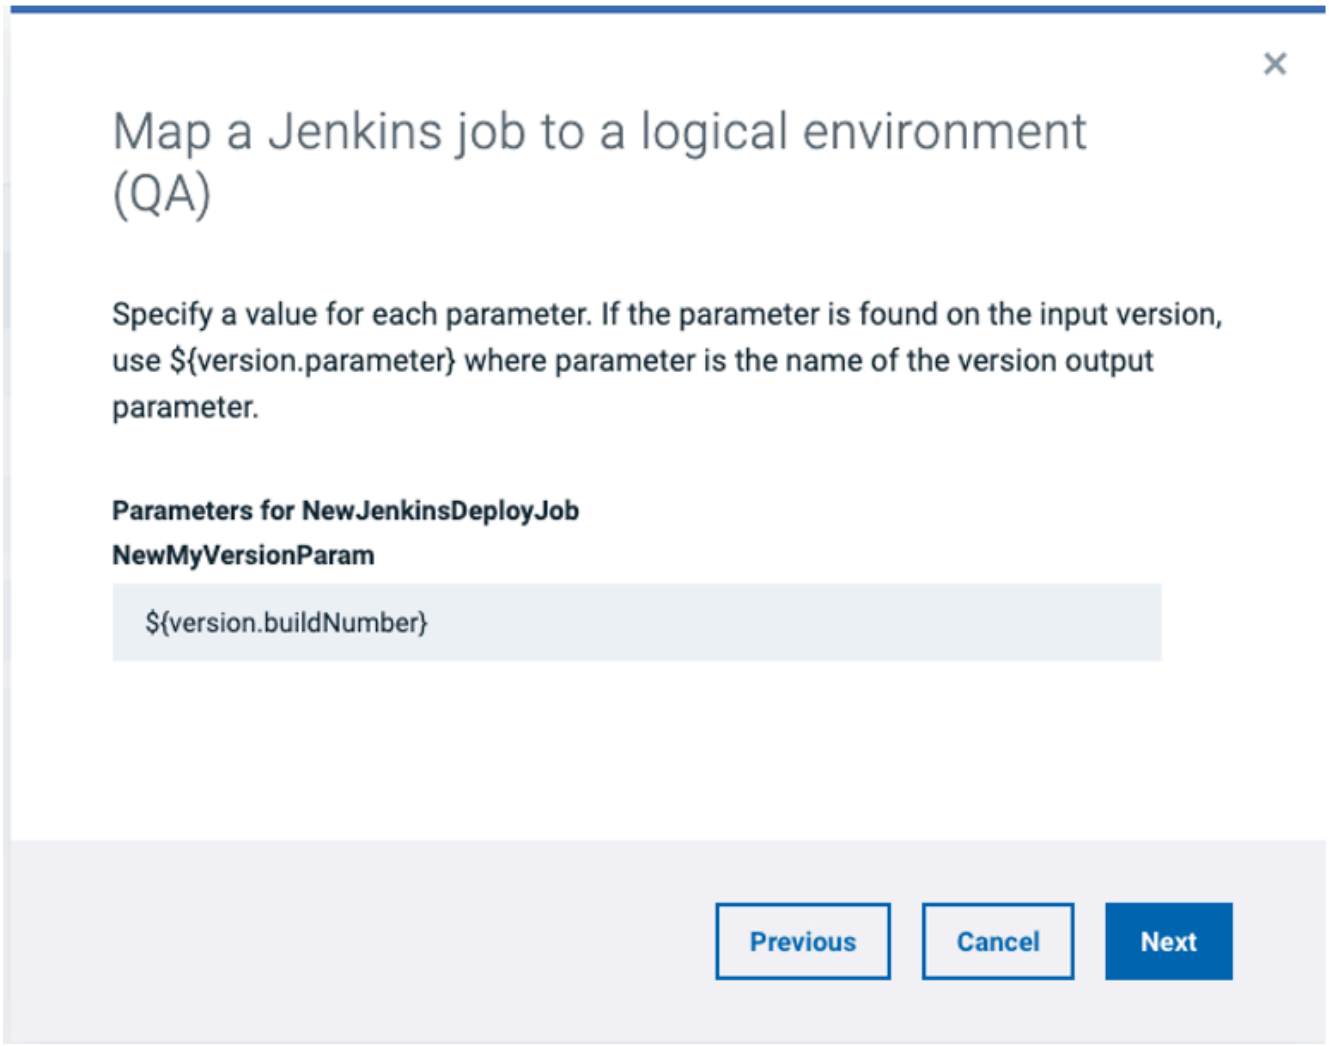
1. From the Measure page, click **Settings > Integrations > Configured**.
   A list of all configured integrations are displayed.
2. Click overflow menu for configured **Jenkins (Legacy)** plug-in and then click **Migrate**.
   The **MIGRATE JENKINS INTEGRATION** window is displayed. You can view the road-map of migration process. Before you begin the migration process, ensure that you have taken the backup of database.
3. On the **MIGRATE JENKINS INTEGRATION** window, click **Continue**.
   The **Add Jenkins Integration** window is displayed.
4. On the **Add Jenkins Integration** window, enter the value for all required fields to create new integration of **Jenkins** and then click **Add** to add the integration details.
   The migration process starts automatically and it reaches to **complete** step of migration process.
5. Click **Close** to close **Migrate Jenkins Integration window**.
   You have successfully migrated integration of **Jenkins (Legacy)** to **Jenkins**.

Results

You can see the **Jenkins** integration data in Velocity.

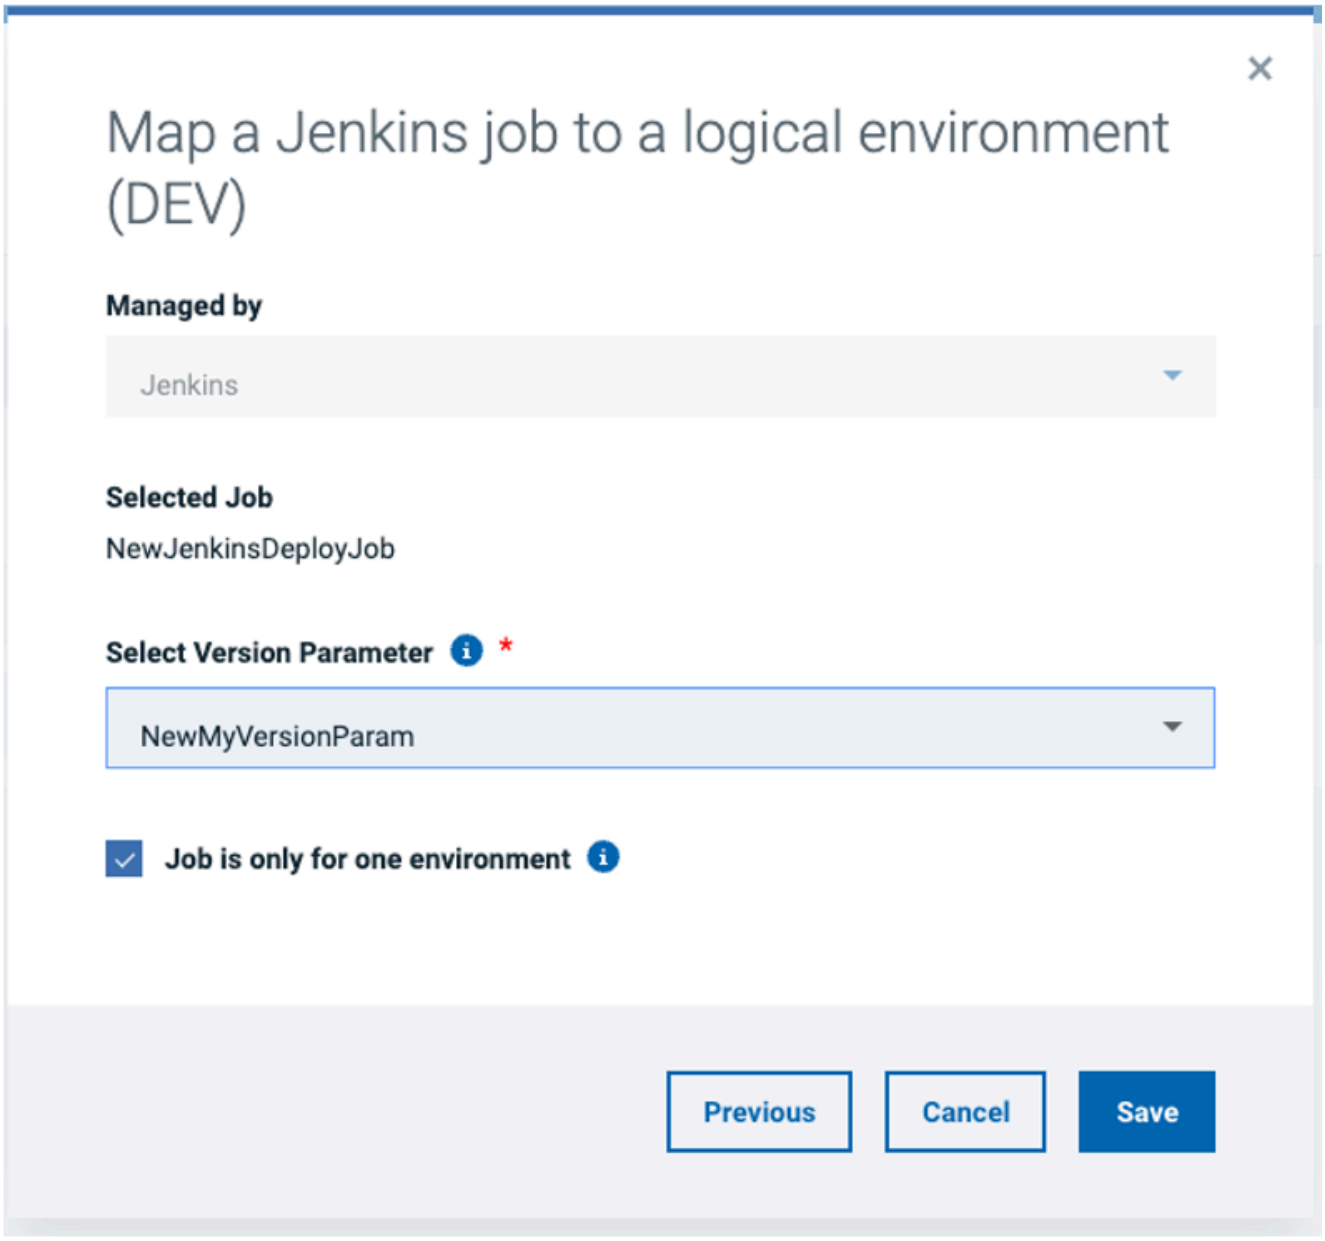
What to do next

Go to pipeline of any value stream and add Jenkins application. While configuring the Jenkins job to logical environment ensure that you use `${version.buildNumber}` parameter.



Map a Jenkins job to a logical environment (QA)
Specify a value for each parameter. If the parameter is found on the input version, use ${version.parameter} where parameter is the name of the version output parameter.
Parameters for NewJenkinsDeployJob
NewMyVersionParam
${version.buildNumber}
Previous
Cancel
Next

Choose the required parameter in **Select Version Parameter**



field.

Migrating integration of UrbanCode Deploy (Legacy) to HCL DevOps Deploy (Deploy)

Migrating integration of UrbanCode Deploy (Legacy) to DevOps Deploy.

Before you begin

You must have completed the following tasks:

- Ensured that you have taken Back up the database, see instructions in this page.
- Ensured that there is no **Releases** with **UrbanCode Deploy (Legacy)** task is **In progress** or **Scheduled** for later.
- Ensured that there is no **UrbanCode Deploy (Legacy)** deployment is **In progress** or **Scheduled** for later.

About this task

To migrate the integrations of UrbanCode Deploy (Legacy) to DevOps Deploy, complete the following steps:

1. From the Measure page, click **Settings > Integrations > Configured**.
   A list of all configured integrations are displayed.
2. Click overflow menu for configured **UrbanCode Deploy (Legacy)** plug-in and then click **Migrate**.
   The **MIGRATE URBANCODE DEPLOY(HCL LAUNCH) INTEGRATION** window is displayed. You can view the stages of the migration process.
3. On the **MIGRATE URBANCODE DEPLOY(HCL LAUNCH) INTEGRATION** window, click **Continue**.
4. The **URBANCODE DEPLOY (Legacy)** integration is migrated to DevOps Deploy integration. The integration name is changed by appending **--migrated-EXT**.
   The migration process automatically installs latest available version of the DevOps Deploy plugin. If any version of DevOps Deploy plugin is already installed, the migration process uses that version of the plugin for migrating the integration.

Results

All **URBANCODE DEPLOY (Legacy)** task type changes to DevOps Deploy task in templates.

What to do next

You can schedule the deployment for DevOps Deploy applications by using the migrated DevOps Deploy integrations.

Uploading a build to a pipeline

builds/apiDriven

```
curl -k -X POST 'https://localhost/api/v1/builds/apiDriven' \
    -H 'Authorizat1on: UserAccessKey <User Access Key>' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":"<Version Name>",
        "application":{"externalId":"efecb73f-dclc-4d3d-b3bb-
        38339445e892"},
        "url":"<Build URL>",
        "revision":"<Commit SHA>"
    }'
```

Table 1201. builds/apiDriven parameters

Parameter	Type	Required	Description
UserAccesKey	string	false	User access key
version	string	true	JSON object with either 'externalId' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})

Table 1201. builds/apiDriven parameters (continued)

Parameter	Type	Required	Description
application	object	false	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
url	URL	false	URL link to build in external tool
revision	string	true	SHA of the commit linked to the build

Example

Example

```
curl -k -X POST 'https://localhost/api/v1/builds/apiDriven' \
    -H 'Authorizat1on: UserAccessKey 3b3ec6cc-1e37-4353-bc3a-46b493eed4e6' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":"1.0",
        "application":{"externalId":"b900ff5b-1fff-44ab-bcc6-9d39d5937026"},
        "url":"https://test.com",
        "revision":"12345678"
    }'
```

Uploading deployment status

deployments/apiDriven

```
curl -k -X POST 'https://localhost/api/v1/deployments/apiDriven' \
    -H 'Authorizat1on: UserAccessKey <User Access Key>' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":{"name":"<Version Name>",
        "application":{"externalId":"efecb73f-dclc-4d3d-b3bb-
        38339445e892"},
        "url":"<Deployment URL>",
        "environment":{"name":"DEV"}
    }'
```

Table 1202. deployments/apiDriven parameters

Parameter	Type	Required	Description
UserAccesKey	string	false	User access key

Table 1202. deployments/apiDriven parameters (continued)

Parameter	Type	Required	Description
version	object	true	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
application	object	true	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
url	URL	false	URL link to build in external tool
environment	object	true	JSON object with either 'externalId' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})

Example

Example

```
curl -k -X POST 'https://localhost/api/v1/deployments/apiDriven' \
    -H 'Authorization: UserAccessKey 324adfe9-cc97-43fa-81c6-e248ceeb726a' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":{"name":"1.0",
        "application":{"externalId":"f2262e67-6516-4597-92a6-cfe537abdd00"},
        "url":"http://example.com",
        "environment":{"name":"DEV"}
    }'
```

Getting started with GraphQL in Measure

You can use GraphQL Playground in explore and test APIs interactively before using them in real scenarios. This GraphQL playground provides a convenient environment to use queries and mutations, that helps you understand the available data and how to structure requests effectively.

GraphQL is a flexible and efficient query language for APIs that allows you to request exactly the data you need. Unlike traditional REST APIs that return fixed data structures, GraphQL helps you define the shape of the response, fetch related data in a single request, and interact with data using queries (to read data) and mutations (to create or update data).

With GraphQL in Measure, you can use queries to retrieve value stream data, such as work items, deployments, commits, and other DevOps artifacts, and use mutations to create or manage resources.

Setting up GraphQL with API endpoints

Before you begin, you must create a user access key. See Managing User access keys (UAKs) on page 1820.

Follow the steps to set up and authenticate the GraphQL Integrated Development Environment (IDE) in DevOps Velocity:

1. Navigate to the Velocity instance GraphQL interface using `https://my_velocity:port/graphiql`.
2. Click the Set Headers icon.
3. Enter **Authorization** in the **Header key** field.
4. Enter the user access key in the **Value** field.

After the authentication is complete, you can start using different GraphQL APIs to validate responses and refine your queries. The GraphQL Playground also provides built-in documentation for each query and mutation, allows you to easily explore available fields, input parameters, and response structures.

After testing, you can use these APIs in your applications or leverage them to create and manage resources in Measure for bulk operations or automation scenarios without using the UI.

Mutations

Mutations are used to create new data, update existing data, and delete existing data.

Here are a few examples of mutations that you can use in Velocity.

- Create a Value Stream

  A Value Stream represents the flow of work items through a pipeline. It helps you visualize how work items move from one stage to another across various tools in the pipeline. To create a new value stream, you can use the following GraphQL mutation:

  ```
  mutation {
    createValueStream(
      name: "string"
      description: "string"
      tenantId: "_____"
      team: { id: "string", name: "string" }
      workflow: "_____"
    )
  }
  ```

- Add an environment to a pipeline

  A pipeline defines the series of steps required for deploying software, while stages represent the different phases of the pipeline (for example, build, deploy, test). To add a new stage to a pipeline, you can use the following GraphQL mutation:

  ```
  mutation {
    addPipelineStages(
      pipelineId: "Pipeline_ID",
      stages: [{ name: "<Stage_name>", type: "<Stage_type>" }]
    ) {
      _id
      name
      type
      description
      planId
      triggers {
  ```

```
      _id
      name
    }
    gates {
      _id
      name
    }
    cf_space_id
    promoteTo
    latestAutopromotionStatus
    deploymentModes
    defaultDeploymentMode
    groupsAndUsers
    solutionVersionId
  }
}
```

- Add an application to a pipeline

  To add an application to a pipeline, you can use the following mutation:

```
mutation {
  addApplications(
    pipelineId: "_____"
    applications: [{ name: "string" }]
    processes: [{ name: "string" }]
    type: "string"
  ) {
    _id
    name
    tenant_id
    description
    stages {
      _id
      name
      type
      description
      planId
      triggers
      gates
      cf_space_id
      promoteTo
      latestAutopromotionStatus
      deploymentModes
      defaultDeploymentMode
      groupsAndUsers
      solutionVersionId
      solutionVersion
    }
    applications {
      _id
      name
      type
      description
      processes
      source
      inputJobId
      stages
      subApplications
```

```
      children
      level
      external_id
      selectedChildren
      versionRegEx
    }
    synchronize
    team {
      id
      name
      tenantId
    }
    created
    stats {
      leadTime
    }
  }
}
```

Queries

You can access detailed information from Measure by using GraphQL queries.

The following are some example queries that demonstrate how to retrieve various types of data.

- Get application data by using the application ID

  You can retrieve detailed information about a specific application by using its ID and the following query:

```
{
  applicationById(id: "<Application_ID>", tenantId: "<Tenant_ID>", loadChildren: true) {
    _id
    id
    external_id
    tenant_id
    integration_id
    name
    alphaNumericName
    active
    createdAdHoc
    json_data
    type
    version
    level
    childrenIds
    children {
      _id
      id
      external_id
      tenant_id
      integration_id
      name
      alphaNumericName
      active
      createdAdHoc
      json_data
      type
```

```
      version
      level
    }
  }
}
```

- Retrieve the application environment details by tenantID

  To retrieve all unique application environment details for a given tenantID, you can use the following query::

```
{
  applicationEnvironmentsByTenantId(tenantId: "TenantID") {
    _id
    id
    external_id
    tenant_id
    name
    app_id
    external_app_id
    active
    json_data
    type
    version
    inventory {
      external_version_id
      components
    }
  }
}
```

- Retrieve application environment name by tenantID

  To retrieve all unique application environment names for a given tenantID, you can use the following query:

```
{
  uniqueApplicationEnvironmentNamesByTenantId(tenantId: "_____") {
    name
  }
}
```

How to

The topics in this section describe how to work with Measure features. Tutorials and workbooks are available for users of all experience levels.

Creating reports

Use the **Home** page to create one of the following reports.

About this task

- Custom
- Delivery Transformation
- Recent Activity

- Team Performance
- Audit

1. From the **Home** page, click **Insights > Reports**.
2. Click to **Add report**.
3. On the **New report** page, in the **Type of report** field, select the type of report from the list.
4. Enter the name of the report in the **Report name** field.
5. Enter a report description in the **Description** field.
6. Select an icon for the report in the **Icon** field.
7. Click **Add**.
   After the report is created you can immediately run, edit, and share the report with other users.

Sharing reports

You can share reports with others in your organization and who are authenticated to Measure. By default, you see only the reports that you create.

About this task

When you share a report, the users you are sharing the report with are able to access the report from their Home page. Depending on the access level that you provide, they can modify the report or only view report data.

Note: The data users can view is restricted to data from the teams of which they are a member.

You can remove access at any time by clicking the delete icon next to the email address on the **Share Report** page.

1. From the **Insights > Reports** page, select the report that you want to share.
2. Click

to copy the URL link for sharing the report.
3. Share the URL of the report to required users.

   Note: The user must be authenticated for accessing the reports.

Glossary

This glossary provides terms and definitions for the Measure software and products.

The following cross-references are used in this glossary:

- *See* refers you from a non-preferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

A

activity

Activities include releases, events, and deployment plans that you develop, start, and complete with the product.

agent

A program that runs on a remote computer and communicates with the Measure server. Agents run processes on deployment target systems.

agent relay

A communication proxy for agents that are located behind a firewall or in another network location.

API

An interface that allows an application program that is written in a high-level language to use specific data or functions of the operating system or another program.

Application

One or more computer programs or software components that provide a function in direct support of a specific business process or processes. See also application server.

application environment

A user-defined collection of resources that hosts an application. These application environments refer to environments that are created to be in the product.

application process

A process that is associated with an application. Unlike a component or generic process, an application process is created from application-level steps. Typically, an application process invokes component processes, and orchestrates multi-component deployments. See also component process on page 1900, generic process on page 1901, process on page 1903.

artifact

A deployable item such as a file, image, database, configuration material, or anything else that is associated with a software project. By default, artifacts are stored in CodeStation repository.

authentication realm

An authentication realm manages users and determines user identity. It retrieves information from sources such as LDAP servers and Keystone identity services.

auto task

A task that starts automatically they are eligible to run. Examples of auto task types are HCL DevOps Deploy, Continuous Delivery pipeline, email, and Slack.

B

blackout

A setting that prevents deployments and snapshots from being scheduled. Blackouts solely affect the environment and application that they are applied to.

C

change

An artifact that represents a generalized notion of a development work product, such as a task, defect report, or enhancement request. See also initiative on page 1901.

component

A representation of deployable items and the user-defined processes that operate on them, usually by deploying them.

component process

A process defined for the deployment of components.

component version

See version on page 1904.

D

dashboard

A displayed collection of user-defined data filters and metric charts. Dashboards are used to analyze project data for their quality and efficiency.

dependent task

A task depends on another task to finish before it starts. The task that a dependent task waits for is called a prerequisite task. Dependent tasks cannot start until all its prerequisite tasks are resolved. Dependent tasks are used to ensure that tasks run in the specified order.

deployment

The activities used to deliver a software project to a deployment target. Typically, you run deployments for each stage of your release lifecycle, ending with the production stage when the software becomes generally available. The activities that are performed during a deployment, called tasks, are defined in deployment plans. You start a deployment by starting one of the plan's eligible tasks. You complete a deployment by resolving all the tasks in the deployment plan.

dots

A value stream unit of work, such as a pull request, build, or deployment. Units of work can be combined, such as commits and pull requests, which significantly enhances the data quality of value streams.

duration

The time a task takes to run. Duration is measured from the time a task starts until it is resolved. When you create some task types, you can estimate its expected duration. Duration is reported in minutes.

E

environment

A collection of resources that identify the components that can be deployed by the parent application and the agents that do the work.

events

Release-related activities that are applied to releases and tracked with a calendar. You can use events to organize your releases and other time-dependent activities, such as holidays and blackouts.

execution pattern

The order in which tasks in a deployment plan become eligible to run. By default, a plan's execution pattern is sequential. Sequential tasks run in order beginning with the first task in the plan. You can combine tasks into groups and assign the parallel execution pattern to the group. Parallel tasks can run in any order and run simultaneously.

G

gate

A requirement that must be met before an application can move on to the next stage.

generic process

Processes that are designed to run outside typical component or application processing. See also application process on page 1899, component process on page 1900, process on page 1903.

group

A logical container that serves as a mechanism to grant permissions to multiple users.

I

initative

An action to take for the change occurred.

insights

A set of related features such as metric data dashboards, reports, and the application portfolio.

integration

Regular communication between Measure and external products and services. Communication with integrated products can be bidirectional.

L

lifecycle

The phases in a release. A lifecycle is a template for the stages of work in a release.

lock

A means of preventing changes being made to a release.

logical environment

A collection of physical environments on page 1902.

M

manual task

A release related task that users must manually complete. See also auto task on page 1899.

metric data

Tools, such as charts and graphs that are applied to project data to assess project quality and progress.

metric definition

A JSON object that defines expected value types and chart default settings.

milestone

A significant event in a project or process that is used to determine progress toward goals.

P

particles

See dots on page 1900.

phase

An organizational segment within a value stream containing the stages, such as "Planning," or "Development,", that define process flow within that group.

physical environment

An actual deployable location, server, hardware, and so on.

pipeline

A sequence of stages that retrieve input and run applications and jobs, such as builds, tests, and deployments.

plugin

A separately installable software module that adds function to an existing program, application, or interface.

portfolio

A collection of application information in one location where you can analyze the data with metric charts and graphs.

process

In Measure, processes define automation activities, such as deploying components.

property

A variable that specifies a value that is provided during process deployment and is associated with a specific Measure object. An individual property's value can be accessed only by certain types of related objects, such as environments, processes, and components.

Q

quality

A user-defined attribute that serves as a gate for applications to enter phases.

R

release

The delivery of multiple applications through one or more phases of a lifecycle.

resource

A user-defined construct that is based on the architectural model of Measure. A resource represents a deployment target.

role

A job function that identifies the tasks that a user can perform and the resources to which a user has access. A user can be assigned one or more roles.

S

segment

A period of time in a deployment plan. Deployment plans can group tasks into segments to specify when tasks are run relative to each other.

snapshot

A collection of specific versions of components. Typically, a snapshot represents a set of component versions that are known to work together.

stage

In the value stream, a subset of a phase that contains data from integrated tools.

swim lane

A representation of value stream data in tabular form where the columns represent value stream stages, and the rows represent users.

T

tag

A label that you can apply to tasks or releases. When applied to tasks, tags can determine task applicability for a given deployment. When applied to releases, tags can be used to organize and filter releases.

task

Represents a business-meaningful activity that has starting and ending points and a measurable duration. Durations are used to estimate deployment times. You add tasks to deployment plans. When you run a deployment, you complete the tasks in the plan

task group

A combination of two or more tasks that are associated into a group. When you form a group, you define the group's execution pattern as sequential or parallel.

team

A team is a collection of users and groups.

token

A particular message or bit pattern that signifies permission or temporary control to transmit over a network.

U

user

A representation of an account on the server. Users can be members of teams and groups. User can be created in Velocity Measure server or import users from an external authentication realm, including an LDAP, Active Directory, or SSO provider.

V

value stream

A representation of the objects. The value stream provides a strategic window into your project workflow.

version

A representation of an Deploy application snapshot.

Chapter 7. Loop Genie overview - Tech Preview

Disclaimer:

This release contains access to the Loop Genie as a Tech Preview in HCL DevOps Loop. The Tech Preview is intended for you to view the capabilities of Loop Genie offered by HCL DevOps Loop, and to provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL provides the information without obligation of support and "as is" without warranty of any kind.

Loop Genie is an AI-powered assistant integrated into DevOps Loop. It provides a unified conversational interface for retrieving information and performing actions across multiple DevOps Loop capabilities.

Loop Genie uses a ReAct (Reason and Act) execution model that dynamically determines the next action required to satisfy a request. Rather than following a fixed sequence of operations, Loop Genie evaluates results after each step and can invoke additional tools as needed until the requested task is completed.

Loop Genie supports multi-step requests that can involve multiple tools in a single interaction. For example, you can create a work item, assign it to a user, and retrieve its status within a single prompt. Loop Genie also produces formatted responses for better readability, replacing raw JSON outputs.

Loop Genie connects with built-in agents to handle prompts securely and efficiently. You can interact with Loop Genie through text or voice input, making it easier to manage teamspaces, add or remove users, create branches, edit files, and manage pull requests without navigating multiple interfaces.

Loop Genie's AI capabilities support integration with **OpenAI**, **IBM watsonx**, **Claude**, and **Gemini**. These integrations provide natural language understanding, context-aware responses, and advanced automation, allowing Loop Genie to perform tasks and retrieve information efficiently across your DevOps Loop environment.

Operational modes

Loop Genie supports the following operational modes:

Query mode

Query mode is the default mode and is designed for information retrieval and exploration. In Query mode, Loop Genie uses read-only tools and does not make changes to your DevOps Loop environment.

You can use the Query mode when you want to retrieve information, search across loops and capabilities, review work items, repositories, or metrics, and explore available resources.

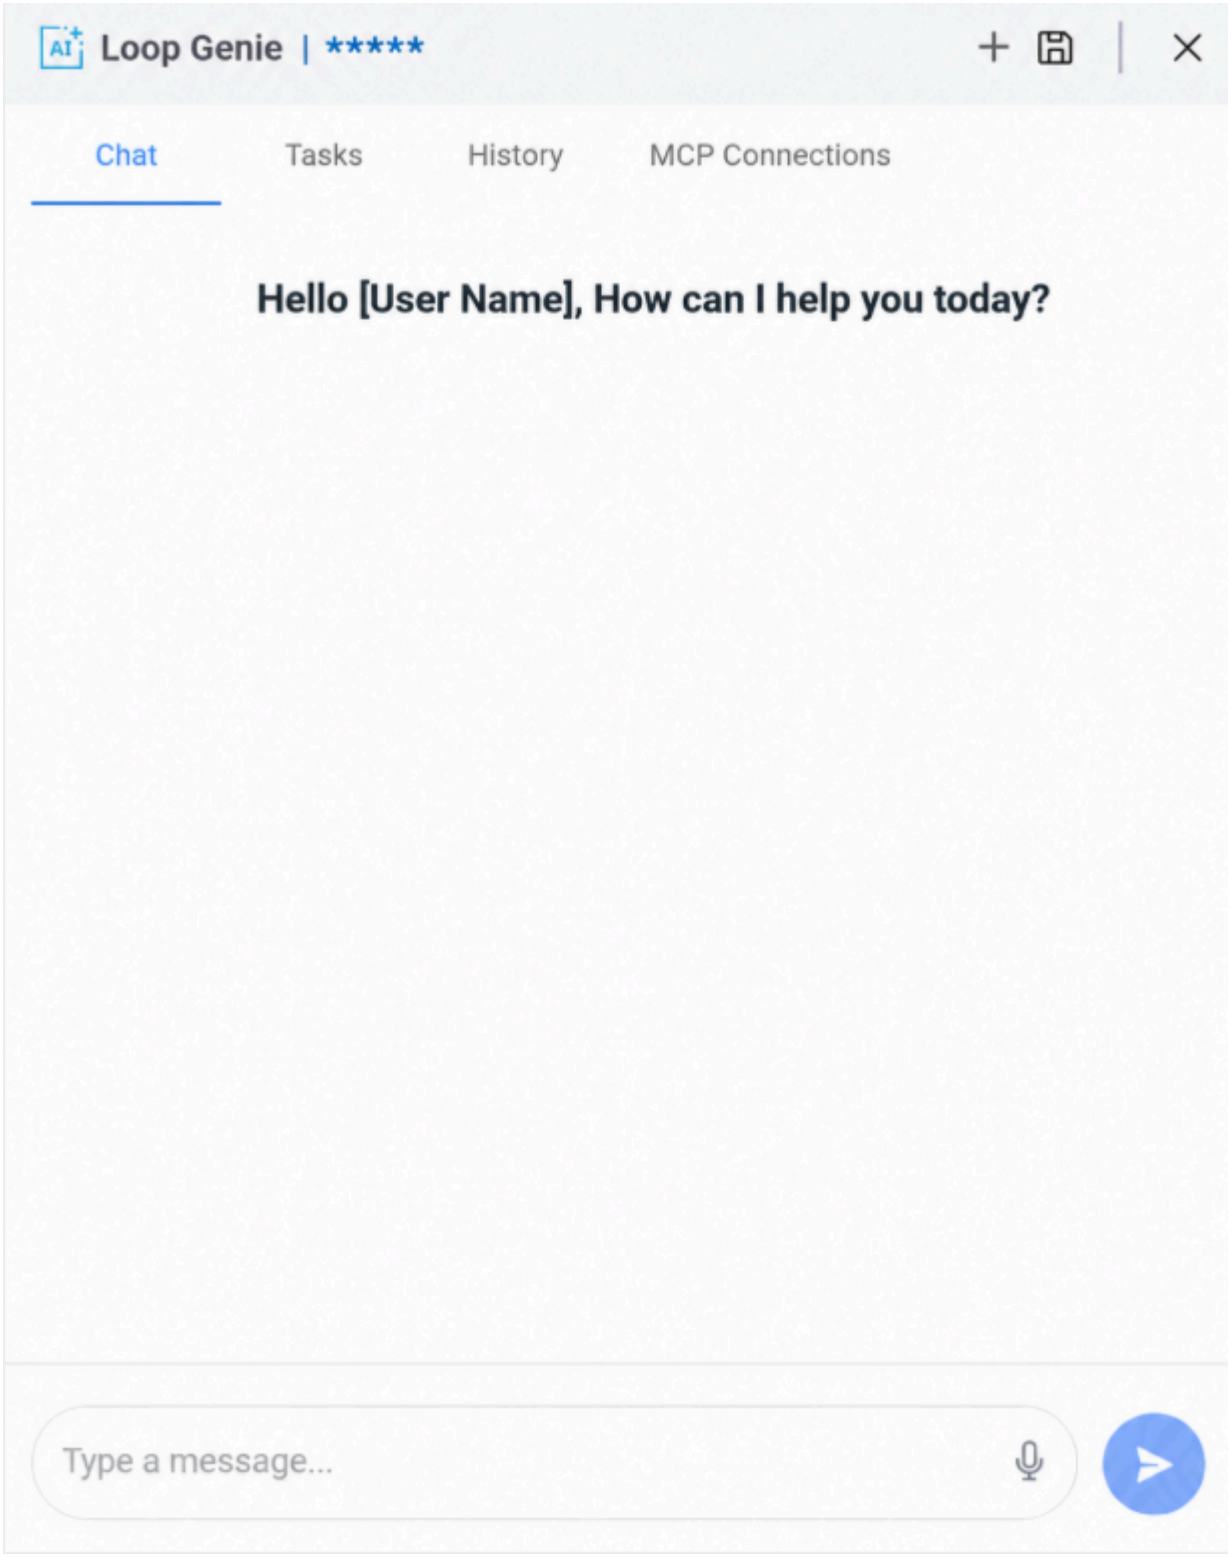
Task mode

Task mode is used for predefined or user-defined tasks that perform actions within DevOps Loop. Depending on the task configuration and assigned permissions, Loop Genie can run write operations such as creating work items, updating records, or modifying repositories.

Loop Genie workspace

Loop Genie provides a unified workspace for interacting with AI-assisted DevOps Loop capabilities. The workspace enables you to submit requests, run predefined tasks, review tool activity, and access previous conversations.

When you click Loop Genie icon in the loop card, the Loop Genie workspace is displayed with following options:



Chat

You can use the **Chat** tab to interact with Loop Genie. The Chat tab provides following:

- Text and voice input
- Streaming responses
- Tool execution visibility
- Context usage monitoring
- Conversation downloads
- New conversation creation

During execution, Loop Genie displays tool activity inline so that you can review the actions performed and the results returned by each tool.

Tasks

You can use the **Tasks** tab to access predefined and custom tasks.

Tasks provide reusable workflows that combine prompts, instructions, and tool access to automate common DevOps activities. Tasks can be categorized and marked as favorites for easier access.

History

Navigate the History tab to review previous interactions.

History is filtered by the selected loop and current user. You can revisit previous conversations, review results, rerun requests, and download conversations for future reference.

MCP Connections

You can view available MCP servers to Loop genie and enable or disable added MCP servers directly from the **MCP Connections** tab.

Monitoring Execution

The workspace displays context usage information during execution. This indicator helps you understand how much context is currently being used by the conversation.

When context usage approaches configured limits, Loop Genie can automatically compress conversation history to continue processing requests.

Stopping execution

If a request is taking longer than expected or is not producing the desired results, click Stop to interrupt the current execution.

Sample multi-step workflow execution in Loop Genie

Scenario: You want to create a new work item in DevOps Loop, assign it to a user, and then fetch its status all in a single request.

Prompt to Loop Genie:

“

Create a new story in the `Payment API` project titled ‘Implement new refund feature’, assign it to `alice@example.com`, and then get the status of the newly created work item.”

”

How Loop Genie handles the execution:

1. **Step 1 – Create Work Item**
   - Calls `plan_create_work_item` with project name, title, and optional fields.
   - Returns the new work item ID.
2. **Step 2 – Assign User**
   - Calls `plan_update_work_item` (or equivalent MCP command) to assign the work item to `abc@example.com`.
3. **Step 3 – Retrieve Status**
   - Calls `analytics_get_work_item_status` with the work item ID to fetch the current status.

Output returned by Loop Genie:

Field	Value
Work Item ID	12345
Title	Implement a new refund feature
Assigned To	abc
Status	Open

Interacting with Loop Genie

You can interact with Loop Genie, an AI assistant, to retrieve information or perform tasks across multiple capabilities and loops within DevOps Loop. The results or actions are displayed directly in the chat interface.

Before you begin

You must have completed the following tasks:

- An AI provider is configured on the **Installed Integrations** page. See AI provider integration for Loop Genie - Tech Preview on page 94.
- Created a loop. See Creating a loop on page 140.

1. Click the button.

   Result

   A chat interface is displayed with a greeting message: *"Hello (username), How can I help you today?"*
2. Perform any of the following actions:
   a. Enter your prompt or query in the chat box.
   b. Navigate to the **Tasks** tab and select the task you want Loop Genie to perform.
3. Click the **Send** icon or press **Enter**.

   Loop Genie processes your query, performs actions, or both, depending on the request. The results or actions are displayed directly in the chat interface.

   During execution, Loop Genie displays tool activity within the conversation. For requests that involve multiple tools or large result sets, information may appear progressively as processing continues. Depending on your configuration, you can review the following execution details:

   - Tool names
   - Tool parameters
   - Execution status
   - Tool results

   Note: The output format might vary between AI providers, which can affect how responses are displayed in Loop Genie.
4. **Optional:** Click the icon to download the conversation in a `.json` format for later reference.
5. **Optional:** Click to close the Loop Genie.

Results

You have interacted with Loop Genie to retrieve information or perform tasks across DevOps Loop capabilities.

Related information

Running a predefined task in Loop Genie on page 3284

Prompt references for Loop Genie on page 3286

Loop Genie tasks

Loop Genie tasks are reusable workflows that help automate common DevOps activities. A task combines instructions, prompts, and tool access into a predefined workflow that can be executed from the Tasks tab in the Loop Genie workspace.

Instead of manually entering prompts for repetitive activities, you can run a task to perform a predefined sequence of actions consistently and efficiently.

Creating a loop automatically makes a set of preloaded tasks available. The system groups these tasks into categories such as build, code, and deployment, helping you quickly find relevant workflows.

Each task is defined as a markdown file and stored in a dedicated repository associated with the loop. These task definitions are version-controlled, and you can update, extend, or customize tasks.

From the **Tasks** tab, you can perform the following actions:

- View available tasks and their descriptions
- Filter tasks by category
- Mark frequently used tasks as favorites
- Select and run tasks directly

When you select a task, it opens in the **Chat** tab where you can enter your own custom prompt and choose to run the workflow or perform specific actions within the task. Tasks provide a more structured and efficient way to interact with Loop Genie by reducing repetitive input and providing consistent and reusable workflows.

Task repository

Task definitions are stored as markdown files in the task repository associated with a loop.

When a loop is created, a task repository is automatically created to store task definitions. These definitions are version controlled and can be updated as requirements change.

Administrators and authorized users can create new tasks, modify existing tasks, and maintain task definitions by updating the files stored in the repository.

How tasks work

When you select a task, Loop Genie loads the task definition and uses the instructions and permissions associated with that task during execution. A task can include:

- Task metadata
- A description
- System instructions
- Tool permissions
- Suggested prompts
- Categories
- Starter actions

Loop Genie uses this information to determine how the task should behave and which tools can be used while processing requests.

Task execution

Tasks use Loop Genie's reasoning and action workflow to process requests. During execution, Loop Genie:

1. Evaluates the task instructions.
2. Determines the next action required.
3. Selects an appropriate tool.
4. Executes the tool.
5. Reviews the result.
6. Continues until the objective is completed.

Depending on the task configuration, multiple tools can be used during a single execution.

Running a predefined task in Loop Genie

You can run predefined tasks that are available in the **Tasks** tab in Loop Genie to run AI-assisted DevOps workflows through configured prompts and toolsets.

Before you begin

You must have completed the following tasks:

- Created a loop. See Creating a loop on page 140.
- An AI provider is configured on the **Installed Integrations** page. See AI provider integration for Loop Genie - Tech Preview on page 94.
- Verified that predefined tasks are available in the **Tasks** tab in Loop Genie.

1. Click the button.
   A chat interface is displayed.
2. Navigate to the **Tasks** tab and select a task.
   The task opens in the **Chat** tab with its details and available steps. You can choose a suggested step or enter a new instruction.
3. Select a step.

   The task runs and returns results based on the predefined System Prompt and toolsets defined in Task's markdown file.
4. Review the results.

Results

You have successfully run a predefined Loop Genie task and received results based on the configured prompts and toolsets.

Creating or modifying a task in Loop Genie

You can create a new or modify an existing Loop Genie task by defining prompts and selecting tools to automate DevOps workflows.

Before you begin

You must have created a loop.

1. Select **Control** from the **Go To** drop-down in the loop.
   The repository associated with the loop is displayed.
2. Navigate to your **TeamSpace** and then select the task repository named as `<loop_name>-Tasks`.

   When a loop is created, a repository is automatically created to store task definitions as markdown files (`.md`). For example: `<loop_name>~TASKS`. You can use this repository to add new task files or modify existing ones.

   Note: As this is a standard source control repository, you can clone it locally, make changes using your preferred editor, and push updates, or edit files directly through the UI.

3. Create a new task file or modify an existing one in the repository.
4. Define or update the task definition file with the required structure and details. Each task file contains YAML front matter that defines how the task appears and behaves.

   Table 1203. YAML front matter for Loop Genie Task

Field	Required	Description
Name	Mandatory	Specifies the name of the task.
Description	Mandatory	Provides a brief description of the task.
Icon	Optional	Specifies the icon for the task. Provide a relative path (for example, `icons/build.svg`) with respect to the current markdown file location. If not provided, a default icon is used.
Categories	Optional	Defines the category of the task. If not specified, the task is displayed under **Others**.
Tools	Optional	Lists the tools that the task can use. Tool names must match exactly. If not provided, all available tools based on the configured MCP are used.
Starters	Optional	Defines conversational prompts for common actions. Each starter must include a **label** (displayed in the UI) and a **prompt** (sent to Loop Genie). The prompt is shown as a tooltip.
System prompt	Mandatory	Defines the behavior and instructions that control how the task executes.

5. Save the file and commit your changes to the repository.

6. Open Loop Genie .
7. Navigate to the **Tasks** tab.
   The created or modified task is displayed.

Results

You have created a new or modified an existing Loop Genie task.

Prompt references for Loop Genie

You can use natural language prompts to interact with Loop Genie and perform actions across DevOps Loop capabilities.

Loop Genie uses a reasoning and action workflow to determine the tools and steps required to satisfy a request. Rather than requiring a separate command for each action, Loop Genie can process multi-step requests and coordinate actions across multiple capabilities within a single prompt.

The prompts in this topic are examples only. You can modify them to match your environment, naming conventions, and workflows.

Writing effective prompts

Describe the outcome that you want to achieve rather than each step. Loop Genie can determine the required sequence of actions and execute the appropriate tools to complete the request.

For example, instead of submitting multiple requests such as:

- Create a work item.
- Assign the work item.
- Retrieve the work item status.

Use a single request such as:

Create a story named "Implement refund feature", assign it to john@example.com, and then retrieve the work item status.

Using tool references

You can type **#** in the prompt field to view available tools from enabled MCP connections.

Examples:

- `#plan_create_work_item`
- `#control_get_pull_request`
- `#analytics_get_work_item_status`

Tool references can help direct Loop Genie to a specific capability or operation when multiple tools are available.

Prompt references

You can use the following prompts to interact with Loop Genie, which responds and performs the specified actions on your DevOps Loop platform. These prompts are for reference only and can be customized based on your environment and version.

Loop Genie supports multi-step workflows. A single prompt can involve multiple capabilities, and Loop Genie executes the required actions as part of a single request.

Table 1204. Sample prompts for DevOps Loop capabilities

Module	Scope	Prompt examples
Loop	Manage loops, projects, users, test projects, and control repositories within a loop.	• List all projects under Loop "TeamAlpha". • Add user "jane.doe@example.com" to Loop "TeamAlpha". • Attach Test Project "QA-Release1" to Loop "TeamAlpha". • Add repository "devops-repo" to Loop "TeamAlpha".
Loop Teamspaces	Manage teamspaces, teamspace users, and invitations.	• Show all teamspaces in DevOps Loop. • List all users in Teamspace "Engineering". • Invite "mark.smith@example.com" to Teamspace "Engineering".
Loop (Plan)	Manage planning activities such as components, work items, and applications.	• List all components for Plan ID "Plan123". • What work item types are supported in Plan "Plan123"? • Show work items for Project "InventoryApp". • List applications under Plan "Release2.0". • Create a Bug work item "Fix login issue" in Project "InventoryApp". • Delete work item ID "4567" from Plan "Plan123".
Loop (OpenSearch)	Search and analyze work items, story points, and statuses.	• Search for work items containing "API Bug" in Sprint "Sprint7". • Show the status of Work Item ID "789".

Table 1204. Sample prompts for DevOps Loop capabilities (continued)

Module	Scope	Prompt examples
		• How many open work items exist in Plan "Plan123"? • Show total story points for Sprint "Sprint5".
Loop (TestHub)	Manage and execute tests and test projects.	• List all TestHub projects for Loop "QA-Team". • List all tests in Project "ReleaseSmokeTests". • Run Test ID "T101" in Project "ReleaseSmokeTests". • Show results for Test ID "T101" in Project "ReleaseSmokeTests". • Get TestHub result for ID "5555".
Loop (Control)	Manage repositories, branches, tags, releases, issues, pull requests, and searches.	• Show details of the authenticated user. • List all organizations linked to my account. • Fork the repository "main-project" to my personal workspace. • Show all repositories I own. • Create a branch "feature-123" in the repository "backend-service". • List branches in repository "frontend-app". • Create release "v1.0" in repository "backend-service". • Get details of release "v1.0" in repository "frontend-app". • List all releases for the repository "api-service". • Create tag "v2.0" in repository "frontend-app". • Get details of tag "v1.0-beta" in repository "backend-service". • List tags in the repository "frontend-app". • Show commits in the repository "backend-service". • Get the content of "README.md" in the repository "frontend-app". • Update file "config.yaml" in repository "api-service". • Get issue #12 from the repository "frontend-app".

Table 1204. Sample prompts for DevOps Loop capabilities (continued)

Module	Scope	Prompt examples
		• List all issues in the repository "backend-service". • Create an issue "Fix API bug" in the repository "api-service". • Edit the comment on issue #12 in repository "frontend-app". • Show comments for issue #34. • List pull requests for the repository "backend-service". • Create a pull request from branch "feature-123" to "main" in the repository "api-service". • Search for team "DevOps" in organization "Enterprise". • Show the current Gitea MCP Server version.

Multi-step prompt examples

Loop Genie can coordinate multiple actions across capabilities within a single request as follows.

- Create a Bug work item named "Fix login issue", assign it to jane.doe@example.com, and then retrieve its status.
- Create a branch "feature-refund-api" in the repository "payment-service" and then show the branch details.
- Add user "jane.doe@example.com" to Loop "TeamAlpha" and then list all users in the loop.
- Create a pull request from the branch "feature-refund-api" to "main" and then show the pull request details.

Depending on the configuration, Loop Genie can display tool activity during execution, including tool names, parameters, execution status, and results. This information helps you understand how requests are processed and provides visibility into actions performed by Loop Genie.

Chapter 8. Troubleshooting

The troubleshooting information can help you diagnose and resolve common issues. If the issue persists after completing the applicable troubleshooting steps, gather the relevant logs and error details before contacting support. You can contact HCL Support if you are unable to troubleshoot the problem. For more information, see HCL Customer Support.

Security Considerations

This document describes the actions that you can take to ensure that your installation is secure, customize your security settings, and set up user access controls in HCL DevOps Loop.

You can find the following information about security considerations for the solution:

- Security considerations for Plan
- Security Considerations for Test
- Security Considerations for Deploy
- Security settings for Measure and Release and Considerations for GDPR readiness
