SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.

5. Identify the test asset that you want to run by performing any of the following actions:
    - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps to provide the variables that specify the device cloud to which the mobile device is attached. You can either enter the variables that must be passed to the test at the test run time or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

11. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.

Export options	Results in...	Actions
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

12. Perform any of the following actions that depend on whether you are using a remote performance agent or a mobile device cloud:
    - Go to Step 13 on page 1164, if you are using an agent.
    - Go to Step 14 on page 1165, if you are using a mobile device cloud.
13. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:
    a. Click the **LOCATION** tab, if it is not already open.

       The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

       Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

       The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

14. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of an AFT Suite to run on a device, emulator, or simulator that is connected to an agent or mobile device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring an AFT Suite to run on a mobile device by using a cloud credential

After you added the test resources that you created in the desktop client to the project, you can configure an AFT Suite to be run on a mobile device by using a cloud credential from Test .

Before you begin

You must have completed the following tasks:

- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:

a. Click **New filter**.
b. Enter a name for the filter.
c. Select an operator, and then add a rule or a group of rules.
d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

   You can select a parameter from the following list:
   - Type
   - Test Asset Name
   - Test Asset Path
   - Last Result
   - Next Run
   - Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

   The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

  Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

  a. Click the **Filter** icon in the **ADVANCED** tab.

     The filter queries that you created and saved are displayed.

  b. Click the filter that you want to apply.

     The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

   Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps in the **ENVIRONMENT** tab:

    a. Select the cloud credential of the mobile device cloud from the **Device cloud credentials** list.

       The list displays the cloud credentials that are configured in the team space. The name of the cloud credential is appended to the name of the mobile device cloud in the list. For example, if the mobile device cloud provider is *BitBar* and the name of the credential is *BB_Account1*, then the name displayed in the list is *Bit Bar - BB_Account1*.

Note: Access to credentials for mobile device cloud services depends on the status of the provider. If you disable a provider on the **Cloud Credentials** page, you cannot access that device cloud provider from the **Device cloud credentials** list.

The devices that are available for testing on the selected mobile device cloud are not displayed because the devices are already specified in the AFT Suite.

Note: If you are connected to either the BitBar Cloud or BrowserStack Cloud, the **Projects** field is displayed.

b. Select the project on the mobile device cloud that you want to use or create a project in the **Projects** field. The project overrides the project that is configured in the AFT Suite.

11. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of an AFT Suite to run on a mobile device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring an API Suite or an API test run

After you added the test resources that you created in the desktop client to the project, you can configure an API Suite or an API test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057, if they apply to the test that you want to configure for a run.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the following tasks if you are running API Suites or tests that use a transport and the transport requires third-party application `Jar` files for a successful run:
  - Read Test run considerations for API Suites or API tests on page 1059.
  - Copied the third-party application `Jar` files to the third-party application folder on the computer where Test is installed, if you are running the API Suite in Kubernetes. See Copying third-party application Jars to Kubernetes on page 736.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.

Tab	Description
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓

	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.

d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

You can select a parameter from the following list:

- Type
- Test Asset Name
- Test Asset Path
- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

◦ Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       Perform the following actions, if applicable for your test:

       ▪ Configuring test log reporting.

         If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

- Overriding results database that is configured in the API Suite project.

Note: You can use any of the databases that are specified in the system requirements as supported databases in Test Integrations and APIs.

Enter the following arguments in the **Program Arguments** field, if you want to override the **Results Database**:

Program Arguments	Description
-resultDatabaseURL *<database_URL>*	Specifies the URL of the results database that overrides the results database that is configured for the project in Test Integrations and APIs.
-resultDatabaseDriver *<driver_name>*	Specifies the driver of the results database that overrides the results database that is configured for the project in Test Integrations and APIs. For example, the driver for a MySQL database is *com.mysql.cj.jdbc.Driver*.
-resultDatabaseUsername *<user_name>*	Specifies the username that is authorized to access the results database that overrides the results database that is configured for the project in Test Integrations and APIs.
-resultDatabasePassword *<encrypted_password>*	Specifies the password that is to be used to authenticate the user to access the results database that overrides the results database that is configured for the project in Test Integrations and APIs. **Note:** You can encrypt the password by using the **EncryptPassword** application that is available in the installation directory of Test Integrations and APIs.

For example, if you want to override the results database that is configured in the Test Integrations and APIs project with a different results database that has the following details:

- MySQL database as the results database with the URL as *jdbc:mysql://localhost:3306/myresultsdb*
- *com.mysql.cj.jdbc.Driver* as the driver for the MySQL database
- *tester* as the username to access the MySQL database
- #com.ghc.*1!9a8521137E0A12994ACF4434E315A2B9* as the encrypted password to authenticate the user name *tester*

The entry in the **Program Arguments** field must be as follows:

```
-resultDatabaseURL  jdbc:mysql://localhost:3306/myresultsdb
-resultDatabaseDriver com.mysql.cj.jdbc.Driver
```

```
-resultDatabaseUsername tester
-resultDatabasePassword #com.ghc.1!9a8521137E0A12994ACF4434E315A2B9
```

Note: You must separate entries in the field with white spaces or with a new-line character.

11. Follow the instructions if the API Suite has an environment or secrets configured:
    a. Click the **ENVIRONMENT** tab, if it is not already open.
    b. Select the API test environment from the list if there are multiple environments configured in the test asset.
    c. Select the classification that contains the secrets to be used for the test run.

Notes:

- The test asset that was created in the desktop client and added to the Git repository must have the environments defined as part of the API test project.
- If the test asset contained secrets, then you must create those secrets in the classifications in the project.

The default value for the environment is the environment configured in the test asset. The default value for secrets is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

    The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

    You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

    Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

    c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

13. Follow the instructions if the test requires a variable that must be passed to the test at the test run time.

a. Click the **VARIABLES** tab, if it is not already open.

b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

The default value for the variables is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

14. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

a. Click the **RESULTS** tab.

b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

15. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

    Kubernetes clusters that are registered with a team space.

    Notes:

    - If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
    - If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

    b. Select the location where you want to run the test asset from the following options:

    - Select the **Default Cluster** when no remote clusters are available in your project.
    - Select the remote cluster from the list when a remote cluster is available in your project.
    - Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

    c. Click **Execute**.

    The test run is initiated.

Results

You have started or scheduled a test run of an API Suite.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains HTML tests

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains HTML tests to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- When you want to run a Compound Test, you must have authored a Compound Test in HCL DevOps Test UI (Test UI) and must have completed the following tasks when you created the Compound Test:
  - Created a Compound Test under a Web UI project in your workspace.
  - Added a Functional HTML Test under the Compound Test.
  - Used the **startBrowser(Firefox,<URL>)** attribute with the browser value set to *Firefox* in the Functional test script.

    Restriction: Functional test scripts that contain the **startApp()** or **callScript()** attributes are treated as non-HTML scripts and are not supported to be used in test scripts in the HTML tests.

  - Linked the dataset that is used in the Functional HTML Test with the Web UI Compound Test only if you want to override this dataset. You must have created the test resources in HCL DevOps Test UI, before committing the test resources to the server project repository. You must have also created the dataset that you want to use to override the dataset linked to the test.
  - Ran the Compound Test that contains the HTML tests on Test UI.
  - Committed the projects that include the Web UI project (with the Compound Test) and the Functional test (with the HTML tests) to the remote repository.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.

- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions in this step if the test requires a variable that must be passed to the test at the test run time.

    You must configure the supported browser by using a variable if the test has a browser configured, which is different from the one that is supported by Test.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.

        i. Enter `RTW_WebUI_Browser_Selection` as the name.
        ii. Enter `Firefox` as the value, if you want to use Firefox as the browser and override the browser that is specified in the HTML test.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

    The default value for the variables is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

    Kubernetes clusters that are registered with a team space.

    Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains Functional HTML tests.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains mobile tests to run by using variables

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains mobile tests to run by using variables from Test . You must specify the variables for the mobile tests to run on mobile devices that are connected to an agent or a device cloud.

Before you begin

You must have completed the following tasks:

- Created a Compound Test that contains the mobile tests to run on a mobile device in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Created a variable file if you want to import the variables file. The file must contain the details of the UI Test agent or the device cloud to which the mobile device is connected.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run a Compound Test, which contains mobile tests to run on a mobile device, emulator, or simulator that is connected to an agent or a device cloud. You must create the tests in Test UI, and then add the test asset to your project on Test. You can then run the mobile tests on the mobile devices that are connected to any of the following agents or clouds:

- Remote UI Test agents. Requires the variables at test run time as specified in Variables for the UI Test agent on page 1199.
- The BitBar Cloud. Requires the variables at test run time as specified in Variables for the BitBar Cloud on page 1199.
- The BrowserStack Cloud. Requires the variables at test run time as specified in Variables for the BrowserStack Cloud on page 1199.
- The pCloudy Cloud. Requires the variables at test run time as specified in Variables for the pCloudy Cloud on page 1200.
- The Perfecto Mobile Cloud. Requires the variables at test run time as specified in Variables for the Perfecto Mobile Cloud on page 1200.

You must provide the details of the UI Test agent or the mobile cloud to which the mobile devices are connected as variables in Step 12 on page 1208. You can either enter the variables or use the file in which you entered the variables.

You must refer to the following tables for the variables that are required for a successful run:

Table 596. Variables for the UI Test agent

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the UI Test agent. For example, *Emulator:Pixel_3a_API_33*.
appium.server.host	Specify the hostname or IP address of the UI Test agent.
appium.server.port	Specify the port on the UI Test agent that is configured to communicate with Test.

Table 597. Variables for the BitBar Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BitBar Cloud. For example, *BitBar Cloud:Google Pixel 7 Pro*.
bitbar.apikey	Specify the user token generated for your BitBar Cloud account to authenticate your connection with the BitBar Cloud.
bitbar.host	Specify the hostname of the BitBar Cloud instance.
bitbar.project	Specify the name of the project that contains the recorded test.
bitbar.testrun	Specify a name for the test run that must be displayed in the BitBar Cloud dashboard for the test run.

Table 598. Variables for the BrowserStack Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BrowserStack Cloud. For example, *BrowserStack Cloud:Google Pixel 7 Pro*.

Table 598. Variables for the BrowserStack Cloud (continued)

Name of the Variable	Action for the Value field
browserstack.host	Specify the URL of the BrowserStack Cloud instance.
browserstack.username	Specify the user name of your BrowserStack Cloud account.
browserstack.apikey	Specify the API key of your BrowserStack Cloud account to authenticate your connection with the BrowserStack Cloud.
browserstack.project	Specify the name of the project that contains the recorded test. **Note:** This variable is optional.

Table 599. Variables for the pCloudy Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the pCloudy Cloud. For example, *pCloudy Cloud:Google Pixel 7 Pro*.
pcloudy.apikey	Specify the API key that is generated for your pCloudy Cloud account to authenticate your connection with the pCloudy Cloud.
pcloudy.username	Specify the username with which you can access the pCloudy Cloud instance.
pcloudy.host	Specify the hostname of the pCloudy Cloud instance.

Table 600. Variables for the Perfecto Mobile Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the Perfecto Mobile Cloud. For example, *Perfecto Mobile Cloud:Google Pixel 7 Pro*.

Table 600. Variables for the Perfecto Mobile Cloud (continued)

Name of the Variable	Action for the Value field
perfecto.securitytoken	Specify the user token generated for your Perfecto Mobile Cloud account to authenticate your connection with the Perfecto Mobile Cloud.
perfecto.host	Specify the hostname of the Perfecto Mobile Cloud instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.

- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
    a. Click **New filter**.
    b. Enter a name for the filter.
    c. Select an operator, and then add a rule or a group of rules.
    d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

    You can select a parameter from the following list:
        - Type
        - Test Asset Name
        - Test Asset Path
        - Last Result
        - Next Run
        - Components

    e. Save the filter query to save and apply the filter query to filter the assets based on the query.

    The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

    Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

    a. Click the **Filter** icon in the **ADVANCED** tab.

    The filter queries that you created and saved are displayed.

    b. Click the filter that you want to apply.

    The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter the following program argument that must be passed to the test run at run time in the **Program Arguments** field:

       Enter `-history testlog` in the **Program Arguments** field.

Important: If the `-history testlog` is not entered in the **Program Arguments** field, the unified report that is generated displays the test steps incorrectly.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Perform the following steps to provide the variables that specify the UI Test agent or cloud to which the mobile device is attached. You can either enter the variables that must be passed to the test at the test run time or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Perform any of the following actions that depend on whether you are using a remote performance agent or a mobile device cloud:
    - Go to Step 15 on page 1210, if you are using an agent.
    - Go to Step 16 on page 1211, if you are using a mobile device cloud.
15. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:
    a. Click the **LOCATION** tab, if it is not already open.

       The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

       Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

       The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent.

If...	Then...	Action
performance agents are added to the project.		You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

16. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains mobile tests to run on a mobile device that is connected to an agent or a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains mobile tests to run by using a cloud credential

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains mobile tests to run by using a cloud credential from Test .

Before you begin

You must have completed the following tasks:

- Created a Compound Test that contains the mobile tests in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

About this task

You can run a Compound Test, which contains mobile tests to run on mobile devices that are connected to a device cloud. You must create the tests in Test UI, and then add the test asset to your project on Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:

a. Click **New filter**.
b. Enter a name for the filter.
c. Select an operator, and then add a rule or a group of rules.
d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

   You can select a parameter from the following list:
   - Type
   - Test Asset Name
   - Test Asset Path
   - Last Result
   - Next Run
   - Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

   The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

  Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

  a. Click the **Filter** icon in the **ADVANCED** tab.

     The filter queries that you created and saved are displayed.

  b. Click the filter that you want to apply.

     The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

   Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps in the **ENVIRONMENT** tab:

    a. Select the cloud credential of the mobile device cloud from the **Device cloud credentials** list.

       The list displays the cloud credentials that are configured in the team space. The name of the cloud credential is appended to the name of the mobile device cloud in the list. For example, if the mobile device cloud provider is *BitBar* and the name of the credential is *BB_Account1*, then the name displayed in the list is *Bit Bar - BB_Account1*.

Note: Access to credentials for mobile device cloud services depends on the status of the provider. If you disable a provider on the **Cloud Credentials** page, you cannot access that device cloud provider from the **Device cloud credentials** list.

If the connection to the mobile device cloud is successful, the **Mobile devices** field is displayed.

b. Select the devices on which you want to run the tests from the list of devices that are displayed in the **Mobile devices** list.

Note: If you are connected to either the BitBar Cloud or BrowserStack Cloud, the **Projects** field is displayed.

c. Select the project on the mobile device cloud that you want to use or create a project in the **Projects** field. The project overrides the project that is configured in the test asset.

11. Click **Advanced** to make the following advanced configurations:

a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

For example, you can set a maximum Java heap size.

b. Enter the following program argument that must be passed to the test run at run time in the **Program Arguments** field:

Enter `-history testlog` in the **Program Arguments** field.

Important: If the `-history testlog` is not entered in the **Program Arguments** field, the unified report that is generated displays the test steps incorrectly.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data.

Option	Description
	Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains mobile tests to run on a mobile device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains Web UI tests

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains Web UI tests to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057, if they apply to the test that you want to configure for a run.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Created a Compound Test that contains Web UI tests in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

    Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

    The default value for each of the fields for the advanced settings is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions in this step if the test requires a variable that must be passed to the test at the test run time.

    You must configure the supported browser by using a variable if the test has a browser configured, which is different from the one that is supported by Test.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.

        i. Enter `RTW_WebUI_Browser_Selection` as the name.
        ii. Enter `Firefox` as the value, if you want to use Firefox as the browser and override the browser that is specified in the Web UI test.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

    The default value for the variables is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 15 on page 1232.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1234.
15. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	**Then...**	**Action**
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

If...	Then...	Action
	You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	

c. Click **Execute**.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains Web UI tests.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Test run configurations on page 1134

Configuring a run of a Compound Test that contains Web UI tests to run by using variables

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains Web UI tests to run by using variables from Test . You must specify the variables for the Web UI tests to run on mobile devices that are connected to an agent or a device cloud.

Before you begin

You must have completed the following tasks:

- Created a Compound Test that contains Web UI tests to run on a mobile device in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Created a variable file if you want to import the variables file. The file must contain the details of the UI Test agent or the device cloud to which the mobile device is connected.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run the Compound Test that contains Web UI tests on a mobile device, emulator, or simulator that is connected to an agent or a device cloud. You must create the tests in Test UI, and then add the test asset to your project on Test. You can then run the Compound Test that contains Web UI tests on a mobile device that is connected to any of the following agents or clouds:

- Remote UI Test agents. Requires the variables at test run time as specified in Variables for the UI Test agent on page 1236.
- The BitBar Cloud. Requires the variables at test run time as specified in Variables for the BitBar Cloud on page 1237.
- The BrowserStack Cloud. Requires the variables at test run time as specified in Variables for the BrowserStack Cloud on page 1237.
- The pCloudy Cloud. Requires the variables at test run time as specified in Variables for the pCloudy Cloud on page 1238.
- The Perfecto Mobile Cloud. Requires the variables at test run time as specified in Variables for the Perfecto Mobile Cloud on page 1238.

You must provide the details of the UI Test agent or the mobile cloud to which the mobile devices are connected as variables in Step 12 on page 1246. You can either enter the variables or use the file in which you entered the variables.

You must refer to the following tables for the variables that are required for a successful run:

Table 601. Variables for the UI Test agent

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use on the UI Test agent. For example, *Chrome(Emulator:Pixel_3a_API_33)*.
appium.server.host	Specify the hostname or IP address of the UI Test agent.
appium.server.port	Specify the port on the UI Test agent that is configured to communicate with Test.

Table 602. Variables for the BitBar Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the BitBar Cloud. For example, *Chrome(BitBar Cloud:Google Pixel 7 Pro)*.
bitbar.apikey	Specify the user token generated for your BitBar Cloud account to authenticate your connection with the BitBar Cloud.
bitbar.host	Specify the hostname of the BitBar Cloud instance.
bitbar.project	Specify the name of the project that contains the recorded test.
bitbar.testrun	Specify a name for the test run that must be displayed in the BitBar Cloud dashboard for the test run.

Table 603. Variables for the BrowserStack Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the BrowserStack Cloud. For example, *Chrome(BrowserStack Cloud:Google Pixel 7 Pro)*.
browserstack.host	Specify the URL of the BrowserStack Cloud instance.
browserstack.username	Specify the user name of your BrowserStack Cloud account.
browserstack.apikey	Specify the API key of your BrowserStack Cloud account to authenticate your connection with the BrowserStack Cloud.
browserstack.project	Specify the name of the project that contains the recorded test.

Table 603. Variables for the BrowserStack Cloud (continued)

Name of the Variable	Action for the Value field
	Note: This variable is optional.

Table 604. Variables for the pCloudy Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the pCloudy Cloud. For example, *Chrome(pCloudy Cloud:Google Pixel 7 Pro)*.
pcloudy.apikey	Specify the API key that is generated for your pCloudy Cloud account to authenticate your connection with the pCloudy Cloud.
pcloudy.username	Specify the username with which you can access the pCloudy Cloud instance.
pcloudy.host	Specify the hostname of the pCloudy Cloud instance.

Table 605. Variables for the Perfecto Mobile Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the Perfecto Mobile Cloud. For example, *Chrome(Perfecto Mobile Cloud:Google Pixel 7 Pro)*.
perfecto.securitytoken	Specify the user token generated for your Perfecto Mobile Cloud account to authenticate your connection with the Perfecto Mobile Cloud.
perfecto.host	Specify the hostname of the Perfecto Mobile Cloud instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.

3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path

- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

◦ Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

◦ If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.

◦ If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:
   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.
   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options:

Schedule	Actions
	▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon . You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

    The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

    You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

    Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

    c. Select the dataset that you want to use in the test run from any of the following options:

    - Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

      Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

    - Select the dataset from the list.

      Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

    - Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

      Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added

datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Perform the following steps to provide the variables that specify the UI Test agent or cloud to which the mobile device is attached. You can either enter the variables that must be passed to the test at the test run time or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

a. Click the **RESULTS** tab.

b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Perform any of the following actions that depend on whether you are using a remote performance agent or a mobile device cloud:
    - Go to Step 15 on page 1247, if you are using an agent.
    - Go to Step 16 on page 1249, if you are using a mobile device cloud.
15. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

a. Click the **LOCATION** tab, if it is not already open.

The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	**Then...**	**Action**
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

If...	Then...	Action
	match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	

c. Click **Execute**.

16. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains Web UI tests to run on a mobile device that is connected to an agent or a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains Web UI tests to run by using a cloud credential

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains Web UI tests to run on devices by using a cloud credential from Test .

Before you begin

You must have completed the following tasks:

- Created a Compound Test that contains the Web UI tests in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

About this task

You can run a Compound Test, which contains Web UI tests on a device cloud. You must create the tests in Test UI, and then add them to your project on Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:
    - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps in the **ENVIRONMENT** tab:

    a. Select the cloud credential of the mobile device cloud from the **Device cloud credentials** list.

    The list displays the cloud credentials that are configured in the team space. The name of the cloud credential is appended to the name of the mobile device cloud in the list. For example, if the mobile device cloud provider is *BitBar* and the name of the credential is *BB_Account1*, then the name displayed in the list is *Bit Bar - BB_Account1*.

    Note: Access to credentials for mobile device cloud services depends on the status of the provider. If you disable a provider on the **Cloud Credentials** page, you cannot access that device cloud provider from the **Device cloud credentials** list.

    If the connection to the mobile device cloud is successful, the **Mobile devices** field is displayed.

    b. Select the devices on which you want to run the tests from the list of devices that are displayed in the **Mobile devices** list.

    Note: If you are connected to either the BitBar Cloud or BrowserStack Cloud, the **Projects** field is displayed.

    c. Select the project on the mobile device cloud that you want to use or create a project in the **Projects** field. The project overrides the project that is configured in the test asset.

11. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

    For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

    If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains Web UI tests to run on a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.

- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Compound Test that contains performance tests

After you added the test resources that you created in the desktop client to the project, you can configure a Compound Test that contains performance tests to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Created performance tests under a Compound Test in HCL DevOps Test Performance (Test Performance).
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **SUITES** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:
    - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path

- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

◦ Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

◦ If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.

◦ If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, AFT XML files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:
   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.
   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options:

Schedule	Actions
	▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

    The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

    You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

    Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

    c. Select the dataset that you want to use in the test run from any of the following options:

    - Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

      Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

    - Select the dataset from the list.

      Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

    - Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

      Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added

datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions if the test requires a variable that must be passed to the test at the test run time.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

    The default value for the variables is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

a. Click the **RESULTS** tab.

b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 15 on page 1269.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1271.
15. Follow the instructions if you want to run a test on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability of the performance agent is displayed.

Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the agent.
The agent that is specified in the test assets is available and other agents added to the project.	Performance agents that have capabilities that match with the agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

If...	Then...	Action
	hover over the performance agent in the **Override** column.	

c. Click **Execute**.

The test run is initiated.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Compound Test that contains performance tests.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a mobile test to run by using variables

After you added the test resources that you created in the desktop client to the project, you can configure a mobile test to run by using variables on a mobile device from Test . You must specify the variables for the mobile test to run on mobile devices that are connected to an agent or a device cloud.

Before you begin

You must have completed the following tasks:

- Created a mobile test in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Created a variable file if you want to import the variables file. The file must contain the details of the UI Test agent or the device cloud to which the mobile device is connected.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run the mobile test after you create the test in Test UI, and then add them to your project on Test. You can then run the mobile test on the mobile devices that are connected to any of the following agents or clouds:

- Remote UI Test agents. Requires the variables at test run time as specified in Variables for the UI Test agent on page 1273.
- The BitBar Cloud. Requires the variables at test run time as specified in Variables for the BitBar Cloud on page 1273.
- The BrowserStack Cloud. Requires the variables at test run time as specified in Variables for the BrowserStack Cloud on page 1274.
- The pCloudy Cloud. Requires the variables at test run time as specified in Variables for the pCloudy Cloud on page 1274.
- The Perfecto Mobile Cloud. Requires the variables at test run time as specified in Variables for the Perfecto Mobile Cloud on page 1275.

You must provide the details of the UI Test agent or the mobile cloud to which the mobile devices are connected as variables in Step 12 on page 1283. You can either enter the variables or use the file in which you entered the variables.

You must refer to the following tables for the variables that are required for a successful run:

Table 606. Variables for the UI Test agent

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the UI Test agent. For example, *Emulator:Pixel_3a_API_33*.
appium.server.host	Specify the hostname or IP address of the UI Test agent.
appium.server.port	Specify the port on the UI Test agent that is configured to communicate with Test.

Table 607. Variables for the BitBar Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BitBar Cloud. For example, *BitBar Cloud:Google Pixel 7 Pro*.
bitbar.apikey	Specify the user token generated for your BitBar Cloud account to authenticate your connection with the BitBar Cloud.

Table 607. Variables for the BitBar Cloud (continued)

Name of the Variable	Action for the Value field
bitbar.host	Specify the hostname of the BitBar Cloud instance.
bitbar.project	Specify the name of the project that contains the recorded test.
bitbar.testrun	Specify a name for the test run that must be displayed in the BitBar Cloud dashboard for the test run.

Table 608. Variables for the BrowserStack Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BrowserStack Cloud. For example, *BrowserStack Cloud:Google Pixel 7 Pro*.
browserstack.host	Specify the URL of the BrowserStack Cloud instance.
browserstack.username	Specify the user name of your BrowserStack Cloud account.
browserstack.apikey	Specify the API key of your BrowserStack Cloud account to authenticate your connection with the BrowserStack Cloud.
browserstack.project	Specify the name of the project that contains the recorded test. **Note:** This variable is optional.

Table 609. Variables for the pCloudy Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the pCloudy Cloud. For example, *pCloudy Cloud:Google Pixel 7 Pro*.

Table 609. Variables for the pCloudy Cloud (continued)

Name of the Variable	Action for the Value field
pcloudy.apikey	Specify the API key that is generated for your pCloudy Cloud account to authenticate your connection with the pCloudy Cloud.
pcloudy.username	Specify the username with which you can access the pCloudy Cloud instance.
pcloudy.host	Specify the hostname of the pCloudy Cloud instance.

Table 610. Variables for the Perfecto Mobile Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the Perfecto Mobile Cloud. For example, *Perfecto Mobile Cloud:Google Pixel 7 Pro*.
perfecto.securitytoken	Specify the user token generated for your Perfecto Mobile Cloud account to authenticate your connection with the Perfecto Mobile Cloud.
perfecto.host	Specify the hostname of the Perfecto Mobile Cloud instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.

Tab	Description
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **TESTS** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:
    - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Perform the following steps to provide the variables that specify the UI Test agent or cloud to which the mobile device is attached. You can either enter the variables that must be passed to the test at the test run time or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project.

Export options	Results in...	Actions
		iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Perform any of the following actions that depend on whether you are using a remote performance agent or a mobile device cloud:
    - Go to Step 15 on page 1284, if you are using an agent.
    - Go to Step 16 on page 1285, if you are using a mobile device cloud.
15. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:
    a. Click the **LOCATION** tab, if it is not already open.

       The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

       Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

       The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

16. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a mobile test to be run on a mobile device that is connected to an agent or device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a mobile test to run on a mobile device by using a cloud credential

After you added the test resources that you created in the desktop client to the project, you can configure a mobile test to run on a mobile device cloud by using a cloud credential from Test .

Before you begin

You must have completed the following tasks:

- Created a mobile test in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

About this task

You can run the mobile test on a mobile device cloud. You must create the test in Test UI, and then add it to your project on Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **TESTS** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

     Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

     Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
JMeter	JMeter Test	✓		✓
Ju	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
Se	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.

- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
    a. Click **New filter**.
    b. Enter a name for the filter.
    c. Select an operator, and then add a rule or a group of rules.
    d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

    You can select a parameter from the following list:
        - Type
        - Test Asset Name
        - Test Asset Path
        - Last Result
        - Next Run
        - Components

    e. Save the filter query to save and apply the filter query to filter the assets based on the query.

    The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

    Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

    a. Click the **Filter** icon in the **ADVANCED** tab.

    The filter queries that you created and saved are displayed.

    b. Click the filter that you want to apply.

    The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps in the **ENVIRONMENT** tab:

    a. Select the cloud credential of the mobile device cloud from the **Device cloud credentials** list.

       The list displays the cloud credentials that are configured in the team space. The name of the cloud credential is appended to the name of the mobile device cloud in the list. For example, if the mobile device cloud provider is *BitBar* and the name of the credential is *BB_Account1*, then the name displayed in the list is *Bit Bar - BB_Account1*.

Note: Access to credentials for mobile device cloud services depends on the status of the provider. If you disable a provider on the **Cloud Credentials** page, you cannot access that device cloud provider from the **Device cloud credentials** list.

If the connection to the mobile device cloud is successful, the **Mobile devices** field is displayed.

b. Select the devices on which you want to run the tests from the list of devices that are displayed in the **Mobile devices** list.

Note: If you are connected to either the BitBar Cloud or BrowserStack Cloud, the **Projects** field is displayed.

c. Select the project on the mobile device cloud that you want to use or create a project in the **Projects** field. The project overrides the project that is configured in the test asset.

11. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

    For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

    If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

    For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.

Option	Description
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a mobile test to run on a mobile device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Resetting the configuration settings for a test run on page 1448

Configuring a run of a Performance test

After you added the test resources that you created in the desktop client to the project, you can configure a Performance test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Created a Performance test in HCL DevOps Test Performance (Test Performance).
- Read Test run considerations for using Machine learning capabilities on page 1064, if you want to configure a run for either a Performance Test or a Schedule that must be analyzed by using Machine Learning capabilities in Test.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **TESTS** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

    Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

    The default value for each of the fields for the advanced settings is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions if the test requires a variable that must be passed to the test at the test run time.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

    The default value for the variables is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project.

Export options	Results in...	Actions
		iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 15 on page 1306.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1307.
15. Follow the instructions if you want to run a test on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability of the performance agent is displayed.

    Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

    The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the agent.
The agent that is specified in the test assets is available and other agents added to the project.	Performance agents that have capabilities that match with the agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the performance agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

The test run is initiated.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Performance test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Web UI test

After you added the test resources that you created in the desktop client to the project, you can configure a Web UI test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057, if they apply to the test that you want to configure for a run.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Created a Web UI test in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.

- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
    a. Click **New filter**.
    b. Enter a name for the filter.
    c. Select an operator, and then add a rule or a group of rules.
    d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

    You can select a parameter from the following list:
        - Type
        - Test Asset Name
        - Test Asset Path
        - Last Result
        - Next Run
        - Components

    e. Save the filter query to save and apply the filter query to filter the assets based on the query.

    The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

    Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

    a. Click the **Filter** icon in the **ADVANCED** tab.

    The filter queries that you created and saved are displayed.

    b. Click the filter that you want to apply.

    The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

- No action is required if you want to initiate the test run immediately after you click **Execute**.

  Important: Click **Execute** only after you have configured the other settings in this dialog.

  Note: The default time for scheduling a run is **Now**.

- Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions in this step if the test requires a variable that must be passed to the test at the test run time.

    You must configure the supported browser by using a variable if the test has a browser configured, which is different from the one that is supported by Test.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    i. Enter `RTW_WebUI_Browser_Selection` as the name.
    ii. Enter `Firefox` as the value, if you want to use Firefox as the browser and override the browser that is specified in the Web UI test.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

The default value for the variables is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 14 on page 1318.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1320.
14. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

    Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

    The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.

If...	Then...	Action
performance agents are added to the project.		
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

15. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

    Kubernetes clusters that are registered with a team space.

    Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Web UI test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Running server test assets

You can run tests that are listed as server test assets created in Test .

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057, if they apply to the test that you want to configure for a run.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created a Web UI test in Test. See Recording a Web UI test on page 771.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select one of the following tabs based on the type of test assets that you want to run:
   - SUITES
   - TESTS
   - ADVANCED

   The test assets in the selected tab are displayed.
5. Identify the Server Test asset that you want to run by scrolling through the list, searching for the test, or applying a filter.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.
   The **Execute test asset** dialog is displayed.
7. Select the version of the test resources that you want to run in the **Version** field.
8. Click **Schedule** and select the time if you want to schedule the test run. Else, skip the step.
9. Enter a label for the test run that helps you to identify the test on the **Results** page.
10. Follow the instructions to select a browser:

    a. Click the **ENVIRONMENT** tab, if it is not already open.

    b. Select an environment from the list that is available for the test run from the **Environment** drop-down list.
    The variables and profile overrides in the selected environment override the values defined in the test when you run a test or suite.

    c. Select a browser or device profile for the test run from the **Browser** drop-down list.
    The browser that is used to record the test is selected as the default browser and the browser specified here overrides the default browser and the browser defined in the profile override.

11. **Optional:** Click the **DATA SOURCES** and select a dataset tab if you are running a test asset that contains datasets.
12. **Optional:** Click the **VARIABLES** tab, and then add or upload variables if the test requires a variable that must be passed to the test at the test run time.
13. **Optional:** Click the **LOCATION** tab, and then select the agent that you have added in the **Override** field.
    After selecting the agent, if the specified browser is not available to the agent, Test displays a warning indicator in the **Environment** tab.
14. Click the **RESULTS** tab and select an option if you want to export the test results to a Jira issue in your Xray project in Jira.
    You must have set up Jira as a change management system and configured the Xray integration to export the results.
15. Click **Advanced** to enter any of the following values that must be passed to the test run if they are applicable for the test:
    - **JVM Arguments**
    - **Program Arguments**
    - **Environment Variables**
16. Click **Execute**.
    The test run is initiated.

Results

You have run a server test asset that is created in Test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Test run configurations on page 1134

Running server test assets on an agent

When you have server test assets that you want to run on a Linux, Mac, or Windows system by using an agent, you can register the agents and run the tests.

Before you begin

You must have completed the following tasks:

- Registered the Linux, Mac, or Windows system using an agent for running tests. See Installing and registering DevOps Test Runtime agents on page 1087.
- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057, if they apply to the test that you want to configure for a run.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Created a Web UI test in Test.

About this task

When you initiate a test run that requires a capability such as the Safari browser, and if you have not specified any agent to run, the test enters a **Waiting for agent** state. This state indicates that the job is valid but is waiting for a suitable agent to run it. If an agent that has the required capability is registered with the project, then the agent picks up the job and runs the test, which is in an **Waiting for agent** state. You can also cancel or stop the test runs that are in the **Waiting for agent** state.

Note: The default time limit for the agent to be in the **Waiting for agent** state is 15 minutes after which the test run attempt stops. If you started the test run from the command line, then the time limit is 60 mins.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run, as indicated in the following table:

If...	Then...
You want to run Suites.	Click the **SUITES** tab.
You want to run a Web UI test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.
5. Identify the test asset that you want to run by scrolling through the list, searching for the test, or applying a filter.
6. Click the **Execute** icon in the row of the identified test asset.
   The **Execute test asset** dialog is displayed.
7. Select the version of the test resources that you want to run in the **Version** field.
8. Follow the instructions to select a browser:

   a. Click the **ENVIRONMENT** tab, if it is not already open.

   b. Select an environment from the list that is available for the test run from the **Environment** drop-down list.

The variables and profile overrides in the selected environment override the values defined in the test when you run a test or suite.

c. Select a browser or device profile for the test run from the **Browser** drop-down list.
The browser that is used to record the test is selected as the default browser and the browser specified here overrides the default browser and the browser defined in the profile override.

9. **Optional:** Click the **DATA SOURCES** and select a dataset tab if you are running a test asset that contains datasets.
10. **Optional:** Click the **VARIABLES** tab, and then add or upload variables if the test requires a variable that must be passed to the test at the test run time.
11. Click the **LOCATION** tab, and then select the agent that you have added in the **Override** field.
After selecting the agent, if the specified browser is not available to the agent, Test displays a warning indicator in the **Environment** tab.
12. Click **Execute**.
The test run is initiated.

Results

You have run server test assets on an agent.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Running server test assets by using a cloud credential

You can run tests that are listed as server test assets created in Test on a device cloud by using a cloud credential.

Before you begin

You must have completed the following tasks:

- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.

- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created a Web UI test in Test. See Recording a Web UI test on page 771.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.

About this task

You can run tests on the supported device clouds such as BrowserStack Cloud, LambdaTest Cloud, and pCloudy Cloud.

Restriction: Tests that you record on a standard browser might fail when you play them back on a device cloud. To increase the probability of successful playback, record tests by using device emulation. See supported device profiles on page 771.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select one of the following tabs based on the type of test assets that you want to run:
   - TESTS
   - ADVANCED

   The test assets in the selected tab are displayed.

5. Identify the Server Test asset that you want to run by scrolling through the list, searching for the test, or applying a filter.
   Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.
6. Click the **Execute** icon in the row of the identified test asset.
   The **Execute test asset** dialog is displayed.
7. Select the version of the test resources that you want to run in the **Version** field.
8. Click **Schedule** and select the time if you want to schedule the test run. Else, skip the step.
9. Enter a label for the test run that helps you to identify the test on the **Results** page.
10. Follow the instructions to select a browser:

    a. Click the **ENVIRONMENT** tab, if it is not already open.

    b. Select an environment from the list that is available for the test run from the **Environment** drop-down list.
    The variables and profile overrides in the selected environment override the values defined in the test when you run a test or suite.

    c. Select a device from the list of devices for the configured device cloud in the **Browser** drop-down list.
    The name of the browser is appended with the name of the device and name of the cloud credential set by the user in the *Browser (Full device name : DeviceCloudName set by the user)* format. For example, if the mobile device is *Galaxy S10* and the cloud credential name is *Lambda*, then the name displayed in the list is *Chrome(Galaxy S10 : Lambda)*.

11. **Optional:** Click the **DATA SOURCES** and select a dataset tab if you are running a test asset that contains datasets.
12. **Optional:** Click the **VARIABLES** tab, and then add or upload variables if the test requires a variable that must be passed to the test at the test run time.
13. Click the **RESULTS** tab and select an option if you want to export the test results to a Jira issue in your Xray project in Jira.
    You must have set up Jira as a change management system and configured the Xray integration to export the results.
14. Click **Advanced** to enter any of the following values that must be passed to the test run if they are applicable for the test:
    - **JVM Arguments**
    - **Program Arguments**
    - **Environment Variables**
15. Click **Execute**.
    The test run is initiated.

Results

You have run a server test asset that is created in Test on a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created Web UI tests, and then created a test suite in Test. See Recording a Web UI test on page 771 and Creating a suite on page 830.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select one of the following tabs to select the test suite that you want to run:
   - SUITES
   - ADVANCED

   The test assets in the selected tab are displayed.
5. Identify the server suite asset that you want to run by scrolling through the list, searching for the test, or applying a filter.
   Clicking the test name displays the **Details** panel. You can view the details of the test asset such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.
6. Click the **Execute** icon in the row of the identified test asset.
   The **Execute test asset** dialog is displayed.
7. Select the version of the test resources that you want to run in the **Version** field.
8. Click **Schedule** and select the time if you want to schedule the test run. Else, skip the step.
9. Enter a label for the test run that helps you to identify the test on the **Results** page.
10. Follow the instructions to select a browser:

    a. Click the **ENVIRONMENT** tab, if it is not already open.

    b. Select an environment from the list that is available for the test run from the **Environment** drop-down list.
    The variables and profile overrides in the selected environment override the values defined in the test when you run a test or suite.

    c. Select a browser or device profile for the test run from the **Browser** drop-down list.
    If you do not specify the browser, the browsers that are configured for individual tests in the test suite are used for the test run.

11. **Optional:** Click the **DATA SOURCES** and select a dataset tab if you are running a test asset that contains datasets.
12. **Optional:** Click the **VARIABLES** tab, and then add or upload variables if the test requires a variable that must be passed to the test at the test run time.

13. **Optional:** Click the **LOCATION** tab, and then select the agent that you have added in the **Override** field.
    After selecting the agent, if the specified browser is not available to the agent, Test displays a warning indicator in the **Environment** tab.
14. Click the **RESULTS** tab and select an option if you want to export the test results to a Jira issue in your Xray project in Jira.
    You must have set up Jira as a change management system and configured the Xray integration to export the results.
15. Click **Advanced** to enter any of the following values that must be passed to the test run if they are applicable for the test:
    - **JVM Arguments**
    - **Program Arguments**
    - **Environment Variables**
16. Click **Execute**.
    The test run is initiated.

Results

You have run a server suite asset that is created in Test.

What to do next

You can perform any of the following tasks:

Running server suite assets by using a cloud credential

You can run a test suite that is listed as server suite asset created in Test on a device cloud by using a cloud credential. The tests in the suite run sequentially on device clouds.

Before you begin

You must have completed the following tasks:

- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created Web UI tests, and then created a test suite in Test. See Recording a Web UI test on page 771 and Creating a suite on page 830.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.

About this task

You can run tests on the supported device clouds such as BrowserStack Cloud, LambdaTest Cloud, and pCloudy Cloud.

Restriction: Tests that you record on a standard browser might fail when you play them back on a device cloud. To increase the probability of successful playback, record tests by using device emulation. See supported device profiles on page 771.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select one of the following tabs to select the test suite that you want to run:
    - SUITES
    - ADVANCED

   The test assets in the selected tab are displayed.
5. Identify the server suite asset that you want to run by scrolling through the list, searching for the test, or applying a filter.

   Clicking the test name displays the **Details** panel. You can view the details of the test asset such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.
6. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.
7. Select the version of the test resources that you want to run in the **Version** field.
8. Click **Schedule** and select the time if you want to schedule the test run. Else, skip the step.
9. Enter a label for the test run that helps you to identify the test on the **Results** page.
10. Follow the instructions to select a browser:

    a. Click the **ENVIRONMENT** tab, if it is not already open.

    b. Select an environment from the list that is available for the test run from the **Environment** drop-down list. The variables and profile overrides in the selected environment override the values defined in the test when you run a test or suite.

    c. Select a device from the list of devices for the configured device cloud in the **Browser** drop-down list. The name of the browser is appended with the name of the device and name of the cloud credential set by the user in the *Browser (Full device name : DeviceCloudName set by the user)* format. For example, if the mobile device is *Galaxy S10* and the cloud credential name is *Lambda*, then the name displayed in the list is *Chrome(Galaxy S10 : Lambda)*.

11. **Optional:** Click the **DATA SOURCES** and select a dataset tab if you are running a test asset that contains datasets.
12. Click the **RESULTS** tab and select an option if you want to export the test results to a Jira issue in your Xray project in Jira.

    You must have set up Jira as a change management system and configured the Xray integration to export the results.
13. Click **Advanced** to enter any of the following values that must be passed to the test run if they are applicable for the test:
    - **JVM Arguments**
    - **Program Arguments**
    - **Environment Variables**
14. Click **Execute**.

    The test run is initiated.

Results

You have run a server suite asset that is created in Test on a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Test run configurations on page 1134

Configuring a run of an SAP GUI test

When you want to run an SAP GUI test, then you must configure a run of SAP GUI test or the Compound Test that contains SAP GUI tests on Test .

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Created a Compound Test that contains SAP GUI tests in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test. Refer to Task flow for running SAP tests on DevOps Test Hub.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run the SAP GUI test or Compound test that contains the SAP GUI test in Test, only by using the remote performance agent installed with the SAP runtime environment. If you have not installed any remote performance agent with the SAP run

time environment, you do not see any agents in the **Override** column and the **Execute** button is disabled so that you cannot run the test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
   The test assets in the selected branch of the repository are displayed on the **Execution** page.
3. Perform any of the following steps based on the test you want to run:
   - Click the **TESTS** tab to run the SAP GUI test.
   - Click the **SUITES** tab to run the compound test that contains the SAP GUI test.
4. Identify the test that you want to run and click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

   Note: If you do not want to continue with the current settings, click **Reset** to reset the settings.

5. Select the version of the test resources that you want to run.
6. **Optional:** Click **Schedule** to select a time for scheduling the test run.
7. **Optional:** Click the **Add a label** icon , type a label to identify the test on the **Results** page, and then press the Enter key.
8. Perform the following steps to select the performance agent and run the SAP GUI tests:

   a. Click the **LOCATION** tab, if it is not already open.

      The performance agents installed with SAP GUI runtime are listed under the **Host** column.

      Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

   b. Select the performance agent where you want to run the test asset in the **Override** column.

9. **Optional:** Click **Advanced** to make the following advanced configurations:

   a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

      For example, you can set a maximum Java heap size.

   b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

      If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. **Optional:** Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

11. **Optional:** Follow the instructions in this step if the test requires a variable that must be passed to the test at the test run time.

    You must configure the supported browser by using a variable if the test has a browser configured, which is different from the one that is supported by Test.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    i. Enter `RTW_WebUI_Browser_Selection` as the name.
- To add new variables from your local computer or from the Git repository that is associated with your project, click the **Upload** icon and choose either **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

The default value for the variables is either null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. **Optional:** Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:
    a. Click the **RESULTS** tab.
    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

13. Click **Execute**.

Results

You have started or scheduled a test run of an SAP GUI test or Compound test that contains SAP GUI test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Web UI test to run by using variables

After you added the test resources that you created in the desktop client to the project, you can configure a Web UI test to run by using variables from Test . You must specify the variables for the Web UI test to run on mobile devices that are connected to an agent or a device cloud.

Before you begin

You must have completed the following tasks:

- Created a Web UI test to be run on a mobile device in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Created a variable file if you want to import the variables file. The file must contain the details of the UI Test agent or the device cloud to which the mobile device is connected.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run the Web UI test on a mobile device, emulator, or simulator that is connected to an agent or a device in a device cloud. You must create the test in Test UI, and then add the test asset to your project on Test. You can then run the Web UI test on the devices that are connected to any of the following agents or clouds:

- Remote UI Test agents. Requires the variables at test run time as specified in Variables for the UI Test agent on page 1341.
- The BitBar Cloud. Requires the variables at test run time as specified in Variables for the BitBar Cloud on page 1341.
- The BrowserStack Cloud. Requires the variables at test run time as specified in Variables for the BrowserStack Cloud on page 1341.
- The pCloudy Cloud. Requires the variables at test run time as specified in Variables for the pCloudy Cloud on page 1342.
- The Perfecto Mobile Cloud. Requires the variables at test run time as specified in Variables for the Perfecto Mobile Cloud on page 1342.

You must provide the details of the UI Test agent or the mobile cloud to which the mobile devices are connected as variables in Step 12 on page 1350. You can either enter the variables or use the file in which you entered the variables.

You must refer to the following tables for the variables that are required for a successful run:

Table 611. Variables for the UI Test agent

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use on the UI Test agent. For example, *Chrome(Emulator:Pixel_3a_API_33)*.
appium.server.host	Specify the hostname or IP address of the UI Test agent.
appium.server.port	Specify the port on the UI Test agent that is configured to communicate with Test.

Table 612. Variables for the BitBar Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the BitBar Cloud. For example, *Chrome(BitBar Cloud:Google Pixel 7 Pro)*.
bitbar.apikey	Specify the user token generated for your BitBar Cloud account to authenticate your connection with the BitBar Cloud.
bitbar.host	Specify the hostname of the BitBar Cloud instance.
bitbar.project	Specify the name of the project that contains the recorded test.
bitbar.testrun	Specify a name for the test run that must be displayed in the BitBar Cloud dashboard for the test run.

Table 613. Variables for the BrowserStack Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the BrowserStack Cloud. For example, *Chrome(BrowserStack Cloud:Google Pixel 7 Pro)*.

Table 613. Variables for the BrowserStack Cloud (continued)

Name of the Variable	Action for the Value field
browserstack.host	Specify the URL of the BrowserStack Cloud instance.
browserstack.username	Specify the user name of your BrowserStack Cloud account.
browserstack.apikey	Specify the API key of your BrowserStack Cloud account to authenticate your connection with the BrowserStack Cloud.
browserstack.project	Specify the name of the project that contains the recorded test. **Note:** This variable is optional.

Table 614. Variables for the pCloudy Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the pCloudy Cloud. For example, *Chrome(pCloudy Cloud:Google Pixel 7 Pro)*.
pcloudy.apikey	Specify the API key that is generated for your pCloudy Cloud account to authenticate your connection with the pCloudy Cloud.
pcloudy.username	Specify the username with which you can access the pCloudy Cloud instance.
pcloudy.host	Specify the hostname of the pCloudy Cloud instance.

Table 615. Variables for the Perfecto Mobile Cloud

Name of the Variable	Action for the Value field
RTW_WebUI_Browser_Selection	Specify the web browser and the device to use in the Perfecto Mobile Cloud. For example, *Chrome(Perfecto Mobile Cloud:Google Pixel 7 Pro)*.

Table 615. Variables for the Perfecto Mobile Cloud (continued)

Name of the Variable	Action for the Value field
perfecto.securitytoken	Specify the user token generated for your Perfecto Mobile Cloud account to authenticate your connection with the Perfecto Mobile Cloud.
perfecto.host	Specify the hostname of the Perfecto Mobile Cloud instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **TESTS** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
JMeter	JMeter Test	✓		✓
Ju	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
Se	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.

- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

  Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

  a. Click the **Filter** icon in the **ADVANCED** tab.

     The filter queries that you created and saved are displayed.
  b. Click the filter that you want to apply.

     The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

a. Click the **DATA SOURCES** tab, if it is not already open.

b. Consider the following information about datasets before you select a dataset:

The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Perform the following steps to provide the variables that specify the UI Test agent or cloud to which the mobile device is attached. You can either enter the variables that must be passed to the test at the test run time or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Perform any of the following actions that depend on whether you are using a remote performance agent or a mobile device cloud:
    - Go to Step 15 on page 1352, if you are using an agent.
    - Go to Step 16 on page 1353, if you are using a mobile device cloud.
15. Follow the instructions if you want to run the tests on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:
    a. Click the **LOCATION** tab, if it is not already open.

       The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability and capabilities of the agent are displayed.

       Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

       The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent.

If...	Then...	Action
performance agents are added to the project.		You must wait until the performance agent is available to run the test on the performance agent.
The performance agent that is specified in the test assets is available and there are other performance agents added to the project.	Performance agents that have capabilities that match with the performance agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

16. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Web UI test to run on a device that is connected to an agent or a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.

- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Test run configurations on page 1134

Configuring a run of a Web UI test to run by using a cloud credential

After you added the test resources that you created in the desktop client to the project, you can configure a Web UI test to run on a device cloud by using a cloud credential from Test .

Before you begin

You must have completed the following tasks:

- Created a Web UI test in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created a cloud credential in your team space that is configured to connect to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

About this task

You can run a Web UI test on a device that is connected to a device cloud. You must create the Web UI test in Test UI, and then add the test asset to your project on Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Click the **TESTS** or the **ADVANCED** tab.
5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

You can select a parameter from the following list:

- Type
- Test Asset Name
- Test Asset Path
- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

◦ Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

◦ If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.

◦ If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, AFT XML files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:
   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.
   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options:

Schedule	Actions
	▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Perform the following steps in the **ENVIRONMENT** tab:

    a. Select the cloud credential of the mobile device cloud from the **Device cloud credentials** list.

       The list displays the cloud credentials that are configured in the team space. The name of the cloud credential is appended to the name of the mobile device cloud in the list. For example, if the mobile device cloud provider is *BitBar* and the name of the credential is *BB_Account1*, then the name displayed in the list is *Bit Bar - BB_Account1*.

       Note: Access to credentials for mobile device cloud services depends on the status of the provider. If you disable a provider on the **Cloud Credentials** page, you cannot access that device cloud provider from the **Device cloud credentials** list.

       If the connection to the mobile device cloud is successful, the **Mobile devices** field is displayed.

    b. Select the devices on which you want to run the tests from the list of devices that are displayed in the **Mobile devices** list.

Note: If you are connected to either the BitBar Cloud or BrowserStack Cloud, the **Projects** field is displayed.

c. Select the project on the mobile device cloud that you want to use or create a project in the **Projects** field. The project overrides the project that is configured in the test asset.

11. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Click **Execute**.
    The test run is initiated.

Results

You have started or scheduled a test run of a Web UI test to run on a device that is connected to a device cloud.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Windows test

After you added the test resources that you created in the desktop client to the project, you can configure a Windows test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Created a Windows test in HCL DevOps Test UI (Test UI) and added the test asset to the project repository on Test.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can run the Windows tests after you create the tests in Test UI, and then add them to your project on Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:
    - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path

- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, AFT XML files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:
   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.
   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options:

Schedule	Actions
	▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       For example, you can set a maximum Java heap size.

    b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

       If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

    c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

    The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

    You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

    Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

    c. Select the dataset that you want to use in the test run from any of the following options:

    - Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

      Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

    - Select the dataset from the list.

      Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

    - Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

      Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added

datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Perform the following steps to provide the variables that must be passed to the test at the test run time. You can either enter the variables or import the file that contains the variables.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.

        i. Enter `Windows_Device_Selection` as the name.
        ii. Enter `<IP_address>` as the value, which is the IP address of the computer that contains the UI Test agent.

- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

  Note: You must have created a file with the variables before you can select the file.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:

- If you want to run the tests on the remote agents, go to Step 15 on page 1375.
- If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1376.

15. Follow the instructions if you want to run a test on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability of the performance agent is displayed.

    Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

    The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	**Then...**	**Action**
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the agent.
The agent that is specified in the test assets is available and other agents added to the project.	Performance agents that have capabilities that match with the agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.

If...	Then...	Action
	the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the performance agent in the **Override** column.	▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

The test run is initiated.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Windows test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a JMeter test

After you added the test resources that you created in JMeter to the server project, you can configure a JMeter test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for JMeter tests on page 1061.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that the JMeter extension on Test is enabled before you configure a test run.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

Important: You can run the JMeter tests only on the default cluster of Test or a remote Kubernetes cluster. You cannot run the JMeter tests on remote agents that are registered with Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:
   - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option.

Schedule	Actions
	You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

   For example, you can set a maximum Java heap size.

b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

For example, enter **-J** to override any JMeter property that is defined in the properties file.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

12. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

    Notes:
    - If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
    - If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

    b. Select the location where you want to run the test asset from the following options:

    - Select the **Default Cluster** when no remote clusters are available in your project.
    - Select the remote cluster from the list when a remote cluster is available in your project.
    - Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

    c. Click **Execute**.

    The test run is initiated.

Results

You have started or scheduled a test run of a JMeter test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a JUnit test

After you added the test resources that contain the Maven project with the JUnit tests to the server project, you can configure a JUnit test run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for JUnit tests on page 1063 before you configure a JUnit test run.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that the JUnit extension on Test is enabled before you configure a test run. See Enabling server extensions on page 740.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

Important: You can run the JUnit tests only on the default cluster of Test or a remote Kubernetes cluster. You cannot run the JUnit tests on remote agents that are registered with Test.

After the test runs, you can view the results of the JUnit test in the following formats:

- Surefire
- JUnit XML Report

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option.

Schedule	Actions
	You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       You can enter a variable that points to the *MAVEN_OPTS* property.

b. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

   For example, if you have created the JUnit tests by using JDK V12, then you must enter the variable as **JDKOTHER** and the value as **jdkv12**, so that the test run uses the JDK in the path `/data/junit-ext/jdks/jdkv12`.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

12. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

    Notes:
    - If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
    - If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

    b. Select the location where you want to run the test asset from the following options:

    - Select the **Default Cluster** when no remote clusters are available in your project.
    - Select the remote cluster from the list when a remote cluster is available in your project.
    - Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

    c. Click **Execute**.

    The test run is initiated.

Results

You have started or scheduled a test run of a JUnit test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Postman test

After you added the test resources that you created and exported from Postman to the server project, you can configure the Postman tests to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for Postman tests on page 1066.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that the Postman extension in Test is enabled before you configure a test run.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

Important: You can run the Postman tests only on the default cluster of Test or a remote Kubernetes cluster. You cannot run the Postman tests on remote agents that are registered with Test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced**, and then enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

    You can enter the command options that you use when you run Postman tests by using Newman, as the program arguments.

    For example, enter **--verbose**, if you want the details of the test run and each request sent.

    Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

    The default value for each of the fields for the advanced settings is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.

Export options	Results in...	Actions
	The issue is created in your project in Jira after the test run is completed.	
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

12. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

    Notes:
    - If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
    - If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

    b. Select the location where you want to run the test asset from the following options:

    - Select the **Default Cluster** when no remote clusters are available in your project.
    - Select the remote cluster from the list when a remote cluster is available in your project.
    - Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

    c. Click **Execute**.

    The test run is initiated.

Results

You have started or scheduled a test run of a Postman test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuring a run of a Rate Schedule or VU Schedule

After you added the test resources that you created in the desktop client to the project, you can configure a Rate Schedule or VU Schedule to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Created Schedules in HCL DevOps Test Performance (Test Performance) and added the test asset to the project repository on Test.
- Read Test run considerations for schedules on page 1067, if you want to configure a run for Rate Schedules or VU Schedules.
- Read Test run considerations for using Machine learning capabilities on page 1064, if you want to configure a run for either a Performance Test or a Schedule that must be analyzed by using Machine Learning capabilities in Test.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Identify the test asset that you want to run by performing any of the following actions:
   - Scroll through the list.

     Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

     Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:

a. Click **New filter**.
b. Enter a name for the filter.
c. Select an operator, and then add a rule or a group of rules.
d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

   You can select a parameter from the following list:
   - Type
   - Test Asset Name
   - Test Asset Path
   - Last Result
   - Next Run
   - Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

   The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

  Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

  a. Click the **Filter** icon in the **ADVANCED** tab.

     The filter queries that you created and saved are displayed.

  b. Click the filter that you want to apply.

     The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

5. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

   Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

6. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:
- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

7. Select the time for scheduling the test run from the following options:

◦ No action is required if you want to initiate the test run immediately after you click **Execute**.

Important: Click **Execute** only after you have configured the other settings in this dialog.

Note: The default time for scheduling a run is **Now**.

◦ Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:

Schedule	Actions
	 e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

8. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

9. Click **Advanced** to make the following advanced configurations:

   a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

      For example, you can set a maximum Java heap size.

   b. Enter program arguments that must be passed to the test run at run time in the **Program Arguments**, if applicable for the test.

      If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

c. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

   For example, enter the environment variables when the third-party libraries that are used in the test run refer to the environment variables for configuration.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

       The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

       You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

       Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

    c. Select the dataset that you want to use in the test run from any of the following options:

       - Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

         Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

       - Select the dataset from the list.

Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions. Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

11. Follow the instructions if the test requires a variable that must be passed to the test at the test run time.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

The default value for the variables is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

12. Follow the instructions if you want to override the Resource Monitoring labels in the test asset with the Resource Monitoring labels that you created in Test:

    a. Click the **Resource Monitoring** tab.

    Note:

    The **Resource Monitoring** tab displays only if you enabled the **Resource Monitoring from Service** option in Test Performance when you created the test asset.

    b. Click , and press the `Ctrl` + `Space bar` keys, or enter the initial letter of a label to select a label in the list.

    Note:

    You can select or add labels only if you added the labels in the **Resource Monitoring Sources** page in Test.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed.

Export options	Results in...	Actions
	selected issue that exists in your Xray project in Jira.	ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 15 on page 1414.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1415.
15. Follow the instructions if you want to run a test on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability of the performance agent is displayed.

    Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

    The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the agent.
The agent that is specified in the test assets is available and other agents added to the project.	Performance agents that have capabilities that match with the agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the performance agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

The test run is initiated.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Rate Schedule or VU Schedule.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Test run configurations on page 1134

Configuring a run of a Selenium test

After you added the test resources that contain the Maven project with the Selenium tests to a server project, you can configure a Selenium test to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for Selenium tests on page 1068 before you configure a Selenium test run.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that the JUnit extension on Test is enabled before you configure a test run. See Enabling server extensions on page 740.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

Important: You can run the Selenium tests only on the default cluster of Test or a remote Kubernetes cluster. You cannot run the Selenium tests on remote agents that are registered with Test.

After the test runs, you can view the results of the Selenium test in the following formats:

- Surefire
- JUnit XML Report

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.

3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

     Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

     Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.

- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

  Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

  a. Click the **Filter** icon in the **ADVANCED** tab.

     The filter queries that you created and saved are displayed.
  b. Click the filter that you want to apply.

     The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

   The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:
   - Expand the list in the **Version** field, find the version of the test resources, and then select the version.

     Use the following details about the version of the test resources that are displayed to identify the version that you want:
     - Commit message.
     - Tags labeled by the user for the version committed.
     - The user who committed the version to the repository.
     - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

     The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.
   - Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

     The version that matches the search criteria is displayed and it is selected for the test run.
8. Select the time for scheduling the test run from the following options:
   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

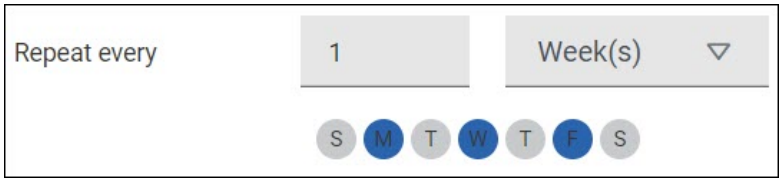
     Note: The default time for scheduling a run is **Now**.
   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date.

<table>
<tr><th>Schedule</th><th>Actions</th></tr>
<tr><td></td><td>c. Select the time at which the test run must start.
d. Select the Never option in the Repeat every field.
e. Click Save.

The test run is scheduled to run at the selected time on the scheduled date.</td></tr>
<tr><td>Recurring test runs</td><td>Perform the following steps:
a. Click the Calendar icon in the row of the Start field.
b. Select the date.
c. Select the time at which the test run must start.
d. Set the frequency at which the test runs must run by entering the number in the Repeat every field, and then select the period from the list. You can select from the following options:
▪ Minute
▪ Hour
▪ Day
▪ Week
▪ Month

For example, if you want the test run to be run every day at the set time, enter <code>1</code> and, then select the Day(s) option.

You can also schedule the test to run at the set time on specific weekdays by selecting the Week(s) option. For example, the following image displays the days selected for the test runs as Monday, Wednesday, and Friday:
 


e. Set the option to end the recurring test runs from the following options:</td></tr>
</table>

Schedule	Actions
	▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

   If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

10. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed to the test run at run time in the **JVM Arguments** field, if applicable for the test.

       You can enter a variable that points to the *MAVEN_OPTS* property.

    b. Enter the environment variables that must be passed to the test run at run time in the **Environment Variables** field, if applicable for the test.

       For example, if you have created the Selenium tests by using JDK V12, then you must enter the variable as **JDKOTHER** and the value as **jdkv12**, so that the test run uses the JDK in the path `/data/junit-ext/jdks/jdkv12`.

    Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

    The default value for each of the fields for the advanced settings is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

12. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of a Selenium test.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Related information

Resetting the configuration settings for a test run on page 1448

Test run configurations on page 1134

Configuration of test runs in a GitHub Actions Workflow

You can configure test runs of test resources that are in a project repository of Test in a GitHub Actions Workflow. You can choose to run test resources that are in your server project in the GitHub Workflow when you do not want to run the test resources without opening the Test project.

Before you configure a test run for any test resources that are in a project repository of Test, you must complete certain tasks. See Prerequisites to run tests in a GitHub Actions Workflow on page 1426.

After you complete the prerequisite tasks, you can proceed to configure a test run in a GitHub Workflow. See Configuring a test run in a GitHub Actions Workflow on page 1427.

Prerequisites to run tests in a GitHub Actions Workflow

Before you configure a test run for any test resources that are in a project repository of Test , you must complete certain tasks to run the test resources in a GitHub Actions Workflow.

You must be familiar with creating projects and running test resources from Test.

You must complete the following tasks to set up and use Test:

- Install Test. See Installation of DevOps Test.
- Possess valid licenses to use Test. See Management of licenses in DevOps Test.
- Create a project on Test. See Creating a project on page 1728.
- Add a repository that contains test resources to the project repository. See Adding repositories to a server project on page 1729.
- Generate the Offline User Token on Test that is required for connecting to Test from another application such as the GitHub Action. See Access management for DevOps Test on page 1709.
- Open the project to view the details of the test resources that you want to run in a GitHub Actions Workflow. You must make a note of the test resource details from the **Execution** page of Test.

  You must note the following details of the test resource that are to be provided in the YAML file for the GitHub Action:
  - The URL of the Test instance.
  - The name of the team space that contains the project on Test.
  - The name of the project on Test that contains the test resources.
  - The branch name of the project repository that contains the test resources.
  - The ID of the test resource.

You must complete the following tasks outside of Test:

- Create an empty Git repository on any GitHub Enterprise server, if you do not already use Git repositories to store the test resources that you create. For more information about creating Git repositories, refer to Creating a new repository.

  If you already use Git repositories to store test resources created, you can use the same Git repositories.

Note: You must have the required privileges in the Git repository to create a GitHub Actions Workflow.

- Enable the GitHub Actions option in the Git repository, if it is not available as an option to use. For more information about enabling the GitHub Actions, refer to Learn about GitHub Actions.

You can continue to configure a run of a test, see Configuring a test run in a GitHub Actions Workflow on page 1427.

Configuring a test run in a GitHub Actions Workflow

After you complete the prerequisite tasks to run tests in a GitHub Actions Workflow, you can configure the test run in a GitHub Actions Workflow. The test is in a project on Test .

Before you begin

You must have completed the following tasks:

- Completed the tasks that are mentioned in Prerequisites to run tests in a GitHub Actions Workflow on page 1426.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Extended the CA list. See Extending the trusted certificate authority list on Linux on page 735 or Extending the trusted certificate authority list on Windows on page 736.

1. Perform the following steps to open the Git repository that you use or created, which has the GitHub Actions option enabled:
    a. Open the Git repository on your GitHub Enterprise server.
    b. Create a folder with the name as `.github/workflows` in the root folder of the repository.
    c. Create an empty YAML file in the `.github/workflows` folder.

    The YAML file is used to define the GitHub Action in the Actions Workflow.
2. Perform the following steps to define the YAML file for the GitHub Action:
    a. Open the GitHub Marketplace (https://github.com/marketplace?type=) in a web browser.
    b. Search for *HCL DevOps Test Hub GitHub Action*.
    c. Open the GitHub Action.
    d. Read through the information provided.
    e. Copy the contents of the YAML file that is provided in the example by clicking the copy icon .
    f. Open the YAML file that is in the `.github/workflows` folder of your repository and paste the copied contents.

g. Enter the valid details as values for the required attributes in the YAML file by following the actions in the following table:

Attribute	Action
Required attributes	
serverURL	Specify the URL of the Test instance.
offlineToken	Specify the Offline User Token that is generated by Test.
teamspace	Specify the name of the team space that contains your project on Test.
project	Specify the name of your project on Test.
branch	Specify the name of the branch in the repository that contains the test resources, which can be found in the **Details** pane of the test resource on the **Execution** page.
assetId	Specify the ID of the test resource, which can be found under the **Git details** section in the **Details** pane of the test resource on the **Execution** page.
Optional attributes	
environment	Specify the environment that is configured in the test.
datasets	Specify the dataset that must be used at test run time, which replaces the dataset that is configured in a test.
labels	Specify text labels to identify a specific test result when the test run is complete.
secretsCollection	Specify the name of the secret collection that is configured in a test.
variables	Specify the name of the variable and its value if your test requires variables during the test run time. **Note:** You can add multiple variables that are separated by a semicolon.

h. Save the YAML file.

3. Perform the following steps to set up a Runner for the GitHub Action in GitHub:

a. Click the Settings icon .

b. Click **Actions > Runners > New self-hosted runner**.

c. Follow the on-screen instructions to set up a self-hosted runner on your computer.

After the runner is installed on your computer, you must verify that the runner is ready to run jobs in the GitHub Actions Workflow and is in the *Active* state. The runner is listed in the **Runners** pane in the Git repository.

4. Perform the following steps to start the GitHub Action in the Workflow:

a. Click the **Actions** option in the Git repository.

The GitHub Action that you configured in the YAML file for Test is displayed as an **Action** under **Workflows**.

b. Click the *HCL DevOps Test Hub GitHub Action*, and then click **Run workflow**.

Results

You have configured and run a resource that is in your project on Test in a GitHub Action Workflow.

What to do next

You can perform any of the following tasks on the Git repository page by clicking the job that was completed:

- View the status of the test run by expanding the **Execute test** section.
- View the links to the test results and reports listed in the **Execute test** section.

You can perform any of the following tasks from Test:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Configuration of a scan of an application code

You can use Test to scan your application code for security vulnerabilities similar to using the HCL® AppScan CodeSweep plugin to scan code in Visual Studio.

Test is enabled to support scanning of your application code that is in a remote repository.

Before you commit your application code to the remote repository, you must complete certain tasks. See Considerations to scan an application code on page 1430.

After you commit the assets to the remote repository, you must complete the following tasks:

1. Log in to Test.
2. Open the project in your team space.

3. Add the remote repository to your project.
4. Open the **Execution page**, and then run a scan of the asset.

For detailed instructions, see Configuring a run to scan the application code on page 1432.

Considerations to scan an application code

When you want to use Test to run a scan of the application code for security vulnerabilities, you must read the considerations that you must take into account and complete certain tasks.

Before you can run a scan of the application code on Test, you must have completed the following tasks:

- Created a file that has the following characteristics:
  - The format of the file must be `yaml`.
  - The name must be `.codesweep`.
- Committed the following assets or resources to the remote repository:
  - The `.codesweep` file.
  - The application code can either be in the root directory or another folder in the root directory.

  Note: The default root directory is the directory that contains the `.codesweep` file.

You can specify the following information in the `.codesweep` file:

- The name of the asset that must be displayed as the test asset in the **Execution** page of Test. The name must be specified at the first level in the file as the value of the **name** attribute.
- Optionally, the name of folders that contain the application code.

  All files and folders in the root directory are scanned as the default action, if no files or folders are specified under the **folders** attribute.

  You can specify the files or folders to scan by using any of the following options:
  - Specify the files or folders by using an `XML` file that is in the same format as the HCL AppScan IRX file.
  - Specify the files or folders in the `.codesweep` file under the **includes** or **excludes** attributes under the **folders** attribute.

- Optionally, you can specify the name of files or folders that must be included in the scan. You must specify the files or folders as the value of the **includes** attribute under the **folders** attribute.
- Optionally, you can specify the name of files or folders that contain the application code that need not be scanned. You must specify the files or folders as the value of the **excludes** attribute under the **folders** attribute.

Note: You cannot use *wildcard* characters to indicate the files or folders anywhere in the `.codesweep` file.

- Optionally, you can specify the rules that are to be ignored in the scan. You can specify the rules by using any of the following options:
  - Specify a file, which is a copy of `~/appscan/custom_scanners_service_ignore.json` that is created by the CodeSweep plugin for Visual Studio. With this method, you can reuse the preferences that you have configured in your development environment.
  - Specify a list of rules. Each rule is defined by a name and a language identifier.
- Optionally, you can specify the criteria for attributes and their values that specify the verdict of the scan and the range for the security errors in the code.

For example, you can consider the following details:

Where...	Is...
The name of the asset that is to be displayed on the **Execution** page	*mycode*
The folder that contains the code to be scanned	*use_code*
The folder that contains the code that is to be excluded in the scan	*do_not_use_code*
The value of the attribute *Verdict*	
The range for the security errors is classified as follows: • *max-high* • *max-medium* • *max-low*	The conditions for a *pass* verdict are as follows: • *0* • *10* • *100*

The contents of the `.codesweep` file is as follows:

```
name: mycode
folders: # default=./ , Optional
    configuration: configuration.xml # XML Configuration file, Optional
    includes: # list of folders to include, Optional
        - use_code
    excludes: # list of folders to exclude, Optional
        - do_not_use_code
```

```
ignore: # Ignore rules, Optional
    file: custom_scanners_service_ignore.json # json file coming from visual code, Optional
    rules: #list of rules to ignore, Optional
        - name: com.ouncelabs.languagelite.nodejs.Rules.NodeJS_PrivateDataExposedviaHTTPURL # Name, Required
          language: NodeJS # Language, Required
        - name: com.ouncelabs.languagelite.nodejs.Rules.NodeJS_PrivateDataExposedviaHTTP # Name, Required
          language: NodeJS # Language, Required
verdict: # PASS verdict, Optional
    max-high: 0 # default=0, Optional
    max-medium: 10 # default=0 , Optional
    max-low: 100 # default=-1 (no limit), Optional
```

You can continue to configure a run of a scan of the code, see Configuring a run to scan the application code on page 1432.

Related information

Configuration of a scan of an application code on page 1429

Configuring a run to scan the application code

After you added the assets in the remote repository to a project in your team space, you can configure a run to scan the application code specified in the `codesweep` file by using the execution service on Test .

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Considerations to scan an application code on page 1430.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Identify the test asset or resource that you want to run by performing any of the following actions:
    - Scroll through the list.

    Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

    Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset or resource by entering any text contained in the test asset or resource name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule, or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

5. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

6. Select the version of the test resources that you want to run by completing any of the following actions:

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

Use the following details about the version of the test resources that are displayed to identify the version that you want:

- Commit message.
- Tags labeled by the user for the version committed.
- The user who committed the version to the repository.
- Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

7. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start.

Schedule	Actions
	d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

8. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

   Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if

you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

9. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

10. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have configured and either started or scheduled a run of a scan of the application code that is specified in the `codesweep` file.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Related information

Management of running tests

Find information about the tasks that you can perform on a test that you configured for a run either while it runs or after it completes the run.

Viewing the state of test assets

After you initiate or schedule a test run on the **Execution** page, you can view the state of the test assets on the **Progress** page by clicking the **Show in the Progress page** icon that is enabled for that test asset on the **Execution** page. You can view all the states of the test asset from the past hour such as `In transition`, `Running`, `Scheduled`, `Completed`, or `Stopped`.

Before you begin

You must have initiated runs of the test assets in your project from the **Execution** page.

Note: The **Show in the Progress page** icon is enabled for the test asset only if a run of the test asset is either started or scheduled.

1. Click **Execution**, if you are not already on the **Execution** page.
2. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

3. Identify the test asset or resource that you want to run by performing any of the following actions:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule	✓		✓

- Search for the test asset or resource by entering any text contained in the test asset or resource name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule, or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

4. Click the **Show in the Progress page** icon in the **Actions** column of the test asset.

The **Progress** page is displayed with the following details:

- The different states of the test asset runs that were initiated or completed in the past hour are displayed as follows:
  - `In transition`
  - `Running`
  - `Completed`
  - `Stopped by User`
  - `Canceled`
- The ID of the selected test asset is applied as a filter and is displayed in the filter row.

  The applied filter is removed along with the displayed items for this filter when you perform any of the following actions on the **Progress** page:
  - You click **Hide inactive**, and then click **Show all**.
  - You visit any other page in the Navigation pane and return to the **Progress** page.

Results

You have viewed all the states of a specific test asset runs that were initiated during the past hour.

What to do next

You can choose to perform any of the following tasks from the **Progress** page:

- Stop test assets that are running. See Stopping test runs on page 1449.
- Cancel scheduled runs. See Canceling scheduled test runs on page 1452.
- View the results or the execution log of the test asset from the **Actions** column by clicking the **Open action menu** icon . See Checking logs on page 1447.
- View the results, reports, and logs of the completed test run from the **Results** page. See Test results on page 1499.

Viewing the progress of running test assets

After you initiate or schedule a test run on the **Execution** page, you can view the progress of the test assets that are running or scheduled to run, from the **Progress** page. You can also view the test assets that have completed their run, are stopped or cancelled, during the past hour.

Before you begin

You must have initiated runs of the test assets in your project from the **Execution** page.

1. Open your project and click **Progress**.

   Any one of the following views is displayed:
   - No test assets are displayed in the **Progress** page if there are no test assets that are running, scheduled to run, or have completed their run in the past hour.
   - Test assets in your project that are in any of the following states are listed:
     - Running
     - Scheduled
     - Completed
     - Stopped
     - Canceled
   - No test assets are displayed but the option **Show all** is enabled. You can click **Show all** to display the test assets that ran in the past hour. Test assets that were hidden from the display when **Hide inactive** was clicked are displayed.

   Note: Test assets are automatically removed from the display after *60 minutes* of being added to the **Progress** page. You can hide the test assets from the display by clicking **Hide inactive**, so that you can view only the test assets that were added to the **Progress** page in the past hour. You cannot use the **Progress** page to view the history of test assets that were run from the **Execution** page.

2. Identify the test asset by performing any of the following actions:
   - Identify the test asset or resource by scrolling through the list.
   - Search for the test asset by entering any text contained in the test asset name in the **Search** text box. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
   - Create a filter query by using the **New filter** option by performing the following steps:
     a. Click **New filter**.
     b. Select an operator, and then add a rule, or a group of rules.
     c. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

        You can select a parameter from the following list:

- Type
- Name
- Started by
- Started on
- Finished on
- Status
- Verdict

d. Apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

e. Save the filter query by performing the following steps, if you want to reuse the filter query later:

i. Click **Save**.
ii. Enter a name for the filter query.
iii. Click **Save**.

◦ Retrieve a saved filter, if you have saved filter queries earlier by performing the following steps:

Note: To open the filter query, you must have created and saved a filter query.

a. Click the **Open filters** icon .
b. Select the saved filter in the **Filters** dialog.
c. Click **Apply** to apply the filter.

The test assets that match the filter criteria are displayed.

◦ Sort the test assets by the user who started the test by clicking the **Started by** column header, and find the test asset listed against your name.
◦ Sort the test assets by the type of the test assets by clicking the **Type** column header, and find the test asset type you ran or scheduled.
◦ Click **Hide inactive** to only display the test assets that are running or scheduled to run. This action removes all completed, canceled, stopped, or failed test assets from the display.

Note: The items in the rows are sorted in an ascending or descending order when the column header is clicked. The following icons show the status of sorting in a column:

- items in the column are not sorted.
- items in the column are sorted in the ascending order or with the earliest record on top.
- items in the column are sorted in the descending order or with the latest record on top.

You can view the following details of the test assets on the **Progress** page:

Column header	Description
Type	Displays the icon for the type of the test asset.
Name	Displays the name of the test asset added to the project from the Git repository. Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.
Started by	Displays the name of the user who started the run of the test asset.
Started on	Displays the date and time when the test run was started.
Finished on	Displays the date and time when the test run completed the run.
Status	Displays the state of the test asset progressively. For example, after the run is in the `Initiated` state, it moves on to the `Running` state and ends in its final state depending on the verdict of the test run as either `Completed`, `Failed`, or `Inconclusive`. If the test run is stopped or a scheduled run is canceled, the status displayed is `Stopped by User` for a stopped run or `Canceled` for a canceled test.

From the **Actions** column, you can perform the following operations on your test asset:

- Stop a run.
- Cancel a scheduled run.
- Cancel scheduled recurring test runs.
- View the test log.
- View the result of the test asset on the **Results** page.
- Query the test result data.

Results

You have viewed the progress of the test assets that you ran from the **Execution** page.

What to do next

You can choose to perform any of the following tasks from the **Progress** page:

- Stop test assets that are running. See Stopping test runs on page 1449.
- Cancel scheduled runs. See Canceling scheduled test runs on page 1452.
- View the results or the execution log of the test asset from the **Actions** column by clicking the **Open action menu** icon . See Checking logs on page 1447.
- View the results, reports, and logs of the completed test run from the **Results** page. See Test results on page 1499.
- Query the test results data. See Test log queries on page 1538.

Checking logs

To verify how the test ran or to debug test run failure, you can check the `Test Log` and `Execution log`.

About this task

The `Test Log` displays the interaction between Test and the application or system under test. After the test run completes, the verdict of the run can be *Pass*, *Fail*, or *Inconclusive*. If the verdict of the run is Pass, the `Test Log` is available in the **Results** page.

The `Execution log` displays the console messages of the run time process that runs the test. This log is useful in determining the cause of the failure if the verdict of the run is *Fail* or *Inconclusive*. You can view the `Execution log` from the **Progress** page.

Viewing the `Test Log`

1. Go to the **Results** page and identify the test that you ran.
2. Click the test so that the **Reports** panel is displayed.
3. Click the **Test Log** in the **Reports** panel.

   The `Test Log` is displayed in a browser window.

Viewing the `Execution` log

4. Go to the **Progress** page and identify the test that is in the *Running* state.
5. Click the **Open action menu** icon.

6. Click **Execution log**.

   The `Execution log` is displayed in a browser window.

Test run configurations on page 1134

Resetting the configuration settings for a test run

When you are configuring a test run either as a first-run or when repeating the run, and you do not want to proceed with the settings configured or saved for the test run, you can reset the configuration settings. Resetting the configuration reverts all the settings to their default values for the test run.

Before you begin

You must be a member of the project with the *Owner* or *Tester* role to run the tests.

You must ensure that you have the **Execute test asset** dialog is displayed before you proceed with resetting the configuration settings for the test run.

About this task

You can reset the configuration settings when you are configuring a test run either for its first run or when you are repeating the test run.

1. Click **Reset** in the **Execute test asset** dialog at any point when you want to reset the configuration settings for the test run.

   Notes:

   - If you have configured some or all of the settings for the current test run and you do not want to continue with those settings, clicking **Reset** resets the settings to their default values.
   - If you are repeating a test run and do not want to use the saved settings from a previous run, clicking **Reset** reverts all the saved settings to their default values.

   The settings in the **Execute test asset** dialog are reset to their default values.
2. Use the following table to find the default values for each of the settings in the **Execute test asset** dialog:

Window or Tab	Field or Setting	Default value is
Execute test asset	Scheduling the test run	**Now** is selected.
Execute test asset	Label for settings	Null or empty field.
Advanced	**JVM Arguments**	Null or empty field.

Window or Tab	Field or Setting	Default value is
	Program Arguments	Null or empty field.
	Environment Variables	Null or empty field.
ENVIRONMENT tab	API test environment	The environment configured in the test asset.
	Secrets collection	Null or empty field.
DATA SOURCES tab	**Override** list	Null or empty field if the asset has no dataset.
		The dataset in the test asset if the asset has one dataset.
		The first dataset on the list of datasets, which are listed in increasing alphabetical order, if the asset has multiple datasets.
VARIABLES tab		Null or empty field.
LOCATION tab	Agents	Null or empty field if the asset has no agents configured.
		The first agent on the list of agents, which are listed in increasing alphabetical order, if the asset has multiple agents configured.

What to do next

You can complete configuring the settings that you want for the test run. See Test run configurations on page 1134.

Stopping test runs

You might want to stop a test run or multiple tests that are running when you realized that you did not configure all the settings or you want to change a few settings for the test runs.

Before you begin

You must have initiated a run for one or multiple test assets from the **Execution** page.

About this task

You can stop either a running test or multiple running tests from the **Progress** page. You can stop the test if it is in either the `In transition` or `Running` state. You cannot stop the test run if the test has already completed its run.

1. Go to the **Progress** page and identify the tests in any of the following ways that you want to stop:

   You can select the tests that satisfy the following conditions:

- The test must be either in the `In transition` or `Running` state.
- The **Stop execution** icon in the **Actions** column must be enabled for the test.
- The checkbox must be enabled for the test.

2. Perform the actions in the following table:

If...	Action...
You want to stop any test that is running	Perform any of the following actions: ◦ Click the **Stop execution** icon in the **Actions** column of the selected test. ◦ Click the checkbox in the row of the selected test, and then click **Stop selected**. The **Stop execution** dialog is displayed.
You want to stop multiple tests that are running	Perform any of the following actions: ◦ Click the checkbox in the row of the selected tests, and then click **Stop selected**. ◦ Click the **Select all** checkbox in the header row, and then click **Stop selected**. **Note:** All running tests are selected when you click the **Select all** checkbox. The **Stop execution** dialog is displayed.

3. Perform the following steps in the **Stop execution** dialog that is displayed:

   a. Set the timeout period for stopping the test run. Enter a numeric value and select the unit from the options available as *Seconds*, *Minutes*, or *Hours*.

   The time out period is the time during which the test run is allowed to stop on its own and after the timeout period, the test is forced to stop abruptly.

   Important: If the timeout period is not set, a value of *30 seconds* is considered as the default timeout period.

   b. Perform any of the following actions:

   - Keep the **Capture results** option selected, if you want the results to be captured for the test.

     The captured results for the test are available to view from the **Results** page.
   - Clear this option if you do not want to capture the results.

Note: The **Capture results** option is selected as the default option.

Important: The results are always captured for API suites even if you clear the **Capture results** option.

c. Perform any of the following actions:

- Keep the **Execute 'finally-block', if present** option selected, if you want the *finally-block* code in the test script, if present, to be run before the test run is stopped.
- Clear this option if you do not want to run the *finally-block* code in the test script.

Note: The option **Execute 'finally-block', if present** is selected as the default option.

Restriction: The *tear-down* steps equivalent to the **'finally-block'** code, if present in API suites are not controllable at test runtime. The **Execute 'finally-block', if present** option has no impact on API suites.

d. Click **Stop execution**.

A notification is displayed that the running tests are stopped.

Note: If the test run completes before you can configure the options for stopping the test run, a notification is displayed in the **Stop execution** dialog that the test asset has completed its run.

Results

You have successfully stopped a running test or stopped multiple running tests. The stopped test runs are displayed on the **Progress** page with the status as *Stopped by User*. Stopped tests are not considered in the count of tests executed that are displayed on the **Overview** page.

What to do next

You can re-initiate the test run from the **Execution** page or from the **Results** page by completing the configurations that you want for the test.

You can view the results or the execution log of the stopped test from the **Actions** column on the **Progress** page by clicking the **Open action menu** icon .

Canceling scheduled test runs on page 1452

Canceling scheduled test runs

You might want to cancel a scheduled test run, scheduled recurring test runs, or multiple scheduled test runs when you realized that you did not configure all the settings for the runs, want to change a few settings, or do not want those tests to run.

Before you begin

You must have scheduled runs for one or multiple test assets from the **Execution** page.

About this task

You can cancel a scheduled test run, all instances of a scheduled recurring test runs, or multiple scheduled tests from the **Progress** page.

1. Preform any of the following actions:
   - Click **Scheduled** under the **Next Run** column on the **Execution** page.

     The test is displayed on the **Progress** page. If you selected a test that was scheduled as a recurring test, then all the tests that ran and the next scheduled test run are displayed.

     Go to Step 2 on page 1452.
   - Go to the **Progress** page and identify the tests in any of the following ways that you want to cancel:

     You can select the tests that satisfy the following conditions:
     - The test must be in the `Scheduled` state.
     - The **Cancel** icon ⊗ in the **Actions** column must be enabled for the test.
     - The checkbox must be enabled for the test.

     Go to Step 2 on page 1452.
2. Perform the actions in the following table:

If...	Action...
You want to cancel any test run that is scheduled.	Perform any of the following actions: ◦ Click the **Cancel** icon ⊗ in the **Actions** column of the test that displays *Scheduled* as the status. ◦ Click the checkbox in the row of the test that is scheduled, and then click **Stop selected**. The **Cancel scheduled execution** dialog is displayed. Go to Step 3 on page 1453.
You want to cancel all scheduled instances of the recurring test runs.	
You want to stop multiple test runs that are scheduled	Perform any of the following actions:

If...	Action...
	◦ Click the checkbox in the row of the selected tests, and then click **Stop selected**. ◦ Click the **Select all** checkbox in the header row, and then click **Stop selected**. **Note:** All scheduled tests are selected when you click the **Select all** checkbox. The **Cancel scheduled execution** dialog is displayed. Go to Step 3 on page 1453.

3. Click **Yes** in the **Cancel scheduled execution** dialog.
   Result
   .

   A notification is displayed that the scheduled test runs are canceled.

Results

You have successfully canceled a scheduled test, all instances of the scheduled recurring tests, or multiple scheduled tests. The canceled test runs are displayed on the **Progress** page with the status as *Canceled*. The canceled test runs are not displayed on the **Results** page and are not considered in the count of tests executed that are displayed on the **Overview** page.

What to do next

You can re-initiate the test run from the **Execution** page by completing the configurations that you want for the test.

Stopping test runs on page 1449

Management of virtualized services

You can find information about the tasks that you can perform on and manage the virtualized services that run on Test . You can start or stop the virtual services that are available to Test. You can view the routing rules and usage statistics of virtualized services, agents, or intercepts that are connected to Test.

You can create stubs or virtual services in HCL DevOps Test Integrations and APIs (Test Integrations and APIs). You must commit the virtual service resources to a remote Git repository, and then add the Git repository to your project on Test if you used Test Integrations and APIs to create virtual service resources.

You can start a running instance of the virtual services from Test to run on the following locations:

- A registered API agent.
- The default Kubernetes cluster of Test.
- A remote Kubernetes cluster.

You can run all virtual services on registered API agents except the virtual services that use CICS transport, DB2/Z transport, or Istio.

The default Kubernetes cluster or a remote Kubernetes cluster supports running of the following types of virtual services:

- Virtual services that utilize the WebSphere® MQ transport.
- Virtual services that utilize the HTTP transport.

If running a virtual service in a Kubernetes cluster, the following are the considerations that decide the selection of a container:

- Before a container is selected to run a virtual service, it is checked for a previous failure to start a virtual service or for a low heap size, and other conditions. If the container was not found suitable, then it is not selected for running the virtual service.
- Multiple virtual services can be run in the same container if the following conditions are satisfied:
  - Subsequent virtual services are started by the same project member.
  - All virtual services are created and contained in the same Test Integrations and APIs project.
  - The requests to run the virtual services refer to the same version, meaning that the git commit IDs on which they are based are the same. If you use the UI, this means that the **Version** field in the **Execute virtual service** dialog are the same.
  - The settings that you configure in the **Advanced** settings for the virtual services are the same.
  - The datasets selected for an override are the same, if datasets are used.

Working with virtual services

You can perform the following tasks on virtual services on Test:

- Read about the considerations before you configure a run of the virtual services. See Prerequisites for running HTTP virtual services on page 1455.
- Read about the considerations before you configure a run of the virtual service on an API agent. See Considerations for running virtual services on remote API agents on page 1081.
- Set up the HTTP proxy, if you have configured stubs in the test assets to use an HTTP proxy to route requests. See Setting up intercepts on page 1457.

- View all intercepts that are registered with Test including those that you have not configured. See Viewing intercepts that are registered with a team space on DevOps Test on page 1459.
- View virtual service resources in the test assets that are in the repositories added to a project on Test. See Viewing virtual service resources on page 1460.
- Configure runs of virtual services. See Configuring a run of a virtual service on page 1462.
- Configure runs of HTTP virtual services to run without using proxies. See Running HTTP virtual services in Kubernetes cluster without using proxies on page 1477.
- View running instances of virtual services. See Viewing running instances of virtual services on page 1482.
- View configurations of a running virtual service instance. See Viewing configurations of running instances of virtual services on page 1487.
- Modify the configurations of a running virtual service instance. See Modifying configurations of running instances of virtual services on page 1492.
- View details of the usage statistics of the virtual services. See Viewing usage statistics of virtual services on page 1496.
- View routing rules of the intercepts. See Viewing routing rules of the virtual services on page 1494.
- Stop a running virtual service instance. See Stopping virtual services on page 1498.

Prerequisites for running HTTP virtual services

You can find information about the prerequisite tasks that you must complete before you configure a run of the HTTP virtual services in Test .

Prerequisites for running HTTP virtual services in a Kubernetes cluster

You can find information about the tasks that you must complete before you configure a run of the HTTP virtual services in the Test cluster or a remote Kubernetes cluster.

Important: The prerequisites do not apply when you use an API agent to run the HTTP virtual services.

Conditions for running of HTTP virtual services

Before you run the HTTP virtual services in the Test cluster or a remote Kubernetes cluster, you must check for the following conditions and perform the actions indicated:

If...	Then...
You want to route the HTTP traffic via the HTTP proxy either to the virtual service or live systems, based on routing rules.	You must set up the HTTP proxy. See Setting up intercepts on page 1457.
You want to route the HTTP traffic to the virtual service via the HTTP proxy and the proxy is not configured to trust all certificates.	The trust store must be configured to include the certificate authority for the server certificate. See Certificate authority: Importing and extending lists on page 732.

If...	Then...
A client application is sending requests directly to the virtual service.	The client application must trust the certificate authority for the server certificate. See Certificate authority: Importing and extending lists on page 732.

You are working with Test V10.1.3, which is installed on Ubuntu.	HTTP virtual services are exposed via hostnames are of the following form:
	`in-<unique_id>.<INGRESS_DOMAIN>`
	
	Note: The DNS used by a computer that runs a client application or the HTTP proxy that routes traffic to the virtual service needs to resolve such hostnames to the IP address of the ingress domain.
	
	You must perform the following actions that depend on the method you have used to set up the ingress domain:
	• If you used `nip.io` to form the ingress domain, then that virtual services host names are automatically resolved to the IP address of the ingress domain.
	For example, if you used `nip.io` to form the ingress domain as follows:
	`10.1.2.3.nip.io`
	The virtual services hostnames are resolved by `nip.io` to the IP address as `10.1.2.3`.
	• If your ingress domain does not use `nip.io` then you must ensure that the DNS in use by the client application or the HTTP proxy can resolve hostnames of the virtual services to the IP address of the ingress domain. For example, if the ingress domain is as follows:
	`myhost.mycom.com`
	The DNS must resolve `*.myhost.mycom.com` to the IP address of `myhost.mycom.com`.

HTTPS virtual service endpoints

When you want to run an HTTP virtual service where the HTTP transport settings have **Use SSL** enabled, the virtual service endpoint that is exposed for the virtual service instance expects an HTTPS request on port *443*. The exposed endpoint is

managed by the same ingress controller or the HAProxy that is used for the server endpoints. The SSL/TLS termination occurs at the endpoint before the request is routed to the virtual service instance and results in the following implications:

- The **Virtualization (Server) SSL** options that are specified in the HTTP transport have no effect.
- The certificate served by the exposed virtual service endpoint is the same as that of server that is signed by the server certificate authority.

Related information

Setting up intercepts on page 1457

Running HTTP virtual services in Kubernetes cluster without using proxies on page 1477

Setting up intercepts

When you want to run virtual services on Test , you can set up intercepts to route requests to the virtual service. You must configure the intercepts with the Test URL, team space ID, and offline user token that is generated from Test so that the intercepts can register with Test.

Examples of intercepts include the HTTP proxy component of HCL DevOps Test Virtualization Control Panel (Test Virtualization Control Panel) and the HCL DevOps Test Integrations and APIs (Test Integrations and APIs) Java virtualization agent available from the Test Virtualization Control Panel tools page.

Before you begin

You must have completed the following tasks:

- Installed the intercept from Test Virtualization Control Panel of the same version as that of Test. For example, installed the HTTP proxy.
- Read the following procedures:
  - Generating offline user tokens. See Access management for DevOps Test on page 1709.
  - Viewing the *Team Space ID* as the URL alias of the team space. See Viewing the configuration of a team space on page 1719.

About this task

You must edit the `registration.xml` file for the intercept to allow it to register with Test.

1. Perform the following steps in Test:
   a. Log in to Test.

      The **Team Space Dashboard** page is displayed.

   b. Generate the offline user token by clicking the **User** icon , and then click **Create Token**.

   c. Copy the offline user token to a text file.

d. Click the **Settings** icon of the team space in the **My Team Spaces** page.

The **Team Space Configuration** page is displayed.

e. Copy the text that is displayed under **URL alias** as the *Team Space ID*.

2. Perform the following steps to edit the `registration.xml` file for the intercept. For most intercepts this is in the root directory of the extracted intercept compressed file. For the HTTP/TCT proxy it is in the `<DTVCP_install_directory>\httptcp` directory on the computer on which you have installed Test Virtualization Control Panel.

a. Open the `registration.xml` file by using a text editor.

b. Enter the values for the following attributes:

Note: If an entry exists, you must either comment out that entry and add a new one or replace the contents with the values indicated.

Attribute	Value
server base-url	URL of Test
security-token	Offline user token generated from Test
team-space-id	ID of the team space to which the proxies must register

c. Save and close the file.

d. Perform any of the following actions:

- Restart the HTTP proxy, if you updated the `registration.xml` file of the HTTP/TCP proxy.
- Restart the application that is configured to use the any of the other intercepts other than HTTP/TCP.

3. Perform the following steps in Test to view the HTTP proxies that are registered in the team space:

a. Log in to Test.

b. Click **Infrastructure > Agents and Intercepts** to view the registered intercepts.

The intercepts that you configured with your offline user token and *Team Space ID* are displayed.

Results

You have successfully configured intercepts and viewed that they are registered with the team space in Test.

What to do next

You can perform the following tasks:

- Read for the prerequisite tasks that you must perform before you can run the HTTP virtual services. See Prerequisites for running HTTP virtual services in a Kubernetes cluster on page 1455.
- Run the virtual service resource. See Configuring a run of a virtual service on page 1462.
- View the routing rules for the intercept. See Viewing routing rules of the virtual services on page 1494.
- View the routing rules for the intercept in a running instance of the virtual service. See Viewing configurations of running instances of virtual services on page 1487.

Viewing intercepts that are registered with a team space on DevOps Test

After you install the HTTP proxies and configure them with your offline user token, the proxies register with Test in a team space as intercepts and you can view the registered intercepts on the **Agents and Intercepts** page of the team space.

Before you begin

You must have completed the following tasks:

- Completed the prerequisite tasks before you configure a run of the HTTP virtual services. See Prerequisites for running HTTP virtual services in a Kubernetes cluster on page 1455.
- Installed the HTTP proxies of the same version as the version of Test.
- Configured the HTTP proxy with your offline user token so that the proxy can register as an intercept with Test. See Setting up intercepts on page 1457.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test.
3. You can view the intercepts that you own in any of the following ways:
   - Search for the intercept by entering the name of the intercept in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

   - Sort the **Type** column to show the items sorted with the intercepts in the rows at the top of the table.
   - Sort the **Agents** column and identify the intercepts by their names or by their owner.

   You can view the following details about the intercepts that are registered with Test:

- `Any project` is displayed in the **Projects** column indicating that the intercept can be used by virtual services in any project.
- The status of the intercept is displayed in the **Status** column.

Results

You have viewed the registered intercepts from the **Agents and Intercepts** page.

What to do next

You can start the virtual services that use the registered intercepts. See Configuring a run of a virtual service on page 1462.

Viewing virtual service resources

When project repositories contain virtual service resources and you want to view the resources so that you can start them, you can view the virtual services from the **Resources** page in your team space on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created virtual services that use any of the supported transports for tests in Test Integrations and APIs, committed the test resources to the remote repository, and added the repository to your project.

About this task

After you have committed the test assets and resources to the remote repositories and added the repositories to projects in your team space on Test, you can go to the **Resources** page and perform the following tasks:

- View the virtual service resources that are contained in any branch of the repositories that are added to your project.
- View the components in the System Model that are associated with the virtual service resources.
- Create or use saved filters for viewing virtual service resources.
- Run or start an instance of the virtual service resource.
- View the number of instances of the virtual service resources that are running.
- View all instances of a running virtual service on the **Instances** page by clicking the **Show in instances page** icon .

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Resources** in the navigation pane.

The **Resources** page is displayed.

4. Complete the steps for the task that you want to perform as listed in the following table:

Task	Action
Viewing the virtual service resources that are contained in a branch of any of the repositories that are added to your project.	Select the branch of the repository that contains the virtual services that you want to run from the list in the **Branch** field. All virtual services in the selected branch are displayed on the **Resources** page.
Viewing the components that are associated with the virtual service resource.	The components that are associated with the virtual service resource are displayed in the **Components** column. Click the component in the **Components** column to view the virtual resource on the **System Model** page.
Creating or using saved filters for viewing specific instances of virtual service resources.	To create a query, perform the following actions: a. Click **New filter**. b. Create a rule with an appropriate operator. c. Select criteria such as *Name*, *Path*, *Instance number*, *Instance state*, or *Components*. d. Select the condition, and then enter the value for the criteria. e. Apply the filter query. The virtual services that match the filter criteria are displayed. f. Save the filter query for retrieving it from the saved filters list. To use a saved filter query, perform the following actions: **Note:** To open the filter query, you must have created and saved a filter query. a. Click the **Open filters** icon b. Select the saved filter. c. Apply the filter. The virtual services that match the filter criteria are displayed.
Running an instance of the virtual service resource.	After you identify the virtual service that you want to run, perform the following actions:

Task	Action
	a. Click the **Execute** icon in the row of the identified virtual service. The **Execute virtual service** dialog is displayed. b. Run the virtual service with the settings that are configured in the resource by clicking **Execute** or modify any of the settings, and then click **Execute**. An instance of the virtual service starts to run. The virtual service is displayed with the state as `Running` along with the number of instances that are running in the **Active instances** column.
Viewing the number of instances of the virtual service resources that are running.	If any of the virtual services in the project repositories are started by any project member with the *Tester* or *Owner* role, you can view the number of instances that are running or active from the **Resources** page. The virtual services are displayed with the state as `Running` along with the number of instances that are running, in the **Active instances** column.
Viewing all instances of a running virtual service.	Click the **Show in instances page** icon in the row of the virtual service on the **Resources** page. The **Instances** page is displayed with all the running instances of a particular virtual service. You can also view the number of requests that are received by the virtual service. The number of requests is displayed as the number of hits when you hover the cursor over the text in the **Activity** column.

Results

You have viewed virtual services from the **Resources** page on Test.

Configuring a run of a virtual service on page 1462

Configuring a run of a virtual service

When you have virtual service resources that are in the repositories added to your project on Test , you must configure a run of the virtual service to start an instance of the virtual service in the Test cluster, a remote Kubernetes cluster, or an API agent.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created virtual services that use any of the supported transports for tests in Test Integrations and APIs, committed the test resources to the remote repository, and added the repository to your project.
- Read about the virtual services that are supported on Test. See Supported virtual services on page 707.
- Completed the prerequisite tasks before you configure a run of the HTTP virtual services. See Prerequisites for running HTTP virtual services in a Kubernetes cluster on page 1455.
- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Read and completed the tasks mentioned in Considerations for running virtual services on remote API agents on page 1081, if you want to use a remote API agent as the location to run the virtual services.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Resources** in the navigation pane.

   The **Resources** page is displayed.
4. Select the branch of the repository that contains the virtual services that you want to run from the list in the **Branch** field.

   All virtual services in the selected branch are displayed on the **Resources** page.
5. Identify the virtual service by completing any of the following steps:
   - Search for the virtual service by entering the name or the path of the virtual service in the repository in the **Search** field box.
   - Create a filter query by using the **New filter** option and complete the following steps:
     a. Create a rule with an appropriate operator.
     b. Select criteria such as *Name*, *Path*, *Instance number*, or *Instance state*. Select the condition and enter the value for the criteria. Apply the filter query.

        The virtual services that match the filter criteria are displayed.
     c. Save the filter query for retrieving it from the saved filters list.
   - Retrieve a saved filter by using the **Open filters** icon by completing the following steps:

Note: To open the filter query, you must have created and saved a filter query.

a. Select the saved filter.
b. Apply the filter.

The virtual services that match the filter criteria in the filter that is applied are displayed.

You have identified the virtual service resources that you want to run.

6. Click the **Open action menu** icon in the row of the identified virtual service, and then click **Execute** icon.

The **Execute virtual service** dialog is displayed.

7. Select the version of the virtual service that is in the repository that you want to start by performing any of the following actions:

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

  The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version committed followed by the versions committed previously.
- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

8. Select the environment that was used to bind the physical and logical resource in the API project, in the **ENVIRONMENT** tab.

Important: The configuration that you set for the run in the **Execute virtual service** dialog is preserved when you run the same virtual service again. The configurations that you set are not available to other members when they want to run the virtual service. For example, if you selected an environment, the same environment is selected when you run the virtual service again.

9. Enter a label, if required.

A label that you enter for the test run that helps you to identify the virtual service instance on the **Instances** page. The label that you entered is displayed for the virtual service under the **Labels** column on the **Instances** page. After you have created a label, any member of the project can use that label.

10. Follow the instructions if you want to modify the configurations for the behavior of the virtual service:

a. Click the **BEHAVIOR** tab, if it is not already open.

b. Configure or change the settings for the following options:

Note: The settings displayed are the settings that were configured for the virtual service when it was authored in Test Integrations and APIs.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Performance</td><td>The following settings are available for handling of requests by the virtual service:
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Optimize performance</td><td>If enabled, attempts are made to reduce the amount of processing between the time the virtual service receives a request and the time it sends a response. Specific optimizations depend on the message contents, as in the following examples:
When the virtual service receives requests, all validations are disabled, and for all XML payloads, the store and filter actions are converted to use XPath expressions.
When the virtualization sends responses, any store actions set on a message are disabled, and any XML content is collapsed when the virtual service is compiled instead of being collapsed every time that a response is sent.
The optimization is disabled as the default action for this setting and you can enable the performance optimization if you fully understand the implications of optimizing the performance.</td></tr>
<tr><td>Threads</td><td>The maximum number of threads used in processing requests received by the virtual service. The default number of threads is 10.</td></tr>
</table></td></tr>
<tr><td>Operation</td><td>Specifies an operation referenced by the virtual service.</td></tr>
<tr><td>Response time</td><td>Specifies the response time behavior for responses sent by the virtual service for the selected operation.</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td>You can modify the value by selecting a value from the following options:
<table><tr><th>Option</th><th>Description</th></tr><tr><td>No delay</td><td>Select this option for a response with no delay.</td></tr><tr><td>Minimum delay</td><td>Select this option for a delay in the response by entering the required delay in milliseconds (ms).</td></tr><tr><td>Uniform distribution</td><td>Select this option for a uniformly distributed response time by specifying the minimum and maximum delay in milliseconds (ms).</td></tr><tr><td>Gaussian distribution</td><td>Select this option for a response time with Gaussian distribution by specifying the minimum and maximum delay in milliseconds (ms).</td></tr></table></td></tr>
<tr><td>Passthrough</td><td>Specifies the pass through behavior for the selected operation when requests are not handled within the virtual service.

You can modify the value by selecting a value from the following options:
<table><tr><td>Discard</td><td>This option stops the system under test from receiving the intercepted message. This option can disrupt the calling system. For example, the system might time out while it waits for a reply.</td></tr><tr><td>Pass Through</td><td>This option passes the intercepted message to the system under test, with an optional delay.</td></tr><tr><td>Simulate Error</td><td>This option returns an error to the calling system. The message is not passed to the system under test.</td></tr></table></td></tr>
</table>

11. Follow the instructions, if the virtual service references datasets.
    - You can use the dataset referenced in the asset.
    - You can choose to override the dataset with another data source. If alternative data sources are available, select from the set of overrides available.
12. Follow the instructions if the virtual service requires a variable that must be passed at run time.
    a. Click the **VARIABLES** tab, if it is not already open.
    b. Choose one of the following methods to add the variables:

- To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
- To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

Note: You must have created a file with the variables before you can select the file.

13. Click **Advanced** to make the following advanced configurations:

    a. Enter any JVM arguments that must be passed at run time in the **JVM Arguments** field.

    Note: Each JVM argument should be separated with white space.

    For example, you can set a maximum Java heap size.

    b. Enter the environment variables that must be passed at run time in the **Environment Variables** field, if applicable.

    For example, enter the environment variables when the third-party libraries that are used in the run refer to the environment variables for configuration.

    c. Select the stub logging level for the virtual service from the following options in the **Logging** list:

Option	Description
None	Specifies that the virtual service does not write log messages.
Normal	Specifies that the virtual service writes informational messages.
Debug	Specifies that the virtual service writes informational and debugging messages.

    d. Enter other configuration options as parameters and their values in the **Additional Configuration Parameters** fields, if applicable.

    You can refer to the additional parameters that you can use for virtual services from the topic in the related links.

    For example, if you want to start the virtual service to run in a new container, you can specify the following parameter and its value:

Parameter name	Value
stub.dedicated.container	**true**

Note: Click **Add** to add additional parameters.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for the fields for the advanced settings is null or an empty field.

Notes:

- If you have configured some or all of the settings for the current run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

14. Select the step for the location to run the virtual services based on the following types of virtual services:
    - If you want to run any of the following types of virtual services only in the default Kubernetes cluster or a remote Kubernetes cluster, then go to Step 15 on page 1468.
    - If you want to run the virtual services on a remote API agent that you added to your project, then go to Step 16 on page 1469.
15. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:
    a. Click the **LOCATION** tab, if it is not already open.

    The **Default Cluster** is the default location where the virtual service resource runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

    Important: You must have added the registered remote Kubernetes clusters to your project that are then displayed under the **Override** column:

    Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the virtual service resource runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the virtual service resource from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the virtual service resource.

c. Click **Execute**.
The run is initiated.

16. Follow the instructions if you want to run the virtual services on the remote API agent that is connected to the default Kubernetes cluster:

a. Click the **LOCATION** tab, if it is not already open.

The API agents from the list of registered API agents that match with the attributes or tags configured for the virtual service resources in the project are listed under the **Host** column. The information about the availability of the agent is displayed.

Note: You must have added the API agents to your project from the **Agents and Intercepts** page for the API agents to be displayed under the **Override** column.

The default value for the API agents is null or an empty field if no agents were configured in the project resources. If the project resources contains API agents that match with the agent tags, then the default API agent is the first item to be displayed on the list of API agents listed in the increasing alphabetical order.

b. Select the API agent where you want to run the virtual service in the following scenarios:

If...	**Then...**	**Action**
The API agent that is specified in the project resources is available and no other agents are added to the project.	The API agent that is specified in the project resources is displayed in the **Override** column.	Select the API agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The API agent that is specified in the project resources is not available and no other API agents are added to the project.	There is no API agent displayed for override in the **Override** column.	You cannot run the test on the API agent.

If...	Then...	Action
		You must wait until the API agent is available to run the test on the API agent.
The API agent that is specified in the project resources is available and other API agents added to the project.	API agents that have capabilities that match with the API agent capabilities specified in the project resources are listed in the **Override** column as follows: ▪ API agents with capabilities that best match the capabilities of the API agent in the project resources are at the top of the list. ▪ API agents with capabilities that do not match with the capabilities of the API agent in the project resources are listed subsequently. You can find details of both API agents for the matching capabilities when you hover over the agent in the **Override** column.	Perform any of the following actions: ▪ Select the API agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select an API agent in the **Override** column as the location to run the test.

c. Click **Execute**.

The test run is initiated.

Results

You have started a virtual service from the **Resources** page on Test.

What to do next

After you start a run of a virtual service, you can view the status of the virtual service in any of the following ways:

- On the **Resources** page, the virtual services are displayed with the state as `Running` along with the number of instances that are running in the **Active instances** column.
- On the **Resources** page, you must click the **Show in instances page** icon in the row of the virtual service to view all the running instances of a particular virtual service on the **Instances** page.

- Go to the **Instances** page by clicking **Virtualization > Instances**. You can view instances of all the virtual services that are running and are displayed with the state as `Running` under the **State** column. You can also view the requests that are received by the virtual service. The number of requests is displayed as number of hits when you hover the cursor over the text in the **Activity** column.

You can view the details, configuration settings, routing rules, usage statistics, or logs of a specific running instance of the virtual service. See Viewing configurations of running instances of virtual services on page 1487.

You can modify the behavior or the logging level of a running instance of the virtual service that you started before running tests on them. See Modifying configurations of running instances of virtual services on page 1492.

When you have completed testing the virtual service, you must stop the running virtual service. See Stopping virtual services on page 1498.

Additional configuration parameters for virtual services on page 1471

Additional configuration parameters for virtual services

You can find information about the additional configuration parameters that you can set when you want to run virtual services on Test.

When you use the server UI to start the virtual service, some of the parameters are handled by fields in the **Execute virtual service** dialog.

You can enter the other parameters as a *name-value* pair in the **Additional configuration parameters** field that is displayed in the **Advanced** settings panel of the **Execute virtual service** dialog.

The following additional configuration parameters are supported when you configure a run for a virtual service.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
To specify a unique identifier for use in the generated host name. **Note:** This parameter applies only if the virtual service is run in a Kubernetes	`stub.ingress.host.identifier`	Any <custom_id> that you specify. **Note:** The **<custom_id>** must start and end with an alphanumeric character. The characters supported	*mystub*	See Running HTTP virtual services in Kubernetes cluster without using proxies on page 1477, to know how the identifier you specified is used.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
cluster and not on an API agent.		include a-z, 0-9, and a hyphen. No other characters can be used in the **<custom_id>**. The **<custom_id>** must not be longer than 32 characters.		
To specify whether a virtual service instance should be run in a dedicated container. **Note:** This parameter applies only if the virtual service is run in a Kubernetes cluster and not on an API agent.	`stub.dedicated.container`	• *true* • *false* **Note:** The default value is *false*.	*true*	A dedicated container is used to run a single virtual service instance.
To specify whether performance optimization is enabled	`stub.performance.optimize`	• *true* • *false*	*true*	The performance optimization is enabled for the virtual service.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
for the virtual service instance. The value set overrides the setting from the stub definition. This option can be set in the **Behavior** tab from the UI.		**Note:** The default value is *false*.		
To specify the number of threads to be used for processing requests for the virtual service instance. The value set overrides the setting from the stub definition. This option can be set in the **Behavior** tab from the UI.	`stub.worker.thread.count`	Any number that you specify as number of threads to use.	*15*	15 threads are used for processing requests for the virtual service instance.
To specify the stub logging level for the virtual service instance. The value set overrides the setting from the stub definition. This option can be set in the **Advanced** settings from the UI.	`stub.logging.level`	• *none* • *normal* • *debug*	*debug*	The virtual service writes informational and debugging messages to the container log.
To specify the pass-through behaviour type of the virtual service instance. The value set overrides the	`stub.pass.through.behavior`	Valid values depend on the stub operation transport type but can be as follows:	*simulate_error*	This option returns an error to the calling system. The message is not passed to the system under test.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
setting from the stub definition. This option can be set in the **Behavior** tab from the UI.		• *simulate_error* • *discard* • *pass_through*		
To specify the delay in passing through from the virtual service instance. The value set overrides the setting from the stub definition.	`stub.pass.through.delay.period`	Any number of seconds in milliseconds.	*10000*	A delay of 10 seconds in passing through from the virtual service instance.
To specify the status code to use in the virtual service instance response when simulating an error. The value set overrides the setting from the stub definition. **Note:** Applies to HTTP stubs. This option can be set in the **Behavior** tab from the UI.	`stub.pass.through.status.code`	You must specify a valid HTTP status code as the value. For example, `503`.	*500*	The HTTP error code of `500` is sent in the response if the virtual service simulates an error when passing through.
To specify the reason phrase to use in the virtual service instance response when simulating an error. The value set overrides the setting from the stub definition.	`stub.pass.through.reason.phrase`	You must specify the text of the status message as the value.	*my custom error msg*	The text that you specify is set as the HTTP reason phrase in the response if the virtual service simulates an error when passing through.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
Note: Applies to HTTP stubs. This option can be set in the **Behavior** tab from the UI.				
To specify the type of response-time behavior that is required for the virtual service instance. The value set overrides the setting from the stub definition. This option can be set in the **Behavior** tab from the UI.	`stub.response.time.type`	• *no_delay* • *minimum_delay* • *gaussian* • *uniform* • *performance_profile* **Note:** *performance_profile* is only valid if the stub operation in the stub definition is defined to use a performance profile.	*no_delay*	The virtual service sends a response without any delay.
To specify the minimum time for the response time behaviour required for the virtual service instance. The value set overrides the setting from the stub definition.	`stub.response.time.minimum`	Any number of seconds in milliseconds.	*5000*	The virtual service sends a response after a minimum delay of 5 seconds.

Requirement	Configuration parameter name	Supported values	An example value	Result of using the example value
This option can be set in the **Behavior** tab from the UI.				
To specify the maximum time for the response time behaviour required for the virtual service instance. The value set overrides the setting from the stub definition. This option can be set in the **Behavior** tab from the UI.	`stub.response.time.maximum`	Any number of seconds in milliseconds.	*20000*	The virtual service must send a response after a maximum delay of 20 seconds.
To override the value of for an input tag used by the virtual service.	`stub.input.tag.`*`name`*, where *name* is the name of the input tag that you want the virtual service to use.	The value to set for the input tag.	You can specify a tag name as `stub.input.tag.mytag` with a value of *red*.	The input tag named *mytag* will have the value *red* when the virtual service is run.

Virtual services where the stub definition refers to multiple operations

When a stub definition has two or more events that refer to different operations and each operation has a different behavior, you must specify the *<operation_id>* suffixed to the configuration parameter name in the **Additional configuration parameters** field.

Note: The *<operation_id>* is the internal ID of the operation that is found in the **Documentation** tab when you open the operation in Test Integrations and APIs.

When the stub definition refers to multiple operations and you want to start a run of a virtual service, you must append the *<operation_id>* to the *<parameter_name>* in the **Additional configuration parameters** field.

The configuration parameter names that you must use for the virtual service, which is associated with a particular operation are as follows:

- `stub.pass.through.behavior.<operation_id>`
- `stub.pass.through.delay.period.<operation_id>`

- `stub.pass.through.status.code.<operation_id>`
- `stub.pass.through.reason.phrase.<operation_id>`
- `stub.response.time.type.<operation_id>`
- `stub.response.time.<operation_id>`
- `stub.response.time.maximum.<operation_id>`

For example, if the *<operation_id>* is *7281b750:162483a09f1:-7e68*, the parameter name for the `stub.response.time.type` option that you must specify is `stub.response.time.type.7281b750:162483a09f1:-7e68`.

Related information

Configuring a run of a virtual service on page 1462

Running HTTP virtual services in Kubernetes cluster without using proxies

When you run HTTP virtual services in the Kubernetes cluster of Test or a remote Kubernetes cluster, the endpoint on which the virtual service is exposed externally uses a host name that includes a generated ID. If a client application is required to call the virtual service directly via its external hostname and not via the HTTP proxy, then you might want to determine the hostname to configure the client first before you start the virtual service.

Important: This task does not apply when you use an API agent to run the HTTP virtual services.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in a team space on Test and added the repository that contains the HTTP virtual services.
- Completed the prerequisite tasks before you start HTTP virtual services. See Prerequisites for running HTTP virtual services in a Kubernetes cluster on page 1455.
- Selected the branch of the Git repository to view test resources on the **Execution** page.

About this task

When you installed Test on Ubuntu, the default HTTP virtual service endpoints are of the following form:

```
in-<unique_id>.<ingress_domain>
```

For example, with an ingress domain as **10.1.2.3.nip.io**, a virtual service endpoint might be as follows:

```
in-cd3a755635574c6fa7e264911301821a.10.1.2.3.nip.io
```

When you installed Test 10.2.1 or earlier on Red Hat OpenShift, the default HTTP virtual service endpoints are of the following form:

```
<ingress_domain_first_label>-<unique_id>.<remainder_of_ingress_domain>
```

For example, with an ingress domain as **dth.mycluster-123456-0000.region.containers.appdomain.cloud**, a virtual service endpoint might be as follows:

```
dth-cd3a755635574c6fa7e264911301821a.mycluster-123456-0000.region.containers.appdomain.cloud
```

The **<unique_id>** is generated when the virtual service is started. The full hostname can be viewed in the **Routing to** field of the routing rule created for the virtual service on the **Intercept Rules** page. When traffic is routed to the virtual service via the HTTP proxy, a client application is unaware of this hostname. If the client application is required to call the virtual services directly, it must be aware of the hostname of the virtual service.

To allow a hostname to be known before you start the virtual service, you can replace the generated ID with a user defined value that is specified as an additional configuration parameter when starting the stub. This value is referred to as **<custom_id>**.

Notes:

- The value of the **<custom_id>** that you specify is used as the **<unique_id>** for the virtual service.
- The **<custom_id>** must start and end with an alphanumeric character. The characters supported include a-z, 0-9, and a hyphen. No other characters can be used in the **<custom_id>**. The **<custom_id>** must not be longer than 32 characters.

Restriction: The **<custom_id>** must be unique to a virtual service that is running. You must not assign the same **<custom_id>** to another virtual service that is running simultaneously. Doing so might result in an undefined behavior of the virtual service.

For example, on Ubuntu, if you specify the value of the **<custom_id>** for the virtual service as `stub123-test` and Test has an ingress domain as **10.1.2.3.nip.io**. Then the hostname of the virtual service endpoint is as follows:

```
in-stub123-test.10.1.2.3.nip.io
```

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Resources** in the navigation pane.

   The **Resources** page is displayed.

4. Select the branch of the repository that contains the virtual services that you want to run from the list in the **Branch** field.

   All virtual services in the selected branch are displayed on the **Resources** page.

5. Identify the virtual service that you want to run.
6. Click the **Open action menu** icon in the row of the identified virtual service, and then click **Execute** icon .

   The **Execute virtual service** dialog is displayed.

7. Select the version of the virtual service that is in the repository that you want to start by performing any of the following actions:

   - Expand the list in the **Version** field, find the version of the test resources, and then select the version.

     Use the following details about the version of the test resources that are displayed to identify the version that you want:
     - Commit message.
     - Tags labeled for the version committed.
     - The user who committed the version to the repository.
     - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

     The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version committed followed by the versions committed previously.

   - Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

     The version that matches the search criteria is displayed and it is selected for the test run.

8. Select the environment that was used to bind the physical and logical resource in the API project, in the **ENVIRONMENT** tab.

   Important: The configuration that you set for the run in the **Execute virtual service** dialog is preserved when you run the same virtual service again. The configurations that you set are not available to other members when they want to run the virtual service. For example, if you selected an environment, the same environment is selected when you run the virtual service again.

9. Enter a label, if required.

   A label that you enter for the test run that helps you to identify the virtual service instance on the **Instances** page. The label that you entered is displayed for the virtual service under the **Labels** column on the **Instances** page. After you have created a label, any member of the project can use that label.

10. Follow the instructions if you want to modify the configurations for the behavior of the virtual service:

    a. Click the **BEHAVIOR** tab, if it is not already open.

    b. Configure or change the settings for the following options:

Note: The settings displayed are the settings that were configured for the virtual service when it was authored in Test Integrations and APIs.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Performance</td><td>The following settings are available for handling of requests by the virtual service:
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Optimize performance</td><td>If enabled, attempts are made to reduce the amount of processing between the time the virtual service receives a request and the time it sends a response. Specific optimizations depend on the message contents, as in the following examples:
When the virtual service receives requests, all validations are disabled, and for all XML payloads, the store and filter actions are converted to use XPath expressions.
When the virtualization sends responses, any store actions set on a message are disabled, and any XML content is collapsed when the virtual service is compiled instead of being collapsed every time that a response is sent.
The optimization is disabled as the default action for this setting and you can enable the performance optimization if you fully understand the implications of optimizing the performance.</td></tr>
<tr><td>Threads</td><td>The maximum number of threads used in processing requests received by the virtual service. The default number of threads is 10.</td></tr>
</table></td></tr>
<tr><td>Operation</td><td>Specifies an operation referenced by the virtual service.</td></tr>
<tr><td>Response time</td><td>Specifies the response time behavior for responses sent by the virtual service for the selected operation.

You can modify the value by selecting a value from the following options:</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>No delay</td><td>Select this option for a response with no delay.</td></tr>
<tr><td>Minimum delay</td><td>Select this option for a delay in the response by entering the required delay in milliseconds (ms).</td></tr>
<tr><td>Uniform distribution</td><td>Select this option for a uniformly distributed response time by specifying the minimum and maximum delay in milliseconds (ms).</td></tr>
<tr><td>Gaussian distribution</td><td>Select this option for a response time with Gaussian distribution by specifying the minimum and maximum delay in milliseconds (ms).</td></tr>
</table>
</td></tr>
<tr><td>Passthrough</td><td>Specifies the pass through behavior for the selected operation when requests are not handled within the virtual service.

You can modify the value by selecting a value from the following options:
<table>
<tr><td>Discard</td><td>This option stops the system under test from receiving the intercepted message. This option can disrupt the calling system. For example, the system might time out while it waits for a reply.</td></tr>
<tr><td>Pass Through</td><td>This option passes the intercepted message to the system under test, with an optional delay.</td></tr>
<tr><td>Simulate Error</td><td>This option returns an error to the calling system. The message is not passed to the system under test.</td></tr>
</table>
</td></tr>
</table>

11. Click **Advanced** to make the following advanced configurations:

    a. Enter the following configuration options as parameters and their values in the **Additional Configuration Parameters** fields.

Parameter name	**Value**
stub.ingress.host.identifier	**<custom_id>**

12. Click **Execute**.

    The run is initiated.

Results

You have started an HTTP virtual service that does not use a proxy. The virtual service exposes the hostname that contains a custom ID that you specified.

What to do next

After you start a run of a virtual service, you can view the status of the virtual service in any of the following ways:

- On the **Resources** page, the virtual services are displayed with the state as `Running` along with the number of instances that are running in the **Active instances** column.
- On the **Resources** page, you must click the **Show in instances page** icon in the row of the virtual service to view all the running instances of a particular virtual service on the **Instances** page.
- Go to the **Instances** page by clicking **Virtualization > Instances**. You can view instances of all the virtual services that are running and are displayed with the state as `Running` under the **State** column. You can also view the requests that are received by the virtual service. The number of requests is displayed as number of hits when you hover the cursor over the text in the **Activity** column.

Viewing running instances of virtual services

After you start virtual services from the **Resources** page, you can view the instances of the virtual services that are running from the **Instances** page on Test . You can view the details, configuration settings, routing rules, usage statistics, or logs of a specific running instance of the virtual service. You can also stop the running instance.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Started the virtual service resources as a *Tester* or *Owner* from the **Resources** page.

About this task

After you started the virtual services from the **Resources** page on Test, you can go to the **Instances** page and you can perform the following tasks:

- View all running instances of the virtual services that are contained in the project repositories.
- View the components in the system model that are associated with the virtual service instances.
- Search for a specific instance of the virtual service for which you want to view the details.
- Create or use saved filters for viewing specific running instances of the virtual service.
- View the details, configuration settings, routing rules, usage statistics, or logs of a specific running instance of the virtual service.
- Change the behavior or logging level of a running instance of the virtual service before you run tests on the virtual service.

- Stop a specific running instance of the virtual service.
- Stop multiple instances or all instances of the virtual service that are running.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Instances** in the navigation pane.

   The **Instances** page is displayed.

   Any one of the following views is displayed:
   - No instances of virtual services are displayed if there are no instances that are running or were stopped in the past hour.
   - All running instances of virtual services in your project are displayed.
   - No running instances of virtual services are displayed but the option **Show all** is enabled. You can click **Show all** to display the instances that were stopped in the past hour. Instances that were hidden from the display when **Hide inactive** was clicked are displayed.

     Note: All instances that were stopped are automatically removed from the display after *60 minutes* of being stopped. You cannot use the **Instances** page to view the history of stopped instances. You can hide the stopped instances from the display by clicking **Hide inactive**, so that you can view only the running instances.

   You can find the following information about the running instances that are displayed on the **Instances** page.
   - The name and path of the virtual service in the project repository are displayed in the **Name** column.
   - The tags or labels added to the instance when the run was configured is displayed in the **Labels** column.
   - The name of the environment associated with the operation in which the virtual service was created in Test Integrations and APIs is displayed in the **Environment** column.
   - The state of the running instance is displayed as `Running` in the **State** column.
   - The activity of the running instance of the virtual service based on the number of requests received in the previous hour is displayed in the **Activity** column. The activities are classified and displayed as indicated in the following table:

Activity load	**Activity displayed as**
Received *0* requests	`None`
Received *1 - 10* requests	`Low`
Received *11 - 100* requests	`Mid`
Received *101 - 1000* requests	`High`

Activity load	Activity displayed as
Received more than *1000* requests	`Very High`

- The **Stop** icon is displayed in the **Actions** column and stops the running instance of the virtual service, when clicked.

4. Complete the steps for the task that you want to perform as listed in the following table:

Task	Action
Searching for a specific instance of the virtual service for which you want to view the details or want to stop the instance.	Enter either the complete text or part of the text in the name or the path of the virtual service that is in the repository in the **Search** field. The instances of the virtual services that match the text searched are displayed.
Viewing the component associated with the running instance of the virtual service.	You can view the name of the associated component that is displayed on the **Instances** page in the **Filter** row only if you clicked the icon on the **System Model** page to view all running instances of the virtual services .
Creating or using saved filters for viewing specific instances of virtual service resources.	To create a query, perform the following actions: a. Click **New filter**. b. Create a rule with an appropriate operator. c. Select criteria such as *Name*, *Path*, *Labels*, *Environment*, *State*, *Activity*, or *Location*. d. Select the condition, and then enter the value for the criteria. e. Apply the filter query. The virtual services that match the filter criteria are displayed. f. Save the filter query for retrieving it from the saved filters list. To use a saved filter query, perform the following actions: **Note:** To open the filter query, you must have created and saved a filter query. a. Click the **Open filters** icon. b. Select the saved filter. c. Apply the filter. The virtual services that match the filter criteria are displayed.
Viewing the details, configuration settings, routing rules, usage	After you identify the virtual service instance for which you want to view the details, perform the following actions:

Task	Action
statistics, or logs of a specific running instance of the virtual service.	a. Click the **Expand** icon in the row of the identified instance of the virtual service. The **Details** panel of the instance is displayed. You can find the following details about the instance displayed: ▪ Name ▪ Path ▪ Labels ▪ API Environment ▪ Asset ID ▪ Git Repo ▪ Version ▪ Started at ▪ Started by ▪ Execution location ▪ Associated components ▪ Execution location b. Click **Configuration** to expand the panel and view the configuration details of the virtual service. You can find the following configuration details about the instance displayed: ▪ Dataset overrides ▪ Variables ▪ JVM args ▪ Environment variables ▪ Additional parameters c. Click **Behavior** to expand the panel and view the behavior that was configured for the virtual service. d. Click **Routing Rules** to expand the panel and view the routing rules that were configured in the virtual service. e. Click **Statistics** to expand the panel and view the graphical representation of the activities performed by the virtual service. f. Click **Diagnostics** to expand the panel and view the logging configuration of the virtual service and the links to the logs.
Changing the behavior or logging level of a running instance of the virtual service.	After you identify the virtual service instance for which you want to view the details, perform the following actions: a. Click the **Expand** icon in the row of the identified instance of the virtual service. The **Details** panel of the instance is displayed.

Task	Action
	Perform any of the following actions: ◦ Click **Behavior** to expand the panel. Perform the following steps to change the behavior configurations: a. Click the **Edit** icon . b. Select a different operation for the virtual service, if available. c. Select a different response time and enter the values for the delay that you want to set. d. Click **apply**. ◦ Click **Diagnostics** to expand the panel. Perform the following steps to change the logging level configuration: a. Click the **Edit** icon . b. Select a different logging level. c. Click **apply**.
Stopping a specific running instance of the virtual service.	a. Click the **Stop** icon in the row of the virtual service instance. b. Click **Ok** in the **Stop virtual service instance** dialog that is displayed. The running virtual service instance is stopped.
Stopping multiple running instances or all the running instances of virtual services.	a. Perform any of the following actions: ▪ Select the checkbox in the row of the virtual service instances that you want to stop, and then click **Stop selected**. ▪ Select the **Select all** checkbox in the header row, and then click **Stop selected**. **Note:** All running instances are selected when you click the **Select all** checkbox. b. Click **Ok** in the **Stop all selected virtual service instances** dialog that is displayed. The running virtual service instances are stopped.

Results

You have viewed running instances of the virtual services from the **Instances** page on Test.

What to do next

You can perform the following tasks:

- View the configurations of a running instance of the virtual service. See Viewing configurations of running instances of virtual services on page 1487.
- Modify the behavior or logging level of a running instance of the virtual service before you run tests on the virtual service. See Modifying configurations of running instances of virtual services on page 1492.
- Stop a running instance or all running instances of the virtual services. See Stopping virtual services on page 1498.

Viewing configurations of running instances of virtual services

After you start virtual services from the **Resources** page, you can view the details, configuration settings, routing rules, usage statistics, or logs of a specific running virtual service instance from the **Instances** page on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Started the virtual service resources as a *Tester* or *Owner* from the **Resources** page.

About this task

After you have started the virtual services from the **Resources** page on Test, you can go to the **Instances** page and view the information about a specific running virtual service instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Instances** in the navigation pane.

   The **Instances** page is displayed with all running instances of the virtual services that are in your project.
4. Identify the running instance of the virtual service of which you want to view the details, configuration settings, and other information.
5. Click the **Expand** icon of the instance of the virtual service.

   The **Details** panel of the instance is displayed with the following details about the virtual service instance:

Note: The information displayed pertains to the configuration settings that were configured in the virtual service at the time it was created or run.

Option	Information displayed
Name	Displays the name of the virtual service.
Path	Displays the path of the virtual service resource in the project repository.
Labels	Displays the labels or tags that were entered for the virtual service when a run of the virtual service was configured.
API Environment	Displays the name of the environment associated with the operation in which the virtual service was created in Test Integrations and APIs or the environment selected for the run.
Asset ID	The ID of the virtual service resource in the project repository that was started as an instance.
Git Repo	The git repository added to the project that contains the virtual service resources.
Version	Displays the version of the virtual service resource that is in the project repository that was started as an instance.
Started at	Displays the date and time when the virtual service instance started.
Started by	Displays the name of the project member who started the virtual service instance.
Associated components	Displays the components in the system model that are associated with the virtual service.
Execution location	Displays the location of the Kubernetes cluster on which the virtual service instance ran. **Note:** The name of the remote Kubernetes cluster is displayed if the virtual service instance ran on the remote cluster or *Default Cluster* is displayed if the virtual service ran on Test.

The other panels that you can view are as follows:

- Configuration
- Behavior
- Routing Rules
- Statistics
- Diagnostics

6. Expand each panel by clicking the panel to view the information in that panel.

   You can view the following information in the different panels:

<table>
<tr><th>Panel</th><th>Details</th></tr>
<tr><td>Configuration</td><td>
The Configuration panel of the instance is displayed when expanded with the following details about the virtual service instance:

Note: The information displayed pertains to the configuration settings that were configured in the virtual service at the time it was created or run.

<table>
<tr><th>Option</th><th>Information displayed</th></tr>
<tr><td>Dataset overrides</td><td>Displays the dataset overrides that were configured when executing the virtual service instance.</td></tr>
<tr><td>Variables</td><td>Displays the variables that were configured when executing the virtual service instance.</td></tr>
<tr><td>JVM args</td><td>Displays the JVM arguments that were configured when executing the virtual service instance.</td></tr>
<tr><td>Environment variables</td><td>Displays the environment variables that were configured when executing the virtual service instance.</td></tr>
<tr><td>Additional parameters</td><td>Displays the additional parameters that were configured when executing the virtual service instance.</td></tr>
</table>
</td></tr>
<tr><td>Behavior</td><td>
The Behavior panel of the instance is displayed when expanded with the following details about the virtual service instance:

Note: The information displayed pertains to the configuration settings that were configured in the virtual service at the time it was created or run.

<table>
<tr><th>Option</th><th>Information displayed</th></tr>
<tr><td>Performance</td><td>Displays the optimization setting and the maximum number of threads in use by the virtual service.</td></tr>
<tr><td>Operation</td><td>Displays the operations referenced by the virtual service. You can select each operation to view the related response time and the pass through settings.</td></tr>
<tr><td>Response time</td><td>Displays the response time option that is in use for the selected operation within the virtual service.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Panel</th><th>Details</th></tr>
<tr><td></td><td>
<table>
<tr><th>Option</th><th>Information displayed</th></tr>
<tr><td>Passthrough</td><td>Displays the pass through option that is in use for the selected operation within the virtual service.</td></tr>
</table>
</td></tr>
<tr><td>Routing Rules</td><td>
The Routing Rules panel of the instance is displayed when expanded.

The routing rules that relate to the virtual service are displayed.

<table>
<tr><th>Column</th><th>Description</th></tr>
<tr><td>Activity</td><td>Indicates the routing type.</td></tr>
<tr><td>Target</td><td>Displays the endpoint of the target service for which requests are being routed.</td></tr>
<tr><td>Recipient</td><td>Displays the endpoint of the virtual service that receives the routed requests</td></tr>
</table>

You can expand the panel for each intercept by clicking on the expand icon . You can then find the following information:

<table>
<tr><th>Tab</th><th>Description</th></tr>
<tr><td>Details</td><td>
The Details panel provides the following information:

<table>
<tr><th>Option</th><th>Information displayed</th></tr>
<tr><td>Condition</td><td>Lists the condition that causes the traffic to be routed to a virtual service.

You can view the detailed condition of the rule defined for the intercept by clicking the View icon .

The detailed condition of the rule is displayed in the Full condition window.

 Note: You can copy the detailed condition if you intend to use it elsewhere.</td></tr>
<tr><td>Routing to</td><td>Lists the virtual service to which traffic is routed.</td></tr>
<tr><td>Created by</td><td>Lists the user who created the rule.</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Panel</th><th>Details</th></tr>
<tr><td></td><td>
<table>
<tr><th>Tab</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Option</th><th>Information displayed</th></tr>
<tr><td>Created at</td><td>Lists the date and time when the rule was created.</td></tr>
</table>
</td></tr>
<tr><td>Activity</td><td>The Activity panel lists the log of the activities performed in relation to the routing rule. This panel also displays the details of the activity, date and time, and message for that activity.</td></tr>
</table>
</td></tr>
<tr><td>Statistics</td><td>The Statistics panel of the instance is displayed when expanded.

The requests received by the instance of the virtual service in the previous hour are displayed as a graph. The total requests received is indicated in the Total hits field and the activity load in the previous hour are displayed in the Activity field.

The view can be refreshed by clicking the Refresh icon .</td></tr>
<tr><td>Diagnostics</td><td>The Diagnostics panel of the instance is displayed when expanded with the following details:
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Logging</td><td>Displays the logging level that was configured for the virtual service.</td></tr>
<tr><td>Execution ID</td><td>Displays the ID of execution for the virtual service instance.</td></tr>
<tr><td>Stubs runtime ID</td><td>Displays the ID of the runtime where the virtual service instance runs. If executed on a cluster the value is that of the label execution-stubs-runtime-id on the pod that runs the virtual service instance. If executed on an API agent, the value is the ID of the engine on which the virtual service instance runs.</td></tr>
<tr><td>Init container log</td><td>Displays the link to the log of the Init container.</td></tr>
</table>
</td></tr>
</table>

Panel	Details	
	Option	**Description**
		Note: This logs contains messages that relate to configuring the container which is ready to run the virtual service.
	Main container log	Displays the link to the log of the main container. This log contains messages logged by the virtual service based on the selected logging level.
	Pod events log	Displays the link to the log of the pod events log. This log contains messages logged in the pod for the virtual service events.

Results

You have viewed the information about the configuration, routing rules, usage, or logs of the virtual service instance.

What to do next

You can modify the behavior or logging level configurations of the running virtual service instance before you run tests on the instance. See Modifying configurations of running instances of virtual services on page 1492.

Related information

Configuring a run of a virtual service on page 1462

Modifying configurations of running instances of virtual services

After you start virtual services from the **Resources** page and before you run tests on the virtual service, you might want to modify the configurations for the behavior or the logging level of the running instance.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Started the virtual service resources as a *Tester* or *Owner* from the **Resources** page.

About this task

After you have started the virtual services from the **Resources** page on Test , you can go to the **Instances** page and identify the running instance of the virtual service for which you want to modify the configurations. You can modify the configurations for the behavior or logging levels of the running instance of the virtual service.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects >** ***project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Instances** in the navigation pane.

   The **Instances** page is displayed with all running instances of the virtual services that are in your project.
4. Identify the running instance of the virtual service for which you want to modify the configurations.
5. Click the **Expand** icon of the instance that you want to modify the configurations.

   The **Details** panel of the instance is displayed.
6. Click **Behavior** to expand the panel and perform the following steps to change the configurations:

   a. Click the **Edit** icon .

      The options that you can modify are enabled for editing.

   b. Select a different operation for the virtual service, if available, from the list for the **Operation** option.

   c. Select a different response time from the list for the **Response time** option, and then enter the values for the delay that you want to set.

      You can modify the value by selecting a value from the following options:

Option	Description
No delay	Select this option for a response with no delay.
Minimum delay	Select this option for a delay in the response by entering the required delay in milliseconds (ms).
Uniform distribution	Select this option for a uniformly distributed response time by specifying the minimum and maximum delay in milliseconds (ms).
Gaussian distribution	Select this option for a response time with Gaussian distribution by specifying the minimum and maximum delay in milliseconds (ms).

   d. Click **apply** to apply the modified settings.

7. Click **Diagnostics** to expand the panel and perform the following steps to change the logging level that is configured:

    a. Click the **Edit** icon .

    The **Logging level** option is enabled for editing.

    b. Select a different logging level from the following options.

Option	Description
None	Specifies that the virtual service does not write log messages.
Normal	Specifies that the virtual service writes informational messages.
Debug	Specifies that the virtual service writes informational and debugging messages.

    c. Click **apply** to apply the modified settings.

Results

You have viewed and modified the configurations of a running virtual service instance from the **Instances** page on Test.

What to do next

You can run tests that are in an API Suite in your project, which then run on the virtual service instance. See Configuring an API Suite or an API test run on page 1174.

Viewing routing rules of the virtual services

When you run virtual services that are created to run on proxies or intercepts and have routing rules defined, you can view the proxies or intercepts and the routing rules from the **Intercept Rules** page.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Started the virtual service resources as a *Tester* or *Owner* from the **Resources** page.

About this task

After you run the virtual service resources that are in your project on Test , you can view the routing rules for the running instances of the virtual service resources, from the **Intercept Rules** page.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

The **Overview** page is displayed.

3. Click **Virtualization > Intercept Rules** in the navigation pane.

   The **Intercept Rules** page is displayed.

   The agents, proxies, or intercepts that are configured in the virtual service resources that are in your project are displayed.

   You can find the following information that is displayed on the **Intercept Rules** page.

Column	Description
Activity	Lists the agent or proxy.
Target	Lists a summary view of the endpoint that was recorded or virtualized.
Recipient	Lists the destination where messages sent to are captured.

4. Expand the proxy or intercept panel by clicking the **Expand** icon .

   The details of the proxy or intercept are displayed in the **Details** tab in the expanded panel.

5. Click each tab to view the following information:

<table>
<tr><th>Tab</th><th>Description</th></tr>
<tr><td>Details</td><td>The Details panel provides the following information:
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Condition</td><td>Lists the condition that causes the traffic to be recorded or routed to a virtual service.

You can view the detailed condition of the rule defined for the proxy or intercept by clicking the View icon .

The detailed condition of the rule is displayed in the Full condition window.

Note: You can copy the detailed condition if you intend to use it elsewhere.</td></tr>
<tr><td>Routing to</td><td>Lists the virtual service to which traffic is routed.</td></tr>
<tr><td>Created by</td><td>Lists the user who created the rule.</td></tr>
<tr><td>Created at</td><td>Lists the date and time when the rule was created.</td></tr>
</table></td></tr>
<tr><td>Activity</td><td>The Activity panel lists the log of the activities performed by the proxy or intercept. This panel also displays the details of the activity, date and time, and message for that activity.</td></tr>
</table>

Results

You have viewed the routing rules for the virtual service, proxy, or intercept that are running or connected to Test.

What to do next

You can perform any of the following tasks:

- You can view the usage statistics of the virtual services that are running. See Viewing usage statistics of virtual services on page 1496.
- You can stop the running instances of the virtual services. See Stopping virtual services on page 1498.

Related information

Management of virtualized services on page 1453

Viewing usage statistics of virtual services

After you start virtual service resources that are in the project repositories, and then run tests on the virtual service, you can view the usage statistics of the virtual services from the **Usage** page on Test .

Before you begin

You must have completed the following tasks:

- Completed the prerequisite tasks before you configure a run of the HTTP virtual services. See Prerequisites for running HTTP virtual services in a Kubernetes cluster on page 1455.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Verified the version of the supported assets and resources that you want to use. See Supported versions of assets and resources on page 705.
- Started the virtual service resources as a *Tester* or *Owner* from the **Resources** page.
- Ran API Suites with tests that run on the virtual service resources that are configured.

About this task

After you run the virtual services that are in a project, you can view details of the usage statistics of the virtual services from the **Usage** page on Test.

Restriction: The usage statistics of virtual services if they are run on Test Integrations and APIs agents, are collected only if the agents are of the same version as Test.

Important: The settings such as the **Period**, or **From** and **To** that you configure to view the usage details are retained for you during your ongoing session and the settings are retained even when you perform the following activities:

- Log out of the server and log in again.
- Log in after a server restart.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Click **Virtualization > Usage** in the navigation pane.

   The **Virtual Service Usage** page is displayed.

   The total requests that were received by all virtual services on the server are displayed as a graph.

   The default view displays the usage data of the virtual services that are gathered during the previous week and grouped in an hourly interval. The total requests received from when the virtual service was started are displayed.

   The metric data that is reported is for the number of requests that are received by a virtual service. The requests can be requests, messages, or other calls that are received by the virtual service.
4. Change the default settings to view the graph for the period for which you want to view the usage.

   You can change the default view by selecting an option from the following options:

Option	Description
During the last Hour	Displays the usage data of the virtual service that are gathered during the previous hour and grouped in a 20-second interval.
During the last 24 hours	Displays the usage data of the virtual service that are gathered during the previous day and grouped in an eight-minute interval.
During the last 7 days	Displays the usage data of the virtual service that are gathered during the previous week and grouped in an hourly interval. **Note:** This is the default view.
Custom Range	Displays the usage data of the virtual service that are gathered during the date range specified in the **From** and **To** fields. You can select the date and time for both the **From** and **To** fields. The data is dynamically grouped in intervals that depend on the range selected.

   Note: You can refresh the view at any time to present the graph for the latest data by clicking **Refresh**.
5. View details of the virtual service by hovering the mouse over any of the data-points to view the details at that point.

The following details about the virtual service are displayed when you hover the mouse over the data-point:

- The date and time of the request received.
- The number of requests received.

Results

You have viewed the usage details of the virtual services in your project that ran on Test.

What to do next

You can perform any of the following tasks:

- You can view the routing rules defined in the virtual service, agent, proxy, or intercept. See Viewing routing rules of the virtual services on page 1494.
- You can stop the virtual service instances that are running. See Stopping virtual services on page 1498.

Related information

Management of virtualized services on page 1453

Stopping virtual services

After you started instances of the virtual services from the **Resources** page on Test , you must stop the running instance from the **Instances** page when you do not want to use the instance. You can stop a single instance, multiple, or all running instances.

Before you begin

You must have started the virtual service from the **Resources** page. See Configuring a run of a virtual service on page 1462.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the virtual service resources in the test assets by clicking **My Projects > *project_name***.

   The **Overview** page is displayed.
3. Go to the **Instances** page and identify the instance of the virtual service that you want to stop.

   You can select the virtual service instances that satisfy the following conditions:
   - The virtual service instance must be either in the `In transition` or `Running` state.
   - The **Stop** icon in the **Actions** column must be enabled for the virtual service instance.
   - The checkbox icon must be enabled for selection for the virtual service instance.
4. Perform the actions indicated in the following table:

If...	Action...
You want to stop any virtual service instance that is running	Perform any of the following actions: ◦ Click the **Stop** icon in the **Actions** column of the virtual service instance. The **Stop virtual service instance** dialog is displayed. ◦ Select the checkbox in the row of the virtual service instance, and then click **Stop selected**. The **Stop all selected virtual service instances** dialog is displayed.
You want to stop multiple virtual service instances that are running	Perform any of the following actions: ◦ Select the checkbox in the row of the virtual service instance, and then click **Stop selected**. ◦ Select the **Select all** checkbox in the header row, and then click **Stop selected**. **Note:** All running instances are selected when you select the **Select all** checkbox. The **Stop all selected virtual service instances** dialog is displayed.

5. Click **Ok**.

   A notification is displayed that the running virtual service instances are stopped.

Results

You have stopped a single instance, multiple, or all running virtual service instances. The stopped virtual service instance on the **Instances** page is displayed with the status as *Stopped by User* in the **State** column.

What to do next

You can restart the virtual service by completing the configurations that you want from the **Resources** page.

You can open and view the `Main container log` of the stopped virtual service.

Test results

After the tests, Suites, or schedules are run and completed, you can view the results and open the reports in Test to analyze the verdict, the performance, and statistics. You can also re-execute tests and schedules from the **Results** page with the same commit id.

Summary

The **Results** page displays the verdict summary for all the tests run in the project.

In this page, you can perform any of the following tasks:

- Displaying the suites only, or the tests only, or tests and suites that are run with advanced settings.
- Searching for test results. You can filter test results by using any of the following ways:
  - By using the **Search** field to search for results by name. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
  - By selecting predefined time interval from the **Selection interval** list.
  - By selecting **To** and **From date** from the **Date Interval** option.
  - By clicking verdict from the **Verdict summary** slider (*Pass*, *Fail*, *Inconclusive*, or *Error*).
  - By creating filter queries.
- Configuring the information displayed on the **Results** page from the **View Settings** window by clicking the **Settings** icon .
- Downloading the result list as a `.csv` file by clicking the **Download** icon .
- Adding labels if you have a tester or an owner role.
- Adding text in the **Notes** field. You can also group the notes similar to a conversation in a chat channel.
- Locking test results: Locked results can be unlocked by the project owner or the project member who locked the results.
- Deleting test or suite results.

  Note: When you delete the result of a suite run, the results associated with the tests and suites within that suite are also deleted. Test results that are part of a suite run cannot be selected individually. To delete such results, you must select and delete the parent test suite run.

- Comparing performance reports.
- Viewing trending reports.
- Viewing multiple reports depending on the test types and the parameters set when you execute the tests: Statistics reports, Functional Test reports, Test logs or Result data queries
- Re-executing tests with the same commit id.

  For more details, see the links in the next section of this page.

If you added any additional properties under the **Additional Configuration Parameters** section in the **Execute test asset** window, then these properties are displayed in the following sections after the test run:

- The **Properties** column on the **Results** page.
- The **Summary** section on the **Functional Report** page.
- The **Properties** section on the **Test log** page.

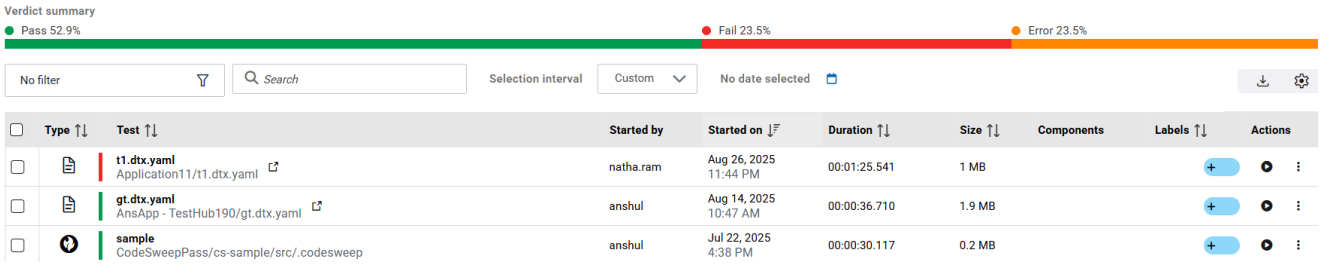
Test results and reports

Test provides a single location for hosting the results and reports of all tests run on different desktop clients and for tests run from the server.

Test results list

When a test run is complete, you can see the results on the **Results** page that you open from **Analyze > Results** in the navigation pane.

The list of test results is organized based on the test type. You can display the suites only in the **Suites** tab, or the tests only in the **Tests** tab, or the tests and suites that are run with advanced settings in the **Advanced** tab.



Results, reports, and logs are generated for tests run from Test, or from desktop clients such as Test Performance, Test UI, or Test Integrations and APIs.

You must have configured the desktop clients to publish reports of tests that are run from the desktop client to the Test. For more information about the publishing procedure, refer to the links at the end of this page.

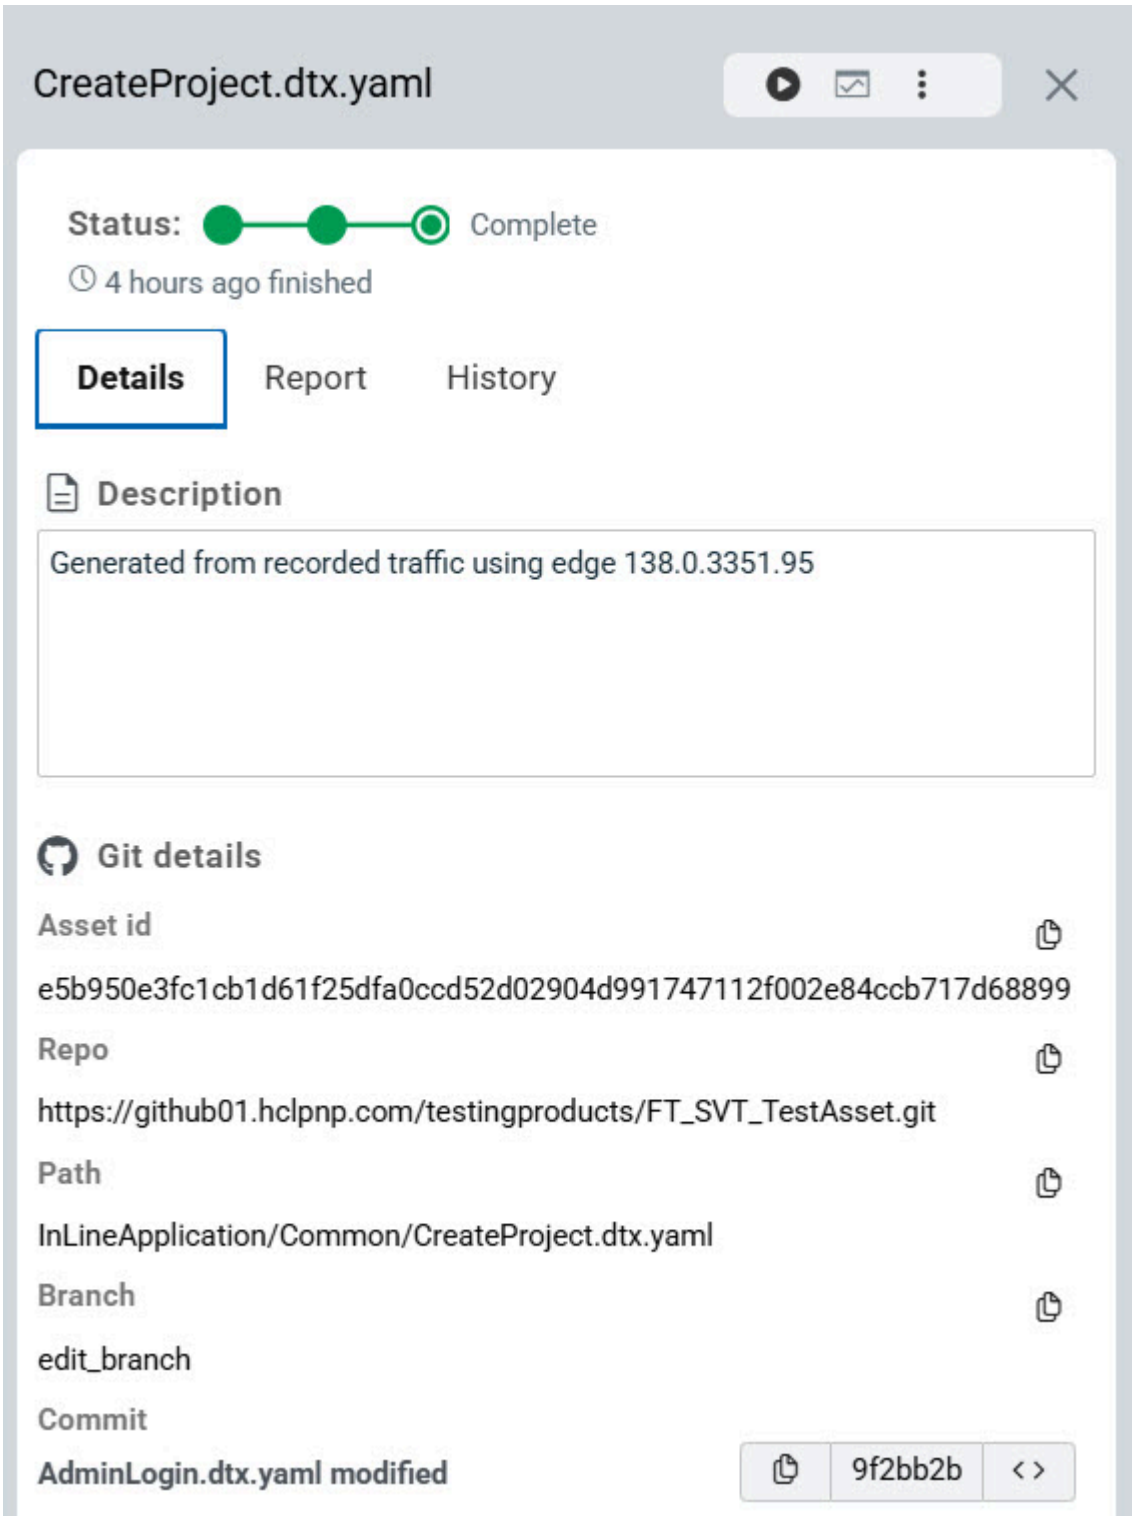
When you click the test result, a results panel is displayed with information in the following tabs:

- Details
- Reports
- History

Test result details

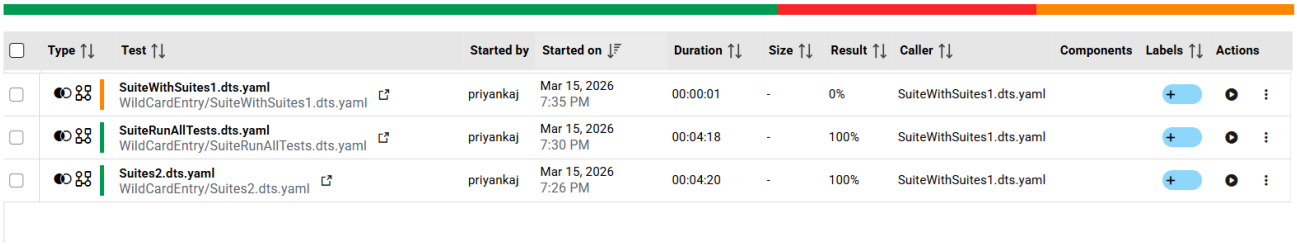
You can view the following details about the test assets used in the test run in the **Details** tab:

- The status of the test results, the date and time it was executed and completed.
- The details about the Git repository that contains the test assets.



You can configure the information displayed on the **Results** page from the **View Settings** window. You access this window by clicking the **Settings** icon .

Depending on the attribute you selected in the **View Settings** window, the selected attributes are displayed in the columns of the **Results** page.



The **Result** page supports selecting individual items from the list. When a row is selected, the corresponding high-level information is displayed in the top banner of the Test Editor.

The **Result** column displays the pass percentage for a test or suite. For a test, when you hover over the percentage, you can see a description indicating the number of steps that passed. For a test suite, the description indicates the number of tests that passed.

The **Caller** column displays the name of the suite that invoked the result.

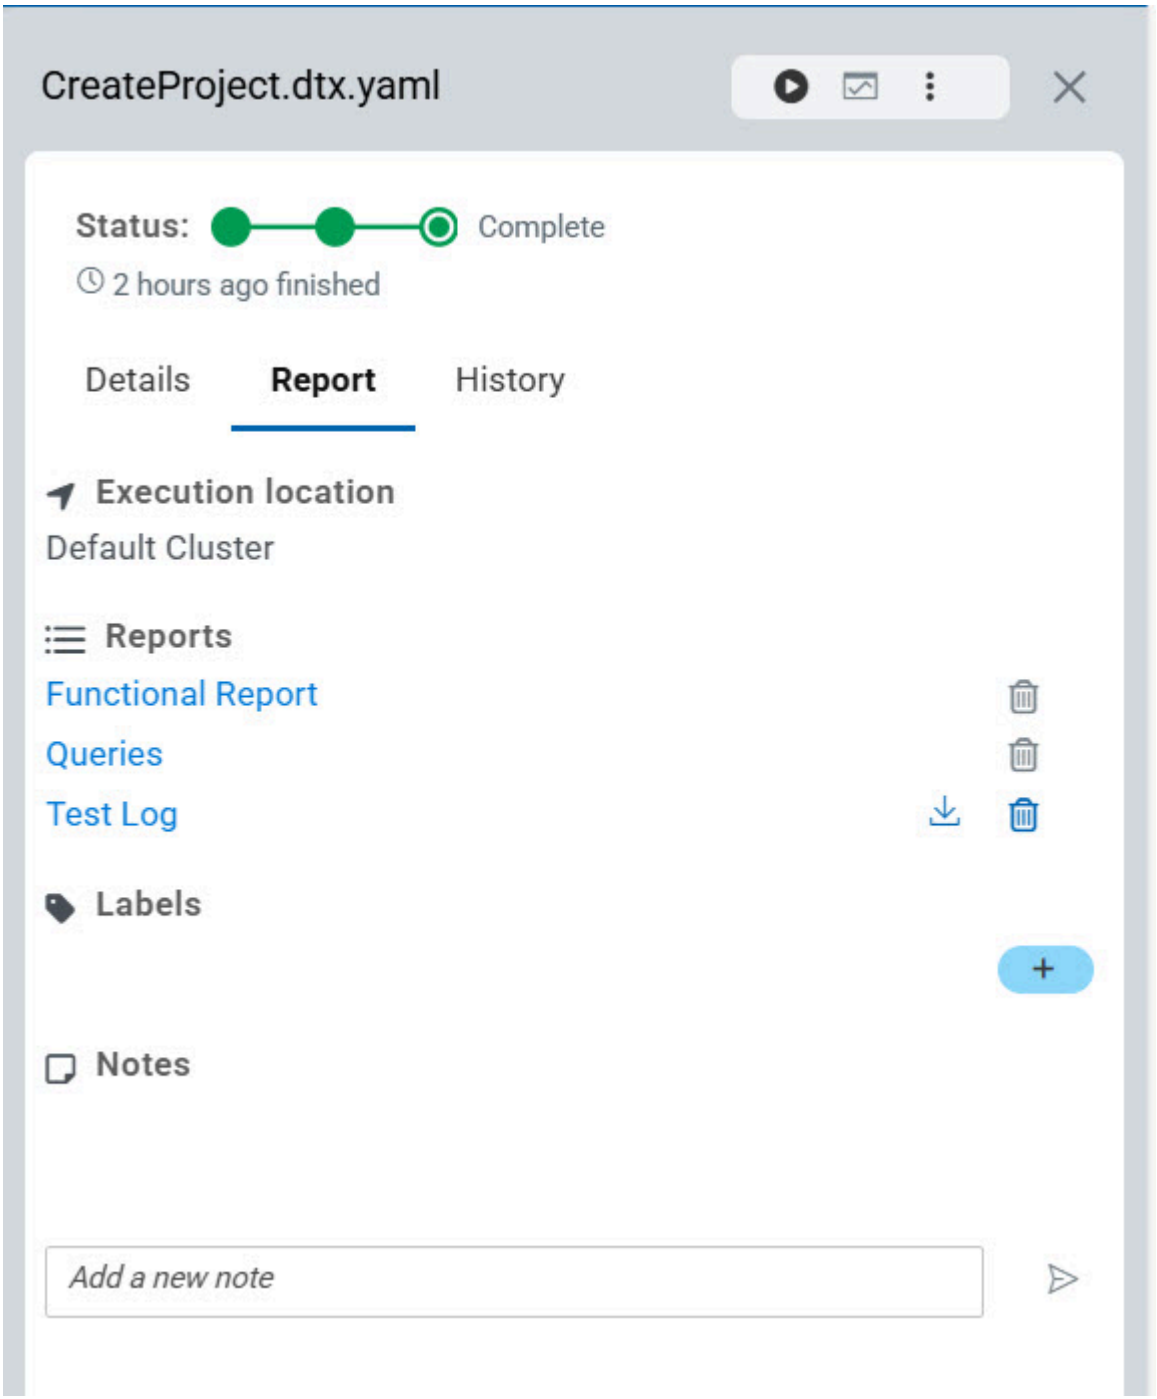
The icon in the **Type** column indicates that the test or suite was run as part of another suite. Hover over the icon to view the name of the suite in which the test or suite was run.

You can click the **Download** icon to download the list displayed on the **Results** page. The result list is downloaded into your local file system as a Comma Separated Values (CSV) file.

Reports

The **Report** tab provides the following information:

- The location where the test was run.
- The reports that are generated for the test run.
- The labels that you created for the test during its configuration for a run.
- Notes that you can add to the specific test run result or displays the notes already added by you or others.
- The size column displays the total disk usage of each test result. The size is rounded up and displayed in human-readable units. Hover over the size to view the exact disk usage. You can also sort by size.



You can perform the following actions on the reports and logs that are displayed on the **Reports** tab:

- View the report that opens in a web browser by clicking the report.
- Download the report by clicking the **Download** icon . You can enter a name and select the location on your computer where you want to save the report.

  The report is downloaded in any of the following formats:

- A compressed file and contains the HTML pages for the supported tests.
- A compressed file that contains the Surefire report.
- A PDF for the supported tests.

Note: For tests that contain more than 30 test steps, the details of the test steps are not included in the PDF.

- Delete the report by clicking the **Delete** icon .

Note: The deleted report is not available on the server. You might have to run the test again to generate the report.

As a default configuration, test logs are delivered in a traditional format for the executed Compound Tests and schedules.

The reports are generated for Compound Tests, Schedules, and Test Suites, or for other tests that are run from a desktop client or from Test.

The following table lists the reports that are generated for each type of test and the links to help pages.

Table 616. Analyzing Reports

Report	Tests type	Product	More information
Functional Report	Server Test	Test	Viewing a Functional Report on page 1511
	Server Suite		
	API Test	Test Integrations and APIs	
	API Suite		
	Compound Test		
	Functional test	Test UI	
	AFT Suite		
	Compound Test		
Functional Test Report	API Suite	Test Integrations and APIs	Viewing reports
	Compound Test	Test UI	Unified Report
	AFT Suite		
	Functional test (For Web UI tests)		
Mobile and Web UI Report	Compound Test	Test UI and Test Performance	Mobile and web UI test result reports

Table 616. Analyzing Reports (continued)

Report	Tests type	Product	More information
	AFT Suite	Test UI	
Statistics Report	Compound Test	Test UI and Test Performance	Reports and counters. Service Performance report. From the Statistic reports, you can add counters. Refer to Adding additional counters on a separate page.. You can also display the statistics of counters on graphs. Refer to Displaying counter data in tables or as graphs..
	AFT Suite	Test UI	
	VU Schedule	Test Performance	
	Rate Schedule		
	Functional test (For Web UI tests)		
Test Log	Compound Test	Test UI and Test Performance	
	AFT Suite	Test UI	
	API Suite	Test Integrations and APIs

Creating search queries to filter test results

To filter the test and suite results list, you can create a search query that you apply as a filter in Test .

About this task

To filter the list of test and suite results, you can use rules and group of rules in your query. This procedure explains how to create a query that contains two rules and a group of rules as an example, and how to select other filters.

1. Click **New filter** on the Result page.

Follow these steps to add a rule in your query:

2. Select **Add a rule** in your query, and enter or select the required attribute in the fields to define the rule:

    a. Select the first attribute that you want to query in the drop-down list.
    Example
    Select **Verdict**.

    b. Select the condition as *equal to (=)* or *not equal to (!=)*, *Contain* or *Not contain*.
    Example
    Select **=**.

    c. Select a value for the first attribute you selected.
    The content of this field depends on the option you selected as first attribute. Enter a value for the **id**, **TypeTest**, **Version**, **Result**, **Labels**, **Branch**, **Test path**, and **Text** attributes. For the other attributes, select a value in the drop-down list.
    Example
    Select **Fail**.

    d. Select either the **AND** or the **OR** operator in the first field to add a condition to compare the first rule with another rule.

    e. Select **Add rule** in the drop-down list.

    f. Select an attribute, a condition, and select or enter a value.
    Example
    Select **Test** as an attribute, select **=** as a condition operator, and enter *mytest* as a value.

Follow these steps to add a group in your query:

3. Select **Add group** in the drop-down list.

   Note: A group is a collection of rules and can also contain other groups within a query. You can add a rule or a group within this group.

4. Select a condition operator.

   Example

   Select **Or**.

5. Select **Add rule** in the drop-down list to add a rule in the group.
6. Select the required an attribute, an operator, and enter a value for the rule.

   Example

   Select the **Type** attribute, **=** as an operator, and **Compound Test** as a value.

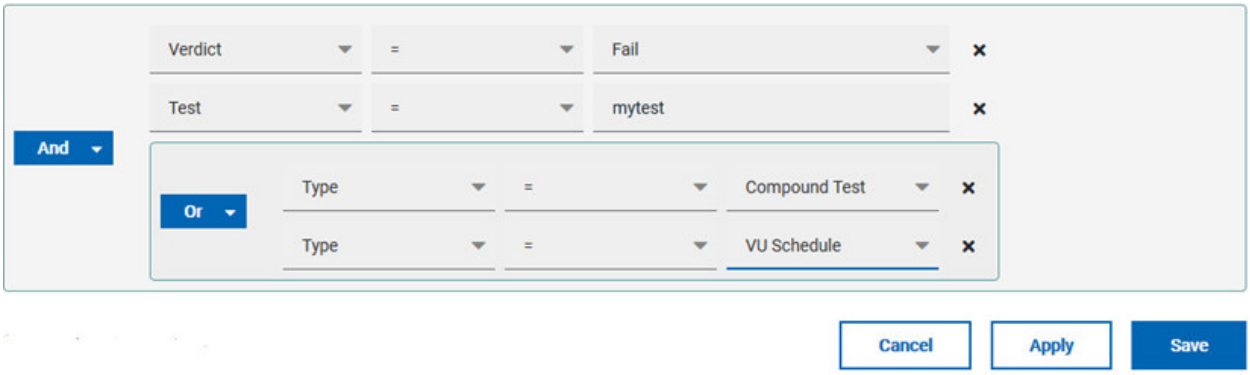
7. Select **Add rule** to add another rule in the group.
8. Select and enter the appropriate parameters as you did for the other rules.

   Example

   Select **Type** as an attribute, **=** as a condition, and **VU Schedule** as a value.

9. Click **Apply** if you want to apply the filter now.

   You can cancel the query or save the query when the results are found.



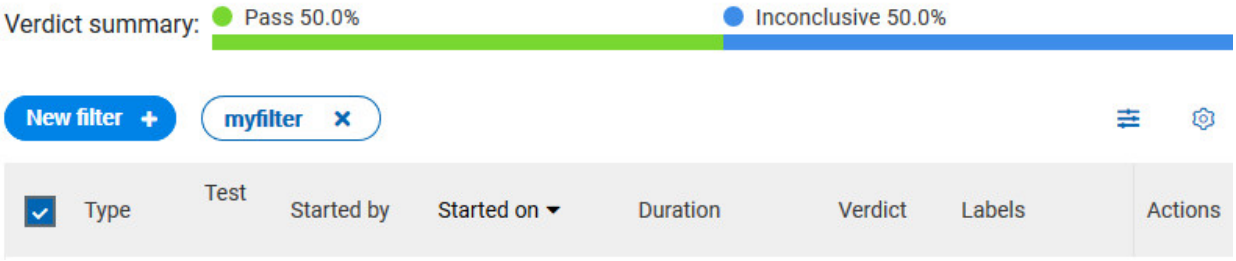
10. Click **Save**.

Proceed as follows to select your filters:

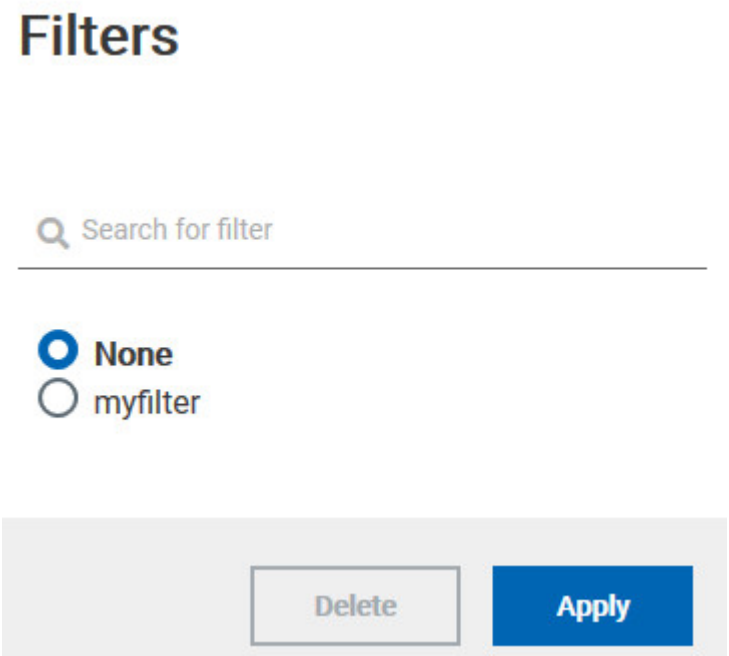
11. Enter a name for the filter and save in the dialog that is displayed.

    Result

    The filter is displayed as a favorite filter.



12. Click the icon to select the filters you created from the list of saved filters.



13. Click a filter in the list of saved filters. If a filter does not display in the list, enter the name of a filter in the search field and select it.

Note: You can delete a filter from the list or disable filters by selecting **none** in the list.

14. Apply the selected filter.

Result

The filter is displayed as a new favorite filter in the **Results** page.

Comparing test reports

After you run performance tests, you can analyze the difference between two or multiple test results in Test . For example, you can compare the performance of an application at different time slots or different milestone builds between two test results.

About this task

You can compare the test runs for performance tests that are in the same project or in different projects.

1. Select results in the **Results** page by checking the boxes in the first column.
2. Click the icon

Note: When comparing multiple runs, you cannot compare multiple time-ranges or stages.

Result

The two or multiple test results are displayed in a browser window in the same report.

Viewing trending reports

When the performance test runs are complete, you can view the trend of response time for an application over a period of time in Test from trending reports. In addition to the response time, you can view the trend for the loops, transactions, and performance requirements for the application.

About this task

The trending reports are available for performance tests only.

1. Select results in the first column in the **Results** page.
2. Click the icon to view the trending reports.

Note: When comparing multiple runs, you cannot compare multiple time-ranges or stages.

Results

You can analyze the trend information for multiple test results in the same report from a browser window.

Viewing a Functional Report

When the test run is complete, you can view the **Functional Report** in Test . The report contains a summary of the execution, the test environment, a detailed view of all tests, and the test steps that you executed.

1. Go to **Analyze > Results** in the navigation pane.

   The test assets that have completed their run are listed.

2. Select the tab based on the type of test assets that you ran as indicated in the following table:

If...	Then...
You ran AFT Suites, API Suites, Server Suites, or Compound Tests.	Click the **SUITES** tab.
You ran API Tests, Functional Tests, or Server Tests.	Click the **TESTS** tab.
You ran Suites or Tests and you want to find the test assets by using custom filters.	Click the **ADVANCED** tab.

3. Click the test asset under the **Test** column.

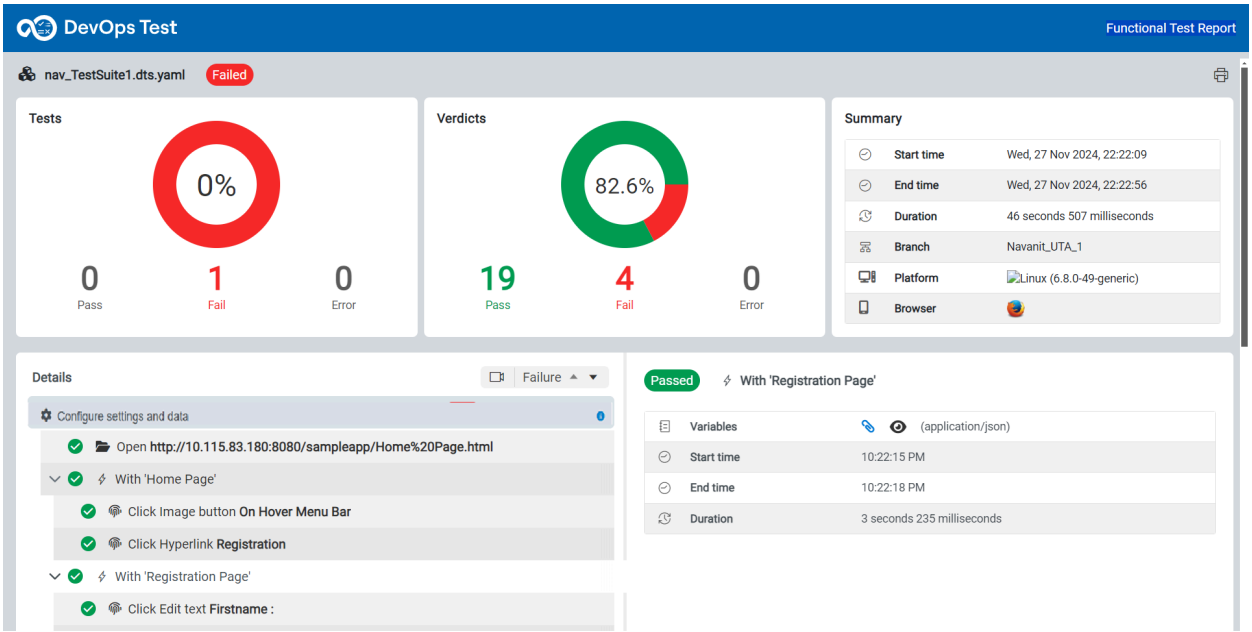
   The results and reports panel is displayed.

4. Click the **Reports** tab, if it is not already open.
5. Click the **Functional Report** link.

   The **Functional Report** opens in a new tab.

   You can see the following information in the report:

   - Click the **Configure settings and data** node to view the initial variable values and dataset details used during test run. Variable details are now displayed directly in the parent activity viewer for better readability and navigation.
   - The top-level steps and first-level child steps are automatically expanded to provide better visibility.
   - A summary of the test run, including passed or failed status, count of passed or failed tests or test steps, and the verification points.
   - A summary of the test environment with the details of deployments, datasets, and components.
   - A detailed view of all tests that were executed in the case of an intelligent test suite, or in the case of a test with invoked tests.
   - A detailed view of all steps that were executed for each of the tests, including screenshots if any.



6. In the report, you can perform the following actions:

   a. Click the **Print** icon to print the report or save it as a PDF.

   b. Click the **Browse Screenshots** icon to view all the screen captures taken during the test run.

   c. Click the **View content** icon to view the variables or stack trace, if available.

d. Click the **Download attachment** icon to download the variables or stack trace as a `.txt` file, if available.

e. Click the **Previous failure** icon and **Next failure** icon to navigate between the failed steps, if there are failed steps in the report.

Results

You have viewed the **Functional Report** and analyzed the summary of the tests that you ran.

Navigating to a test, suite, or step from the functional report

You can navigate to the related test, suite, or specific step from the functional report to investigate failures, review details, or make corrections. By using this feature, you can locate test resources faster and fix issues quickly.

Before you begin

You must have run a test or suite in Test.

1. Go to **Analyze > Results** in the navigation pane.

   The test assets that have completed their run are listed.

2. Select the tab based on the type of test assets that you ran as indicated in the following table:

If...	Then...
You ran AFT Suites, API Suites, Server Suites, or Compound Tests.	Click the **SUITES** tab.
You ran API Tests, Functional Tests, or Server Tests.	Click the **TESTS** tab.
You ran suites or tests, and you want to find the test assets by using custom filters.	Click the **ADVANCED** tab.

3. Click the test asset under the **Test** column.

   The result and report panel is displayed.

4. Click the **Reports** tab, if it is not already open.
5. Click the **Functional Report** option.

   The functional report page opens in a new tab.

6. Click the expand icon to view the result details in a functional report., then

   The individual test steps or suite results are displayed

7. Click the **Open** icon to access the specific test, suite, or a step in the **Test Editor**.
   If the selected test, suite, or a step is on a different branch, the **Open Asset** dialog prompts you to switch to the appropriate branch before opening the asset in the **Test Editor** page.

   If the selected test, suite, or a step is on the same branch, it opens directly in the **Test Editor** in a new tab.

   Note: The **Open** icon is disabled if the test, suite or a step is deleted or renamed.

Results

You have directly navigated to a selected test, suite, or specific step from the functional report.

Re-executing tests from results

You can re-execute a test, a schedule, a collection of tests or schedules from Test if you want to retain the same commit id.

Before you begin

You must have executed a test or multiple tests from the **Execution** page in Test.

Re-executing a test from the **Results** view requires a Tester or an Owner role.

About this task

The following procedure describes how to re-execute a single test or multiple tests at a time.

Perform all the following steps from the Results page.

- Proceed as follows to re-execute one test at a time:

  1. Identify the test that you want to re-execute and click the **Re-execute** button in the Actions column.
     Result
     The **Execute test asset** dialog displays the same parameters as the ones that were set to execute the initial test from the **Execution** page.

  2. Select another **Version** of the test.

     Note: If you select another version of the test, the settings configured in the dialog and in the **Environment**, **Data Sources** and **Locations** tabs might change.

  3. Modify the **Schedule** parameters.

Note: If you don't want to execute the test now, schedule the time when you want the test to be re-executed.

4. Click the **Environment** tab and select another **API test environment** if multiple environments were initially set for a test that is running an API Suite.
5. Click the **Data Sources** tab and select an override option if multiple data sources were defined for the initial test run.
6. Click the **Variables** tab and add a new variable if you want to re-execute a test asset with a different variable from the one configured in the asset.
7. Click the **Location** tab to override the default cluster location if the test asset has static agents configured.
8. Click **Advanced** to modify the advanced parameters that were set for the initial test run.
9. Enter a new instance of **Java arguments** if applicable to the test.
10. Enter the environment variables that must be passed to the test run at runtime in the **Environment Variables** field.
11. In the **Resource Monitoring** tab, click the , and press the Ctrl + Space keys, or enter the initial letter of a label to select a label in the list and override the current sources in the schedule.

    Note: The **Resource Monitoring** tab is displayed for performance schedules and only if you have enabled the **Resource Monitoring from Service** option from Test Performance.

    The label field is grayed if you don't have any label entered in your current project. To collect data during the test execution, you must first enter labels in the Resource Monitoring sources page from Test.

    For more details about controlling Resource Monitoring sources and labels, see the links at the end of this page.

12. Click the **Re-execute** icon to re-execute the test now or at a scheduled time.

- Proceed as follows to re-execute multiple tests at a time:

1. Click the checkboxes for the tests that you want to re-execute.
   You can select them one by one or select all of them.
   Result
   A toolbar is displayed.
2. Click the **Re-execute** icon in the toolbar.

Result

A message indicates the number of selected tests and the number of tests to be re-executed. The tests are re-executed with the same initial commit ids and parameters.

3. Click **Execute**.

Result

You can view the results, logs, and reports of the re-executed tests in the **Results** page.

Test results data in Grafana

By using Test Results Data and Grafana, you can retrieve and explore test log data that is generated in Test. You must install and configure the Test Results Data plugin in Grafana and create an instance of a data source that you use to explore your test log data.

Grafana is a visualization and analytics software. You can use Grafana to explore Test metrics.

You must use Test Results Data, which is a data source plugin, to make requests to Test and represent data in a Grafana dashboard.

Installing and configuring the DevOps Test Hub Results Data plugin

You must install and configure the DevOps Test Hub Results Data plugin that is packaged along with Test to view and analyze the log data in Grafana. You can view the test log data that is generated when you run a test from Test in a Grafana dashboard.

Before you begin

You must have installed Grafana on your computer.

1. Perform the following steps to install the DevOps Test Hub Results Data plugin:
    a. Download the DevOps Test Hub Results Data plugin from the following URL:

    ```
    <your server address>/test/artifacts/grafana/devops-testhub-datasource.zip
    ```

    b. Install the DevOps Test Hub Results Data plugin by extracting the compressed file into your Grafana plugin directory.
    c. Restart the Grafana server.
2. Perform the following steps to configure the data source by using the DevOps Test Hub Results Data plugin:

a. Enter the address of the local Grafana server in your web browser:

Important: You must sign in with `http://localhost:3000` or `http://localhost:8080` URLs to use the plugin.

b. Follow these steps to verify that the DevOps Test Hub Results Data plugin is available in Grafana:
   i. Click **Administration > Plugins and data > Plugins** in the left navigation panel of Grafana.
   ii. Enter **DevOps Test Hub Results Data** in the search bar in the **Plugins** tab.
   iii. Click **DevOps Test Hub Results Data** in the search results.

   The DevOps Test Hub Results Data page is displayed. You can find the links to Test documentation and the description of the plugin on this page.

c. Perform the actions indicated in the following table to create an instance of a data source in Grafana by using the DevOps Test Hub Results Data plugin on the **DevOps Test Hub Results Data** page:

Note: Users with the role of a server administrator can add data sources.

Options	Actions
If you want to create an instance of the data source in Grafana by using the proxy connection	Perform the following steps: i. Click **Add new data source**. The data source configuration panel is displayed. ii. Click **Default** if you want to set the data source as the default data source in Grafana. iii. Enter a name to identify the data source. iv. Enter the URL of Test in the **Server** field. v. Enter the token that you created in Test. **Note:** The **Use proxy** is enabled by default. vi. Click **Save and test**. **Note:** If the server certificate is self-signed, an error message is displayed. You must add the CA certificate to establish the connection with the server. vii. Perform the following steps to add the CA certificate: 1. Enable **With CA Cert** by using the toggle icon. 2. Add the CA certificate in the **CA Cert** field that you saved during the installation of Test. 3. Click **Save and test**.

Options	Actions
If you want to create an instance of the data source in Grafana with additional Helm parameters **Important:** Before you install Test, you must use an additional Helm command parameter **router.allowedOrigin** during the installation. You can also run this command after installation. See the Additional Helm parameters topic in the related information section.	Perform the following steps: i. Click **Add new data source**. The data source configuration panel is displayed. ii. Click **Default** if you want to set the data source as the default data source in Grafana. iii. Enter a name to identify the data source. iv. Enter the URL of Test in the **Server** field. v. Enter the token that you created in Test. vi. Disable **Use proxy** by using the toggle icon. vii. Click **Save and test**.

Results

You have installed and configured the DevOps Test Hub Results Data plugin in Grafana.

What to do next

You can retrieve the test log data from Test by using queries.

Viewing test results data in Grafana

After you install and configure DevOps Test Hub Results Data plugin in Grafana, you can retrieve the test log data that is generated in Test and view the test results data in Grafana. You can use queries to display graphs, statistics, or tables. You can also view the details in a Grafana dashboard.

Before you begin

You must have completed the following tasks:

- Ran tests to get test logs results in Test. For more information about the procedure, refer to Test logs on page 1523.
- Installed the DevOps Test Hub Results Data plugin and created an instance of data source for DevOps Test Hub Results Data. See Installing and configuring the DevOps Test Hub Results Data plugin on page 1516.
- Opened Grafana with one of these ports: `http://localhost:3000` or `http://localhost:8080`.

1. Click **Explore** in the **Toggle** menu in Grafana.

   The **Data query** page with the default data source is displayed.
2. Select **DevOps Test Hub Results Data** from the list of data sources.
3. Select the type of query by performing any of the following actions when you want to view statistics, events, or activities from the test data:

To view	Actions
The variation of a metric over time.	Perform the following steps: a. Click the time-series statistics tab icon . b. Go to Step 4 on page 1519.
The values of the metric computed over the entire time range.	Perform the following steps: a. Click the overall statistics tab icon . b. Go to Step 4 on page 1519.
The events recorded in the test log.	Perform the following steps: a. Click the **Events** tab. b. Go to Step 4 on page 1519.
The activities recorded for all events in the test log.	Perform the following steps: a. Click the **Activities** tab. b. Go to Step 4 on page 1519.

4. Define the scope for the query by performing the actions indicated in the following table:

Options	Actions
If you want to use the data from the team space	**Note:** You can select the team space as the scope for your query only if you want to view the time-series statistics or overall statistics. Perform the following steps: a. Select the **Team Space** option. b. Select the team space from the list of team spaces that are listed. c. Select either **Service**, if you want to use Resource Monitoring data or **Stubs**, if you want to use the virtual service data in the query. d. Go to Step 5 on page 1520.
If you want to use the data from your project	**Note:** You can select the project as the scope for your query if you want to view any of the supported query types. Perform the following steps: a. Select the **Project** option. b. Select the project from the list of projects that are listed. c. Select the **Result** option. d. Select the result from the list of results that are displayed. Alternatively, you can also enter text for the name or ID of the result in the **Search** field, and then select the result from the listed items. e. Go to Step 5 on page 1520, if you selected the query type as time-series statistics or overall statistics, or go to Step 6 on page 1521, if you selected the query type as **Events** or **Activities**.

5. Perform the following steps to select metrics for your query:

   a. Select a metric from the list of metrics in the row of the **Metrics** option.

   b. Assign a name for the metric that helps you identify it, by entering text in the **Metric** field.

   c. Select the aggregation factor for the metric. For example, select **Sum** to add all values of the metric.

   d. Optionally, click the icon to add a separator.

      With separators, you can view details of a specific project or test result in comparison with the values of the metric across projects or results in the team space or project.

   e. Optionally, click the **Cumulated** toggle-button if the values for the metric must be added cumulatively over time. The default option is set to be non-cumulative.

f. Add another metric by clicking the **Add metric** icon .

Note: If you added multiple metrics and you want to remove a metric, you can click the **Remove metric** icon of the metric.

g. Go to Step 7 on page 1521.

6. Perform the following steps for the **Events** or **Activities** query type:

a. Enter the **Query Filters**.

b. Enter the **Timing value** and **Value**.

The timing values are sorted in ascending order. The value must be numeric so that it can be used in a graph.

Tip: To find all the information needed on the **Explore** page of DevOps Test Hub Results Data, perform any of the following actions:

- Select a result on the **Queries** page in Test and copy the result number, query filters for the events or the activities, query filters, and timing values. You can find the project number in the URL of the **Queries** page.
- Click **Copy curl command** on the **Queries** page in Test and paste the curl command in a text editor. You can find all the information you need in the following command.

7. Click **Add query** if you want to combine queries from different projects, results ids, or with different properties in the query filters.
8. Click **Run query**.

Results

You configured a query to get the test log data from Test, and you can view and analyze the log data displayed for your query.

What to do next

You can build a dashboard including graphs, charts, gauges, tables to get customized visual representations of your test result data and select options to display the test result values. See Dashboard overview for more details about dashboards in Grafana.

Viewing Surefire format reports

After you execute JMeter, JUnit, API, and Functional tests with advanced settings in Test , you can view the test results in a Surefire format report by using dedicated URLs.

Before you begin

You must have configured your tests with one of the following parameters:

- For JMeter, JUnit, Postman, and HCL® AppScan Suites, set the **history** parameter with **cisterna** value in the **Additional Configuration Parameters** field in the **Advanced** settings.
- For API Suites, AFT Suites, Compound Tests, Functional tests, and API tests, set the **-history cisterna** parameter in the **Program Arguments** field in the **Advanced** settings.

About this task

When a test run is complete, you can see the test result data in a report that is in a Surefire format. You can view this report by using dedicated URLs.

1. Click **Analyze > Results** in the navigation pane.
   Result
   The **Results** page is displayed.
2. Click a test result, and note its project identifier and test result identifier (ID) in the URL of the test log that is displayed in your browser. The URL is in the following format: `https://myProductionServer.com/test/#/Initial/project/<ProjectID>/analyze/test-log/<ResultID>`.
   The identifiers are required to view the Surefire test logs in the following steps.
3. Enter one of the following URLs with the appropriate information in a web browser or in an external tool that you use to view Surefire reports:
   - `/rest/projects/<ProjectID>/data/views/surefire/`

     Enter your REST API address and the project identifier to view the list of all test cases in the project with details about their status.

     Example: `https://myProductionServer.com/rest/projects/230200/views/surefire/`
   - `/rest/projects/<ProjectID>/results/<ResultID>/data/views/surefire/`

     Enter your REST API address, the project identifier, and the test result identifier to view the results for this test result id in the project.

     Example: `https://myProductionServer.com/rest/projects/230200/results/80250/data/views/surefire/`

Results

The test result reports are displayed in a Surefire format.

Test logs

When you start a run of a test asset, Test starts to log information about the test run in a test log. You can view the test log while the test runs and after the run is completed from the **Test Log** page.

Overview

Test captures the test log for the supported tests that you can run on Test. For the list of supported tests, see Supported suites and tests on page 706.

Test uses a built-in PostgreSQL database to store information about the test while the test runs on the server. Test captures and displays the test log as the default configuration and you do not have to configure other settings during or after installation of the server.

Supported formats of test logs

The formats in which you can view the test logs are as follows:

Table 617. Supported formats for test log display

Log format	Description	Action
Default format	Displays the test log in the built-in format on the **Test log** page. For example, the test log can be as follows:  Click the **Configure settings and data** node to view the initial variable values and dataset details used during test run. Variable details are now displayed directly in the parent activity viewer for better readability and navigation. The top-level steps and first-level child steps are automatically expanded to provide better visibility.	You do not have to set any Program argument while you configure the test run.

Table 617. Supported formats for test log display (continued)

Log format	Description	Action

Text format	Displays the test log in a plain text format and is displayed in a different browser tab or window than the one that displays the **Test log** page. For example, the test log can be as follows:
	`----------`
	`Name: autoResults`
	`Description:`
	`Test Version: null`
	`Verdict: fail`
	`Type: com.ibm.rational.test.lt.lttest`
	`----------`
	`----------`
	`Name: DefaultSchedule`
	`Description:`
	`Timestamp: May 25, 2022 at 9:24:10 AM GMT`
	`null`
	`Event type: com.ibm.rational.test.lt.scheduleStart`
	
	`Properties:`
	`Test Log Filter (ALL): 100 (ALL)`
	`Test Log Filter (WARNINGS): 100 (ALL)`
	`Test Log Filter (ERRORS): 100 (ALL)`
	`Type: start`
	`----------`
	`----------`
	`Name: DefaultUserGroup`
	`Description:`
	`Timestamp: May 25, 2022 at 9:24:10 AM GMT`
	`null`
	`Event type: com.ibm.rational.test.lt.usrGroupStart`
	
	`Properties:`
	`Type: start`
	`----------`
	`----------`
		You must set the **-history testlog** Program Argument in the **Advanced** settings dialog while you configure the test run.

Activities and events

The information about the tests that is collated by Test can be classified into the following types:

Table 618. Types of information collated for test logs

Information type	Description
Activity	Specifies the events that are performed when the test runs as part of a test step. An activity comprises different events and is represented as a collection of events that were performed over time. For example, opening a specific web page by using a web browser in the test can be an activity that comprises the different events such as connecting to the web site, sending of a request, and receiving a reply. Each of these events might take a specific amount of time, which are captured in the test log.
Event	Specifies an action performed as part of a test step.

Table 618. Types of information collated for test logs (continued)

Information type	Description
	For example, start connection can be an event in a test that requires a specific web page to be opened in a web browser, as detailed in the example for an activity. The exact time at which this event occurred when the test ran is captured in the test log.

Test log tasks

You can find information about the tasks that you can perform on the the test logs in the **Test log** page. The test logs for the tests that you ran on Test are displayed in the **Test log** page.

The tasks that you can perform on the test logs are summarized in the following table:

Table 619. Test log tasks

Task	More information
Viewing test logs after you start a test run on the **Execution** page.	Viewing test logs after you start a test run on page 1525
Viewing test logs after the test run is completed.	Viewing test logs after the test run is completed on page 1526
Viewing details about the test log.	Test log details on page 1530

Viewing test logs after you start a test run

When you configure and start a test run, you can view the test log that is created progressively while the test runs.

Before you begin

You must have configured and started a test run. See Test run configurations on page 1134.

Note: You must have opened the **Execution** page to start the test run.

1. Click **Show in progress page** icon in the **Actions** column of the test asset on the **Execution** page.

   The asset is displayed on the **Progress** page.
2. Click the **Open action menu** icon.
3. Click the **View test log** option.

The **Test log** page is displayed with the test log collated for test run.

Note: Because the test log is collected progressively as the test runs, you must click **Refresh** to view the latest or the updated test log.

Results

You have viewed the test log for the test asset that you ran.

What to do next

You can view the details of the test log and decide on the actions you might want to take on the test log. See Test log details on page 1530.

Viewing test logs after the test run is completed

After you configure a test run and the run is completed, you can view the test log that is created for the test.

Before you begin

You must have configured and started a test run, and noted that the test run has the status as *Complete* displayed on the **Progress** page.

About this task

You can view the test log that is created for a specific test run from the following pages:

- The **Progress** page. To view the test log from the **Progress** page, go to Step 1 on page 1526.
- The **Results** page. To view the test log from the **Results** page, go to Step 2 on page 1527.
- The **Test log** page. To view the test log from the **Test log** page, go to Step 3 on page 1529.

1. Perform the following steps after the test completes its run:
    a. Go to **Execute > Progress**, if you are not already on the **Progress** page.

        The test assets that are running or have completed their run are listed. If you are already on the **Progress** page, only the test asset that you selected on the **Execution** page is displayed with the status as *Complete*.

    b. Click the **Open action menu** icon ⋮ under the **Actions** column in the row of the test asset.

    c. Click the **View test log** option.

        The **Test log** page is displayed with the test log collated for test run.

        The top-level steps and first-level child steps are automatically expanded to provide better visibility.

Click the **Configure settings and data** node to view the initial variable values and dataset details used during test run. Variable details are now displayed directly in the parent activity viewer for better readability and navigation.

d. Go to Results on page 1530.

2. Perform the following steps after the test completes its run:

a. Go to **Analyze > Results**.

The test assets that have completed their run are listed.

b. Select the tab based on the type of test assets that you ran as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, Rate Schedules, VU Schedules, JMeter tests, JUnit tests, or Postman tests..	Click the **SUITES** tab.
You ran API tests, Functional tests, or Performance tests.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, when you ran Suites and tests.	Click the **ADVANCED** tab.

c. Identify the test asset that you ran by performing any of the following actions:

- Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all Functional tests that are in the branch.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:

i. Click **New filter**.
ii. Enter a name for the filter.
iii. Select an operator, and then add a rule, or a group of rules.
iv. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

You can select a parameter from the following list:

- Type
- Test Asset Name
- Test Asset Path
- Last Result
- Next Run
- Components

v. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

i. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

ii. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you ran.

d. Click the test asset under the **Test** column.

The results and reports panel is displayed.

e. Click the **Reports** tab, if it is not already open.

f. Click the **Test Log** link.

The test log created for the test run is displayed in the **Test log** page.

g. Go to Results on page 1530.

3. Perform the following steps after the test completes its run:

a. Go to **Analyze > Test Log**.

   The **Test log** page is displayed. The test assets that were run are displayed.

b. Identify the test asset by its name or the type for which you want to view the test log.

c. Click the test asset under the **Test** column.

   The test log created for the test run is displayed.

d. Go to Results on page 1530.

Results

You have viewed the test log for the test asset that you ran.

What to do next

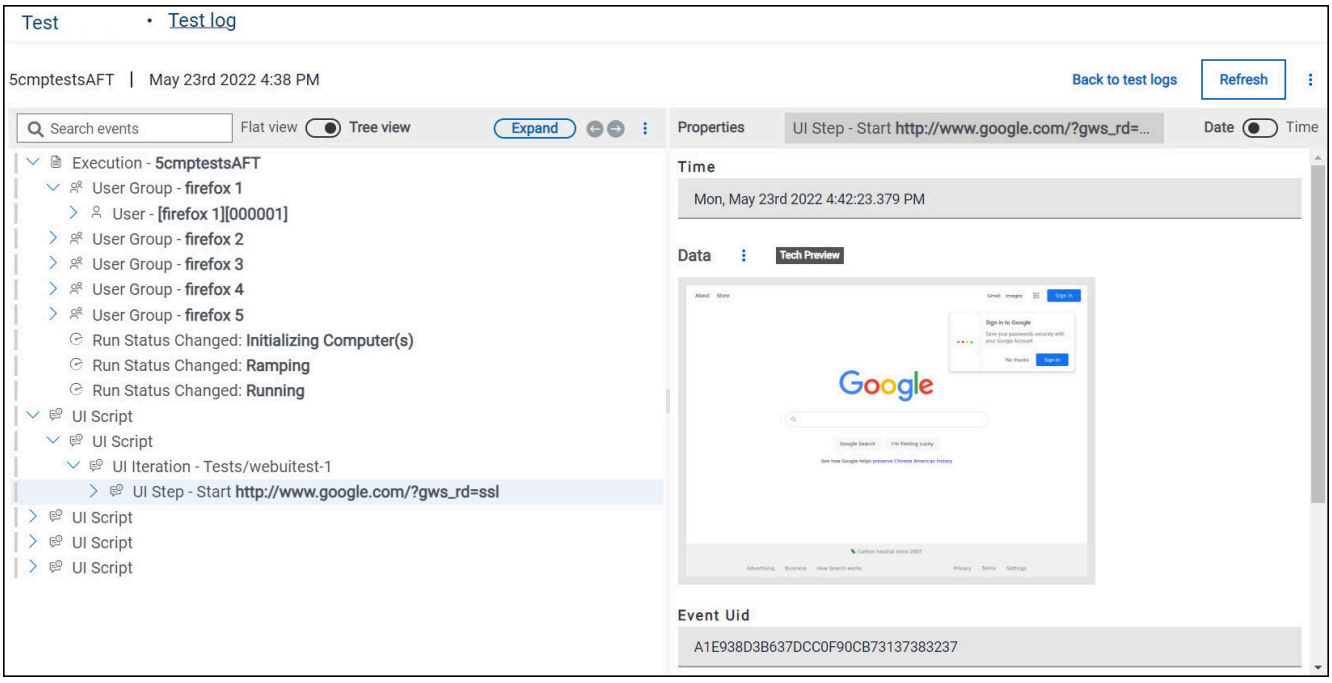
You can view the details of the test log and decide on the actions you might want to take on the test log. See Test log details on page 1530.

Test log details

You can find information about the details that are displayed for a test log on the **Test log** page. You can also find information to use the different options in the UI to change the view of the test log, find details of the events captured, navigate through the log, view or download attachments that are captured.

Before you can view the test log, you must have started a test run and opened the test log that is displayed on the **Test log** page.

An example of a test log that is displayed on the **Test log** page is as follows:



You can find the following details that are displayed on the **Test log** page:

Table 620. Test log details

Details about...	Examples as displayed in the Test log page...
The project name	An example of the project name that is displayed is as follows: Test
The name of the page	An example of the page name that is displayed is as follows: • Test log You can click the Test log link to view the test logs of all tests that ran in your project, if you are viewing the test log of a specific test run.
The name of the test asset	An example of the name of the asset that is displayed is as follows: 5cmptestsAFT
The date and time when the test run was started from the **Execution** page	An example of the date and time when the test run was started that is displayed is as follows:

Table 620. Test log details (continued)

Details about...	Examples as displayed in the Test log page...
	May 23rd 2022 4:38 PM
The activities and events captured in the test log are displayed in the **Tree view** in the **Test log** panel.	An example of the log in the tree view that is displayed is as follows: An event in the test log. Details of the event is displayed in the **Properties** panel.	An example of the details that is displayed in the **Properties** panel is as follows:

Table 620. Test log details (continued)

Details about...	Examples as displayed in the Test log page...
	The link to a URL that is recorded in an event. The URL is displayed as a link. When you click this link, the specific URL opens in a web browser.	An example of a link recorded in the event. An attachment of an event in the test log. The details of the attachment is displayed in the **Properties** panel.	An example of a text extracted from the attachment.

Table 620. Test log details (continued)

Details about...	Examples as displayed in the Test log page...
The reason of a Verification Point (VP) that is captured in an event in the test log is displayed in the **Properties** panel.	An example of the reason in a VP that is displayed in the **Properties** panel is as follows:

You can perform the actions detailed in the following table to change the view of the test log, find details of the events captured, navigate through the log, view or download attachments that are captured.

Table 621. Tasks that you can perform on the Test log page

Task	Action
Changing the *Tree view* to a *Flat view* for the display of events in the test log panel. **Note:** The *Tree view* is the default view of the events in the test log.	Click to toggle from the **Tree view** to the **Flat view**. **Note:** You can change the view from the one that is displayed by clicking .
Expanding the display of events in the test log panel.	Click to expand the events that are contained within the event selected in the test log panel. For example, the collapsed view in the test log panel can be as follows: 
Table 621. Tasks that you can perform on the Test log page (continued)

Task	Action
	When the event is expanded, the view in the test log panel can be as follo  ws:
Collapsing the display of events in the test log panel.	Click Collapse to collapse the events that are contained within the event selected in the test log panel.
Viewing primary activities when all activities are displayed.	Perform the following actions in the test log panel: 1. Click the **Open action menu** icon. 2. Click **Show only primary activities**. The primary activities captured in the test log are displayed.
Viewing all activities when only primary activities are displayed.	Perform the following actions in the test log panel: 1. Click the **Open action menu** icon. 2. Click **Show all activities**. All the activities captured in the test log are displayed.

Table 621. Tasks that you can perform on the Test log page (continued)

Task	Action
Viewing failures captured in the test log.	The test log displays events marked with a colored vertical bar as follows: • A green bar is marked for an event that passed in the test step. • An orange bar is marked for an event that had an error in the test step. • A red bar is marked for an event that failed in the test step. For example, the view can be as follows:  You can navigate up and down in the view from one error or failed event to another one by using arrows .
Searching for events in the test log.	In the search bar, you can enter text to find instances of events and properties that match with the text you entered. As a result of the search, the title of the nodes in the view and the names of the properties are highlighted. When the number of results found is displayed, you can press the **F3** key to navigate from one search result to another in the tree view or flat view. You can press **Ctrl** and **F3** to navigate from one result to another in the properties pane.
Viewing the properties related to the event that you select in the test log panel.	When you select an even in the test log panel, its properties are displayed in the properties panel. For example, the details that are displayed for an event can be as follows:

Table 621. Tasks that you can perform on the Test log page (continued)

Task	Action
	 You can view the following information: • The variable in the event is displayed. • The date stamp showing the time at which the event was captured in the test log. You can toggle between the calendar time and the duration from the time the test started its run in the cluster by clicking the **Date** and **Time** toggle icon . In the example, the date that is displayed in the **Time** field is as follows: When the **Time** option is selected, the duration that is displayed in the **Time** field is as follows:

Table 621. Tasks that you can perform on the Test log page (continued)

Task	Action
	 This time is the time that has elapsed from the start of the test run to the event in the test step. • The name of the event. • The event ID. • Data that was captured as part of the test step. The items that are captured can be images, text files, PDF files, XML files, JSON files, and other supported formats. You can view the attachment that is in the **Data** field, if it is supported to be viewed in a web browser by clicking the attachment. The attachment displays in a browser tab other than the one in which the **Test log** page is displayed. You can also copy the URL of the attachment or download a copy to your computer to use the attachment elsewhere.
Viewing all test logs in the **Test log** page.	When you view the test log of a specific test asset and you want to return to the **Test log** page to view the test logs of the other test assets, you can click the **Back to test logs** option.

Test log queries

When a test run is complete in Test , if a test log is generated, you can run queries to extract and view test log data. The query is used to search for the events or activities in the test logs with a project or a result scope.

The query page contains a configuration section in which you enter and select search criteria.

The difference between an activity and an event are the following ones:

- An activity is characterized by a duration whereas an event is characterized by a particular time.
- An activity contains events.

When you define the search criteria and run a query, the returned test log data is displayed in a table. You can manage the data in the table by adding, moving, or deleting the columns.

Prerequisites

To get result log data queries, you must configure your tests with one of the following parameters to enable the test log and data query process:

- For JMeter, JUnit, Postman and HCL AppScan CodeSweep Suites, set the **history cisterna** parameter in the **Additional Configuration Parameters** field in the **Advanced** settings

.
- For API tests and Suites, AFT Suites and Functional test, and Compound Tests, set the **-history cisterna** parameter in the **Program Arguments** field in the **Advanced** settings.

Note: When you set this parameter, you can run your queries to collect test log data into Test.

Query scope

A **Test result query** link is available in the test reports in the **Results** page when a test log is generated. If you click the link, it opens the query page in Test where you can view all the events or all the activities for the current test result only. In the **Scope** field of the query page, you find the result id. You can run new queries with different properties as search criteria for this result.

You can also run new queries with different properties as search criteria for all the results in a project if you open the query page from **Analyze > Queries** in the navigation pane. In this case, the **Scope** field is at the project level.

In the **Queries** page, you can perform the following actions:

- Filter the events or activities.
- Sort your query results in an ascending or a descending order.
- Add, move, or delete fields in the columns of the table that displays the data of the query.
- Save a query, rename, reset or delete a query.
- Export a query.

You can export the queries to Shell, Curl, or PowerShell scripts. You can select the script, the output format, and the number of results that are returned by the query.

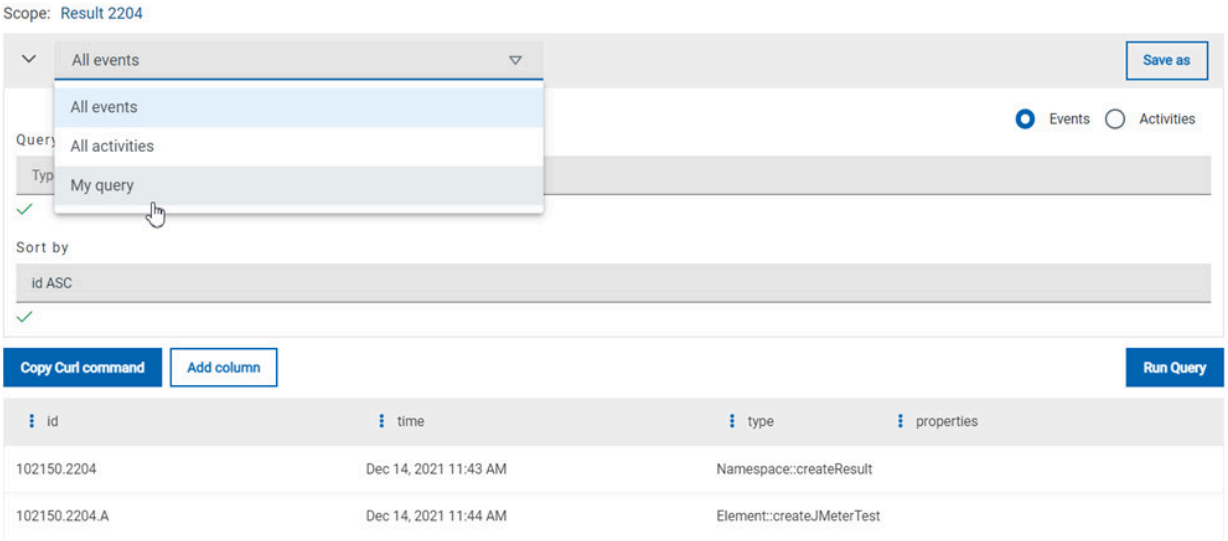
Configuring and running log queries

When a test run is complete and a test log created, you can configure and run queries to view test log data in Test for one test log result or for all the test log results in a project.

Before you begin

You must have completed the following tasks:

- Configured and run a test. See Test log queries on page 1538.
- Opened the Queries page from the Results page or the navigation panel.



About this task

In the **Queries** page, you can configure a query and save it. You can customize the way the log data is displayed in the results table.

1. Click **Events** or **Activites**.
2. Enter properties and operators in the **Query filters** to filter the list of events or activities.

   Note: You can use the **Ctrl-Space** keyboard shortcut in this field to get the list of properties and operators that you can enter as filters to create your query.

   Example: Select **Activities** and enter 'type is JUnitTest' in **Query filters**.

3. Click **Run Query**.
4. Perform the following steps to save a query:

   a. Click **Save as**.
   b. Enter a name to identify the new query and click **Save**.

   Example: Enter 'My query'.

   Result

   The new query is displayed in the events and activities list.
5. Perform any of the following actions to configure the results table:

- Enter a property followed by the **ASC** operator or **DESC** in **Sort by** to sort the data in the table.

  Note: ASC is used to sort the data from the lowest value to the highest value and **DESC** to filter the data in a descending order. You can use the **Ctrl-Space** keyboard shortcut to assist you. If you enter a combination of sort criteria, separate them with commas.

  Example: Click the **Sort by** field, press **Ctrl-Space** and select in the list 'time' and enter 'ASC'.

- Click the action menu in a column of the table to change the column display, and then perform any of the following actions:
  - Click **Insert new column**, enter a field name in **Search new column** and click **Add**.
  - Click **Move** to move a column before or after another one in the table.
  - Click **Remove** to remove a column from the table.
- Follow these steps to add a column to the end of the table:
  a. Click **Add column**.

     Result: A window opens.

  b. Enter a field name in **Search new column**.
  c. Click **Add**.

6. Click **Save** to save the configuration of the results table.
7. Follow these procedures to manage your query after it is created:

   - Click the action menu that is next to the **Save** button and select **Reset** if you have just modified a query and you want to undo your modification.
   - Click the action menu and select **Delete** to delete the new query from the **Events and activities** list.
   - Click **Copy Curl command** if you want to export a query.

     Note: The curl command is copied to the clipboard. You can paste it in a command interface to use the query in an external tool.

Adding additional properties in test results

When you want to add additional properties to be included in test results after the test is run, you can do so by configuring a webhook to receive the customized results and defining the parameters in Test .

Before you begin

You must have completed the following tasks:

- Read and understood Configuration of a webhook on page 1762.
- Read and understood Configuring a webhook template on page 1763 and Configuring a server webhook on page 1771.

About this task

You can set up webhooks to send notifications to various messaging apps such as Microsoft Teams or Slack, or to any application that can receive an HTTP POST request, whenever specific events happen on Test. For instance, a webhook can be triggered when a test run fails. After the event, the payload that is received by the application contains the details of the event, including the additional parameters that are added. If you want the result events to be correlated when using systems such as DevOps Velocity, you must add the properties that are present in the webhook template as additional parameters in the **Execute test asset** window.

1. Navigate to your project in Test.
   The **Overview** page of the project is displayed.
2. Click **Manage > Webhooks**.
   The **Templates** tab is displayed.
3. Click **New Template**.
   The **New template** page is displayed.
4. Perform the following actions on the **DETAILS** tab.
   a. Enter a unique name for the template.
   b. Create a new channel type by clicking **Create new channel type ...** option.

      The **New channel type** dialog is displayed.

   c. Enter a unique name for the channel type, and then enter a description for the channel type.
5. Click **Apply**.
   The channel type is created and added to the **Channel Type** list.
6. Click **This template is suitable for events** and select the events from the **Execution Events** list.
7. Click the **Template** tab.
8. Click one of the following icons to select a predefined template sample in the **Template body**:
   - The **infinity** icon to insert a DevOps Velocity template
   - The **cloud** icon to insert a cloud event JSON template
   - The **Microsoft Teams** icon to replace a template with a Microsoft Teams template
   - The **Slack** icon to replace a template with a Slack template

   A message is displayed about the action that inserts a text in the template body.
9. Click **Ok**.
10. The text is inserted in the **Template body**.
11. Click **Apply**.
    The template is created and added to the **Templates** tab.
12. Click the **Webhooks** tab, and then click **New Webhook**.
    The **New Webhook** page is displayed.

13. Enter a name for the webhook in the **Name** field.
14. Enter the callback URL of the application or channel for which you are configuring a webhook in the **Webhook URL** field.
15. Click the **Channel Type**, and then select the channel type that you just created from the list.
16. Enter a description for the webhook in **Description**.
17. Select the template that you just created from the drop-down list.
18. Click **Apply**.
    The webhook is created and added to the **Webhooks** tab.
19. Click **Execution**, in the navigation pane.
20. Select the test that you want to run and click in the **Actions** column to open the **Execute test asset** window.
21. Click **Advanced settings**.
22. Enter a parameter name that starts with result.property in the first edit field under **Additional Configuration Parameters**.
    For example, result.property.test_version.
23. Enter a value for the newly added parameter in the second edit field under **Additional Configuration Parameters**. For example, v1.5.14.
24. Click **Add** for the added parameter.
    You can add multiple parameters.
25. Click **Execute**.

Results

The additional parameter values are captured while your test is running. You can see the values in the response notification that you get for the webhook after the test run is complete.

What to do next

Navigate to the application or channel for which you have configured the webhook for receiving test result notifications, and then view the results.

Prerequisites to running tests on page 1057

Test run configurations on page 1134

Machine learning capabilities in DevOps Test

Test uses Machine learning (ML) algorithms to analyze tests that match certain requirements and criteria, and then presents the findings as insights and recommendations after the tests are run. You can use the insights and recommendations to interpret the test results and identify the problem areas in the system under test.

Test has incorporated ML capabilities to provide an automated means to identify problems in the system under test.

Tests analyzed through ML

The following types of tests are supported for analysis by using ML capabilities in Test:

- Performance tests
- Schedules

Parameters analyzed through ML

The following parameters in Performance tests or Schedules are supported for analysis by using ML capabilities in Test:

- The **Response Time Lock-Step Pattern** parameter.
- The **Response Time Standard Deviation Pattern** parameter.
- The **Throughput Drop Pattern** parameter.
- The **Performance Agent Health** parameter.

Test uses different analyzers for each of the parameters. For example, Test uses the **Response Time Lock-Step Pattern** analyzer to analyze the tests for the **Response Time Lock-Step Pattern** parameter.

Criteria for analysis of the parameters

The following table lists the criteria used by the analyzers for analysis of the parameters in Test:

Parameter analyzed	Criteria for analysis
Response Time Lock-Step Pattern	The analyzer identifies the **Response Time Lock-Step Pattern** parameter in the overall page response time observed against the user count based on the following criteria: • Tests have a minimum of 20 users. • Tests run for longer durations for a trend to be observed. • Tests contain a minimum of three different user groups and each group has an activity of more than two minutes.
Response Time Standard Deviation Pattern	The analyzer attempts to detect the response time of pages that are more than thrice the value of the standard deviation calculated for the page response time as the **Response Time Standard Deviation Pattern** parameter.
Throughput Drop Pattern	The analyzer attempts to detect sudden drops in network throughput as the **Throughput Drop Pattern** parameter that is based on the following criteria:

Parameter analyzed	Criteria for analysis
	Note: Sudden drops in throughput might be related to the performance tool itself, issues with network connectivity, or issues with signal-scalability of the system under test. • Tests have a minimum of 20 users. • Tests have stages with a reasonably high number of samples within a stage. • The length and intensity of the throughput drops that are less than 20% of the median observed within a stage are considered by the analyzer. When no throughput is received within 60 seconds, such drops are considered in the analysis. Short shark-tooth patterns in drops are not considered by the analyzer. • Parts of the stage with increasing users are not considered for analysis. For example, when the test adds one user every minute and the user range is between one user to 500 users, the **Throughput Drop Pattern** parameter is not analyzed.
Performance Agent Health	The analyzer inspects the health of agents that are participating in a performance execution and identifies potential configuration issues based on the following criteria: • **Minimum requirements** ◦ At least 10 users ◦ At least 10-minute run time ◦ Requires schedule with at least 1 static agent (Performance Agent Health insight is not generated if you are running the test on local host) • **Blocking threads** ◦ Considered as Blocking threads when 90% of available threads are used for 20% of the run time • **Pegged CPU** ◦ Considered as Pegged CPU when 90% of CPU is utilized for 10% of the run time • **Pegged CPU for interval** ◦ Considered as Pegged CPU for interval when there are intervals of high CPU utilization greater than 95% For example, above 95% of CPU utilized for 50% of a 10-minute interval or 98% of CPU utilized over a shorter interval. ◦ Considered as Pegged CPU for interval when there are spikes in CPU utilization during long test runs

Parameter analyzed	Criteria for analysis
	The agents that are not configured properly can distort performance assessments of the system under test. The analyzer can provide multiple insight types. The insight recommendation texts are parametrized and they provide specific recommendations such as identifying the agents with issues. You can view the following insights: • Pegged CPU for run insight • Pegged CPU for interval insight • Blocked thread insight

Analysis at the project level

When you as a *Project Owner* or *Tester* configure a run of a Performance Test or a Schedule from your project in Test, you must ensure that the criteria required for ML analysis are met. During the test run, Test uses its ML capabilities to analyze the supported parameters and presents its findings as insights on the **Insights** page.

Any member of your project can view the insights by clicking **Analyze > Insights** from the navigation in the project or from the **Insights** section on the **Overview** page in the project.

Project members after viewing the insights can react by either agreeing or disagreeing with the insights suggested by Test.

Analysers in a team space

You can view the list of analysers and description about the analyzers available in a Team space by clicking **Infrastructure > Analyzers** from the navigation in the team space. Also, you can enable or disable the analyzer, view the count of the reviewed insights and the review history of the insights generated by the analyzers.

After viewing the recommendation for a specific parameter, members of the project can alter the default threshold value that specifies the level of confidence required in the analysis of the parameter and run the tests again to improve the accuracy of the recommendations and insights.

You can also improve the accuracy of the recommendations by running multiple tests with differing loads repeatedly.

Using Machine learning capabilities

You can find information in the following documentation about using Machine learning (ML) capabilities in Test:

- To understand the requirements of Performance tests or Schedules that are analyzed by using ML capabilities in Test, see Test run considerations for using Machine learning capabilities on page 1064.
- To configure a run of a Performance Test, see Configuring a run of a Performance test on page 1296.
- To configure a run of a Schedule, see Configuring a run of a Rate Schedule or VU Schedule on page 1404.
- To view the ML insights into the Performance tests or Schedules in your project, which were analyzed after a run, see Viewing Machine learning insights on page 1547. You can also select your reaction to agree or disagree with the insights provided when you view the insight.

- To understand how to interpret the insights, see Interpretation of insights on page 1549.
- To view the ML analysis of the supported parameters when Performance tests or Schedules that are in different projects in your team space are run, see Viewing Machine learning analyzers on page 1553.
- To understand how to interpret the recommendations of the ML analysis of the supported parameters, see Interpretation of parameter analysis on page 1555.
- To view the reactions of project members to the ML insights, see Viewing reactions marked by members to Machine learning insights on page 1558.
- To modify the settings of the ML analyzer for a specific parameter, see Modifying Machine learning analyzer settings on page 1560.
- To delete the ML insights provided about the Performance tests or Schedules that were analyzed, see Deleting Machine learning insights on page 1562.
- To rerun the ML analysis without rerunning the test asset, see Rerunning Machine learning (ML) analysis on page 1563.

Viewing Machine learning insights

When you want to use Machine learning (ML) capabilities in Test , you need to run Performance Tests or Schedules that conform to certain criteria. After the test run is completed, you can view the ML insights on the **Insights** page in your project.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Ran the Performance Test or Schedule that matches the minimum requirements for ML analysis in Test. See Configuring a run of a Compound Test that contains performance tests on page 1260 or Configuring a run of a Rate Schedule or VU Schedule on page 1404.

About this task

If the Performance Tests or Schedules match the requirements and criteria for ML analysis, Test analyzes the test results for the relevant parameter and presents its findings as insights into the parameter.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Perform any of the following actions to view the insights:
   - Scroll down the **Overview** page to see the **Insights** section.

     Go to Step 4 on page 1548 for the actions that you can perform to view the insights.
   - Click **Analyze > Insights** in the navigation pane.

The **Insights** page is displayed.

Go to Step 5 on page 1548 for the actions that you can perform to view the insights.

4. Perform the following steps to view a specific insight from the **Overview** page:

   The **Insights** section on the **Overview** page displays a table of the insights for the supported parameters identified from the tests that were run in the project. The table lists the level of confidence with which the analysis of the specific parameter was done, the parameter analyzed, the name of the test asset, and the timestamp of the completed analysis.

   a. Click any item in the row of a specific insight to view the details of that insight.

      The **Insights** page is displayed with the details of the specific insight.

      Note: If you want to view the list of the other insights that are available in your project, you can click **Back to all insights**, and the list of available insights in the project is displayed in a tabular view.

   b. Go to Step 6 on page 1548.

5. Perform the following steps to view a specific insight from the **Insights** page:

   a. Identify the test asset or the parameter by performing any of the following actions:

      - Search for the test asset or parameter by entering any text contained in its name in the **Search** field.
      - Sort the items in the table of insights by clicking any of the column headers, and then identify the insight.

        For example, you can sort the items based on the name of the test asset in an ascending order or descending order, and then identify the test that you ran.

      You identified the insight.

   b. Click the **Expand** icon > of the insight.

      The details of the specific insight are displayed.

   c. Go to Step 6 on page 1548.

6. Perform the following steps when the details of the insight are displayed.

   a. Read the details about the analysis and the issues that are identified by the analyzer.

   b. Correlate the graph analyzed by the analyzer with your observations on the parameter.

   c. Select your reaction to either agree or disagree with the insight by performing the following actions:

- Click the **Agree** icon, if you agree with the insights provided.

  After you agree, the icon changes to and displays the text `Agreed by username` when you hover over the icon.

- Click the **Disagree** icon, if you disagree with the insights provided.

  After you disagree, the icon changes to and displays the text `Disagreed by username` when you hover over the icon.

Note: A member of a project can only react once by either agreeing or disagreeing with the insight.

Results

You viewed the details of the insights into the parameters that are analyzed by Test.

What to do next

You can perform any of the following tasks:

- Understand how to interpret the insights. See Interpretation of insights on page 1549.
- Delete an insight. See Deleting Machine learning insights on page 1562.
- Rerun the analysis so that the deleted instance of the insight is redisplayed. See Rerunning Machine learning (ML) analysis on page 1563.

Interpretation of insights on page 1549

Interpretation of insights

You can find information about interpreting the Machine learning (ML) insights into the supported parameters that are analyzed by Test after certain tests are run.

Parameters analyzed through ML

The following parameters in Performance tests or Schedules are supported for analysis by using ML capabilities in Test:

- The **Response Time Lock-Step Pattern** parameter.
- The **Response Time Standard Deviation Pattern** parameter.
- The **Throughput Drop Pattern** parameter.
- The **Performance Agent Health** parameter.

Test analyzes the parameters based on certain criteria as detailed in Criteria for analysis of the parameters on page 1544 and then presents its findings as insights about the parameters.

Details of the insights

The insights about the parameters analyzed are displayed in the **Insights** section on the project **Overview** page or on the **Insights** page in a project.

The insights analyzed for the parameters from various tests that were run in the project are listed in a table. The table lists the following information:

- Name of the test asset in the **Test** column.
- The parameter analyzed in the **Insight** column.
- The level of confidence with which the analysis of the parameter was done in the **Confidence** column. The level of confidence displayed for the analysis can be as *Lowest*, *Low*, *Medium*, *High*, or *Highest*. You can view the confidence level as a number when you hover the cursor over the text in the **Confidence** column.
- The timestamp of the completed analysis in the **Identified on** column.
- The labels that you added for the specific test run in the **Labels** column.
- The components in the System Model that are associated with the test asset in the **Components** column.

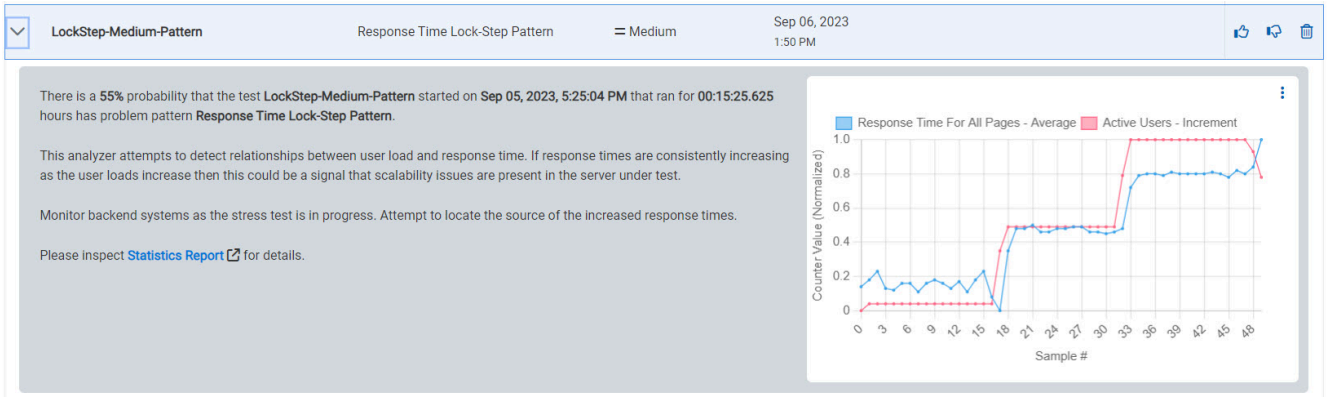
You can click the **Expand** icon to view the details of the insight.

You can find information as an example about the following insights that help you to interpret the insight:

- Insights on the Response Time Lock-Step Pattern parameter on page 1550
- Insights on the Response Time Standard Deviation Pattern parameter on page 1551
- Insights on the Throughput Drop Pattern parameter on page 1551
- Insights on the Performance Agent Health parameter on page 1552

Insights on the Response Time Lock-Step Pattern parameter

When you expand the insight about the **Response Time Lock-Step Pattern** parameter, you can view the details displayed similar to the following sample:

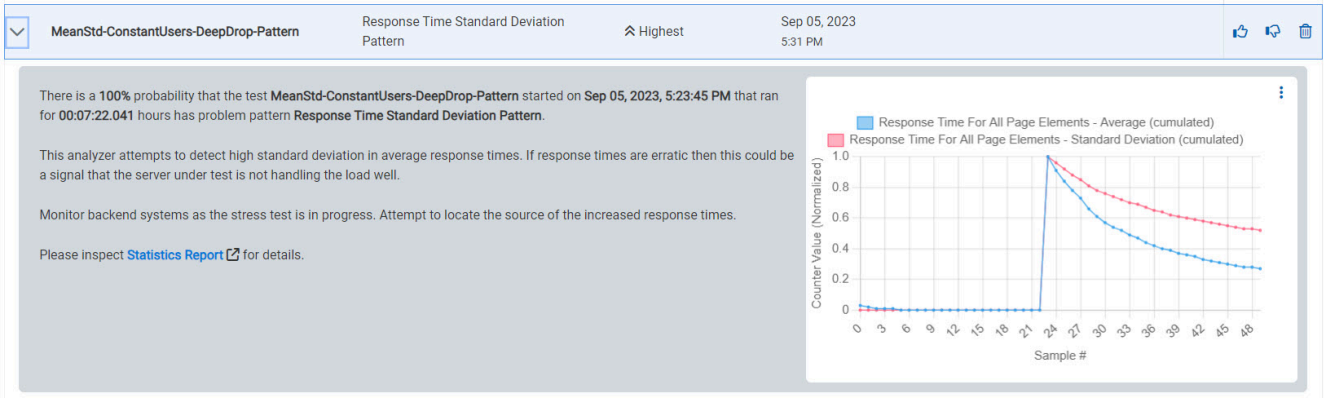


The following information is displayed as insights into the test on analyzing the **Response Time Lock-Step Pattern** parameter:

- The probability of finding a problem in the test.
- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as suggestions.
- The graph of the observed data points.
- The link to the Statistics Report generated for the test.

Insights on the Response Time Standard Deviation Pattern parameter

When you expand the insight about the **Response Time Standard Deviation Pattern** parameter, you can view the details displayed similar to the following sample:

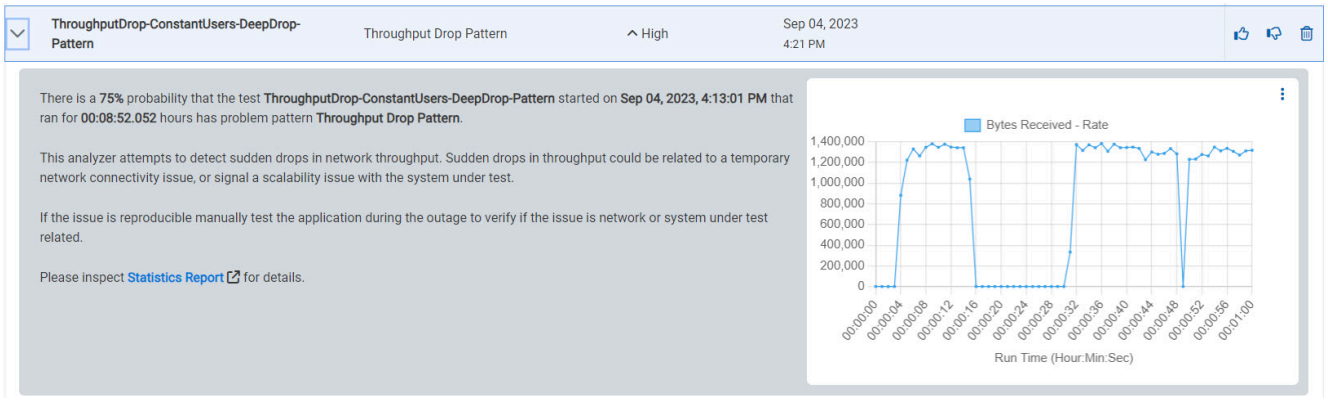


The following information is displayed as insights into the test on analyzing the **Response Time Standard Deviation Pattern** parameter:

- The probability of finding a problem in the test.
- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as suggestions.
- The graph of the observed data points.
- The link to the Statistics Report generated for the test.

Insights on the Throughput Drop Pattern parameter

When you expand the insight about the **Throughput Drop Pattern** parameter, you can view the details displayed similar to the following sample:

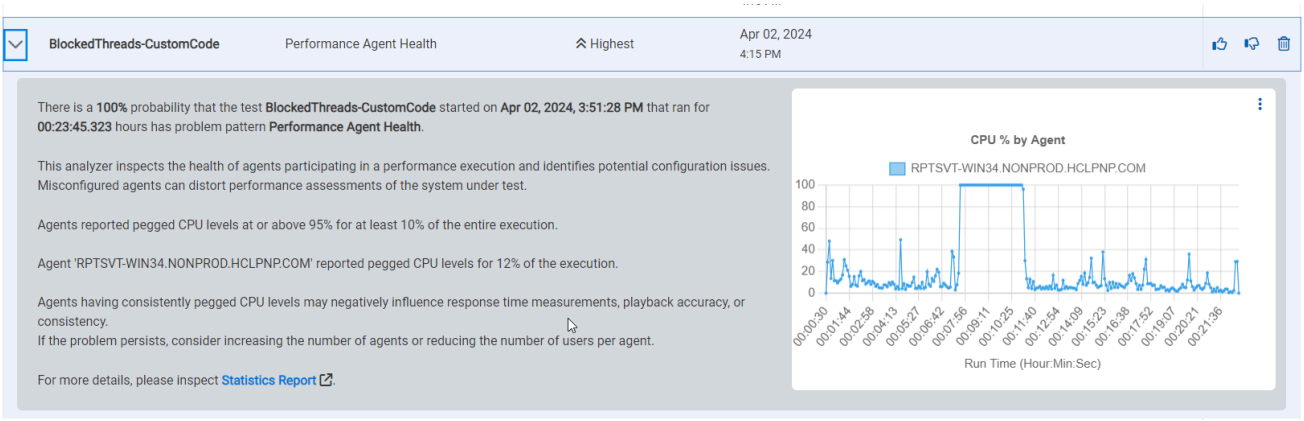


The following information is displayed as insights into the test on analyzing the **Throughput Drop Pattern** parameter:

- The probability of finding a problem in the test.
- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as suggestions.
- The graph of the observed data points.
- The link to the Statistics Report generated for the test.

Insights on the Performance Agent Health parameter

When you expand the insight about the **Performance Agent Health** parameter, you can view the details displayed similar to the following sample:



The following information is displayed as insights into the test on analyzing the **Performance Agent Health** parameter:

- The probability of finding a problem in the test.
- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as suggestions.
- The graph of the observed data points.
- The link to the Statistics Report generated for the test.

Viewing Machine learning insights on page 1547

Viewing Machine learning analyzers

Test analyzes certain types of tests that are run in a team space by using its Machine learning (ML) capabilities. You can view the list of analysers and description about the analyzers available in a Team space.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Ran the Performance Test or Schedule that matches the minimum requirements for ML analysis in Test. See Configuring a run of a Compound Test that contains performance tests on page 1260 or Configuring a run of a Rate Schedule or VU Schedule on page 1404.

About this task

If the Performance Tests or Schedules that are run from projects in a team space match the requirements and criteria for ML analysis, Test analyzes the tests during their runs.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Analyzers** in the navigation pane.

   The **Analyzers** page is displayed.

   You can view the parameters that are supported for ML analysis listed in a tabular format. The information displayed is as follows:

Column header	Description
Status	Displays the status of the parameter analysis as active or inactive in the team space. The default value of the analysis is set as active or enabled.
Name	Displays the name of the parameters that are supported for ML analysis, which is as follows: ◦ **Response Time Lock-Step Pattern** ◦ **Response Time Standard Deviation Pattern** ◦ **Throughput Drop Pattern** ◦ **Performance Agent Health**
Version	Displays the version of the ML analyzer.
Last Run	Displays the date when the tests were run for the analysis.

<table>
<tr><th>Column header</th><th>Description</th></tr>
<tr><td>Unreviewed insights</td><td>Displays the number of insights into the specific parameter analyzed from different tests that are not reviewed by the project members.</td></tr>
<tr><td>Actions</td><td>Displays the following icons for the actions that you can perform on each parameter analyzed:
<table>
<tr><th>Icon</th><th>Description</th></tr>
<tr><td> </td><td>Displays the Edit Analyzer dialog when clicked. You can modify the analyzer settings for subsequent analysis.</td></tr>
<tr><td> </td><td>Displays a dialog that contains the list of the reactions marked by different members on insights into the specific parameter when clicked. The agreement or disagreement reactions by members with the date and time of marking them are listed in chronological order in the dialog. You can view the insight on the Insights page in the project when you click .</td></tr>
</table>
</td></tr>
</table>

3. Click the **Expand** icon of the parameter to view the details.

   The details of the parameter are displayed.

4. Read the details about the analysis and recommendations for troubleshooting or resolving the problems detected in the analysis.

   See the information in the related links to understand how to interpret the analysis of the parameters.

Results

You viewed the details of the parameters that are analyzed by Test in tests that were run in the team space.

What to do next

You can perform any of the following tasks:

- Understand how to interpret the recommendations from the analysis of the parameters. See Interpretation of parameter analysis on page 1555.
- View reactions by members to an insight. See Viewing reactions marked by members to Machine learning insights on page 1558.
- Modify the ML analyzer settings. See Modifying Machine learning analyzer settings on page 1560.

Related reference

Interpretation of parameter analysis on page 1555

Interpretation of parameter analysis

You can find information about interpreting the details of each of the Machine Learning (ML) analyzers that analyze the parameters after certain tests are run in Test .

Parameters analyzed through ML

The following parameters in Performance tests or Schedules are supported for analysis by using ML capabilities in Test:

- The **Response Time Lock-Step Pattern** parameter.
- The **Response Time Standard Deviation Pattern** parameter.
- The **Throughput Drop Pattern** parameter.
- The **Performance Agent Health** parameter.

Test analyzes the parameters based on certain criteria as detailed in Criteria for analysis of the parameters on page 1544. The ML analyzers analyze the results of tests run in all projects in a team space for each of the parameters. The analyzers present their findings on each of the parameters as an insight on the **Insights** page in the project.

Details of the parameters analyzed

The details about the parameters analyzed are displayed on the **Analyzers** page in the team space.

The parameters are listed in a table with the following information:

Column header	Description
Status	Displays the status of the parameter analysis as active or inactive in the team space. The default value of the analysis is set as active or enabled.
Name	Displays the name of the parameters that are supported for ML analysis, which is as follows: • **Response Time Lock-Step Pattern** • **Response Time Standard Deviation Pattern** • **Throughput Drop Pattern** • **Performance Agent Health**
Version	Displays the version of the ML analyzer.
Last Run	Displays the date when the tests were run for the analysis.
Unreviewed insights	Displays the number of insights into the specific parameter analyzed from different tests that are not reviewed by the project members.
Actions	Displays the following icons for the actions that you can perform on each parameter analyzed:

Column header	Description
	<table><tr><th>Icon</th><th>Description</th></tr><tr><td> </td><td>Displays the **Edit Analyzer** dialog when clicked. You can modify the analyzer settings for subsequent analysis.</td></tr><tr><td> </td><td>Displays a dialog that contains the list of the reactions marked by different members on insights into the specific parameter when clicked. The agreement or disagreement reactions by members with the date and time of marking them are listed in chronological order in the dialog. You can view the insight on the **Insights** page in the project when you click .</td></tr></table>

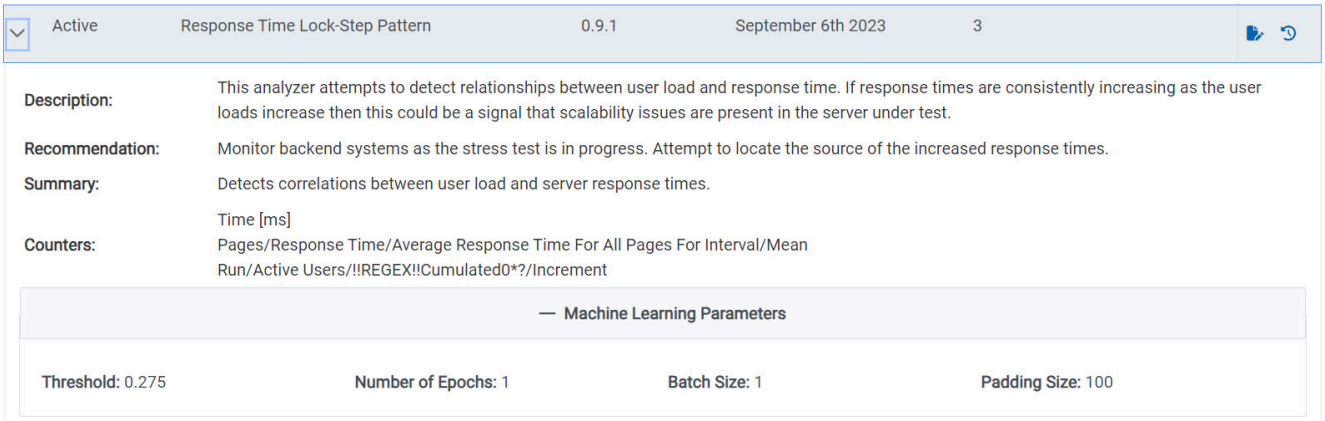
You can click the **Expand** icon to view the details of the parameter analyzed.

You can find information as an example about the following parameters that help you to interpret the parameter analysis:

- The Response Time Lock-Step Pattern parameter analyzer on page 1556
- The Response Time Standard Deviation Pattern parameter analyzer on page 1557
- The Throughput Drop Pattern parameter analyzer on page 1557

The Response Time Lock-Step Pattern parameter analyzer

When you expand the **Response Time Lock-Step Pattern** parameter, you can view the details displayed similar to the following sample:



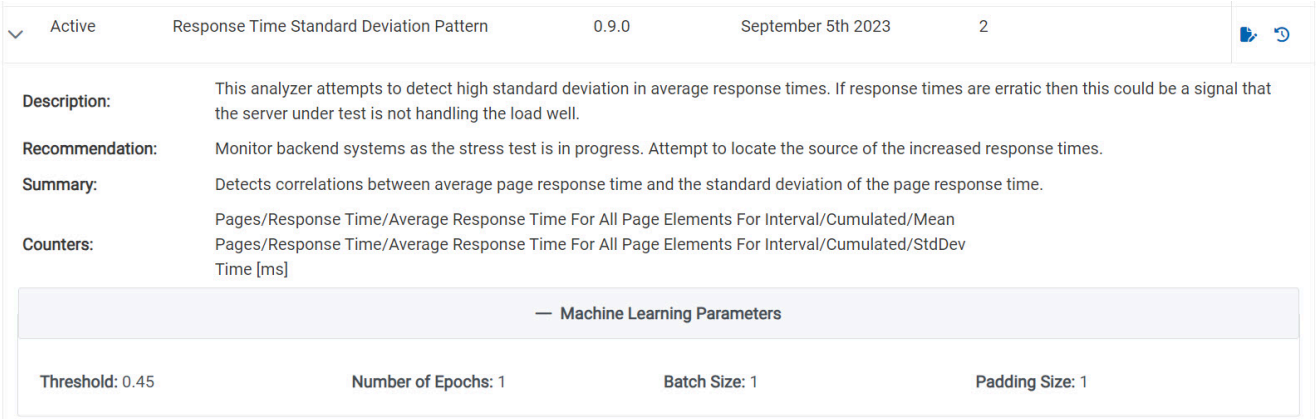
The following information is displayed for the **Response Time Lock-Step Pattern** parameter:

- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as a recommendation.
- The summary of the analysis.

- The counters used in the analysis.
- The parameters used in the analysis.

The Response Time Standard Deviation Pattern parameter analyzer

When you expand the **Response Time Standard Deviation Pattern** parameter, you can view the details displayed similar to the following sample:

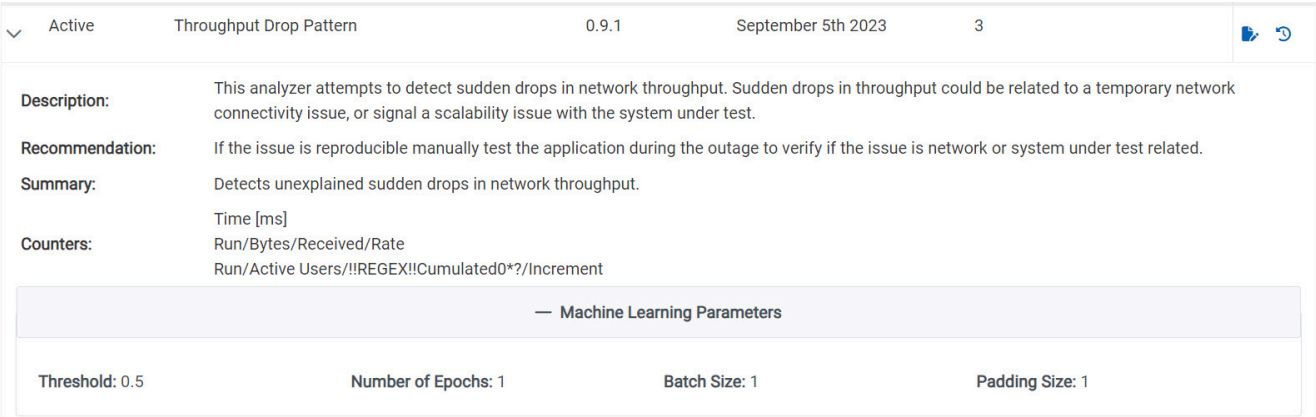


The following information is displayed for the **Response Time Standard Deviation Pattern** parameter:

- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as a recommendation.
- The summary of the analysis.
- The counters used in the analysis.
- The parameters used in the analysis.

The Throughput Drop Pattern parameter analyzer

When you expand the **Throughput Drop Pattern** parameter, you can view the details displayed similar to the following sample:

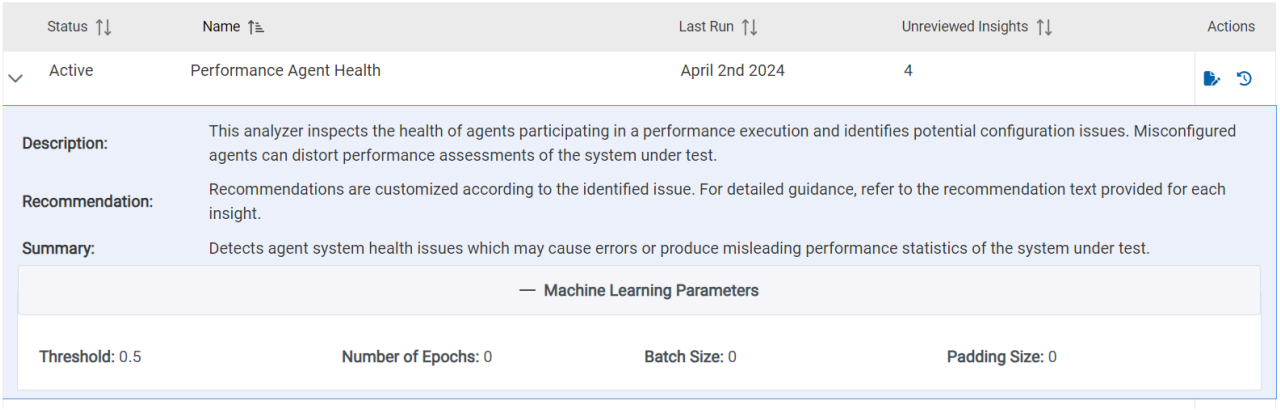


The following information is displayed for the **Throughput Drop Pattern** parameter:

- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as a recommendation.
- The summary of the analysis.
- The counters used in the analysis.
- The parameters used in the analysis.

The Performance Agent Health parameter analyzer

When you expand the **Performance Agent Health** parameter, you can view the details displayed similar to the following sample:



The following information is displayed for the **Performance Agent Health** parameter:

- The description of how the ML analyzer has attempted to analyze the parameter in the test.
- The methods to control the problems are provided as a recommendation.
- The summary of the analysis.
- The parameters used in the analysis.

Related information

Viewing Machine learning analyzers on page 1553

Viewing reactions marked by members to Machine learning insights

You can view the reactions that members of a project mark to show their agreement or disagreement with the insights into the parameters on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Ran the Performance Test or Schedule that matches the minimum requirements for ML analysis in Test. See Configuring a run of a Compound Test that contains performance tests on page 1260 or Configuring a run of a Rate Schedule or VU Schedule on page 1404.
- Viewed the ML insights and marked your reaction to an insight. See Viewing Machine learning insights on page 1547.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Insights** in the navigation pane.

   The **Insights** page is displayed.
4. Identify the test asset or the parameter by performing any of the following actions:

   - Search for the test asset or parameter by entering any text contained in its name in the **Search** field.
   - Sort the items in the table of insights by clicking any of the column headers, and then identifying the insight.

     For example, you can sort the items based on the name of the test asset in an ascending order or descending order, and then identify the test that you ran.

   You identified the insight.
5. Use the information in the following table to interpret the reactions marked for the insight:

If the icon is displayed as	Interpretation of the reaction
	None of the members agreed with the insight.
	At least one member agreed with the insight. **Note:** The name of the member who reacted is displayed as `Agreed by` *`username`* when you hover over the icon.
	None of the members disagreed with the insight.
	At least one member disagreed with the insight. **Note:** The name of the member who reacted is displayed as `Disagreed by` *`username`* when you hover over the icon.

Results

You viewed the member reactions to an insight from the **Insights** page.

What to do next

You can perform any of the following tasks:

- Modify the threshold value of a specific parameter based on the number of disagreements marked by members so that you can improve the accuracy of the insight. See Modifying Machine learning analyzer settings on page 1560.
- Repeat the test runs with the updated thresholds to improve the Machine Learning insights for the specific parameter. See Test run configurations on page 1134.

Modifying Machine learning analyzer settings

When you want to change the decision threshold set for a Machine learning (ML) analyzer or disable the analyzer, you can modify the settings from the **Analyzer** page.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Ran the Performance Test or Schedule that matches the minimum requirements for ML analysis in Test. See Configuring a run of a Compound Test that contains performance tests on page 1260 or Configuring a run of a Rate Schedule or VU Schedule on page 1404.
- Viewed the insights into tests provided by ML analysis. See Viewing Machine learning insights on page 1547.
- Viewed the reactions from members of your project to the ML insight. See Viewing reactions marked by members to Machine learning insights on page 1558.
- Viewed the history of member reactions for a specific parameter analyzer from the **Analyzers** page. See Viewing Machine learning analyzers on page 1553.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Analyzers** in the navigation pane.

   The **Analyzers** page is displayed. You can view the parameters that are supported for ML analysis listed in a tabular format.

3. Identify the parameter whose analyzer you want to modify, and then click the **Edit Analyzer** icon in the **Actions** column in the row of the parameter.

   The **Edit Analyzer** dialog is displayed.

4. Perform any of the following actions to modify the default settings for the ML analysis of the specific parameter.

If you want to...	Action
Disable the analysis for the specific parameter.	Perform the following steps: a. Click **Is Enabled** to switch the analysis from being enabled or active to become disabled or inactive. **Note:** If you modify the default setting to be disabled, Test does not perform ML analysis of the specific parameter when tests are run subsequently. b. Click **Submit**.
Enable the analysis for the specific parameter, if it is disabled.	Perform the following steps: a. Click **Is Enabled** to switch the analysis from being disabled or inactive to become enabled or active. b. Click **Submit**.
Increase or decrease the threshold level.	Perform the following steps: a. Edit the value in the **Decision Threshold** field and enter a value as required. The threshold value determines the level after which the ML analysis identifies an insight into the specific parameter when the test runs. **Note:** You can retain the default values for the decision threshold initially until a large number of tests are run that contribute to the insights for a specific parameter. You can change the value to a higher threshold when there are a large number of records learned by the ML analyzers. b. Click **Submit**.

Results

You either disabled or enabled the analyzer or changed the decision threshold set for a ML analyzer.

What to do next

You can perform any of the following tasks:

- Rerun the analysis of the test with the changed threshold values without running the tests again. See Rerunning Machine learning (ML) analysis on page 1563.
- Run tests if you changed the decision threshold values so that the ML analysis uses the changed values. See Test run configurations on page 1134.

- View insights into the specific parameter whose decision threshold was modified after the test runs are completed. See Viewing Machine learning insights on page 1547.
- View the ML recommendations for the specific parameter whose decision threshold was modified. See Viewing Machine learning analyzers on page 1553.

Deleting Machine learning insights

After you view the Machine learning (ML) insights into the tests, you might want to delete the insight if many members of your project disagree with the insight.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Viewed the insights into tests provided by ML analysis. See Viewing Machine learning insights on page 1547.
- Viewed the reactions from members of your project to the ML insight. See Viewing reactions marked by members to Machine learning insights on page 1558.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Perform any of the following actions to view and identify the insight:
   - Scroll down the **Overview** page to see the **Insights** section.

     The **Insights** section on the **Overview** page displays a table of the insights for the supported parameters identified from the tests that were run in the project. You can identify the insight and click any item in the row of the identified insight to display the insight on the **Insights** page.
   - Click **Analyze > Insights** in the navigation pane. The **Insights** page is displayed. You can identify the insight that you want to delete.
4. Click the **Delete** icon from the **Actions** column that is in the row of the identified insight.

   The **Delete Insight** dialog is displayed.
5. Click **Yes**.

   The insight is deleted and a confirmation message is displayed.

Results

You deleted an insight into the test arrived at by ML analysis of the test.

What to do next

You can perform any of the following tasks:

- Run tests to let the ML analyzers reanalyze and present the insights. See Test run configurations on page 1134.
- Rerun the analysis without running the tests again so that the deleted instance of the insight is redisplayed. See Rerunning Machine learning (ML) analysis on page 1563.

Rerunning Machine learning (ML) analysis

If you change the decision threshold value set for a parameter analyzer, you can then rerun the analyzer to analyze the parameter for the changed threshold and present the insight without running the tests again.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results** from the navigation pane in your project.

   The **Results** page is displayed.
4. Click the **SUITES** tab, if you ran a Schedule or the **TESTS** tab, if you ran a Performance Test.
5. Identify the test result for which you want to rerun the analysis by performing any of the following actions:
   - Search for the test result by entering any text contained in the test asset name in the **Search** field.
   - Sort the items in the table of results by clicking the **Started by** column header, and then identifying the test runs that you started.
6. Click the **Open action menu** icon from the **Actions** column that is in the row of the identified test result.
7. Click **Rerun analysis** .

   The parameter is analyzed again with the changed threshold vale and the insight presented.

Results

You started the ML analysis of the previously analyzed test result so that the insight can be displayed based on the changed threshold value without running the test again.

Resource monitoring

When you apply load to a system under test, the amount of resources consumed by your system is increasing. If the capacity of the resources does not match the load, you can see performance issues in the results. Resource monitoring in Test helps you monitoring the resources of a system and establish the performance metrics and usage data of the system. Thus, you can observe the health of these resources while a schedule is running.

You can use resource monitoring while running a schedule to capture data, such as processor or memory usage, or to monitor the availability of hosts and services by using counters. Test provides a comprehensive view of a system under test

to help determine problems. Hosts and services can be servers, virtual machines, or any local host or network services. You can also monitor remote hosts and services with agents.

Monitoring a host or a server

You can use resource monitoring to monitor any host and network service. This method is used for host targets that the service can reach directly. With Test, you can also monitor performance metrics that are collected and stored by a monitoring system that is monitoring a host. You can use a Prometheus server or a data collector through an exporter, OpenMetrics exporter, for example.

To monitor resources on a local system, you must add the source of the resource monitoring data from the resource monitoring page. Then you have to enter some connection settings and select the counters to monitor the sources. The metrics and usage data are exposed in a graph for each selected counter.

Monitoring a remote host with monitoring agents

You can monitor remote hosts and services with agents through wider sets of data collectors, computers, and networks. The purpose is to capture CPU load, disk space, memory, and the running process for example.

Agent-based monitoring is useful when remote services are not directly accessible from Test through the network. Agents are closer to the target that you want to monitor. You can set up the agent on an authorized host, for example, when access to an Apache httpd or NGINX server status page or a JVM JMX port, a Prometheus server, or an OpenMetrics exporter is restricted to one or few client hosts only. The configuration task is simplified, and no security changes are required.

Agent-based monitoring is mandatory to collect data from a Windows or Linux Performance host.

To monitor a host across a monitoring agent, you must first set up a resource monitoring agent on the target host for which you want to collect the performance statistics and usage data. The agent establishes a connection with Test. When the connection is set, the agent is showing up in the list of agents on the resource monitoring main page. Then, you can select the agent in the list of target sources in the dialog **Access target from** in the dialog that opens from **Add a Source**.

To learn more about configuring the resource monitoring sources, counters, and agents and collecting and viewing the data inTest, go through the information in the following links.

Resource monitoring capabilities

With Test , you can monitor a host or a service that you add to a project as a source. You can select the statistics counters that are used to collect metrics and the resource usage data throughout the monitoring system. You can visualize metrics and data that are gathered during the monitoring process in Test. You can add the resource monitoring sources and counters in a team space or in a project to collect metrics and resource usage data.

Requirements:

- You must be a *Team Space Owner* to create, modify and remove resource monitoring sources in a team space. Any team space *Member* (not owner) can only view resource monitoring sources.
- You must be a project *Owner* to create, modify and remove resource monitoring sources in a project. Any project *Member* (not the owner) can only view resource monitoring sources.

Supported sources

With Test, you can monitor resources for the following sources:

- **Apache httpd server**: You can optionally use agents.
- **NGINX and NGINX Plus**: You can optionally use agents.
- **Java Virtual Machine**: You can optionally use agents.

  You can monitor JVM resources from a local or a remote system. Some parameters must be set in the command before running the Java Virtual Machine. For more details, see the link to the page about starting a Java Virtual Machine on this page.

- **Windows Performance host**:

  To monitor the performance of a Windows host, you must have installed an agent on the target Windows host

  or on a Windows host that is configured to access the performance data of the Windows host target.

- **Linux Performance host**:

  To monitor the performance of a Linux host, you must have installed an agent on the target Linux host.

- **Prometheus server**:

  You can monitor metrics of a host under test that are collected by a Prometheus server. Prometheus collects metrics from monitored targets by regularly requesting appropriate HTTP endpoints on these targets (called *scraping*).

  The metrics data are collected through data collectors sets (groups of monitoring counters) that are tracking the system performance. The performance data results are stored in the Prometheus database so that they can be consumed by external systems through a REST API.

  In Test, you can query these performance metrics collected by Prometheus servers. 'PromQL' is the language for querying Prometheus metric data. Refer to Prometheus PromQL documentation for information about this query language.

  You can select default queries, or create additional ones.

  A Prometheus server is required. It must be configured to scrap a set of exporters, every 15 seconds by default. Pushgateway, service discovery, and Alertmanager are optional.

If Test cannot directly reach the Prometheus server, you can consider setting up an agent on an authorized host or on the same host that is running Prometheus.

- **OpenMetrics exporter**:

  You can monitor the metrics of a host under test that are collected and exposed through an OpenMetrics format or a Prometheus exporter format.

  Test can scrap metrics exposed by an OpenMetrics or Prometheus exporter through metric counters. No Prometheus server installation is required, you only need to set up one or multiple OpenMetrics, or Prometheus exporters that fit your software or host target.

  If Test cannot directly reach the Prometheus server, you can consider setting up an agent on an authorized host or on the same host that is running Prometheus.

Monitoring an NGINX server

To monitor an NGINX server, you must add the NGINX server source to Test , enter connection settings and select the counters that are used to capture the monitoring usage data.

Before you begin

You must have logged in Test and be the owner of an existing new project.

If you monitor a remote host, it must be connected with the computer that you use to access resource monitoring. See Resource monitoring agents on page 1581.

You can optionally use agents.

About this task

This task applies to NGINX and NGINX Plus.

If you use an agent to connect

1. Click **Infrastructure > Resource Monitoring**.
   The resource monitoring page opens.
2. In the resource monitoring page, click **Add a Source** and select **Add an NGINX server...**.
3. Fill in the following connection settings in the **New server** dialog:

   a. In **Target host**, enter the IP address or hostname and port number of the host where the server to monitor is installed.

   Note: For hosts that are already connected to Test through an agent, you have only the **Access target from** field enabled. Move directly to step 4.

   b. In **Server edition**, select the appropriate server from the drop-down list.

c. In **Path to the status page of the server**, enter the name of the page to view the status of the server.

Note: If you select NGINX Plus (with API version 3) as a source, you must specify the name of the path to view the API root of the NGINX Plus server.

d. In **Security**, select the following options:

Secured with TLS/SSL

If the application server is secured with TLS/SSL.

Trust self-signed certificate

To accept the server certificate.

Do not verify hostname

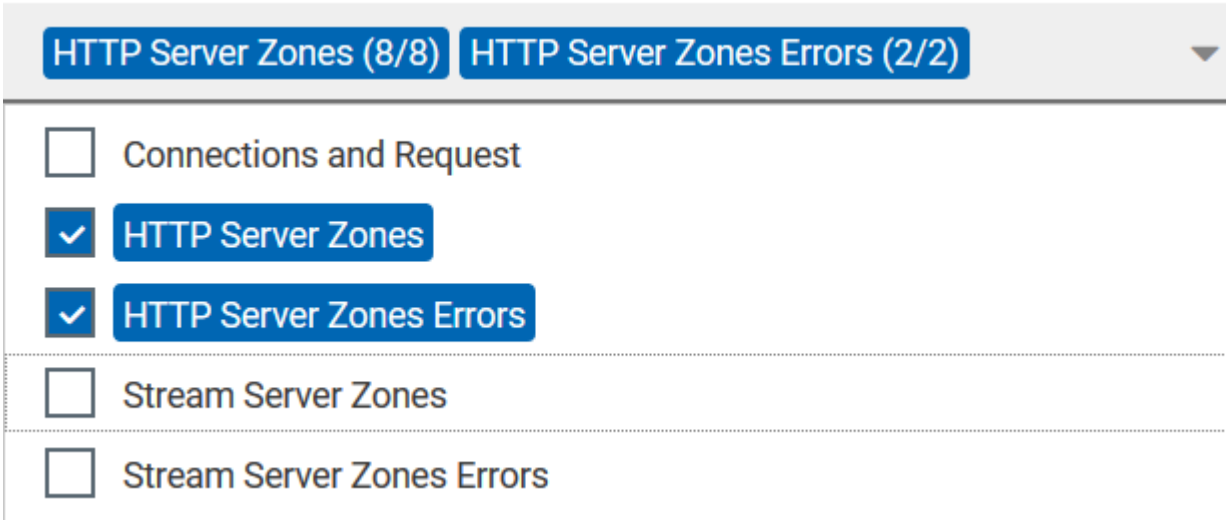
To ignore verification of the hostname in the certificate.

Require credentials

If the server requires log-in credentials, enter a **User name** and **Password**.

e. Click **Add**.
The **Choose Data Counters** dialog opens.

4. Select and save the statistics counters to monitor the source. You can select them from the list where they follow the server logical organization.
For a faster selection, select the counters from the built-in sets drop-down list where they are organized by theme and save your selection.



Note:

For Docker host, you can select different sets of counters.

- The first level of counters: Generic counters that are related to a Docker Image and all its running Docker Containers (in an exit, running or paused, created, restarted, removing, dead or transitive state).
- The second level of counters: Specific counters that are related to the existing Docker Containers.

Results

When the selected counters are saved, two tables are displayed in the resource monitoring main page. They contain the total number of sources you have added and the number of sources ordered by type.

What to do next

You can click the links in the tables to view the performance metrics of your monitored system.

Related information

Viewing resource monitoring usage data on page 1603

Monitoring an Apache httpd server

To monitor an Apache httpd server, you must add the Apache httpd server source to Test , enter connection settings and select the counters that are used to capture the monitoring usage data.

Before you begin

You must be logged in Test and be the owner of an existing new project.

You can optionally use agents. See Resource monitoring agents on page 1581.

1. Click **Infrastructure > Resource Monitoring**.
   The resource monitoring page opens. See Resource monitoring agents on page 1581.

2. In the resource monitoring page, click **Add a Source** and select **Add an Apache httpd server...**.
3. Fill in the following connection settings in the **New server** dialog:

   Note: For hosts that are already connected to Test through an agent, you have only the **Access target from** field enabled. Move directly to step 4.

   a. In **Target host**, enter the IP address or hostname and port number of the host where the server to monitor is installed.

   b. In **Server edition**, select the appropriate server from the drop-down list.

   c. In **Path to the status page of the server**, enter the name of the page to view the status of the server.

   d. In **Security**, select the following options:

      Secured with TLS/SSL

      If the application server is secured with TLS/SSL.

      Trust self-signed certificate

      To accept the server certificate.

      Do not verify hostname

      To ignore verification of the hostname in the certificate.

      Require credentials

      If the server requires log-in credentials, enter a **User name** and **Password**.

4. Click **Add**.
   The **Choose Data Counters** dialog opens.
5. Select and save the statistics counters to monitor the source. You can select them from the list where they follow the server logical organization.
   For a faster selection, select the counters from the built-in sets drop-down list where they are organized by theme and save your selection.

Results

When the selected counters are saved, two tables are displayed in the resource monitoring main page. They contain the total number of sources you have added and the number of sources ordered by type.

What to do next

You can click the links in the tables to view the performance metrics and resource monitoring usage data for the monitored server.

Monitoring metrics collected by a Prometheus server

You can monitor your system resources by using metrics data that are collected by a Prometheus server while executing a schedule.

Before you begin

You must have created a project in Test .

You must have installed and configured a Prometheus server.

Read the concept information about resource monitoring and monitoring Prometheus server source. See Resource monitoring on page 1563

About this task

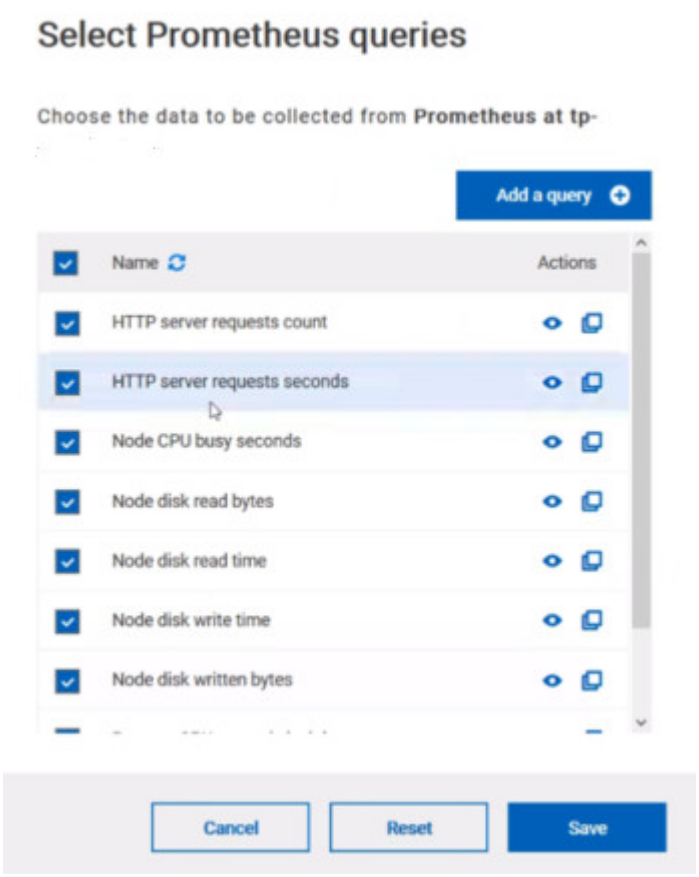
The following procedure describes how to select and create Prometheus queries in Test. You must set a connection between Test and the Prometheus server first to access to the Prometheus queries.

Enter the connection settings, then select queries.

1. Click **Add a source** and select **Add a Prometheus Server**.
2. Enter the connection settings in the **New server** dialog box,.
    a. In **Target host**, enter the IP address or host name and port number of the host where the Prometheus server is installed.
    b. Enter the **Path to the API root of Prometheus** to point to the Prometheus API where the monitoring data are saved.
    c. Enter the security parameters if required. For information about this section, see related links.
    d. Click **Add** to close the dialog.

    Result

    The Prometheus server source is created successfully in the background and a dialog opens to select the Prometheus data queries.
3. In the **Select Prometheus queries** dialog, select queries that are available in the list to collect Prometheus metrics data by clicking the checkboxes.
    You can reset the selection.



4. Follow these steps to create a query:

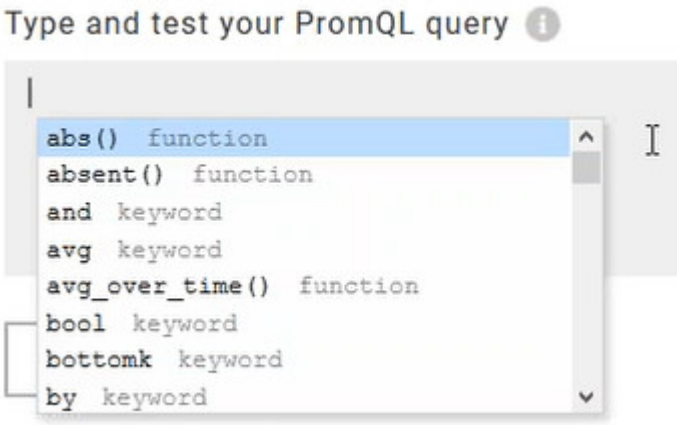
    a. Click **Add a query**.

    b. Enter a name for the new query in the **Create a Prometheus query** dialog.

    c. Enter a PromQL query.any keyword and press Ctrl+Space in the **Type and test your PromQL query.**

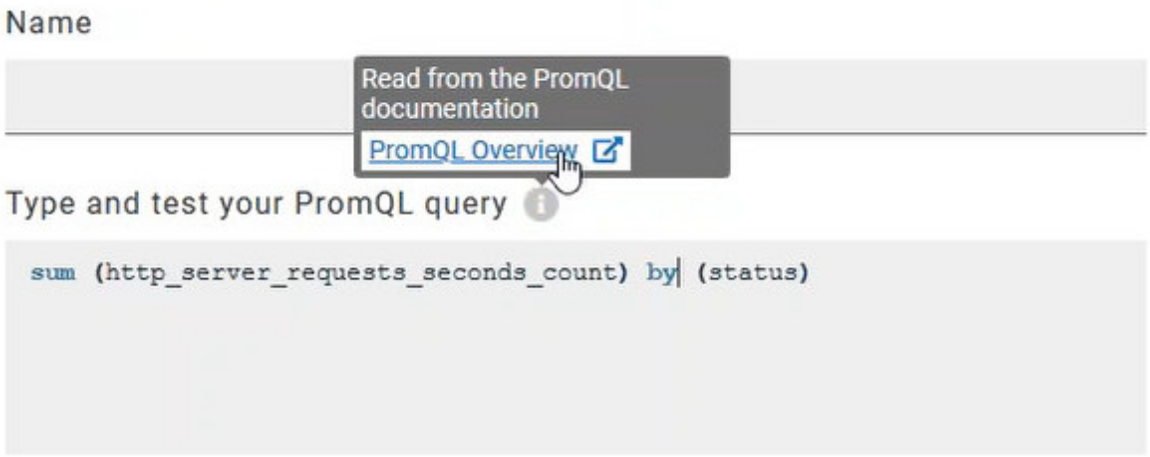
    Result

    All the possible combinations of keywords and metrics related to your searched keyword are listed.



d. Select a query in the list.

e. Click the link that points to the 'Querying Prometheus documentation' page in the information tool tip to find other examples of queries in a web page that you can use as samples.



f. Click **Test query.**
If the test is successful, a green check is displayed, otherwise you get a red check with an error message.

g. Click **Create**.

5. Proceed as follows to duplicate a query:

a. Click the **Duplicate** icon to duplicate a standard query.

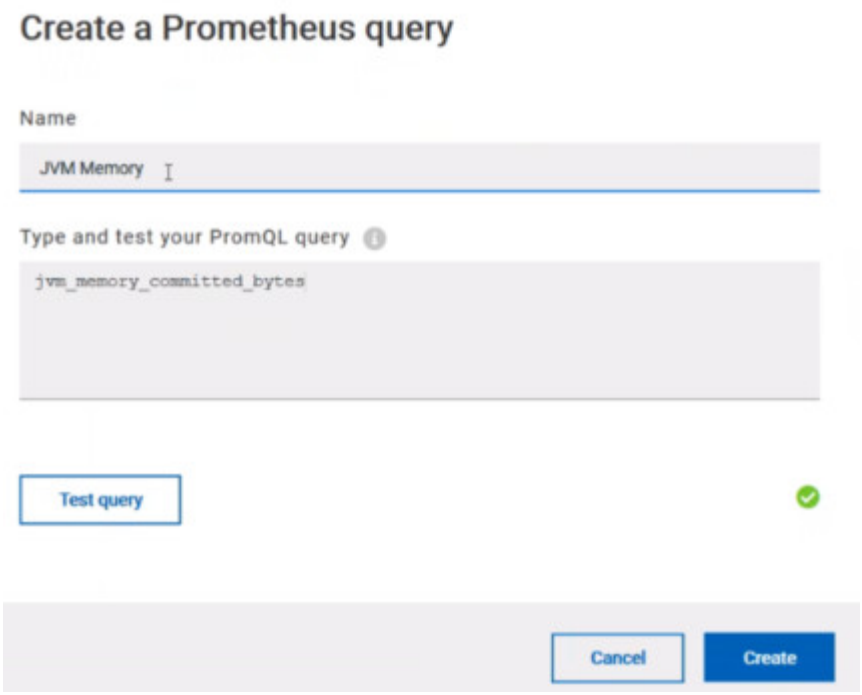
b. Rename the duplicated query in the **View the Prometheus query** dialog.
Make sure that the name you give to the query is not already used.

c. Modify the query type.

d. Test the query .

e. Click **Create**.

Note: You can click Create or Duplicate only if the test of the query is successful and the name of the query is not already in use.



6. Proceed as follows to modify a query:
   a. Click the **Modify** icon .
   b. Modify the name and type of the query.
   c. Test the query.
   d. Click **Update**.
   e. Delete duplicated or created queries.
   f. Click **Save** to close the **Select Prometheus queries** dialog.
7. Click Save and close the **Select Prometheus queries** dialog.

Results

The resource monitoring page displays the total number of sources you have added to your project and the number of sources ordered by type in cards.

What to do next

Click the links in the cards to go to the sources page and see the performance metrics for each source you added to your project. For more details, see Viewing resource monitoring usage data on page 1603

Monitoring metrics exposed by an OpenMetrics exporter

With Test , you can monitor your system resources by using metrics data that are exposed by an OpenMetrics or a Prometheus exporter through metric counters while executing a schedule.

Before you begin

You must have at least one exporter or software to expose monitoring metrics with an OpenMetrics or Prometheus format.

You must have created a project in Test.

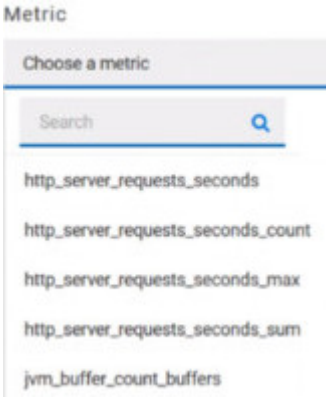
No Prometheus server installation is required, you only need to set up one or multiple OpenMetrics, or Prometheus exporters that fit your software or host target. Refer to the link at the end of this page to see the list of exporters.

About this task

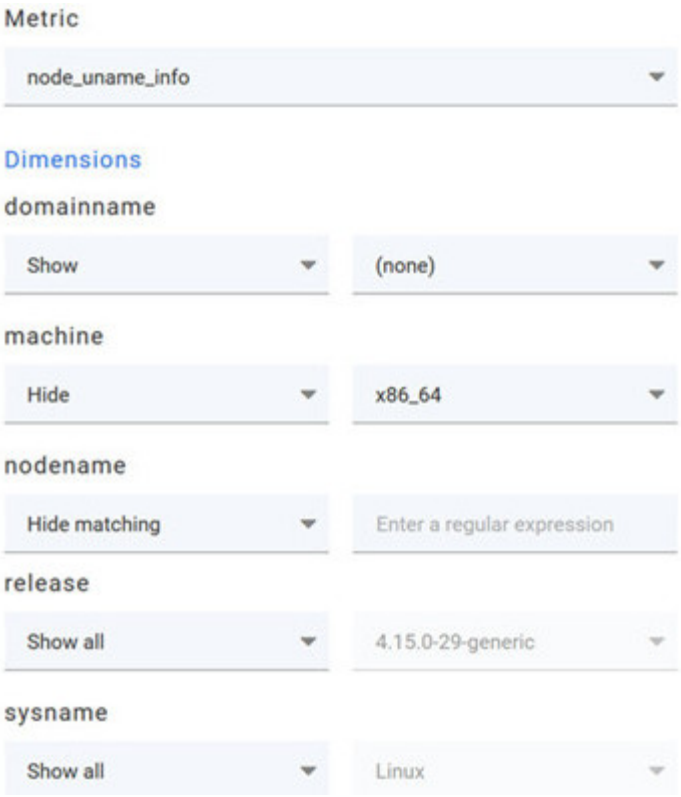
The following procedure describes how to select and create OpenMetrics counters in Test. You must set a connection between Test and the OpenMetrics exporter to select counters.

1. Click **Add a source** and select **Add an OpenMetrics exporter** .
2. In the **New OpenMetrics exporter** dialog that opens, enter the OpenMetrics exporter details to access its exposition endpoint as follows:
    a. In **Target host**, enter the IP address or host name and port number of the host where the server is installed.
    b. Enter the **Path to the exposition endpoint** to point to the application where the data performance results must be stored. As the path depends on the type of exporter used, refer to the exporter's documentation and configuration to indicate the right path.
    c. In **Security**, enter the security parameters if required.
    d. Click **Add** to close the dialog.
    Result
    The source is created successfully in the background. A dialog box opens to select the OpenMetrics counters.
3. Click the checkboxes to select counters in the **Select OpenMetrics counters** dialog.
4. Follow these steps to create a counter:
    a. Click **Add a counter**.
    b. Enter a name for the new counter, in the **OpenMetrics counter**.

c. Select metrics in the drop-down list or enter a keyword in the **Dimensions** field to enable the dynamic input help. You can also use the search field that appears in the list of metrics.

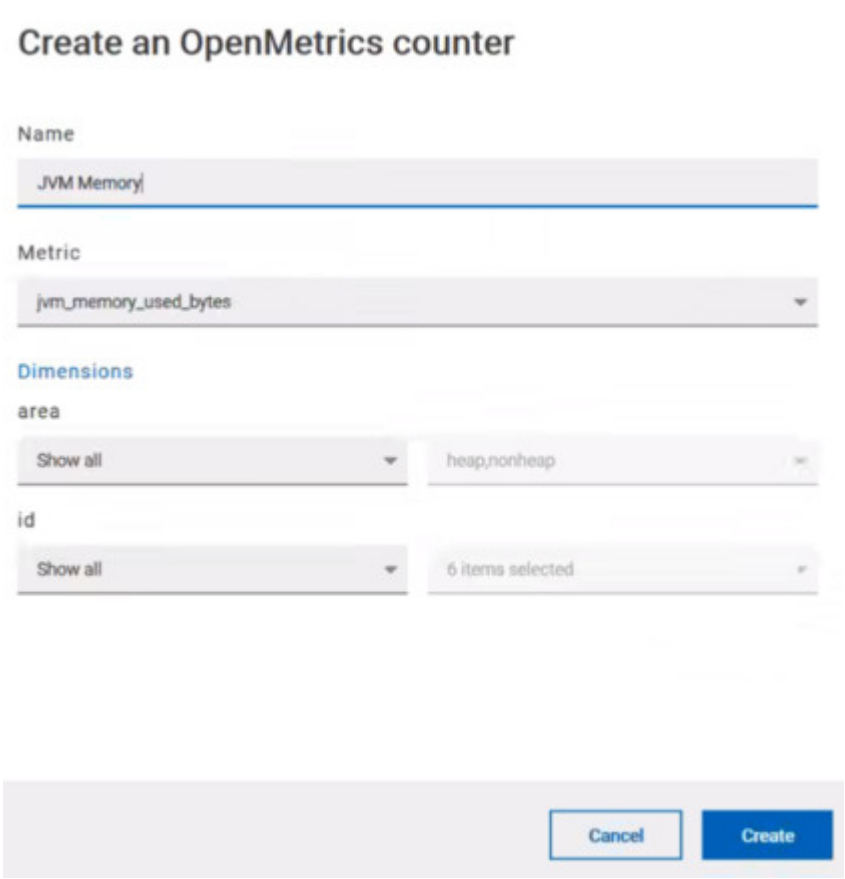


d. Select **Dimensions** from the dynamic fields when they are required.



e. Select the appropriate OpenMetrics counter that you are looking for.

f. Click **Create**.



5. Follow these steps to duplicate a counter:
    a. Select a counter in the list, and click the **Duplicate** icon .
    b. Modify the name of the counter and the Dimensions.
    c. Click **Create**.
6. Proceed as follows to modify a new counter:
    a. Click the **Modify** icon.
    b. Modify the name, Metrics, and Dimensions of the counter in the **Modify the OpenMetrics counter**.
    c. Click **Update**.

Note: You can create, duplicate, or update a counter only if the name of the counter is not already used.

7. Click **Save** and close the **Select OpenMetrics counters** dialog.

Note: You can delete counters, but only the ones that you created or duplicated.

Results

The resource monitoring page displays the total number of sources you have added to your project and the number of sources ordered by type in cards.

What to do next

Click the links in the cards to go to the sources page and see the performance metrics for each source you added to your project. For more details, see Viewing resource monitoring usage data on page 1603.

Monitoring a Java Virtual Machine

To monitor a Java Virtual Machine, you must add the Java Virtual Machine source to the project in Test , and then select the counters that are used to capture the monitoring metrics.

Before you begin

You must have completed the following tasks:

- Configured and started the Java Virtual Machine from a command to connect it Test.

  See Starting a Java Virtual Machine on page 1593.
- Logged in Test. You must be the owner of an existing new project.
- You can optionally use agents. See Resource monitoring agents on page 1581.

About this task

The Java Virtual Machine source is added to the list of resource monitoring sources when the agent is installed.

1. Click **Infrastructure > Resource Monitoring**.
   The resource monitoring page opens.
2. In the resource monitoring page, click **Add a Source** and select **add a Java Virtual Machine**.
3. Fill in the following connection settings in the **New server** dialog:

   Note: For hosts that are already connected to Test through an agent, you have only the **Access target from** field enabled. Move directly to step 4.

   a. In **Target host**, enter the IP address or hostname and port number of the host where the server to monitor is installed.

   b. In **Server edition**, select the appropriate server from the drop-down list.

   c. In **Path to the status page of the server**, enter the name of the page to view the status of the server.

   d. In **Security**, select the following options:

Secured with TLS/SSL

If the application server is secured with TLS/SSL.

Trust self-signed certificate

To accept the server certificate.

Do not verify hostname

To ignore verification of the hostname in the certificate.

Require credentials

If the server requires log-in credentials, enter a **User name** and **Password**.

4. Click **Add**.
5. Select and save the statistics counters to monitor the source. You can select them from the list where they follow the server logical organization.
   For a faster selection, select the counters from the built-in sets drop-down list where they are organized by theme and save your selection.
   Result

   When the selected counters are saved, two tables are displayed in the resource monitoring main page. They contain the total number of sources you have added and the number of sources ordered by type.

What to do next

You can click the links in the tables to view the performance metrics and usage data in a graph for the monitored Java Virtual Machine.

Resource monitoring agents

You can connect agents to Test from other hosts to monitor a larger set of data collectors, computers, servers, or systems, or if a server to monitor requires authorization access. To monitor these remote servers, you must configure and run the agents so that a connection is set between Test resource monitoring service and the agents. You can configure the resource monitoring agents in a team space or in a project.

Requirements:

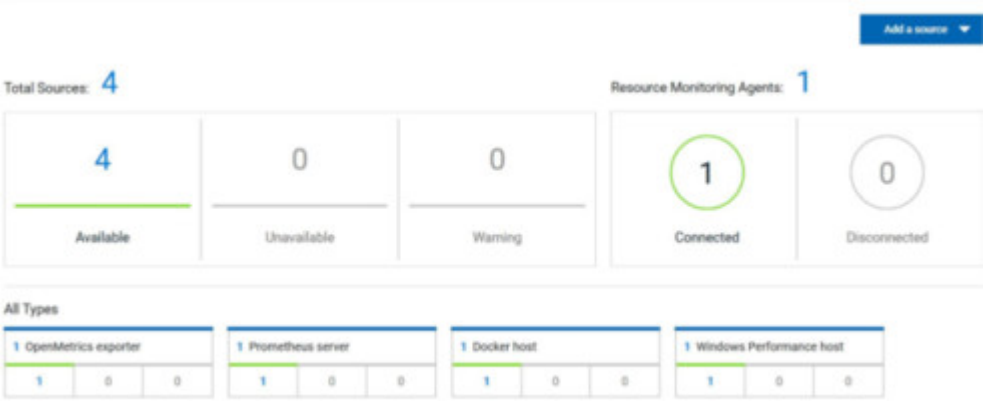
- To connect resource monitoring agents to Test in a team space, you must be a *Team Space Owner*. Any other team space *Member* (not owner) can only view the resource monitoring agents.
- To connect resource monitoring agents to Test in a project, you must be a project *Owner*. Any project *Member* (not the owner) can only view the resource monitoring agents.
- Agent-based monitoring is mandatory to collect data from a Windows or Linux Performance host.

For testing, you might need many hosts. For example, you might have one host with the application server, another host with the database server, and some hosts to apply the user load. Due to network or firewall issues, sometimes, it becomes difficult for multiple hosts to connect to each other. Resource monitoring agents are installed on the target hosts so that they can establish a connection with Test to gather resource statistics of the target host.

The agents always try to connect with the server through the HTTPS protocol. You must install the agent and start it. From the resource monitoring page in Test, you can copy the command lines to download files and run the agents. When you stop the agent, the monitoring sources that you have already added persist but the live data will not be available.

You can configure your resource monitoring agent as a service so that the agent automatically runs when the host is restarted. For details, see the documentation pages about starting resource monitoring agents on Windows or Linux.

When the agent is connected to Test, it is added to the main page of the resource monitoring service. Then, you can select the agent to connect to a server from **Add a Source**.



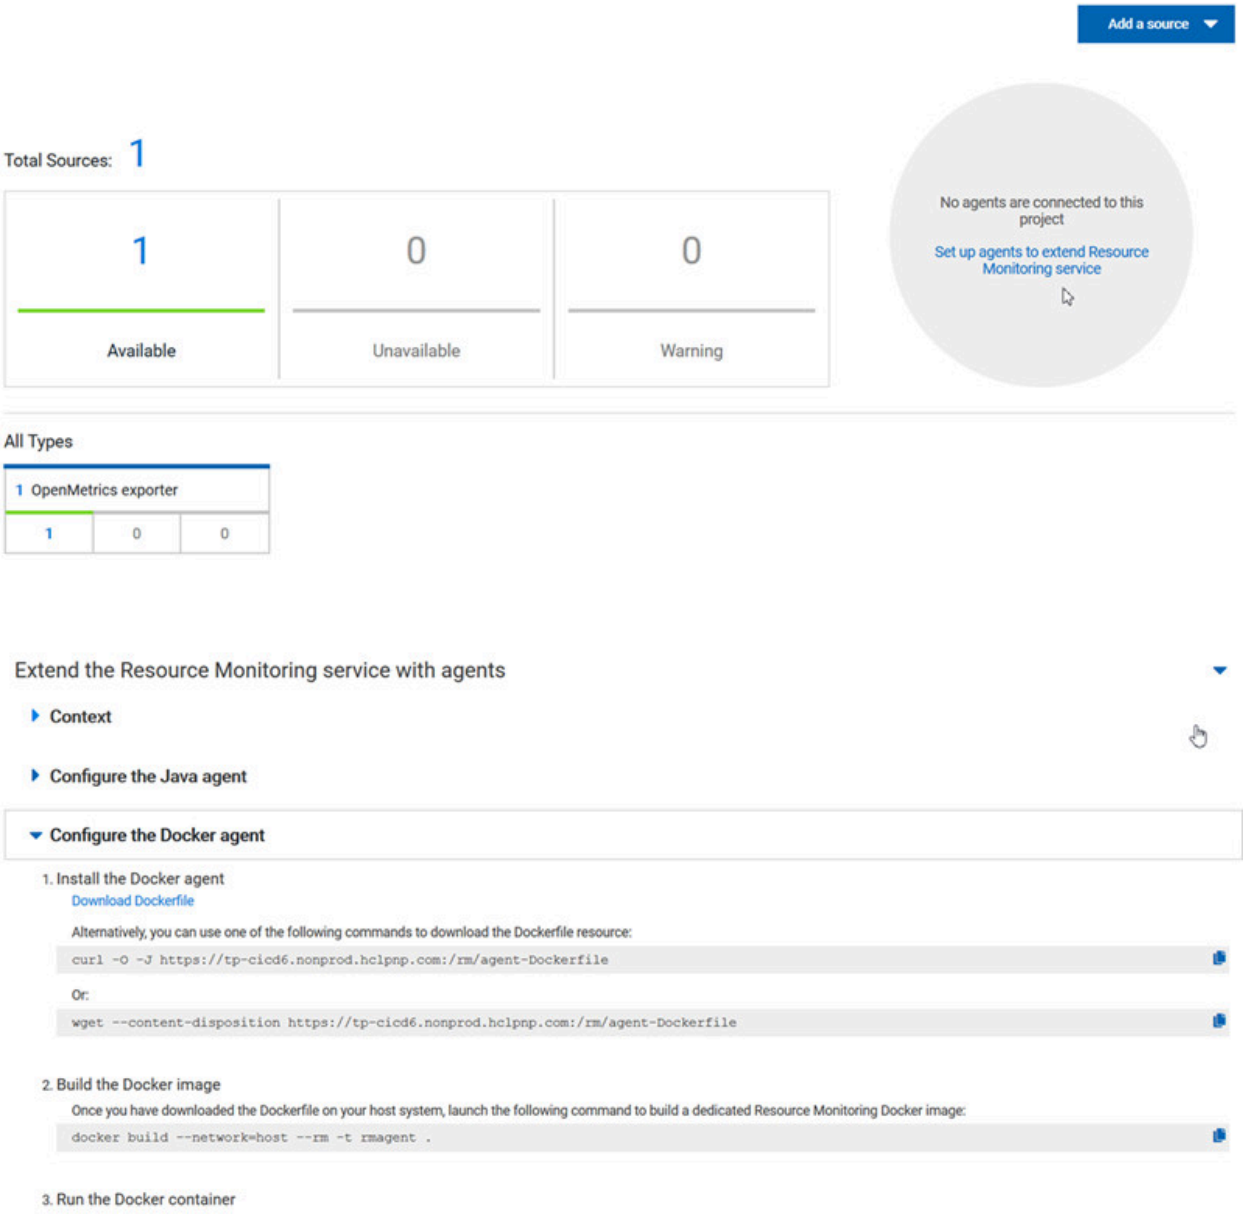
Installing and running a Docker agent on a remote host

You must install the resource monitoring Docker agents on the target host for which you want to monitor the resources and collect the metrics. You need to run an agent to establish a connection with Test .

Before you begin

- The resource monitoring service does not require access to the agent host but the agent must have reached the service host over HTTPS.
- The Docker agent must have been launched in a Docker container and requires Docker 19.03.
- Read and been familiar with the requirements to install and configure the resource monitoring agents on Test. See Resource monitoring agents on page 1581.

1. Click **Set up Agents to extend Resource Monitoring service** link in Test to access the agents page where you can find the instructions and commands that are to be used to install and run the agents.



2. Expand **Configure the Docker agent** and click **Download Dockerfile** to download a Docker agent.
   You can also use the *curl* or *wget* commands to download the agent without accessing the resource monitoring web UI.

   For more facility, use the code snippets to copy and fill in the commands with the valid offline token and the Docker file name.

   For Windows:

   ```
   curl -O -J https://hostName/rm/agent-Dockerfile
   ```

   For Linux:

```
wget --content-disposition hostName/rm/agent-Dockerfile
```

3. Copy the build command that is under **Build the Docker image**, paste it in your console and run it to build a resource monitoring Docker image.
   Before you start the a Docker agent, you must build a Docker image.

   ```
   docker build --network=host --rm -t rmagent
   ```

4. Follow these steps to run the agent:

   a. Click to fill in the appropriate command for Windows or Linux with the valid offline token.

   b. Click to copy the command to clipboard and paste the command in the console.

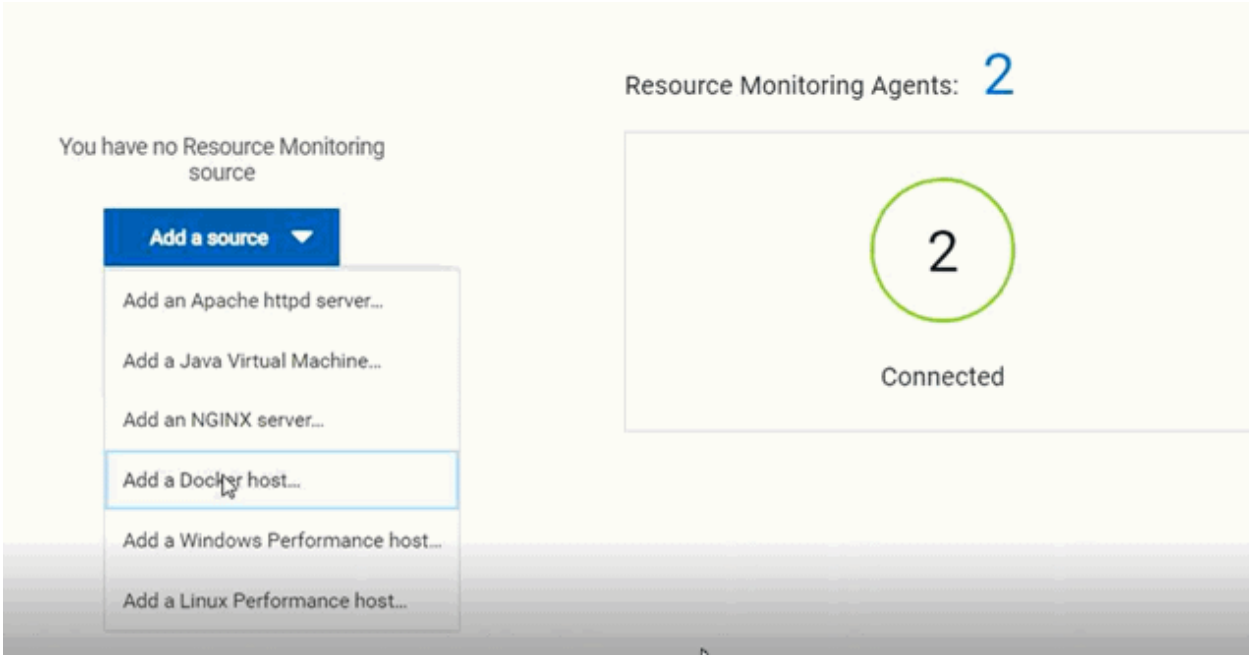
   - Command on Windows:

   ```
   docker run -it --rm --privileged -e PROJECT_ID=230200 -e HCL_ONETEST_OFFLINE_TOKEN=(Enter your
    offline token here) --network host -v //var/run/docker.sock:/var/run/docker.sock rmagent
   ```

   - Command on Linux:

   ```
   docker run -it --rm --privileged -e PROJECT_ID=230200 -e HCL_ONETEST_OFFLINE_TOKEN=(Enter your
    offline token here) --network host -v /var/run/docker.sock:/var/run/docker.sock -v /etc:/etc
    -v /proc:/proc rmagent
   ```

   c. Paste the command in the console and run the command.



Results

When the agent is started, the agent is connected to Test. The agent is displayed in the list of connected resource monitoring agents with the hostname and status of the agent. The agent is also added to the main page of the resource monitoring service in Test.

What to do next

You can add a new resource monitoring source. It can be collected from a service or from the named agents, depending on the capabilities supported by the environment.

Related information

Resource monitoring capabilities on page 1564

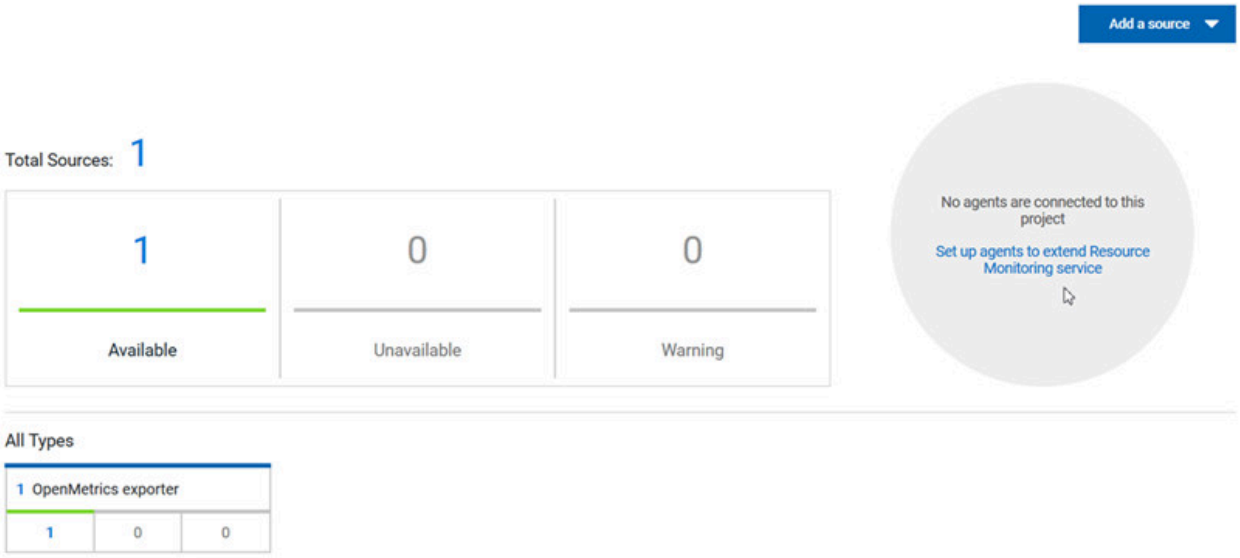
Installing and running a Java agent on a remote host

You must install the resource monitoring java agent on the target host for which you want to monitor the resources and collect the metrics of Test . You need to run the agent to establish a connection with Test.

Before you begin

- The resource monitoring service does not require access to the agent host but the agent must have reached the service host over HTTPS.
- The Java agent must have been launched from a jar file and requires a Java 17 virtual machine.
- Read and been familiar with the requirements to install and configure the resource monitoring agents on Test. See Resource monitoring agents on page 1581.

1. Click **Set up Agents to extend Resource Monitoring service** link in Test to access the agents page where you can find the instructions and commands that you can use to install and run the agents.



2. Expand **Configure the Java agent** and click **Download jar file** to download the Java agent.
   You can also use the *curl* and *wget* commands to download the agent without accessing the resource monitoring web UI. For more facility, use the code snippets to copy and fill in the commands with the valid offline token and the jar file name.

With curl:

```
curl -O -J https://hostName/rm/Agent-jar
```

With wget:

```
wget --content-disposition https://hostName/rm/Agent-jar
```

3. Configure the command as follows to run your agent:
    a. Copy the appropriate command for Windows or Linux with the code snippets.
    b. Enter the path to the directory that contains the agent .jar file, and paste the command.

Example

To connect resource monitoring agents to Test in a team space use the following commands:

On Windows:

```
set HCL_ONETEST_OFFLINE_TOKEN=(Enter your offline token here)
java -jar (Enter the name of the downloaded jar file here) --ServiceUrl=https://hostName/rm
 --spaceId=<team-space_id>
```

On Linux:

```
sudo HCL_ONETEST_OFFLINE_TOKEN=(Enter your offline token here) java -jar (Enter the name of the
 downloaded jar file here) --ServiceUrl=portNumber/rm --spaceId=<team-space_id>
```

Example

To connect resource monitoring agents to Test in a project use the following commands:

On Windows:

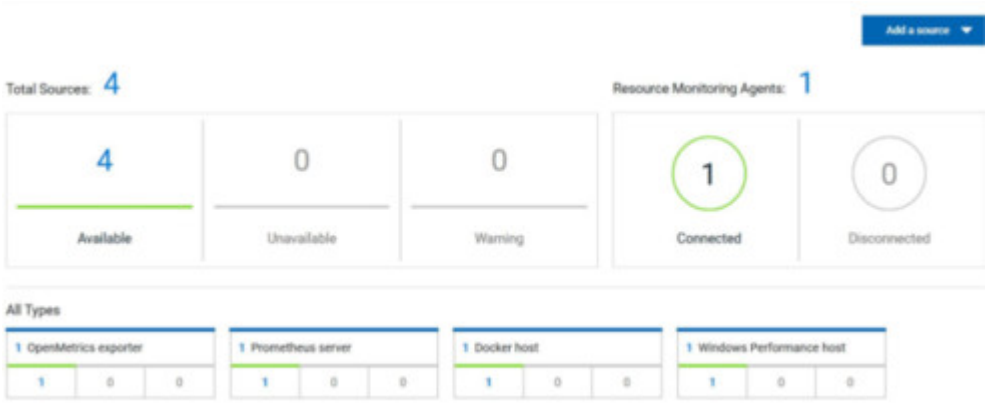
```
set HCL_ONETEST_OFFLINE_TOKEN=(Enter your offline token here)
java -jar (Enter the name of the downloaded jar file here) --ServiceUrl=https://hostName/rm
 --projectId=<project_id>
```

On Linux:

```
sudo HCL_ONETEST_OFFLINE_TOKEN=(Enter your offline token here) java -jar (Enter the name of the
 downloaded jar file here) --ServiceUrl=portNumber/rm --projectId=<project_id>
```

Results

When the agent is started, the agent is connected to Test. The agent is displayed in the list of connected resource monitoring agents with the hostname and status of the agent. The agent is also added to the main page of the resource monitoring service in Test.



What to do next

You can use another method to start an agent. See Starting a resource monitoring Java agent as a service on Windows on page 1587 or Starting a resource monitoring Java agent as a service on Linux on page 1590. You can then add a new resource monitoring source. Resource monitoring metrics can be collected from a service or from the named agents, depending on the capabilities supported by the environment.

Related information

Resource monitoring capabilities on page 1564

Starting a resource monitoring Java agent as a service on Windows

To ensure that the resource monitoring Java agent starts by itself when the host is running, you can set up the environment in such a way that the resource monitoring agent can be started as a service.

Before you begin

You must have completed the following tasks:

- Installed Java 17 on the host.
- Added Test to the PATH environment variable.
- Created an offline token to connect the agent securely with appropriate permissions.

Note: You can create an offline token from the User menu of the resource monitoring page or you can re-use your active offline token. The token expires if it is not used for a month.

To allow remote access to the performance data on Windows 10, you must have considered the following information:

- The username and password are the same on the local and remote servers. Otherwise you must have provided remote server credentials.
- The remote user must be a member of the Performance Monitor Users group (start `lusrmgr.msc` and add the user to this group).
- The Remote Registry service must be running on the remote host (start `services.msc`) and must have verified the Remote Registry status).
- File and printer sharing must be enabled on the Network Interface of the remote host that is implied in the communication with the local host.
- You must have activated the following Windows Firewall rules so that the remote firewall does not block the access:
  - File and Printer Sharing (NB-Name-In)
  - File and Printer Sharing (NB-Session-In)
  - File and Printer Sharing (*)

1. Download the latest release of *winsw*.
   You can choose to download `WinSW.Net2.exe` or `WinSW.Net4.exe` depending on the version of .Net framework that you already have on the host Windows.
2. Create a folder on your local hard drive like `RMAgent-winservice`.
3. Copy the downloaded executable to this new folder and rename the file to `RMAgent-winservice.exe`.
4. Create a new text file in the same folder and name it `RMAgent-winservice.xml`.
5. Copy and adapt the following content to this new RMAgent-winservice.xml file to set up the offline token:

```
<service>
      <id>RMAgent-winservice</id>
      <name>Resource monitoring agent</name>
      <description>This service runs the resource monitoring agent.</description>
      <executable>java</executable>
      <env name="HCL_ONETEST_OFFLINE_TOKEN" value="(Enter your offline token here"/>

      <arguments>-jar %BASE%\RMAgent.jar --serviceUrl=https://<service-host>/rm --projectId=<projet-id>
 --autoUpgradeDownloadThen=execute:cmd,/c,start,%BASE%\auto-upgrade.bat</arguments>
      <onfailure action="restart" delay="10 sec"/>
      <logmode>rotate</logmode>
</service>
```

Notes:

- Replace *<service-host>* by the hostname of the host that runs Test.
- Replace *<project-id>* which is the number that you find after /projects/ in the browser's URL when you browse to this project.

6. Create a new text file in the same folder and name it `auto-upgrade.bat`.
7. Copy the following content to this new file to upgrade the agent `.jar` file automatically:

```
@echo off
for /f "tokens=*" %%a in ('dir /b /od %BASE%\com.hcl.test.rm.agent-*.jar') do set newest=%%a
%BASE%\RMAgent-winservice.exe stop
del %BASE%\RMAgent.jar
mklink %BASE%\RMAgent.jar %BASE%\%newest%
%BASE%\RMAgent-winservice.exe start
```

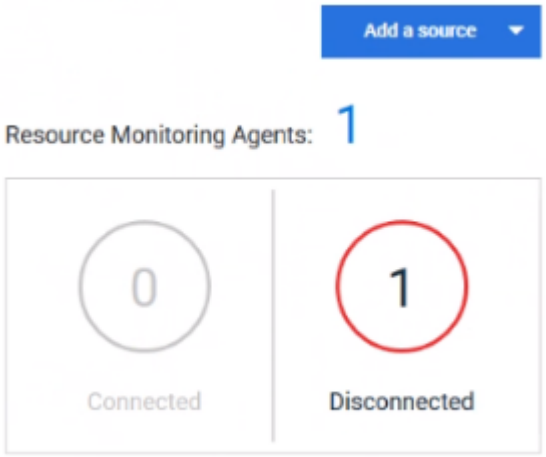
8. Start the command prompt as an administrator and change the directory to the newly created directory: `RMAgent-winservice`.
9. Download the agent .jar file that is available from the agents page in the resource monitoring service, under the **Extend the Resource Monitoring service with agents** section and save it to the same directory.
10. Enter the following command in the command prompt to create a symbolic link named `RMAgent.jar` to the agent jar file:

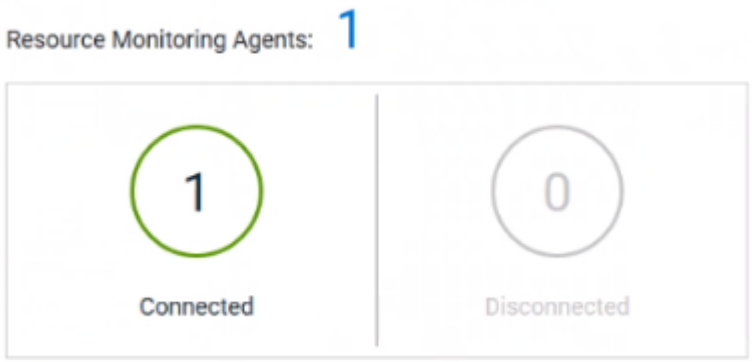
    ```
    mklink RMAgent.jar com.hcl.test.rm.agent-<version-and-datetime>.jar
    ```

11. Enter the following commands:

    ```
    RMAgent-winservice install
    ```

    ```
    RMAgent-winservice start
    ```





Notes:

In the Services Windows application, you can check whether the service is up and running. You can see in the resource monitoring page whether the resource monitoring agent is disconnected or connected.

The resource monitoring agents write the logs to the same folder in files named `RMAgent-winservice.out.log`, `RMAgent-winservice.err.log` and `RMAgent-winservice.wrapper.log`. If the Windows service for the agent is not started or if it is not connected to the resource monitoring service, verify the log files.

Results

The Java agent starts as a service on Windows. When the agent is connected to Test, it is automatically added to the list of resource monitoring sources in Test.

What to do next

You can monitor the Windows agent by selecting counters. See Monitoring a Windows Performance host on page 1579.

Starting a resource monitoring Java agent as a service on Linux

To ensure that the resource monitoring Java agent starts by itself when the host is restarted, you can set up the environment in such a way that the resource monitoring agent can be started as a service.

Before you begin

You must have completed the following tasks:

- Installed Java 17 on the host.
- Added Test to the PATH environment variable.
- Created an offline token to connect the agent securely with appropriate permissions.

Note: You can create an offline token from the User menu of the resource monitoring page or you can re-use your active offline token. The token expires if it is not used for a month.

About this task

This topic relies on systemd services that are the default on most modern Linux distributions. Other ways mi require adaptations of the instructions but the provided script will be a good basis in most cases.

1. Create a folder on your local hard drive like `/opt/RMAgent-linuxservice`.
2. Download the agent .jar file that is available from the Agents page in the resource monitoring service, below the **Extend the Resource Monitoring service with agents** section and save it to the same directory.
3. Create a new file `/etc/systemd/system/RMAgent-linuxservice.service`.

4. Add the following content to this new file:

```
[Unit]
Description = Resource monitoring agent
After = network.target

[Service]
Type = forking
ExecStart = /opt/RMAgent-linuxservice/RMAgent-linuxservice.sh start
ExecStop = /opt/RMAgent-linuxservice/RMAgent-linuxservice.sh stop
Restart = on-failure
RestartSec = 10

[Install]
WantedBy = multi-user.target
```

5. Create another file `/opt/RMAgent-linuxservice/RMAgent-linuxservice.sh`.

```
#!/bin/sh

#!/bin/sh

# Update the 3 following variables with the Server's hostname, project id and offline token:
SERVICE_URL=https://<hostname>/rm
PROJECT_ID=<project-id>
export HCL_ONETEST_OFFLINE_TOKEN=<offline-token>

ARGS="--serviceUrl=$SERVICE_URL --projectId=$PROJECT_ID --autoUpgradeDownloadThen=exitFailure"
SCRIPT=$(readlink -f "$0")
RMAGENT_HOME=$(dirname "$SCRIPT")

# Ensure we're using the latest downloaded jar file
PATH_TO_JAR=`ls -t $RMAGENT_HOME/com.hcl.test.rm.agent-*.jar | head -1`
if [ -z "$PATH_TO_JAR" ]
then
  cd $RMAGENT_HOME && { curl -k -O -J $SERVICE_URL/agent-jar; cd -; }
  PATH_TO_JAR=`ls -t $RMAGENT_HOME/com.hcl.test.rm.agent-*.jar | head -1`
  if [ -z "$PATH_TO_JAR" ]
  then
    echo "Start the server at $SERVICE_URL to allow download of the latest agent jar file"
    echo "Exiting..."
    exit 1
  fi
fi
SERVICE_NAME="Resource monitoring agent"
#Pid file will reside in this script’s folder
PATH_TO_PID=$RMAGENT_HOME/RMAgent-pid
#Log file will reside in this script’s folder
PATH_TO_LOG=$RMAGENT_HOME/RMAgent.log

case $1 in
    start)
        echo "Starting $SERVICE_NAME ..."
        if [ ! -f $PATH_TO_PID ]; then
            nohup java -jar $PATH_TO_JAR $ARGS >> $PATH_TO_LOG 2>&1 &
                        echo $! > $PATH_TO_PID
            echo "$SERVICE_NAME started ..."
```

```
        else
            echo "$SERVICE_NAME is already running ..."
        fi
    ;;
    stop)
        if [ -f $PATH_TO_PID ]; then
            PID=$(cat $PATH_TO_PID);
            echo "$SERVICE_NAME stopping ..."
            kill $PID;
            echo "$SERVICE_NAME stopped ..."
            rm $PATH_TO_PID
        else
            echo "$SERVICE_NAME is not running ..."
        fi
    ;;
    restart)
        if [ -f $PATH_TO_PID ]; then
            PID=$(cat $PATH_TO_PID);
            echo "$SERVICE_NAME stopping ...";
            kill $PID;
            echo "$SERVICE_NAME stopped ...";
            rm $PATH_TO_PID
            echo "$SERVICE_NAME starting ..."
            nohup java -jar $PATH_TO_JAR $ARGS >> $PATH_TO_LOG 2>&1 &
                        echo $! > $PATH_TO_PID
            echo "$SERVICE_NAME started ..."
        else
            echo "$SERVICE_NAME is not running ..."
        fi
    ;;
esac
```

Notes:

- Replace *<service-hostname>* by the hostname of the host that runs Test.
- Replace *<project-id>* which is the number you'll find after `/projects/` in the browser's URL when browsing to this project.

Results

The resource monitoring Java agent starts automatically when the host restarts. The Linux agent is added to the main page of the resource monitoring service in Test.

What to do next

You can monitor the Linux Performance host source by adding counters. See Monitoring a Linux Performance host on page 1580.

Starting a Java Virtual Machine

To monitor the sources from a Java Virtual Machine (JVM), you must first start the JVM. You must enter the IP address of the JVM, the IP port, and the security parameters in the command before running the Java Virtual Machine.

1. Enter The IP address of the JVM (local or remote host) and the IP port in the command that is used to run the Java Virtual Machine.
2. **Optional:** You can use the authentication security data to start the virtual machine. In this case, you must enter the name of the password file. You can also enter the name of an access file that might be needed if user privileges are required.

Example

Parameters used to launch a JVM without security:

```
java
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=9010
-Dcom.sun.management.jmxremote.local.only=false
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
-jar MyapplicationFile.jar
```

Parameters used to launch a JVM with authentication security:

```
java
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=9010
-Dcom.sun.management.jmxremote.local.only=false
-Dcom.sun.management.jmxremote.authenticate=true
-Dcom.sun.management.jmxremote.ssl=false
-Dcom.sun.management.jmxremote.password.file=jmxremote.password
-Dcom.sun.management.jmxremote.access.file=jmxremote.access (this command is optional)
-jar MyapplicationFile.jar
```

Managing sources

After you add and connect monitoring sources to your project, you might want to modify the sources in you project and the configuration of the sources.

Before you begin

You must be a project owner or team space owner to add or delete sources.

About this task

In the page where you can view the resource monitoring usage data and metrics, you can also manage your sources. You can modify or delete a source, add or change statistic counters, add labels to identify the sources and use them when you execute a test to collect resource monitoring results.

1. Click **Infrastructure > Resource Monitoring** in the navigation pane.
   If you have sources and agents in your project, you can see the cards with the number of available sources and agents in your project.
2. Click a link in the card of available sources to open a list of sources.
3. Perform any of the following actions for a monitoring source:
   - Click the **Delete** icon to delete the monitoring source and click **Delete** to confirm the deletion in the dialog box.

     The source is removed from the list of sources.
   - Click the **Edit** icon to change the target host settings.

     You can change the target host address, the port, the path to the server status page and the security parameters.
   - Click the **Selection** icon to select additional counters or change the selected counters for other ones. The changes are reflected in the resource monitoring usage data graph.
   - Click to add a label to identify the source.
   - Click **Add a source** to add a source to your project from the list of sources.

Creating labels

After you connect a host or service to a project, you can add monitoring labels to identify the monitoring sources that are used when you execute a schedule from Test . You can also use labels in any test to collect resource monitoring usage data during a test run for a defined period of time.

Before you begin

You must have connected sources to your project in Test. See Resource monitoring capabilities on page 1564.

About this task

You must be a project owner to add labels to the resource monitoring sources in a project and you must be a team space owner to add labels in a team space.

1. Click a source that is available in your project, either in the **Total Sources** cards or in the **All Types** cards from the resource monitoring page.
2. Click under the **Labels** column of a resource monitoring source to add a label.
3. Enter a name for the label and press the Enter key.

Note: You can add one label or multiple labels for the same resource monitoring source. A label can contain a maximum of 200 characters.

Tip: You can create the same label for different sources that belong to the same logical group to monitor the whole group with only one label.

Results

The host source is identified by a label.

What to do next

You can use the created labels in tests to collect resource monitoring results or persistent usage data. See Controlling resource monitoring sources in a schedule on page 1595 and Collecting and viewing resource monitoring usage data on page 1601.

Controlling resource monitoring sources in a schedule

In Test , you can control the resource monitoring sources that are collected in a performance schedule and override them with the labeled resource monitoring sources that are available in your current Server project.

Before you begin

- You must have performed the following tasks in HCL DevOps Test Performance (Test Performance):
  - Created a performance schedule of **Rate** or **VU** type.
  - Added resource monitoring sources, or the labels of resource monitoring sources to a schedule. See Adding resource monitoring sources to a performance schedule by using labels.
  - Enabled Test as resource monitoring service only if you want to replace resource monitoring labels set in Test Performance with the labels that you created in Test.
- You must have created a project and added resource monitoring sources to your project in Test. See Resource monitoring capabilities on page 1564.

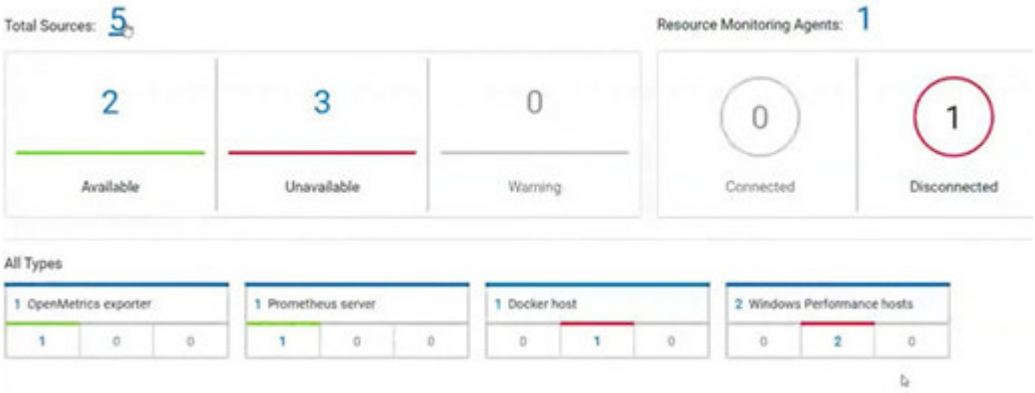
About this task

This procedure describes how to create resource monitoring labels in Test and how to use them to override the source or label settings related to resource monitoring in a performance schedule. The procedure applies to the following use cases:

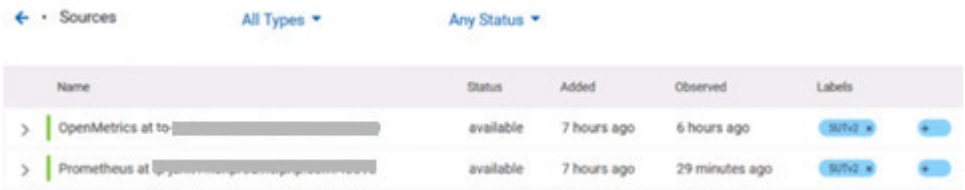
- To replace the resource monitoring labels that were initially set in a schedule from Test Performance with the labels that you create in Test.
- To enable resource monitoring sources that were not enabled from Test Performance. In that case, you can enable resource monitoring sources from the **Execution** dialog in Test.
- To ignore resource monitoring sources that were set in the schedule and to change them for labels that match sources that are available in the Test project.

Notes: You must be a project owner to add labels to the resource monitoring sources in a project and you must be a team space owner to add labels in a team space. You must have a project owner or a tester role access to add labels to a performance schedule in a project.

1. Click a source that is available in your project, either in the **Total Sources** cards or in the **All Types** cards from the resource monitoring page.



2. Click + under the **Labels** column of a resource monitoring source to add a label.



3. Enter a name for the label and press the Enter key.

   Example: Enter 'SUTv2' in three different resource monitoring sources.

Note: You can add one label or multiple labels for the same resource monitoring source. A label can contain a maximum of 200 characters.

Tip: You can create the same label for different sources that belong to the same logical group to monitor the whole group with only one label.

4. Click **Execution** in the navigation pane and click on a performance schedule in the list of tests to execute a schedule.
5. Click the **Resource Monitoring** tab in the **Execute Test Asset** dialog.

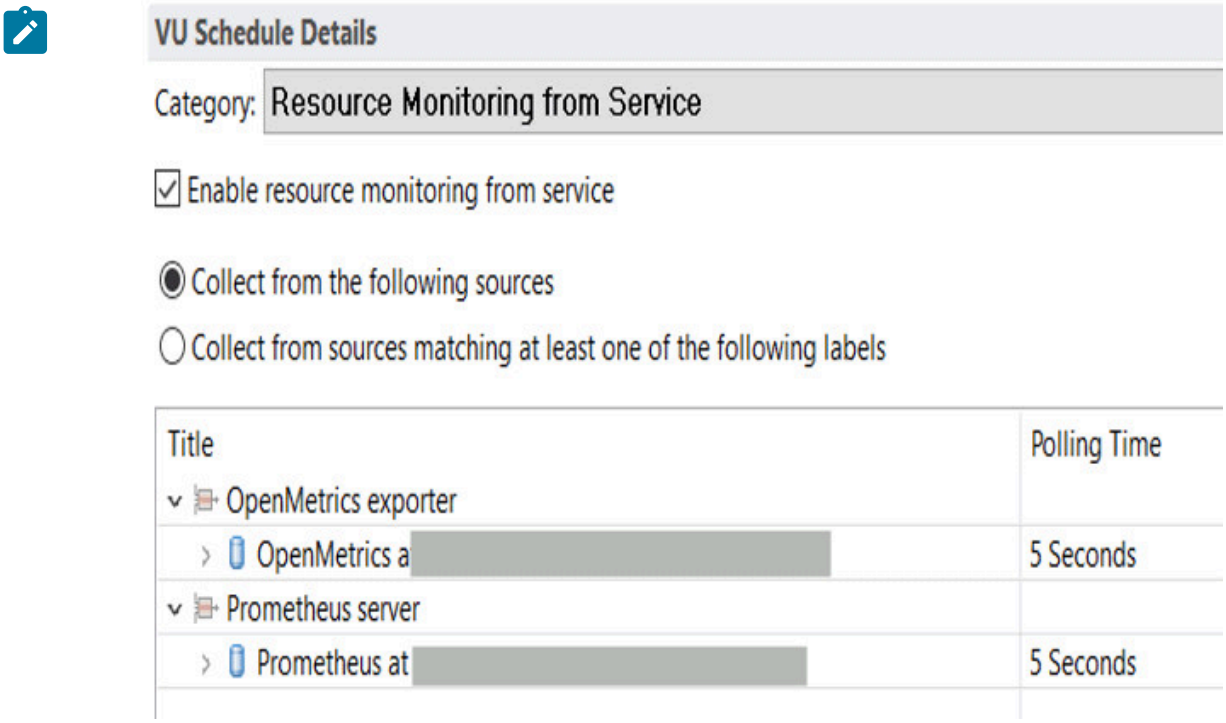
Note: There are different use case scenarios:

- If the **Resource Monitoring from Service** option was not enabled in Test Performance (see Figure 1), no source is available in Test project.

  Figure 1:

  
  A message indicates in the **Resource Monitoring** tab that Resource Monitoring was not enabled. You can run the schedule with the resource monitoring sources that are created and labeled in Test (steps 1 to 6 in this procedure) by selecting labels that are in your Test project (step 6).
- If the **Resource Monitoring from Service** option was enabled in Test Performance, and data is collected from the sources you added to the performance schedule in Test Performance (see Figure 2), the **Resource Monitoring** tab displays the list of these sources that are available in your Test project.

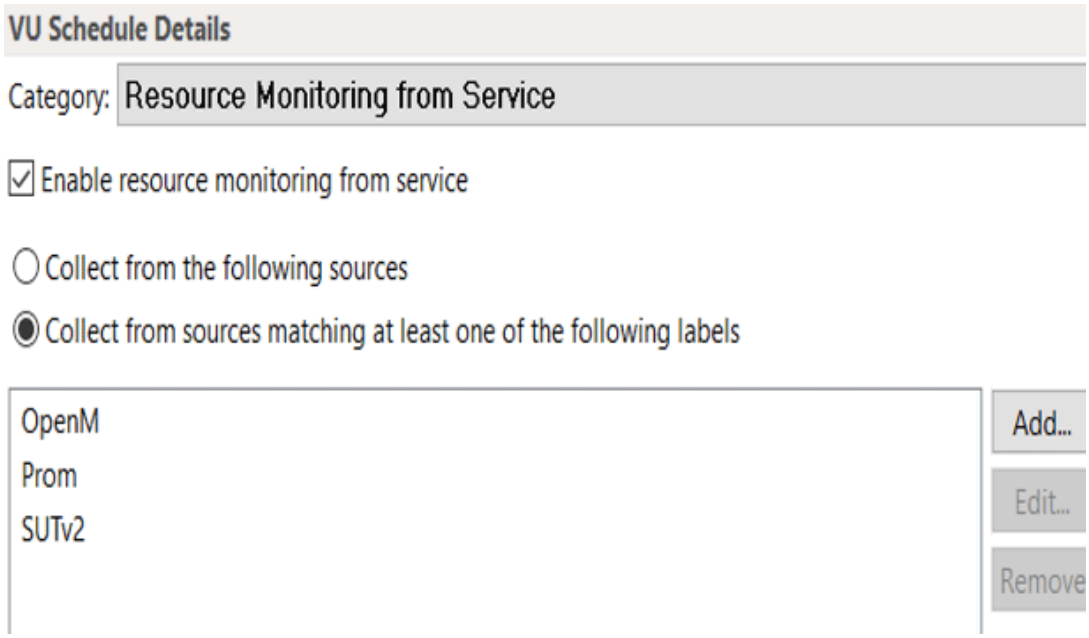
  Figure 2:



To override the initial sources with the sources that you created in Test, select the labels that are in your Test project and that match the Server sources (step 6 in this procedure).

- If you added sources to your performance schedule by using labels in Test Performance (see Figure 3), the **Resource Monitoring** tab displays the list of labels that are available in your Test project.

Figure 3:



To select resource monitoring labels from your schedule, follow step 6 in this procedure.

In the list of sources or labels that is displayed in the **Resource Monitoring** tab:

- Green icons identify either labels that match the sources or sources that are found in the current project.
- Red icons indicate that the sources are not running,
- Yellow icons identify either labels that do not match the sources, or sources that are not found in the current project.

  Data is collected for the sources that match labels only.

6. Click the + , and press the `Ctrl` + `Space` keys, or enter the initial letter of a label to select a label in the list.

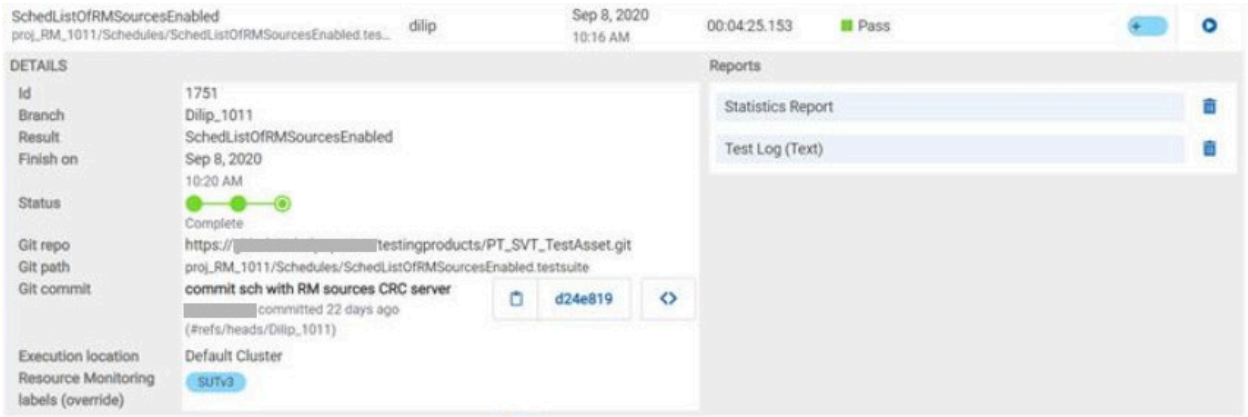
   Example: Select **SUTv3**.

   You can see all the labels that you added to the resource monitoring sources in Test.

Note: You can select labels matching resource monitoring sources that are created in a team space in addition to the ones that are created in a project.

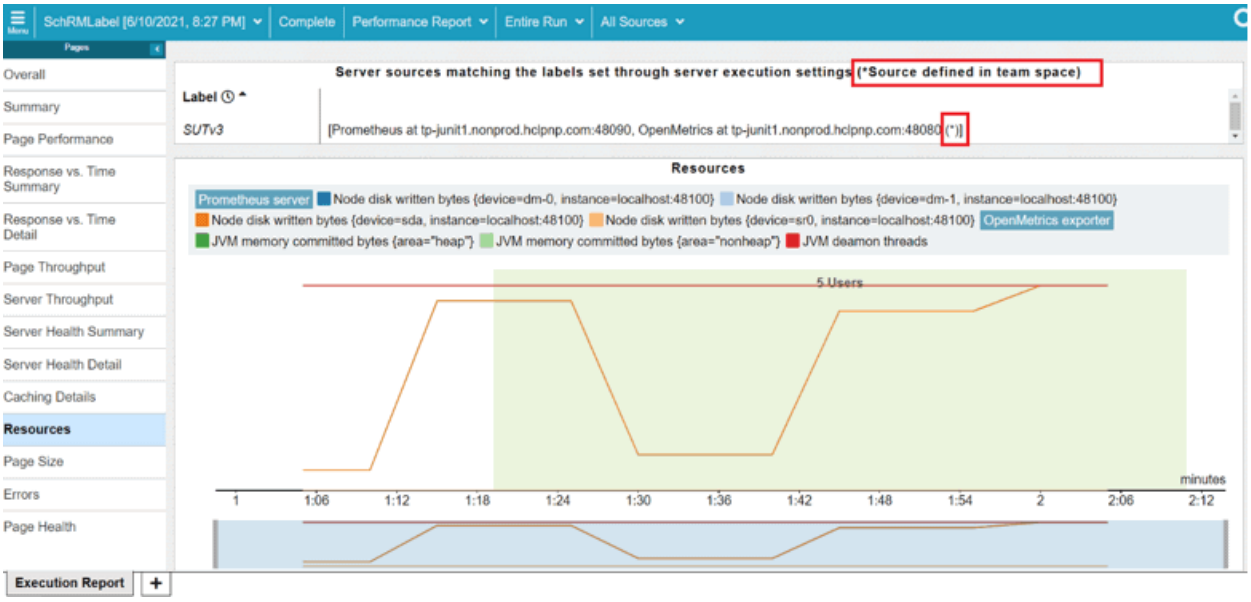
7. Select the labels that match the sources.
8. Click **Execute** to execute the performance schedule.
9. Click the **Result** view in the navigation bar of Test when the schedule is complete.
10. Expand the performance schedule result to see the resource monitoring label name in the **Details** card.

The **Details** card displays the resource monitoring labels that are used in the schedule to override the initial labels and collect resource monitoring sources (in the example, the 'SUTv3' label). For other details about the **Results** page, see the link at the end of this page.



In the **Report** card, you find the link to the Statistics Report that is generated. In the **Resource** tab of the Statistics Report, you can view the information related to the Server sources matching the labels set in the schedule.

11. Click the **Statistics Report** link in the **Reports** card to see the performance metrics of the monitoring sources matching the selected labels.



Example: You can see the statistics for the sources tagged with the 'SUTv3' label.

Note: In the Resources report, each resource name followed by an asterisk identifies a resource monitoring source that is defined in a team space.

Collecting and viewing resource monitoring usage data

With Test , you can collect resource monitoring data in a timeframe and view the resource monitoring usage data in a graph while the test is running. You can also create queries to retrieve the resource monitoring usage data.

About this task

While monitoring a system, you can view the current data in a graph but you might also want to view persistent data that is collected during a test run in a time frame. To view the persistent data, you can configure the test with additional parameters before the test execution. While the test is running, you can view the resource monitoring usage data in a graph. When the test is running or complete, you can create queries to retrieve the collected data results.

To collect and view resource monitoring data, perform these tasks:

1. Configure a test with two additional parameters in the advanced settings.
2. View the resource monitoring usage data in a graph.
3. Create queries to retrieve the resource monitoring usage data.

Related information

Creating queries for resource monitoring usage data on page 1607

Configuring a test

You must configure a test with two parameters to collect resource monitoring usage data in a time frame when the test is running.

Before you begin

You must have completed the following tasks:

- Added and configured a source.
- Created resource monitoring labels for your source.

About this task

You can collect resource monitoring usage data during a test run for all types of monitoring sources, and all test types, except API stubs.

1. Click **Execution**, in the navigation pane.
2. Select the test that you want to run and click in the **Actions** column to open the **Execute test asset** window.
3. Click **Advanced settings**.
4. Enter the following parameters and values in **Additional Configuration Parameters**:

Parameter name	Value
rm.log.labels	Enter a label name in the second edit field as the parameter value. If you enter multiple labels, enter a comma to separate them in the list. **Example:** For two labels with the following names: 'LabelA' and 'LabelB': rm.log.labels LabelA,LabelB If a label contains a comma in its name, you must add two commas in order to collect the resource monitoring usage data. **Example:** For a label named 'Label1A,Label1B', enter the following parameter and value: rm.log.labels Label1A**,,**Label1B
rm.log.period.seconds	Enter a sampling period in the second edit field as the parameter value. The minimum period is one second.

5. Click **Add** for each parameter.
6. Click **Execute**.

Results

The monitoring data is collected while your test is running. You can see the collected data in a graph of the resource monitoring page, even 3 minutes after the test is complete.

What to do next

You can view the resource usage data on the **Resource Monitoring** page in Test and Grafana.

- Viewing resource monitoring usage data on page 1603
- Viewing resource monitoring usage data on Grafana on page 1605

Viewing resource monitoring usage data

After you add and configure monitoring sources in Test , you can view the resource monitoring usage data in a graph for each monitored source and for each selected counter.

Before you begin

You must have completed the following tasks:

- Added and connected a monitoring source, and an agent when required, to your project to be able to view the list of available sources and agents, and the resource monitoring usage data in your project.
- Configured a test with advanced parameters to view persistent usage data in a graph.

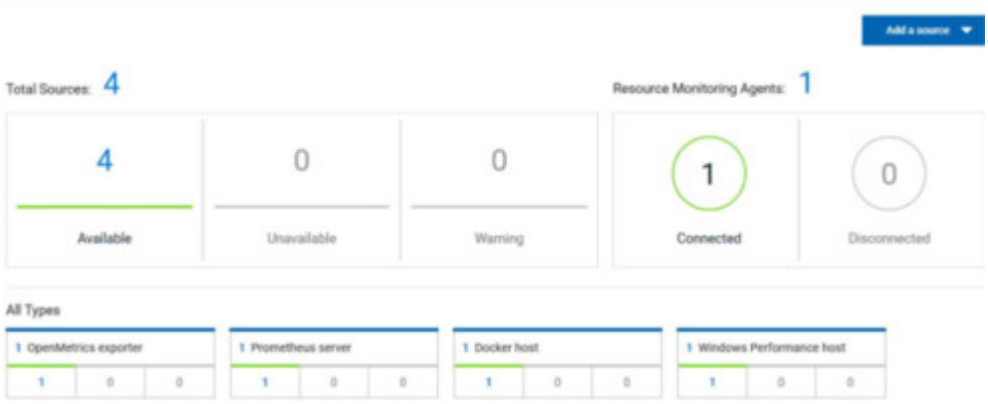
About this task

After you add a monitoring source to Test, configure the source and select monitoring counters, you can view the current resource monitoring usage data for each selected counter in a graph. If you configure the test to collect data, you can also view the resource monitoring usage data that is collected for a defined timeframe. In this case, the data is still visible in the graph three minutes after the test run is complete. After this time, you can create queries to retrieve the data.

Note: For a Prometheus source, as data comes from the Prometheus database, it no longer shows up in the graph when the test run is complete. However, the data is collected and shows up in the queries if it matches a label.

1. Click a link either in the **Total Sources** cards or in the **All Types** cards from the resource monitoring page to access the resource monitoring usage data.
   The tables display the total number of sources in your project and the number of sources by type. You can also view the number of available and unavailable sources, and the number of sources that contain warnings. If you have added '4' sources to your project, for example, click '4' in the table to access the page where you can see the resource usage data for each source.

   If you have added agents to your project, you can also view the number of agents that are connected and disconnected to your project.

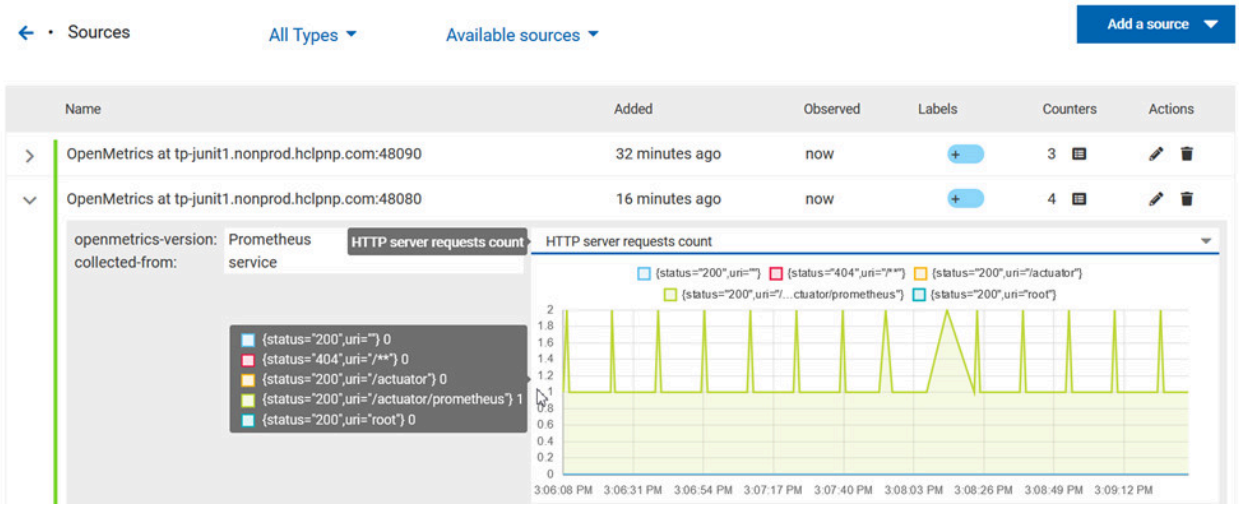


Result

The list of sources is displayed in a new page.

You can filter the list of sources by collector type or by status.

2. Expand a monitoring source under the **Name** column to see the current monitoring data usage in a graph.
3. Click the down arrow to select a counter in the list.
   A graph is displayed for each counter.



What to do next

From the page where you can view the resource monitoring usage data, you can also manage your sources. See Managing sources on page 1593.

Related information

Collecting and viewing resource monitoring usage data on page 1601

Creating queries for resource monitoring usage data on page 1607

Viewing resource monitoring usage data on Grafana

After you add and configure monitoring sources in Test , you can view the resource monitoring usage data in a graph for each monitored source and for each of the selected counters on Grafana.

Before you begin

You must have completed the following tasks:

- Added and connected a monitoring source, and an agent when required, to your project to view the list of available sources and agents, and the resource monitoring usage data in your project.
- Configured a test with advanced parameters to view persistent usage data in a graph. See Configuring a test on page 1601.
- Installed the DevOps Test Hub Results Data plug-in and created an instance of data source for DevOps Test Hub Results Data. See Installing and configuring the DevOps Test Hub Results Data plugin on page 1516.
- Opened Grafana with one of these ports: `http://localhost:3000` or `http://localhost:8080`.
- Started the test execution on Test.

About this task

After you add a monitoring source to Test, you must configure the source, and select monitoring counters. You can view the resource monitoring usage data for each of the selected counters in a graph on Grafana. You must configure the test to collect and view the resource monitoring usage data that is collected for a defined timeframe. During the test execution, the data can be seen with the default time range on Grafana. After the test execution is complete, you must carefully select the time range so that it corresponds to the test execution start and end time.

1. Click **Explore** in the **Toggle** menu in Grafana.

   The **Data query** page with the default data source is displayed.
2. Select **DevOps Test Hub Results Data** from the list of data sources.
3. Select the type of query by performing any of the following actions when you want to view statistics from the test data:

To view	Actions
The variation of a metric over time.	Perform the following steps: a. Click the time-series statistics tab icon . b. Go to Step 4 on page 1605.
The values of the metric that are computed over the entire time range.	Perform the following steps: a. Click the overall statistics tab icon . b. Go to Step 4 on page 1605.

4. Define the scope of the query by performing the actions indicated in the following table:

Options	Actions
If you want to use the data from the team space	Perform the following steps: a. Select the **Team Space** option. b. Select the team space from the list of team spaces that are listed. c. Select **Resource Monitoring** from the list in the **Service** option. d. Go to Step 5 on page 1606.
If you want to use the data from your project	**Note:** You can select the project as the scope for your query if you want to view any of the supported query types. Perform the following steps: a. Select the **Project** option. b. Select the project from the list of projects that are listed. c. Select the **Service** option. d. Select **Resource Monitoring** from the list e. Go to Step 5 on page 1606.

5. Optionally, enter a name for the metric that helps you identify it in the **Metric** field.
6. Select a metric from the list of metrics in the row of the **Metrics** option.
7. Select the aggregation factor for the metric. For example, select **Sum** to add all values of the metric.
8. Optionally, click the **Cumulated** toggle button to add the values for the metric cumulatively over time.

   Note: The **Cumulated** is set to off. This is the default selection.

9. Add another metric by clicking the **Add metric** icon .

   Note: If you added multiple metrics and you want to remove a metric, you can click the **Remove metric** icon of the metric.

10. Click **Add query** if you want to combine queries from different projects, results ids, or with different properties in the query filters.
11. Click **Run query**.

    Result

    A graph is displayed for the selected metrics.

Results

You viewed the resource monitoring usage data in a graph for each monitored source and for each of the selected counters on Grafana.

What to do next

You can build a dashboard including graphs, charts, gauges, and tables to get customized visual representations of your resource monitoring usage data. See Dashboard overview.

Creating queries for resource monitoring usage data

After you execute a test to collect resource monitoring usage data, you can create queries in Test to retrieve the data.

Before you begin

You must have added resource monitoring sources to a project.

About this task

You can no longer view the monitoring usage data in graphs 3 minutes after completion of the test. However, you can create queries to retrieve the list of activities and events in your tests. You can use the following procedure as an example to create your own queries.

1. Follow these steps to filter the list of activities that are collected for a duration of less than 300 seconds:
    a. Click **Activities**.
    b. Enter `'Type is RMsource and duration < 300'` in the **Query filters** field.
    c. Enter `'time ASC'` in the **Sort by** field to sort data by ascending order.
    d. Click **Run Query**.
    e. Click **Save as**.
    f. Enter a name to identify the new query and click **Save**.

    The list of activities that are collected for a duration of less than 300 seconds is displayed in the query result table, and this list is sorted in an ascending order.
2. Follow these steps to filter the list of observations that are performed during a test execution and defined by the test result identifier:
    a. Click **Events**.
    b. Enter the following filters in the **Query filters** field:

    ```
    type is observation and anyParentActivity matches ( anyChildActivity matches (requesterNature = 'test-result' and requesterId=1202 ))
    ```

    c. Enter `'time ASC, parentActivity.description ASC, specifier ASC'` in the **Sort by** field to sort data by ascending order.

    Note: You can use the **Ctrl-Space** keyboard shortcut to enter the properties and operators.

    d. Click **Run Query**.
    e. Click **Save as**.
    f. Enter a name to identify the new query, and then click **Save**.

    The new query results are displayed in the table of activities and events.
3. Follow these steps to manage your query:

- Click the action menu that is next to the **Save** button and select **Reset** if you have just modified a query and you want to undo your modification.
- Click the action menu and select **Delete** to delete the new query from the **Events and activities** queries list.

4. Follow any of these steps to configure the query result table:
   - Click the action menu in a column of the table to change the column display, and then perform any of the following actions:
     - Click **Insert new column**, enter a field name in **Search new column** and click **Add**.
     - Click **Move** to move a column in the table.
     - Click **Remove** to remove a column from the table.
   - Follow these steps to add a column at the end of the table:
     a. Click **Add column**.

     Result: A window opens.

     b. Enter a field name in **Search new column**.
     c. Click **Add**.
5. Click **Save** to save the configuration of the results table.

Results

You have created two queries in your project to display:

- The list of activities that are collected for a duration of less than 300 seconds.
- The list of observations that are performed during a test execution and defined by the test result identifier.

Configuring and running log queries on page 1539

Configuration of a change management

When you use any application to create and track defects (bugs), issues, or other work items, you can configure the application as a change management on Test . You can then create defects (bugs), issues, or other work items without the need to open your application.

You use Test to run tests for the software that you develop and view their results. When you discover that you might want to raise defects (bugs), issues, or other types of work items for these tests, you are required to open the application that you use. You can only then, create defects (bugs), issues, or other work items in your application.

When you configure your application as a change management on Test, you can create defects (bugs), issues, or other work items without the need to open your application.

You can find details in the following table about the usage of the applications that you can configure as a change management on Test.

Note: You can configure only one application as the change management on Test.

Issue tracking application	Usage as a change management	Go to...
Atlassian Jira Software	You can create stories, defects, or tasks as issues in your project in Jira from Test and also launch your project in Jira from Test to track and manage these issues.	Configuration of Atlassian Jira as a change management on page 1609
Azure DevOps	You can create work items in your project in Azure DevOps from Test and also launch your project in Azure DevOps from Test to track and manage these work items.	Configuration of Azure DevOps as a change management on page 1621
DevOps Plan	You can use Plan as a change management in Test. You can also launch Plan from Test to track and manage change requests and other records.	Configuration of DevOps Plan as a change management on page 1630

Configuration of Atlassian Jira as a change management

You can use Atlassian Jira as a change management in Test to create issues in the Jira project for the tests that ran in Test. The links to the Jira issues are displayed on the **Results** page in Test, and you can then view and track the Jira issues in Jira.

Prerequisites

Before you configure Jira as a change management on Test, you must have completed the following tasks:

- Installed Jira Software. See Supported installations on page 1609.
- Ensured that you obtained the access and authentication details to Jira from the Jira administrator.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

Supported installations

The following types of Jira Software installations are supported that can be configured as a change management on Test:

- On-premise Jira Software installations.
- On-cloud Jira Software installations.

Task flow

You can follow the tasks that are listed in the following table when you want to use Jira as a change management on Test. The table also provides you the links to the information about the tasks.

Task	Go to...
Configure Jira as a change management on Test.	Configuring Jira as a change management on page 1610
Create defects or issues for tests that ran on Test.	Creating Jira issues for the test results on page 1612
View details of the Jira issues that you created from Test.	Viewing details of the Jira issues on page 1618

You can manage the Jira settings that you configured in Test. You can edit the saved configuration or you can delete the configuration. For more information, see Managing the Jira configuration on page 1620.

Configuring Jira as a change management

You must configure Jira as a change management in your project in Test so that can create issues in the Jira project for the tests that ran.

Before you begin

You must have completed the following tasks:

- Verified that you can access Jira.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

About this task

With the introduction of OAuth 2.0 authentication for the connection between Test and Jira, you must be familiar with the creation of Apps that are based on the OAuth 2.0 integration. There can be more than one method in the Atlassian Developer console that you can configure the created App. One such method is adopted in the configuration of an App in Jira.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Click **Add Change Management Integration** option within the **Change Management** section.
5. Perform the following steps in the **Add Jira configuration** dialog:

a. Enter the URL of the Jira server or Jira cloud in the **Jira URL** field, and then click **Next**.

   Test provides the *Callback URL* that you must use to generate the Client ID and Client secret for the App in Jira.

b. Click the **Atlassian Developer console** link.

   The **Atlassian Developer console** page is displayed.

   Perform the following steps on the **Atlassian Developer console** page:

   i. Click **Create > OAuth 2.0 integration**.
   ii. Enter a name for the App in the **Name** field.
   iii. Click the **I agree to be bound** checkbox, and then click **Create.**

      The App is created in the Atlassian Developer Console and the details are displayed for the App.

   iv. Click **Authorization** in the navigation, and then click **Add** in the row of OAuth 2.0 (3LO).

      The OAuth 2.0 configuration page is displayed. You must paste the *Callback URL* provided by Test.

   v. Copy the *Callback URL* from the **Add Jira configuration** dialog in Test and then paste it into the **Callback URL** field.
   vi. Click **Save changes**.

      The App in Jira is configured to authenticate the requests from Test by using the OAuth 2.0 protocols.

   vii. Click **Permissions** and then, click the **Configure** option in the row of **Jira API**.
   viii. Click **Edit Scopes** on the **Jira API** page, and then select the following scopes for your App that are required for a successful connection with Test:
      - View Jira issue data
      - Manage Jira global settings
      - View user profiles
      - Create and manage issues

   ix. Click **Save** to save the App settings.
   x. Click **Settings** and scroll down the page to view the **Authentication details** panel.

      The **Client ID** and **Secret** must be copied from the **Settings** page to the corresponding fields on the **Add Jira configuration** dialog.

c. Click the **Copy** icon in the **Client ID** field to copy the key, and then paste the copied key in the **Client ID** field on the **Add Jira configuration** dialog.

d. Click the **Copy** icon in the **Secret** field to copy the key, and then paste the copied key in the **Secret** field on the **Add Jira configuration** dialog.

6. Click **Save** on the **Add Jira configuration** dialog.

You added the URL of the Jira cloud and configured an App in Jira to authenticate the connection with Test by using OAuth 2.0. You can view that the URL of the Jira server or cloud instance is displayed within the **Change Management** pane.

7. Click the **Configure** icon .

   A page in Atlassian is displayed in a browser that states that the App you created previously is requesting access to your Atlassian account.

8. Read the message that is displayed, and then click **Accept**.

   When the connection between Test and the App in Jira is established successfully, the **Configure Jira project** dialog is displayed with the Jira URL that is configured as a change management system in Test.

9. Select the project in Jira from the list under which you want to create defects.
10. Click **Save**.

Results

You configured Jira as a change management system in Test.

What to do next

You can perform the following tasks:

- View the following configuration details of Jira on the **Change Management** about the Jira configuration:
  - The URL of the Jira server or cloud instance.
  - The project that you selected.
- Create issues for the test results that are available in your project in Test. See Creating Jira issues for the test results on page 1612.

Creating Jira issues for the test results

You can create Jira issues for the tests that ran in Test . The issues are created in the project in Jira that you configured in Test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Configured Jira as a change management for your project in Test. See Configuring Jira as a change management on page 1610.
- Configured a test run. See Test run configurations on page 1134.
- Viewed the results of the completed test runs on the **Results** page. See Test results on page 1499.

About this task

When you want to create a Jira issue in Test, the issue types that display in the **Create an issue in Jira** dialog depend on the configuration done by the administrator of Jira.

The default fields that display on the **Create an issue in Jira** dialog are as follows:

- **Issue Type**
- **Summary**
- **Description**
- **Attach Reports**

If you want to view any additional fields in the **Create an issue in Jira** dialog from Test, then you must inform your Jira administrator to configure those additional fields as the required fields in the project in Jira. You can then use those fields in the **Create an issue in Jira** dialog when you create a defect from Test.

You can refer to the **Related information** section to know more about Jira field configuration.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

   Note: You can click the relevant tab to view the tests that were run earlier.

4. Perform any of the following actions to identify the test asset:

◦ Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	VU Schedule			

- Search for the test by entering any text that is contained in the test asset name in the **Search** field.
- Select the time interval within which the test was run.

  For example, you can select the *Last 24 hours* option to view the tests that were run in the previous 24 hours.
- Select the range of dates within which the test was run.

  You can click the calendar icon to select the date in the first image as the start date, and then select the date in the second image as the end date.

  Note: You can select the range of dates only when you select the time interval as *Custom*.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab, and then select the test type.

  All the tests based on the selected test type are displayed.

  For example, you can select **API Suite** in the **SUITES** tab to display all the API suites or you can select **Functional Test** in the **TESTS** tab to display all the functional tests.
- Click the **Filter** icon in the **ADVANCED** tab, and then perform the following actions to create a filter query:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then select **Add rule** to add a rule or **Add group** to add a group of rules.
  d. Select or enter the relevant parameters, and then either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - ID
     - Type
     - Test
     - Version
     - Result
     - Started on
     - Finish on
     - Duration

- Status
- Verdict
- Labels
- Locked
- Repository
- Branch
- Text

e. Click **Save**.

The filter query is saved and all the tests that match the filter criteria are displayed.

- Perform the following actions in the **ADVANCED** tab to retrieve and apply a previously saved filter query:

a. Click the **Filter** icon .

All the filter queries that you created and saved earlier are displayed.

b. Click the filter query that you want to apply.

All the tests that match the filter criteria are displayed.

You have identified the test that you want to use.

5. Select the step that depends on the role assigned to you in the project on Test:

- If you are a member with a role assigned as *Owner*, go to Step 6 on page 1616.
- If you are a member with a role assigned as *Tester*, and if you did not complete the one-time authorization process, go to Step 7 on page 1616.
- If you are a member with a role assigned as *Tester* and completed the one-time authorization process, go to Step 8 on page 1617.

6. Perform the following steps if you are assigned the role of a project *Owner*:

a. Click the **Jira: Create a Jira issue** icon that is under the **Actions** column in the row of the test.

Alternatively, you can click the test under the **Test** column to view the results panel, and then click the **Jira: Create a Jira issue** icon that is displayed in the panel.

The **Create an issue in Jira** dialog is displayed.

b. Go to Step 9 on page 1617.

7. Perform the following steps if you are assigned the role of a *Tester* and if you have not yet completed the one-time authorization process:

Note: You must complete the one-time authorization process if you are not a project owner.

a. Click the **Jira: Create a Jira issue** icon that is under the **Actions** column in the row of the test.

   Alternatively, you can click the test under the **Test** column to view the results panel, and then click the **Jira: Create a Jira issue** icon that is displayed in the panel.

   The **Configure Jira server to authorize the application** dialog is displayed.

b. Click the URL of the Jira server.

c. Log in to the Jira server account with your valid credentials.

   Note: The **Login** page is displayed only if you are not already logged in to Jira.

d. Read the message that is displayed, and then click **Allow** to authorize the Jira account.

   After the authorization is successful, the **Access Approved** page is displayed with a verification code.

e. Copy the verification code, and then enter the verification code in the field on the **Configure Jira server to authorize the application** dialog of Test.

f. Click **Save**.

g. Go to Step 8 on page 1617.

8. Perform the following steps if you are assigned the role of a *Tester* and you have completed the one-time authorization process:

   a. Click the **Jira: Create a Jira issue** icon that is under the **Actions** column in the row of the test.

      Alternatively, you can click the test under the **Test** column to view the results panel, and then click the **Jira: Create a Jira issue** icon that is displayed in the panel.

      The **Create an issue in Jira** dialog is displayed.

   b. Go to Step 9 on page 1617.

9. Perform the following steps in the **Create an issue in Jira** dialog:

   Note: The fields that are displayed might depend on the fields configured in the Jira project.

   a. Select the issue type that you want to create.

   b. Enter text for the title of the Jira issue. The name of the test is displayed as the default text in the **Summary** field.

You can view the details of the test run that is displayed in the **Description** field. These details are appended to the Jira issue under the **Description** field, after you create the issue.

c. Select the existing labels in your Jira project or enter a new name for the label in the **Label** field, if required.

Note:

If the **Label** field is set to "Required" in your Jira project, you must select an existing label or create a new label by providing a name in the **Label** field. If you don't select an existing label or create a new label, an error message is displayed that indicates the **Label** field is a required field.

d. Select the test reports or test logs of the test run that you want to attach to the Jira issue.

Note: You can select any report, test log, or all the reports and the test log as attachments.

e. Click **Create**.

The issue is created in the project on the Jira server and the link to the issue is displayed in the **Results** panel of the test on Test.

Note: You can create multiple issues for the same test result, if you want.

Results

You created issues in the Jira project for the test results from Test.

The Jira issues are created in the Jira project and the links to the issues are displayed in the **Details** panel of the test result on the **Results** page.

What to do next

You can perform any of the following tasks:

- View details of the Jira issues that you created in Jira for the test. See Viewing details of the Jira issues on page 1618.
- Modify the configuration that you set for Jira on Test. See Managing the Jira configuration on page 1620.

Related information

Specifying Jira fields

Viewing details of the Jira issues

After you create Jira issues in Test , you can view and track the details of the Jira issues in Jira.

Before you begin

You must have completed the following tasks:

- Completed a test run and the test results are available on the **Results** page.
- Created Jira issues against the test results. See Creating Jira issues for the test results on page 1612.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

   Note: You can click the relevant tab to view the tests that were run earlier.

4. Click the test that is listed under the **Test** column.
5. Click the **Report** tab in the **Results** panel, if it is not already displayed.
6. Click the Jira issue link under **Defect tracking**.

   The Jira log-in page is displayed, if you are not already logged into Jira.
7. Enter your username and password.
8. Click **Login**.

   The issue details are displayed in Jira.

   Note: The **Description** field of the Jira issue in Azure DevOps provides additional details of the test that ran in Test such as the name of the test, the person who ran the test, the verdict of the test result, the date and time

of the test run, the links to the test report that is generated in Test, and the link to the query that is created. You can also view the reports that you attached as a compressed file under the **Attachments** field in the Jira issue.

Results

You have viewed the details in Jira of the Jira issue that you created in Test.

Managing the Jira configuration

You can manage the Jira configuration that you set in Test when you want to modify the project configured in Jira or when you want to delete the existing Jira configuration.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you obtained the access and authentication details to Jira from the Jira administrator.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Go to the **Configuration details of Jira** within the **Change Management** section, the configured details of the Jira integration are displayed.
5. Perform any of the following actions when you want to update or delete the Jira server configuration:
   - To update the project in Jira that was set previously in the Jira configuration. Go to Step 6 on page 1620.
   - To delete the Jira configuration. Go to Step 7 on page 1620.
6. Perform the following steps to modify the project in Jira:

   a. Click the **Configure** icon of the Jira integration that you want to manage.
      The **Select project in Jira** dialog is displayed.

   b. Select the project that you want from the list displayed in the **Project** field.

   c. Click **Update** to save the updated project in the Jira server configuration.

7. Perform the following steps to delete the existing Jira server configuration:

a. Click the **Delete** icon .

The **Delete Jira configuration** dialog is displayed.

b. Click **Confirm**.

The Jira configuration is deleted and a confirmation message is displayed.

Note: The links to the issues that you created for the tests that ran are not deleted from the results panel in Test even after you delete the Jira configuration.

Results

You achieved the following results:

- Updated the project in Jira and saved the Jira configuration.
- Deleted the Jira configuration.

Configuration of Azure DevOps as a change management

You can use Azure DevOps as a change management in Test to create work items in the Azure DevOps project for the tests that ran in Test. Links to the Azure DevOps work items are displayed on the **Results** page in Test, and you can then view and track the work items in the Azure DevOps server.

Prerequisites

Before you configure Azure DevOps as a change management in Test, you must have completed the following tasks:

- Ensured that you obtained the access and authentication details to Azure DevOps from the Azure DevOps administrator.
- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

Supported installations

The following types of Azure DevOps installations are supported that can be configured as a change management system on Test:

- On-premise Azure DevOps installations.
- On-cloud Azure DevOps installations.

Task flow

You can follow the tasks that are listed in the following table when you want to use Azure DevOps as a change management in Test. The table also provides you the links to the information about the tasks.

Task	Go to...
Configure Azure DevOps as a change management.	Configuring Azure DevOps as a change management on page 1622
Create Azure DevOps work items for the test asset.	Creating Azure DevOps work items on page 1623
Track and view the details of the created Azure DevOps work items.	Viewing details of the Azure DevOps work items on page 1628

You can edit the saved configuration, or you can delete the configuration and create a new configuration. For more information, see Managing the Azure DevOps configuration on page 1629.

Configuring Azure DevOps as a change management

You must configure Azure DevOps as a change management in your project in Test before you can create work items in the Azure DevOps project for the tests that ran.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that you obtained the access and authentication details to Azure DevOps from the Azure DevOps administrator.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Click the **Add Change Management Integration** option, and then select **Azure DevOps** option from the list.

   The **Configure Azure DevOps** dialog is displayed.
5. You can perform the following actions:

   a. Enter the URL of **Azure DevOps**.

   Note: You must enter the URL of the Azure DevOps in one of the following formats:
   - https://dev.azure.com/{Organization}
   - https://{Organization}.visualstudio.com

- https://{Hostname}:{Port}/{Collection}

  The URL contains information such as the server name (hostname, port, or domain name) and organization name.

b. Click **Next**, and then paste the copied personal access token.

Note: If you do not have your personal access token, you can click **Generate** to generate your personal access token to authorize full access or access to the work items.

c. Click **Next**, and then select an **Azure DevOps** project from the drop-down list.

d. Click **Add**.
The configuration is added and saved within the **Change Management** section under **Configure details of Azure DevOps.**

Results

You configured Azure DevOps as a change management in Test.

What to do next

You can create work items for the test results that are available in your project in Test. See Creating Azure DevOps work items on page 1623.

Creating Azure DevOps work items

You can create Azure DevOps work items for the tests that ran in Test . The issues are created in the project in Azure DevOps that you configured in Test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Configured Azure DevOps as a change management system in Test for your project. See Configuring Azure DevOps as a change management on page 1622.
- Extended the CA list. See Extending the trusted certificate authority list on Linux on page 735 or Extending the trusted certificate authority list on Windows on page 736.
- Configured a test run. See Test run configurations on page 1134.
- Viewed the results of the completed test runs on the **Results** page. See Test results on page 1499.

About this task

When you want to create a Azure DevOps work item on Test, the fields that display in the **Create a work item** dialog depends on the configuration done by the Azure DevOps administrator.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

   Note: You can click the relevant tab to view the tests that were run earlier.

4. Perform any of the following actions to identify the test asset:
   - Scroll through the list.

     Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

     Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test by entering any text that is contained in the test asset name in the **Search** field.
- Select the time interval within which the test was run.

  For example, you can select the *Last 24 hours* option to view the tests that were run in the previous 24 hours.
- Select the range of dates within which the test was run.

  You can click the calendar icon to select the date in the first image as the start date, and then select the date in the second image as the end date.

Note: You can select the range of dates only when you select the time interval as *Custom*.

- Click the **Filter** icon in the **SUITES** or **TESTS** tab, and then select the test type.

  All the tests based on the selected test type are displayed.

  For example, you can select **API Suite** in the **SUITES** tab to display all the API suites or you can select **Functional Test** in the **TESTS** tab to display all the functional tests.

- Click the **Filter** icon in the **ADVANCED** tab, and then perform the following actions to create a filter query:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then select **Add rule** to add a rule or **Add group** to add a group of rules.
  d. Select or enter the relevant parameters, and then either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - ID
     - Type
     - Test
     - Version
     - Result
     - Started on

  e. Click **Save**.

     The filter query is saved and all the tests that match the filter criteria are displayed.

- Perform the following actions in the **ADVANCED** tab to retrieve and apply a previously saved filter query:
  a. Click the **Filter** icon .

     All the filter queries that you created and saved earlier are displayed.

  b. Click the filter query that you want to apply.

     All the tests that match the filter criteria are displayed.

You have identified the test that you want to use.

5. Perform the following actions on the test that was run to create a work item:

   a. Click the **Azure: Create work item** icon that is under the **Actions** column in the row of the test.

      Alternatively, you can click the test under the **Test** column to view the results panel, and then click the **Azure: Create work item** icon that is displayed in the panel.

      The **Create a work item** dialog is displayed.

   b. Perform the actions indicated in the following table for each of the fields:

Field	Description	Action
Project	The name of the Azure DevOps project.	Select the Azure DevOps project from the drop-down list.
Work item type	The type of work item.	Select the work item you want to assign for the test asset.
Title	A title that identifies the work item.	Specify a title for the work item.
Description	A detailed description of the work item.	Enter a description of the work item.

      Note: The other fields selected as **Required** fields on the **Azure DevOps** project are displayed in the **Create a work item** dialog.

   c. Enter the information for all the required fields, and then click **Create**.

      Note: You can create multiple work items for the same test result, if required.

Results

You created work items in the Azure DevOps project for the test results from Test.

The work items are created in the Azure DevOps project and the links to the work items are displayed in the **Details** panel of the test result on the **Results** page.

What to do next

You can perform any of the following tasks:

- View details of the Azure DevOps work items that you created in Azure DevOps for the test. See Viewing details of the Azure DevOps work items on page 1628.
- Modify the configuration that you set for Azure DevOps on Test. See Managing the Azure DevOps configuration on page 1629.

Viewing details of the Azure DevOps work items

After you create a work item in Test , you can view and track the details of the Azure DevOps work item in Azure DevOps.

Before you begin

- Created Azure DevOps work item against the test results. See Creating Azure DevOps work items on page 1623.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

   Note: You can click the relevant tab to view the tests that were run earlier.

4. Click the test that is listed under the **Test** column.
5. Click the **Report** tab in the **Results** panel, if it is not already displayed.
6. Click the Azure DevOps work item link under **Defect tracking**.

   The Azure DevOps log-in page is displayed.
7. Enter your username and password.
8. Click **Login**.

The work item details are displayed in Azure DevOps.

Note: The **Description** field of the work item in Azure DevOps provides additional details of the test that ran in Test such as the name of the test, the person who ran the test, the verdict of the test result, the date and time of the test run, the links to the test report that is generated in Test, and the link to the query that is created.

Results

You have viewed the details in Azure DevOps of the Azure DevOps work item that you created in Test.

Managing the Azure DevOps configuration

You can edit or modify the Azure DevOps configuration that you added and saved to the Change management section on Test . If you do not want to use the existing configuration and want to set up a new Change management configuration, then you can delete the configuration.

Before you begin

You must have completed the following task:

- Been assigned a project *Owner* role.

1. Open the project that you created on Test.
2. Go to **Manage**, and then click **Integration** in the navigation pane.
   The **Integration** page is displayed.
3. Go to the **Configuration details of Azure Devops** within the **Change Management** section, the configured details of the Azure DevOps integration are displayed.
4. Perform any of the following actions:
   - To edit the Azure DevOps configuration. Go to Step 5 on page 1629.
   - To delete the Azure DevOps configuration. Go to Step 6 on page 1630.
5. Follow the step to edit the Azure DevOps configuration:

   a. Click **Edit** icon of the Azure DevOps integration that you want to manage.
      The **Configure Azure DevOps** dialog is displayed.

   b. Edit the URL by performing the following steps:
      i. Enter the URL of **Azure DevOps**.
      ii. Click **Next**.
      iii. Paste the copied personal access token or click **Generate** to generate your personal access token.
      iv. Click **Add**.

      The URL is updated and saved.

   c. Edit the project by performing the following steps:

i. Select an **Azure DevOps** project from the drop-down list.
ii. Click **Add**.

The project is updated and saved.

6. Follow these steps to delete the Azure DevOps configuration:

a. Click the **Delete** icon .
The **Delete Azure DevOps configuration** dialog is displayed.

b. Click **Delete**.
The Azure DevOps configuration is deleted.

Results

You achieved the following results:

- Edited the Azure DevOps configuration and saved the configuration.
- Deleted the Azure DevOps configuration.

Configuration of DevOps Plan as a change management

You can use HCL DevOps Plan (Plan) as a change management to create work items after you run tests on Test . You can then view and track the work items in Plan.

Prerequisites

Before you configure Plan on Test, you must have completed the following tasks:

- Ensured that you obtained the access details and authentication details of Plan from the Plan administrator.
- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

Task flow

You can follow the tasks that are listed in the following table when you want to use Plan as a change management on Test. The table also provides links to the information about the tasks.

	Task	Go to...
1	Configure Plan as a change management.	Configuring DevOps Plan as a change management on page 1631
2	Create work items in Plan for the tests that ran on Test.	Creating work items on page 1632

	Task	Go to...
3	View and track the details of the created work items.	Viewing details of the work items on page 1637

You can manage the Plan settings that you configured in Test. You can edit the saved configuration or you can delete the configuration. For more information, see Managing the DevOps Plan configuration on page 1638.

Configuring DevOps Plan as a change management

You can configure HCL DevOps Plan (Plan) as a change management system in your project to create work items from Test in Plan.

Before you begin

You must have completed the following tasks:

- Read about the prerequisite tasks in Prerequisites on page 1630.
- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you obtained the access details and authentication details of Plan administrator.
- Created a project in your team space in Test. See Creating a project on page 1728.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Click **Add Change Management Integration** option within the **Change Management** section.
5. Select the **DevOps Plan** option from the list.

   The **Configure DevOps Plan application** dialog is displayed.
6. Configure the Plan application by performing the following steps:

   a. Enter the URL of the Plan server.

   Note: You can enter the URL of Plan in any of the following formats:
   - https://*IP_address*:*port*/
   - https://*hostname*/

Where	Is
IP_address	The IP address of the server on which Plan is installed.

Where	Is
port	The port that is used to communicate with Plan .
hostname	The hostname of the computer on which Plan is installed.

b. Enter the ID for the Plan Teamspace.

c. Enter the name of the Plan application.

d. Click **Add**.

The configuration is added and saved within the **Change Management** section under the **Configuration details of DevOps Plan**.

Results

You have configured Plan as a change management in your project on Test.

What to do next

You can perform any of the following tasks:

- Create work items in Plan for the tests that you ran on Test. See Creating work items on page 1632.
- Modify the configuration that you set for Plan on Test. See Managing the DevOps Plan configuration on page 1638.

Creating work items

You can create work items in HCL DevOps Plan (Plan) for the tests that ran on Test . For example, you might want to create a work item in Plan when the test results differ from the expected results.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Configured Plan as a change management in Test. See Configuring DevOps Plan as a change management on page 1631.
- Configured applications in Plan.
- Configured a test run. See Test run configurations on page 1134.
- Viewed the results of the completed test runs on the **Results** page. See Test results on page 1499.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

The **Overview** page of the project is displayed.

3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

   Note: You can click the relevant tab to view the tests that were run earlier.

4. Perform any of the following actions to identify the test asset:

   - Scroll through the list.

     Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

     Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test by entering any text that is contained in the test asset name in the **Search** field.
- Select the time interval within which the test was run.

  For example, you can select the *Last 24 hours* option to view the tests that were run in the previous 24 hours.
- Select the range of dates within which the test was run.

  You can click the calendar icon to select the date in the first image as the start date, and then select the date in the second image as the end date.

  Note: You can select the range of dates only when you select the time interval as *Custom*.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab, and then select the test type.

  All the tests based on the selected test type are displayed.

For example, you can select **API Suite** in the **SUITES** tab to display all the API suites or you can select **Functional Test** in the **TESTS** tab to display all the functional tests.

- Click the **Filter** icon in the **ADVANCED** tab, and then perform the following actions to create a filter query:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then select **Add rule** to add a rule or **Add group** to add a group of rules.
  d. Select or enter the relevant parameters, and then either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - ID
     - Type
     - Test
     - Version
     - Result
     - Started on
     - Finish on
     - Duration
     - Status
     - Verdict
     - Labels
     - Locked
     - Repository
     - Branch
     - Text
  e. Click **Save**.

     The filter query is saved and all the tests that match the filter criteria are displayed.
- Perform the following actions in the **ADVANCED** tab to retrieve and apply a previously saved filter query:
  a. Click the **Filter** icon .

     All the filter queries that you created and saved earlier are displayed.
  b. Click the filter query that you want to apply.

     All the tests that match the filter criteria are displayed.

You have identified the test that you want to use.

5. Perform the following actions on the identified test to create a work item in Plan:

a. Click the **DevOps Plan: Create a work item** icon that is under the **Actions** column in the row of the test.

   Alternatively, you can click the test under the **Test** column to view the results panel, and then click the **DevOps Plan: Create a work item** icon that is displayed in the panel.

   The **Create a work item in DevOps Plan** dialog is displayed.

b. Select the application from the list in the **Application** field.

   Remember: The application that you select must be the application in Plan for which you ran the test.

c. Enter the username in the **Username** field.

   Note: The username is authorized to access the Plan server.

d. Enter the password in the **Password** field to authenticate the username.

   Note: After the credentials that you provided in the **Username** and **Password** fields are authorized by the Plan server, you need not enter these values for subsequent connections to create a work item.

e. Click **Next**.

   The dialog displays the URL of the Plan server and the **Application** that you selected.

f. Select the work item type as *WorkItem*.

g. Click **Next**.

h. Select the project from the list in the **Project** field.

i. Select the type of the work item from the list in the **Type** field.

j. Enter text that is to be used as the title of the work item in the **Title** field. The text entered is displayed as the title in the work item in Plan.

   You can view the details of the test run in the **Description** field, which is appended to the work item that is created for the test run in Plan.

k. Click **Create**.

A work item is created in Plan and a link to the work item is created in the **Report** panel of the **Results** page.

Notes:

- You cannot delete the work item that is created in Plan from Test.
- You can create multiple work items for the same test result, if required.

Results

You have created a work item in Plan from the **Results** page for the test that ran on Test.

What to do next

You can perform any of the following tasks:

- View details of the work items that you created in Plan for the test. See Viewing details of the work items on page 1637.
- Modify the configuration that you set for Plan on Test. See Managing the DevOps Plan configuration on page 1638.

Viewing details of the work items

After you create a work item in HCL DevOps Plan (Plan) from Test , you can view and track the details of the work item in Plan.

Before you begin

You must have completed the following tasks:

- Completed a test run and the test results are available on the **Results** page.
- Created a work item in Plan against the test results. See Creating work items on page 1632.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Analyze > Results**.

   The **Results** page is displayed and all the test assets that were run earlier are displayed in tabs, as listed in the following table:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

Note: You can click the relevant tab to view the tests that were run earlier.

4. Click the test that is listed under the **Test** column.

   The **Results** panel for the test is displayed.

5. Click the **Report** tab in the **Results** panel, if it is not already displayed.
6. Click the work item link under **Defect tracking**.

   The Plan log-in page is displayed.

7. Enter your username and password.
8. Click **Sign In**.

   The work item details are displayed in Plan.

Note: The **Description** field of the work item provides additional details of the test that ran in Test such as the name of the test, the person who ran the test, the verdict of the test result, the date and time of the test run, the links to the test report that is generated in Test, and the link to the query that is created.

Results

You have viewed the details in Plan of the work item that you created in Test.

Managing the DevOps Plan configuration

You can manage the HCL DevOps Plan (Plan) configuration that you set in Test when you want to edit the configuration or when you want to delete the existing configuration.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you obtained the access details and authentication details of Plan from the Plan administrator.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.

3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Click **Add Change Management Integration** option within the **Change Management** section.

5. Perform any of the following actions when you want to edit or delete the Plan configuration:
   - To edit the Plan configuration. Go to Step 6 on page 1639.
   - To delete the Plan configuration. Go to Step 7 on page 1639.
6. Perform the following steps to edit the Plan application that is configured:

   a. Click **Edit** icon .
   The **Modify DevOps Plan configuration** dialog is displayed.

   b. Edit the URL or change it to the one that you want to use in the **URL** field, and then enter the application that you want to use.

   c. Click **Update**.

   The Plan configuration is updated and a confirmation message is displayed.

   d. Go to Results on page 1639.

7. Perform the following steps to delete the existing Plan configuration:

   a. Click the **Delete** icon .

   The **Delete DevOps Plan configuration** dialog is displayed.

   b. Click **Delete**.

   The Plan configuration is deleted and a confirmation message is displayed.

   c. Go to Results on page 1639.

Note: The links to the records that you created for the tests that you ran are not deleted from the results panel in Test even after you delete the Plan configuration.

Results

You achieved the following results:

- Edited and saved the Plan configuration.
- Deleted the Plan configuration.

Integrations with other applications

You can integrate certain applications with Test to run tests, view the test results, and create defects.

Integration plugin compatibility matrix

You can find information about the versions of the integration plugin that are compatible with Test .

The following table lists the versions of the integration plugin that are required to integrate Test with DevOps Deploy, IBM® Engineering Test Management, and Jenkins.

Note: You must download the required version of the integration plugin from My HCLSoftware (MHS) based on the existing version of Test. You can then integrate Test with HCL DevOps Deploy, IBM® Engineering Test Management, and Jenkins.

Test	Engineering Test Management plugin	Jenkins plugin	HCL DevOps Deploy plugin
11.0.9	HCL_DTHub_v1109_ETM_ADAPTER	DTHub-Jenkins-HCL-7.8	DTHub-DD-HCL-5.1 DTHub-DD-HCL-5.1

Integration with Azure DevOps

When you use Azure DevOps for continuous integration and continuous development of your application, you can run tests created for your application and available in a project on Test , in Azure DevOps pipelines by using the HCL DevOps Test Hub extension.

Overview

You can use the HCL DevOps Test Hub extension to integrate Test with Azure DevOps.

The HCL DevOps Test Hub extension enables you to select any type of test available for your project in Test that you can add to your task for the job in the Azure DevOps pipelines.

You can now follow the tasks listed in the task flow table to integrate Test with Azure DevOps. See Task flow for integrating Azure DevOps on page 1642.

Task flow for integrating DevOps Test with Azure DevOps

The table shows the task flow for integrating Test with Azure DevOps by using the HCL DevOps Test Hub extension.
You must perform these tasks in sequence as listed in the following table. The table also provides you the links to the information about the tasks.

S.N.	Tasks	More information
1	Install Test.	Installation of DevOps Test
2	Create tests in the desktop clients for the application that you want to test.	• DevOps Test Performance documentation • DevOps Test UI documentation • DevOps Test Integrations and APIs documentation

S.N.	Tasks	More information
3	Create a project on Test and add the test assets that are created in the desktop clients to your project.	Managing DevOps Test projects on page 1724
4	Create an organization and a project in Azure DevOps for running jobs in Azure DevOps pipelines.	Creating an organization
5	Access the **Visual Studio Marketplace** portal and search for the latest version of the HCL DevOps Test Hub extension.	Visual Studio Marketplace
6	Install the latest version of the HCL DevOps Test Hub extension.	Installing the HCL DevOps Test Hub extension on page 1643
7	Extend the trust certificate if you have used an internal CA certificate.	Certificate authority: Importing and extending lists on page 732
8	Run tests in an Azure DevOps pipeline.	Running tests in an Azure DevOps Pipeline on page 1644

Installing the HCL DevOps Test Hub extension

You must install the latest version of the HCL DevOps Test Hub extension in your Azure DevOps organization before you can use the extension for running your application tests in an Azure DevOps pipeline.

Before you begin

You must have access to the **Visual Studio Marketplace** portal to install the latest version of the HCL DevOps Test Hub extension.

About this task

After you install the latest version of the HCL DevOps Test Hub extension from the **Visual Studio Marketplace** portal in your Azure DevOps organization, you can select the tests that you want to run for your application in an Azure DevOps pipeline by using the HCL DevOps Test Hub extension.

1. Log in to the **Visual Studio Marketplace** portal, if you are not already logged in.
2. Click the **Azure DevOps** tab.

3. Search for the **HCL DevOps Test Hub extension**.
4. Click **HCL DevOps Test Hub extension**.
5. Click **Get it free**.
   Result

   The **Visual Studio Marketplace** portal for the HCL DevOps Test Hub extension is displayed.
6. Select the organization where you want to run your test from the **Select an Azure DevOps Organization** list.
7. Click **Install**.
   Result

   The installation is completed.
8. Click **Proceed to organization**.
   Result

   The **Organization** page in Azure DevOps is displayed.
9. Click **Organization settings > Extensions**.
   Result

   The HCL DevOps Test Hub extension is displayed as an installed extension.

Results

You have installed the HCL DevOps Test Hub extension in your Azure DevOps organization.

What to do next

You can run tests that are available in Test as a job in an Azure DevOps pipeline. See Running tests in an Azure DevOps Pipeline on page 1644.

Running DevOps Test tests in an Azure DevOps Pipeline

After you install the HCL DevOps Test Hub extension in your organization, you can run tests that are available in Test as a job in Azure DevOps pipelines.

Before you begin

You must have completed the following tasks:

- Added the tests that you created in the desktop clients for your application to the project on Test.
- Installed the latest version of the HCL DevOps Test Hub extension in your organization. See Installing the HCL DevOps Test Hub extension on page 1643.
- Installed an agent in your pipeline. See Azure Pipelines agents.
- Extended the CA list. See Extending the trusted certificate authority list on Linux on page 735 or Extending the trusted certificate authority list on Windows on page 736.
- Generated an offline user token from Test. See Generating an offline token on page 1709.

- Created test cases under test plans if you want to view results of the test runs on the Test Plans dashboard.
- Created encrypted secrets or environment variables for your personal access token (PAT), if you want to use an encrypted PAT.

About this task

After you add the HCL DevOps Test Hub extension in your Azure DevOps organization, you can use an existing pipeline or create a new one to add Test test tasks. You can install an agent or use the one that you installed in your default agent pool. You can add Test tests as tasks to your agent job, configure the task, and then run the task in the Azure DevOps pipeline.

If you have created test cases under test plans in a project on Azure DevOps, you must provide the details of the Azure DevOps URL, test plan, test case, and your PAT while you configure the test job in a pipeline so that you can view the results of the test run on your Test Plan dashboard.

1. Open your **Organization** page in Azure DevOps and perform the following steps:
    a. Click the project you want to use.
    b. Initialize the repository by performing the following steps:
        i. Click **Repos** from the left pane.
        ii. Click **Initialize** from the **Initialize with a README or gitignore** section.

        Note: Select the **Add a README** checkbox if it is not selected.

    c. Click **Pipelines** from the left pane.
    d. Click **Create Pipeline**.
    e. Click **Use the classic editor** to create a pipeline without YAML.
    f. Verify the project, repository, and branch for manual and scheduled builds, and then click **Continue**.
    g. Click **Empty job**.
2. Select **Pipeline** and complete the following steps:
    a. Change the name for the build pipeline if required.
    b. Select the **Agent pool** for your build pipeline.

    You can use the agent from the default agent pool or use the one you have installed.

    c. Select the **Agent Specification** for the agent if required.
3. Add a task to the agent job by completing the following steps:
    a. Click the **Add Task** icon for the agent job.
    Result

The **Add tasks** pane is displayed.

b. Search for the HCL tasks defined in the HCL DevOps Test Hub extension.
Result

The tasks that you can select are displayed.

c. Select the **HCL DevOps Test Hub Task**, and then click **Add** to add the task to the agent job.
Result

The selected task is added to the agent job and it is displayed with a warning that some settings require attention. You must configure the settings mentioned in Step 4 on page 1646.

You can also remove the tasks that are not required in your job. Select the tasks in the list that you want to remove. You can then right-click the tasks, and click **Remove selected task(s)** to remove them.

4. Configure the settings by performing the following steps:

a. Select the task version from the list if required.

b. Follow the action for the task by referring to the following table:

Note: All mandatory fields are marked with an asterisk (*) in the UI.

Field	Description	Action
Display name	The default name of the task. The default name that is displayed is **HCL DevOps Test Hub Task**.	Enter a name for the task that helps you to identify the task by changing the default name.
HCL DevOps Test Hub Task service connection	The details of Test to set up a connection with Azure DevOps.	Select the service connection from the drop-down list. If you are selecting the Test service connection for the first time, you must click **New** to add the following details to add Test service connection, and then save the connection details: ▪ **Server URL** - Enter the URL of Test. The format of the URL is as follows: `https://hostname.` ▪ **Offline Token** - Enter the offline token that you generated from Test. ▪ **Service connection name** - Enter a service connection name.

Field	Description	Action
		▪ **Description (optional)** - Enter the details of the service connection if required. ▪ Optionally, select the **Grant access permission to all pipelines** checkbox if required. You can save the service connection details. The service connection is available for selection from the Test service connection drop-down list. **Note:** You can edit or delete the service connection that you added if required. Click **Manage**, and then select the service connection from the **Service connections** list to open the service connection. You can click **Edit** to edit the service connection details. If you want to delete an existing service connection details, click the **Vertical ellipsis** icon, and then click **Delete** to delete the service connection details. Optionally, you can also create, edit, and delete a service connection from your Azure DevOps project dashboard. Open your project, click **Project settings > Service connections**, and then perform any of the following tasks: ▪ Create a new service connection. ▪ Edit or delete an existing service connection that you already added.
Team Space Name	The name of the team space on Test that contains your project with the test assets.	Enter the name of the team space that contains the project. **Note:** The license on the team space must be configured and you must be a member of that team space.
Project	The name of the project containing the test assets in your team space on Test.	Enter the name of the project from the available names in the team space. **Note:** **Note:** The **Project** drop-down list displays the projects where you are an *Owner* or a *member* of Test. You must be an *Owner* or a *Tester* of the

Field	Description	Action
		project that is available in the team spaces to run the tests from the Jenkins server. Azure DevOps pipeline.
Branch	The name of the branch of the repository in your project on Test that contains the test assets.	Enter the branch where the test assets are stored.
Repository Link	The URL or link to the repository in your project that contains the test assets.	Enter the repository path that is configured for the project that contains the test to run.
File Path	The path of the test in the repository of your project.	Enter the path of the test in Test that you want to run.
API Test Environment	The environment defined in the API Suite or test to use in the test run.	Enter the name of the environment that is configured in the test asset for the test created in Test Integrations and APIs. **Note:** This field is applicable only if you are running an API suite test.
Variables	The variable name and its value.	Enter the name of the variable and its value if your test requires variables during the test run time. You must enter the variables in the following format: `name_of_the_variable=value_of_the_varibale` You can add multiple variables to the test run separated by a semicolon. For example, *varname1=value1;varname2=value2*
Datasets	The name with path to the dataset that must be used during the test run.	Enter the path to the dataset if you want to replace the values of the dataset during a test run. You must ensure that both original and new datasets are in the same workspace and have the same column names. When you enter a value for the **Datasets** field, you must also include the path to the dataset. The path must be in the following format:

Field	Description	Action
		`/project_name/ds_path/original_ds.csv:/project_name/ds_path/new_ds.csv` **Note:** You can override multiple datasets that are saved in a different project by adding multiple paths to the dataset separated by a semicolon.
Labels	The option to add labels to the test results when the test run is complete.	Enter the labels to add to test results when the test run is complete. You can add multiple labels to a test result separated by a comma. For example, *label1, label2* After the test run is complete, then the values provided in the **Labels** field are displayed on the **Results** page of Test.
Classification Name	The name of the classification that contains the secrets to be used in certain API Suites or tests.	Enter the name of the classification that contains the secrets to be used in the API Suite or test. **Note:** This field is applicable only if you are running an API suite test.
Azure DevOps Project URL	The URL of the test project in the organization on the Azure DevOps server. **Note:** You must enter the details for this option if you have created test cases under test plans in your Azure project and want to view the test	Enter the URL of the test project in the organization on the Azure DevOps server in the following format: https://<host>/<orgname>/<projectName> You must use this option with the following options: ▪ Azure DevOps PAT ▪ Test Plan Name ▪ Test Case Name

Field	Description	Action
	results on the Test Plans Dashboard.	
Azure DevOps PAT	The personal access token (PAT) of the Azure server where the test project that contains the test plan is hosted. You can also enter the variable for the encrypted PAT that you create in Azure DevOps. **Note:** The token must have read and write access.	Enter your personal access token. You must use this option with the following options: ▪ Azure DevOps Project URL ▪ Test Plan Name ▪ Test Case Name
Test Plan Name	The name of the test plan in your Azure project.	Enter the name of the test plan. You must use this option with the following options: ▪ Azure DevOps Project URL ▪ Azure DevOps PAT ▪ Test Case Name
Test Case Name	The name of the test case under the test plan in your Azure project.	Enter the name of the test case. You must use this option with the following options: ▪ Azure DevOps Project URL ▪ Azure DevOps PAT ▪ Test Plan Name
Fail the job if the test or any of the containing tests fail	The flag to indicate whether the job should be marked as failed when the test or any child test within the test fails.	Select the checkbox.

Field	Description	Action
Export JUnit Report	The location to store the JUnit report of the test.	Enter the path to store the JUnit report that is generated for the test in the XML format. You must specify the complete path to the directory including the file name of the report. For example, `C:/Users/Documents/Reports/junit_test_report.xml`

c. Expand **Control Options** and configure the settings for your task if required.

d. Expand **Output Variables** and configure the settings for your task if required.

5. Select from the following options:

a. Click **Save** to save the configured settings for the task.

Note: The task is not queued for a run.

You can save the task to a build pipeline and opt to run the build at a later time.

b. Click **Save & queue** to save the configurations and queue the run in the pipeline.
Result

The **Run pipeline** dialog is displayed.

6. Complete the following steps:

a. Enter a comment for the test in the **Save comment** field.

b. Select the agent that you configured for the test from the **Agent pool** list.

c. Select the agent specification from the **Agent Specification** list if required.

d. Select the branch from the **Branch/tag** list.

e. Add the variables and demands for the task run from the **Advanced Options** pane if required.

f. Select the **Enable system diagnostics** checkbox for a detailed log view.

g. Click **Save and run**.
Result

The `pipeline summary` page displays the progress of the job run.

Results

You have run the tests for the application that you are testing in the Azure DevOps pipeline.

What to do next

You can perform any of the following actions in Azure DevOps:

- View the test results on the **Task** page by clicking the task.

  The **Reports information** section on the **Task** page displays the names of the report along with its corresponding URLs. The report URLs are the Test URLs where the reports are stored. You can access the report URLs to view the test run information at any point of time.
- View the task logs from the **pipeline summary** page for the job you ran.
- View the test results on the Test Plans Dashboard if you created test cases under test plans in your Azure project.

You can perform any of the following actions in Test:

- View the test results of the test that you ran from Azure DevOps on the **Results** page.
- View the logs and reports of the test that you ran from Azure DevOps by clicking the result panel of the test asset or resource, and then click the log or the report you want to view.

Integration with HCL DevOps Deploy

You can integrate Test with HCL DevOps Deploy (Deploy) to run test assets as a **Process** from Deploy.

When you use Deploy for automating the deployments of your applications to an environment during the development cycle, you can create test assets for your application either in Test or desktop clients. After you configure the project in Test, you can then run those tests assets from Deploy.

You must use the Test Deploy plugin to integrate Test with Deploy. Integrating Test with Deploy automates the process of test runs. If you have many tests to run at regular intervals, you can use Deploy to initiate test runs automatically.

The following table lists the tasks that you must perform to run performance test assets from Deploy:

Tasks	Go to...
Create any or all the following types of test assets in desktop clients to test your application: • API test assets • Functional test assets • Performance test assets	• DevOps Test Performance documentation • DevOps Test UI documentation • DevOps Test Integrations and APIs documentation
Create a project, and then configure the repository in Test.	Working with projects in a team space on page 1725
Install Deploy with at least one agent.	HCL® Launch Documentation.

Tasks	Go to...
	System Requirements for information about specific versions of Deploy requirements.
Install the DevOps Test Hub Deploy plugin on Deploy.	Installing the plugin on HCL DevOps Deploy on page 1653.
Create a **Component** in Deploy.	Creating a component in HCL DevOps Deploy on page 1655.
Create a **Process** for the component in Deploy.	Creating a process in HCL DevOps Deploy on page 1656.
Configure the **Process** that you created for the component in Deploy.	Configuring the process in HCL DevOps Deploy on page 1657.
Create a **Resource** in Deploy.	Creating a resource in HCL DevOps Deploy on page 1661.
Configure the **Resource** in Deploy.	Configuring the resource in HCL DevOps Deploy on page 1662.
Create an **Application** in Deploy.	Creating an application in HCL DevOps Deploy on page 1663.
Configure the **Application** that you use to run performance test assets in Deploy.	Configuring the application HCL DevOps Deploy on page 1664.
Run the test assets from Deploy.	Running tests from HCL DevOps Deploy on page 1666.

Installing the plugin on HCL DevOps Deploy

You must install the DevOps Test Hub Deploy plugin to run test assets from HCL DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Installed Deploy. For more information about the installation, refer to the HCL DevOps Deploy documentation.
  - Been granted access to Deploy.
  - Downloaded the DevOps Test Hub Deploy plugin from the My HCLSoftware (MHS).

    For more information about specific versions of plug-in, see Integration plugin compatibility matrix on page 1639.

1. Log in to Deploy, if you are not already logged in.

   Result

   The Deploy dashboard is displayed.
2. Click **Settings**.

3. Click **Installed Plugins** from the **Automation** pane.
   If you are using Deploy 8.1.1 or older version, then you must click **Automation Plugins** from the **Automation** pane.
4. Click **Load plugin**.
5. Click **Choose File** to locate and open the compressed DevOps Test Hub Deploy plugin file.

   Remember: You must not extract the DevOps Test Hub Deploy plugin compressed file contents.

6. Click **Submit**.
   Result

   The installed plugin is displayed on the **Automation Plugins** tab.

Results

You have installed the DevOps Test Hub Deploy plugin on Deploy.

What to do next

You must create a **Component** in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.

Related information

Installing plug-ins from the Web UI of Deploy

Using a custom trust store for HCL DevOps Deploy

You can use a custom trust store in the DevOps Test Hub Deploy plugin file to establish a trusted and secure connection between the HCL DevOps Deploy (Deploy) server and Test .

Before you begin

You must have completed the following tasks:

You must have completed the following tasks:

- Saved the Certificate Authority (CA) assigned to Test.

  Note: You can contact the administrator of Test if you do not have a copy of the CA.

- Installed Java on the computer from where you access the Test UI.

About this task

If the SSL certificate assigned to Test is signed by an internal Certified Authority (CA), then you must download and import the CA certificate to a custom trust store. You can then use the custom trust store in the Test test process step to establish a trusted and secure connection between the Deploy server and Test.

Note: If the internal CA certificate is already imported to the default trust store that is used by the Deploy server, you need not use a custom trust store.

1. Locate the default trust store file (`cacerts` file) from the JRE directory.
   For example: `C:\Program Files\Java\jdk-18.0.1.1\lib\security`
2. Copy the `cacerts` file to a location of your choice on your computer.
3. Place the CA assigned to Test in the same location where you saved the `cacerts` file.
4. Run the following command from the command-line interface or terminal to import the CA of Test to custom trust store:

   ```
   keytool -import -trustcacerts -file {path to the downloaded CA with the file extension} -alias {label
    for the certificate} -keystore {path to the trust store cacerts file}
   ```

   For example,

   ```
   keytool -import -trustcacerts -file C:\Users\Desktop\cert\ca-master-hcl.crt -alias "otsca" -keystore C:
   \Users\Desktop\cert\cacerts
   ```

   Note: The default password of the trust store is *changeit*. It remains the same for the custom trust store. If you want to change the password, you can run the following command, and then enter the new password:

   ```
   keytool -storepasswd -keystore {path to the trust store cacerts file}
   ```

   For example, `keytool -storepasswd -keystore C:\Users\Desktop\cert\cacerts`

Results

You have successfully imported the downloaded CA to the custom trust store.

What to do next

You can then run the tests that are available in your Test project from the Deploy server.

Creating a component in HCL DevOps Deploy

You must create a component to include artifacts and processes. The artifacts include runnable files, images, databases, configuration instructions. Whereas the processes define the activities that components can perform.

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Components**, and then click **Create Component**.

3. Enter a name for the component in the **Name** field.
4. Enter the details in the other optional fields based on your requirement, and then click **Save**.

   Result

   The component that you created is displayed.

Results

You have created the component in Deploy.

What to do next

You must create a process for the component in Deploy. See Creating a process in HCL DevOps Deploy on page 1656.

Related information

HCL DevOps Deploy Documentation

Creating a process in HCL DevOps Deploy

You must create a process for the component to include step properties for the test that you want to run from HCL DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.

1. Log in to Deploy, if you are not already logged in.

   Result

   The Deploy dashboard is displayed.
2. Click **Components**.

   Result

   A list of components that are available in Deploy is displayed.
3. Select the component from the list for which you want to create a process.
4. Click the **Processes** tab, and then click **Create Process**.

   Result

   The **Create Process** dialog is displayed.
5. Enter a name for the process in the **Name** field.
6. Select **Operational (No Version Needed)** from **Process Type** drop-down list.
7. Verify the **Default Working Directory** field.

The **Default Working Directory** field defines the location that the agent uses to run the process. The default value is `${p:resource/work.dir}/${p:component.name}`.

Where `${p:resource/work.dir}` is the default working directory for the agent and `${p:component.name}` is the name of the component.

8. Click **Save**.
   Result
   The process that you created is listed in the **Processes** tab and the **Design** tab for the process is displayed.

Results

You have created the process for the component in Deploy.

What to do next

You must configure the process in Deploy. See Configuring the process in HCL DevOps Deploy on page 1657.

Related information

HCL DevOps Deploy Documentation

Configuring the process in HCL DevOps Deploy

You must configure the process that you created for the component to organize the steps in the process, specify the properties of the steps, and connect them.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.
  - Created a process for the component in Deploy. See Creating a process in HCL DevOps Deploy on page 1656.

About this task

When you open any process to configure, the process is displayed in the process editor. The process editor lists the plugins and steps. The required **Start** and **Finish** steps represent the beginning and the end of the process and steps are automatically placed on the design area.

You must provide the values for certain fields in the properties for the selected test step to run tests from Deploy.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Components**.
   Result
   A list of components that are available in Deploy is displayed.
3. Select the component from the list in which you created the process.
4. Click the **Processes** tab.
   Result
   A list of processes that are available for the component is displayed.
5. Select the process from the list that you want to configure.
   Result
   The **Design** tab for the process is displayed.
6. Click **HCL DevOps Test Workbench**, and then **HCL DevOps Test Hub** from the left menu.
7. Drag the **Run HCL DevOps Test Hub test** step, and then drop it into the design area.

   Note: The selected test must be placed between **Start** and **Finish** steps.

8. Specify the properties for the selected test by performing the following steps:

   a. Click the **Edit** icon.
      Result
      The **Edit Properties for Run HCL DevOps Test Hub test** dialog is displayed.

   b. Specify the properties for the selected test step by referring to the following table:

      The following table lists the required fields that you must provide to run the test from Deploy:

Fields	Action
Name	Enter the name for the test step.
HCL DevOps Test Hub URL	Enter the URL of Test. If you do not have the details of the custom trust store, you must append #insecure-skip-tls-verify to the URL. For example, https://10.134-.56.236.nip.io/test#insecure-skip-tls-verify
Offline Token	Enter the offline token that you generated from Test.
Team Space Name	Enter the name of the team space that contains the project.

Fields	Action
	Note: The license for the team space must be configured and you must be a member of that team space.
Project Name	Enter the name of the project that are available in the team space.
Repository Link	Enter the URL of the Git repository that you added to your project in Test.
File Path	Enter the path of the test assets that you want to run. You can find the path of the test assets from the **Execution** page in Test

The following table lists the optional fields that you can provide to run the test from Deploy:

Fields	Description
Branch Name	Use this field to enter the name of the branch in the Git repository where you stored test assets.
Datasets	Use this field to enter the path to the dataset if you want to replace the values of the dataset during a test run. You must ensure that both original and new datasets are in the same workspace and have the same column names. When you enter a value for the **Datasets** field, you must also include the path to the dataset. The path must be in the following format: `/project_name/ds_path/original_ds.csv:/project_name/ds_path/new_ds.csv` **Note:** You can override multiple datasets that are saved in a different project by adding multiple paths to the dataset separated by a semicolon.
Environment	Use this field to enter the environment details for the following types of test assets: ▪ APISUITE ▪ APITEST ▪ APISTUB
Labels	Use this field to add labels to test results when the test run is complete.

Fields	Description
	You can add multiple labels to a test result separated by a comma. For example, *label1, label2* After the test run is complete, then the values provided in the **Labels** field are displayed on the **Results** page of Test.
Classification Name	Use this field to enter the name of the Classification if you created secrets for your project and to use Secrets at test run time. This field is mandatory only if you want to run the following types of test assets: ▪ APISUITE ▪ APITEST ▪ APISTUB
Show Hidden Properties	Select this checkbox to display the additional fields that are hidden. You can configure the following fields if you have the details of a custom trust store: ▪ **Custom Trust Store Password**: Use this field to enter the trust store password if you have modified the password while creating the custom trust store. **Note:** If you have not modified the trust store password, you can retain the **Custom Trust Store Password** field blank. ▪ **Custom Trust Store Path**: Use this field to enter the file path of your trust store followed by the file name if Test uses an internal CA certificate and you have imported the certificate to a custom trust store. Also, you can configure the HTTP Proxy to connect to Test by using the following fields: ▪ **HTTP Proxy Host**: Use this field to enter the hostname of the HTTP proxy that you want to connect to Test. ▪ **HTTP Proxy Port**: Use this field to enter the port number where the HTTP proxy is used to listen to both HTTP and HTTPS traffic. ▪ **HTTP Proxy User name**: Use this field to provide the username for the HTTP proxy. ▪ **HTTP Proxy Password**: Use this field to enter a valid password for the user that you specified in the **HTTP Proxy User name** field. **Note:** You can use the HTTP-related fields only when you want to run the following types of test assets:

Fields	Description
	▪ APISUITE ▪ APITEST ▪ APISTUB
Variables	Use this field to enter the name of the variable and its value if your test requires variables during the test run time. You must enter the variables in the following format: `name_of_the_variable=value_of_the_varibale` You can add multiple variables to the test run separated by a semicolon. For example, *varname1=value1;varname2=value2*

Note: In addition to optional fields, you can also use the following fields from Deploy to configure your test run:

- **Working Directory**
- **Precondition**
- **Post Processing Script**
- **Use Impersonation**
- **Auth Token Restriction**

You can accept the default values or change the values based on your requirements. For more information about these fields, see the related links.

c. Click **OK** to save the properties for the test.

9. Click **Save** in the design area.

Results

You have configured the process for the component in Deploy.

What to do next

You must create a resource in Deploy. See Creating a resource in HCL DevOps Deploy on page 1661.

Creating a resource in HCL DevOps Deploy

You must create a resource to associate agents with components that you created in HCL DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Resources**, and then click **Create Top-Level Group**.
   Result
   The **Create Resource** dialog is displayed.
3. Enter a name for the resource in the **Name** field.
4. Click **Save**.

Results

You have created the resource in Deploy.

What to do next

You must configure the resource. See Configuring the resource in HCL DevOps Deploy on page 1662.

Configuring the resource in HCL DevOps Deploy

You must configure the resource to add an agent and associate the agent with the component.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.
  - Created a resource in Deploy. See Creating a resource in HCL DevOps Deploy on page 1661.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Resources**.
   Result
   A list of resources that are available in Deploy is displayed.
3. Perform the following steps to add an agent to the resource:
   a. Click the resource from the list for which you want to add an agent.
   b. Click the **Actions** icon from the last column, and then click **Add Agent**.

c. Select the agent from the drop-down list.

Note: The **Name** field is auto populated with the name of the agent.

d. Click **Save**.

Result

The selected agent is added to the resource and you can view the status of the agent in the **Status** column.

4. Perform the following steps to add a component to the agent:

a. Click the agent from the list for which you want to add a component.

b. Click the **Actions** icon from the last column, and then click **Add Component**.

c. Select the component from the drop-down list.

Note: The **Name** field is auto populated with the name of the component.

d. Click **Save**.

Result

The selected component is added to the agent.

Results

You have configured the resource in Deploy.

What to do next

You must create an application. See Creating an application in HCL DevOps Deploy on page 1663.

Creating an application in HCL DevOps Deploy

You must create an application to fetch all the components together that you want to deploy.

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.

Result

The Deploy dashboard is displayed.

2. Click **Applications**.
3. Click **Create Applications**, and then **New Applications**.
4. Enter a name for the application in the **Name** field.

Result

The **Environments** page for the application that you created is displayed.

Results

You have created the application in Deploy.

What to do next

You must configure the application. See Configuring the application HCL DevOps Deploy on page 1664.

Configuring the application HCL DevOps Deploy

You must configure the application to associate resources with environments and define processes to run test assets.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Created a process for the component in Deploy. See Creating a process in HCL DevOps Deploy on page 1656.
  - Created a component in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.
  - Created a process for the component in Deploy. See Creating a process in HCL DevOps Deploy on page 1656.
  - Configure the process for the component in Deploy. See Configuring the process in HCL DevOps Deploy on page 1657.
  - Created a resource in Deploy. See Creating a resource in HCL DevOps Deploy on page 1661.
  - Configured the resource in Deploy. See Configuring the resource in HCL DevOps Deploy on page 1662.
  - Created an application in Deploy. See Creating an application in HCL DevOps Deploy on page 1663.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Applications**.
   Result
   A list of applications that are available in Deploy is displayed.
3. Click the application that you want to configure from the **Name** column.
   Result
   The **Environments** page for the selected application is displayed.
4. Perform the following steps to create an environment for the application that you selected:

a. Click **Create Environment**.
b. Enter a name for the environment in the **Name** field.
c. Click **Save**.

5. Perform the following steps to configure resources to the environment:

   a. Click the environment that you created.

   b. Click **Add Base Resources**.
   Result
   A list of resources that are available in Deploy is displayed.

   c. Select the checkbox to add resources to the environment.

   d. Click **Save**.
   Result
   You can view the corresponding agent and the component that you added for the resource by using the **Expand** icon.

6. Perform the following steps to add the component to the application:
   a. Click **Applications**, and then select your application from the list.
   b. Click the **Components** tab, and then **Add Components**.
   c. Select the checkbox from the drop-down list to add components to the application.
   d. Click **Save**.
7. Perform the following steps to create a process for the application:

   a. Click the **Processes** tab, and then **Create Process**.

   b. Enter a name for the process in the **Name** field.

   c. Click **Save**.
   Result
   The **Design** tab for the process that you created is displayed.

8. Drag the component process listed under the **Component Process Steps** option from the left navigation pane and drop it into the design area.
9. Select the component process from the drop-down list in the **Operational (No Version Needed) Process** field.
10. Click **Save**.
11. Click the **Edit** icon, and then change the name of the properties.
12. Click **OK**, and then click **Save**.

Results

You have configured the application to run test assets from Deploy.

What to do next

You can run test assets from Deploy. See Running tests from HCL DevOps Deploy on page 1666.

Related information

HCL DevOps Deploy Documentation

Running tests from HCL DevOps Deploy

You can run test assets from HCL DevOps Deploy (Deploy) as a **Process** to test your application under test.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in HCL DevOps Deploy on page 1655.
  - Created a process for the component in Deploy. See Creating a process in HCL DevOps Deploy on page 1656.
  - Configure the process for the component in Deploy. See Configuring the process in HCL DevOps Deploy on page 1657.
  - Created a resource in Deploy. See Creating a resource in HCL DevOps Deploy on page 1661.
  - Configured the resource in Deploy. See Configuring the resource in HCL DevOps Deploy on page 1662.
  - Created an application in Deploy. See Creating an application in HCL DevOps Deploy on page 1663.
  - Configured the application in Deploy. See Configuring the application HCL DevOps Deploy on page 1664.
  - Started the Deploy agent. For more information, refer to the HCL Launch documentation.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Applications**.
   Result
   A list of applications that are available in Deploy is displayed.
3. Click the application that you configured for the test run.
4. Click the **Request Process** icon.
   Result
   The **Create Deployment** page is displayed.
5. Select the process that you created for the application which contains the test assets from the **Process** drop-down list.
6. Click **Next**, and then select the specific version of component, if any.

Note: If you have multiple versions for your component, then only you can choose the required version by clicking the **Add** option.

7. Click **Next**, and then verify the properties for the test run.
8. Click **Next**, and then verify that the status of the **Run Now** option is enabled.
   You can disable the **Run Now** option, and then use the **Date**, **Time**, and **Recurrence Pattern** fields to run tests as **Process** at the scheduled time.
9. Click **Next**, and then verify the details about the **Process**.
10. Click **Submit Deployment** to initiate the test run.

Results

You have run the performance test assets as **Process** from Deploy.

What to do next

You can view the status of the process as follows:

- **Success**: When the test run is successful
- **Failed**: When the test run fails

You can view the details of the test run in the **Execution Log** section. The **Reports information** section on the Log file displays the names of the report along with its corresponding URLs.

Integration with IBM® DevOps Deploy

You can integrate Test with IBM® DevOps Deploy (Deploy) to run test assets as a **Process** from Deploy.

When you use Deploy for automating the deployments of your applications to an environment during the development cycle, you can create test assets for your application in desktop clients. After you configure the project in Test, you can then run those tests assets from Deploy.

You must use the DevOps Test Hub Deploy plugin to integrate Test with Deploy. Integrating Test with Deploy automates the process of test runs. If you have many tests to run at regular intervals, you can use Deploy to initiate test runs automatically.

The following table lists the tasks that you must perform to run performance test assets from Deploy:

Tasks	Go to...
Create any or all the following types of test assets in desktop clients to test your application: • API test assets • Functional test assets • Performance test assets	• DevOps Test Performance documentation • DevOps Test UI documentation • DevOps Test Integrations and APIs documentation

Tasks	Go to...
Create a project, and then configure the repository in Test.	Working with projects in a team space on page 1725
Install Deploy with at least one agent.	Installing the server System Requirements for information about specific versions of Deploy requirements.
Install the DevOps Test Hub Deploy plugin on Deploy.	Installing the DevOps Test Hub Deploy plugin on page 1668.
Create a **Component** in Deploy.	Creating a component in IBM DevOps Deploy on page 1670.
Create a **Process** for the component in Deploy.	Creating a process in IBM DevOps Deploy on page 1671.
Configure the **Process** that you created for the component in Deploy.	Configuring the process in IBM DevOps Deploy on page 1672.
Create a **Resource** in Deploy.	Creating a resource in IBM DevOps Deploy on page 1676.
Configure the **Resource**.	Configuring the resource in IBM DevOps Deploy on page 1677.
Create an **Application** in Deploy.	Creating an application in IBM DevOps Deploy on page 1678.
Configure the **Application** that you want to use to run test assets from Deploy.	Configuring the application in IBM DevOps Deploy on page 1679.
Run the test assets from Deploy.	Running tests from IBM DevOps Deploy on page 1681.

Installing the DevOps Test Hub Deploy plugin

You must install the DevOps Test Hub Deploy plugin to run test assets from IBM® DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Installed Deploy. For more information about the installation, refer to the IBM Urban Code documentation.
  - Been granted access to Deploy.
  - Downloaded the DevOps Test Hub Deploy plugin from the My HCLSoftware (MHS).

    For more information about specific versions of plug-in, see Integration plugin compatibility matrix on page 1639.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Settings**.
3. Click **Installed Plugins** from the **Automation** pane.
   If you are using Deploy 8.1.1 or older version, then you must click **Automation Plugins** from the **Automation** pane.
4. Click **Load plugin**.
5. Click **Choose File** to locate and open the compressed DevOps Test Hub Deploy plugin file.

   Remember: You must not extract the DevOps Test Hub Deploy plugin compressed file contents.

6. Click **Submit**.
   Result

   The installed plugin is displayed on the **Automation Plugins** tab.

Results

You have installed the DevOps Test Hub Deploy plugin on Deploy.

What to do next

You must create a **Component** in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.

Related information

Installing plug-ins from the Web UI of Deploy

Using a custom trust store for IBM® DevOps Deploy

You can use a custom trust store in the DevOps Test Hub Deploy plugin file to establish a trusted and secure connection between the IBM® DevOps Deploy (Deploy) server and Test .

Before you begin

You must have completed the following tasks:

- Saved the Certificate Authority (CA) assigned to Test.

  Note: You can contact the administrator of Test if you do not have a copy of the CA.

- Installed Java on the computer from where you access the Test UI.

About this task

If the SSL certificate assigned to Test is signed by an internal Certified Authority (CA), then you must download and import the CA certificate to a custom trust store. You can then use the custom trust store in the **Run HCL DevOps Test Hub test** process step to establish a trusted and secure connection between the Deploy server and Test.

Note: If the internal CA certificate is already imported to the default trust store that is used by the Deploy server, you need not use a custom trust store.

1. Locate the default trust store file (`cacerts` file) from the JRE directory.
   For example: `C:\Program Files\Java\jdk-18.0.1.1\lib\security`
2. Copy the `cacerts` file to a location of your choice on your computer.
3. Place the CA assigned to Test in the same location where you saved the `cacerts` file.
4. Run the following command from the command-line interface or terminal to import the CA of Test to custom trust store:

   ```
   keytool -import -trustcacerts -file {path to the downloaded CA with the file extension} -alias {label
    for the certificate} -keystore {path to the trust store cacerts file}
   ```

   For example,

   ```
   keytool -import -trustcacerts -file C:\Users\Desktop\cert\ca-master-hcl.crt -alias "otsca" -keystore C:
   \Users\Desktop\cert\cacerts
   ```

   Note: The default password of the trust store is *changeit*. It remains the same for the custom trust store. If you want to change the password, you can run the following command, and then enter the new password:

   ```
   keytool -storepasswd -keystore {path to the trust store cacerts file}
   ```

   For example, `keytool -storepasswd -keystore C:\Users\Desktop\cert\cacerts`

Results

You have successfully imported the downloaded CA to the custom trust store.

What to do next

You can then run the tests that are available in your Test project from the Deploy server.

Creating a component in IBM® DevOps Deploy

You must create a component to include artifacts and processes in IBM® DevOps Deploy (Deploy). The artifacts include runnable files, images, databases, configuration instructions. Whereas the processes define the activities that components can perform.

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Components**, and then click **Create Component**.
3. Enter a name for the component in the **Name** field.
4. Enter the details in the other optional fields based on your requirement, and then click **Save**.
   Result
   The component that you created is displayed.

Results

You have created the component in Deploy.

What to do next

You must create a process for the component in Deploy. See Creating a process in IBM DevOps Deploy on page 1671.

Creating a process in IBM® DevOps Deploy

You must create a process for the component to include step properties for the test that you want to run from IBM® DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Components**.
   Result
   A list of components that are available in Deploy is displayed.
3. Select the component from the list for which you want to create a process.
4. Click the **Processes** tab, and then click **Create Process**.
   Result
   The **Create Process** dialog is displayed.
5. Enter a name for the process in the **Name** field.
6. Select **Operational (No Version Needed)** from **Process Type** drop-down list.
7. Verify the **Default Working Directory** field.

The **Default Working Directory** field defines the location that the agent uses to run the process. The default value is `${p:resource/work.dir}/${p:component.name}`.

Where `${p:resource/work.dir}` is the default working directory for the agent and `${p:component.name}` is the name of the component.

8. Click **Save**.
   Result
   The process that you created is listed in the **Processes** tab and the **Design** tab for the process is displayed.

Results

You have created the process for the component in Deploy.

What to do next

You must configure the process in Deploy. See Configuring the process in IBM DevOps Deploy on page 1672.

Configuring the process in IBM® DevOps Deploy

You must configure the process that you created for the component to organize the steps in the process, specify the properties of the steps, and connect them in IBM® DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.
  - Created a process for the component in Deploy. See Creating a process in IBM DevOps Deploy on page 1671.
  - Generated an offline user token from Test. See Generating an offline token on page 1709.
  - Added the tests assets to the project on Test.

About this task

When you open any process to configure, the process is displayed in the process editor. The process editor lists the plugins and steps. The required **Start** and **Finish** steps represent the beginning and the end of the process and steps are automatically placed on the design area.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Components**.

Result

A list of components that are available in Deploy is displayed.

3. Select the component from the list in which you created the process.
4. Click the **Processes** tab.

   Result

   A list of processes that are available for the component is displayed.
5. Select the process from the list that you want to configure.

   Result

   The **Design** tab for the process is displayed.
6. Click **HCL DevOps Test Workbench**, and then **HCL DevOps Test Hub** from the left menu.
7. Drag the **Run HCL DevOps Test Hub test** step, and then drop it into the design area.

   Note: The selected test must be placed between **Start** and **Finish** steps.

8. Specify the properties for the selected test by performing the following steps:

   a. Click the **Edit** icon.

      Result

      The **Edit Properties for Run HCL DevOps Test Hub test** dialog is displayed.

   b. Specify the properties for the selected test step by referring to the following tables:

      The following table lists the required fields that you must provide to run the test from Deploy:

Fields	Action
Name	Enter the name for the test step.
HCL DevOps Test Hub URL	Enter the URL of Test. If you do not have the details of the custom trust store, you must append #insecure-skip-tls-verify to the URL. For example, https://10.134-.56.236.nip.io/test#insecure-skip-tls-verify
Offline Token	Enter the offline token that you generated from Test.
Team Space Name	Enter the name of the team space that contains the project.

Fields	Action
	Note: The license for the team space must be configured and you must be a member of that team space.
Project Name	Enter the name of the project that are available in the team space.
Repository Link	Enter the URL of the Git repository that you added to your project in Test.
File Path	Enter the path of the test assets that you want to run. You can find the path of the test assets from the **Execution** page in Test

The following table lists the optional fields that you can provide to run the test from Deploy:

Fields	Description
Branch Name	Use this field to enter the name of the branch in the Git repository where you stored test assets.
Datasets	Use this field to enter the path to the dataset if you want to replace the values of the dataset during a test run. You must ensure that both original and new datasets are in the same workspace and have the same column names. When you enter a value for the **Datasets** field, you must also include the path to the dataset. The path must be in the following format: `/project_name/ds_path/original_ds.csv:/project_name/ds_path/new_ds.csv` **Note:** You can override multiple datasets that are saved in a different project by adding multiple paths to the dataset separated by a semicolon.
Environment	Use this field to enter the environment details for the following types of test assets: ▪ APISUITE ▪ APITEST ▪ APISTUB
Labels	Use this field to add labels to test results when the test run is complete.

Fields	Description
	You can add multiple labels to a test result separated by a comma. For example, *label1, label2* After the test run is complete, then the values provided in the **Labels** field are displayed on the **Results** page of Test.
Classification Name	Use this field to enter the name of the Classification if you created secrets for your project and to use Secrets at test run time. This field is mandatory only if you want to run the following types of test assets: ▪ APISUITE ▪ APITEST ▪ APISTUB
Show Hidden Properties	Select this checkbox to display the additional fields that are hidden. You can configure the following fields if you have the details of a custom trust store: ▪ **Custom Trust Store Password**: Use this field to enter the trust store password if you have modified the password while creating the custom trust store. **Note:** If you have not modified the trust store password, you can retain the **Custom Trust Store Password** field blank. ▪ **Custom Trust Store Path**: Use this field to enter the file path of your trust store followed by the file name if Test uses an internal CA certificate and you have imported the certificate to a custom trust store. Also, you can configure the HTTP Proxy to connect to Test by using the following fields: ▪ **HTTP Proxy Host**: Use this field to enter the hostname of the HTTP proxy that you want to connect to Test. ▪ **HTTP Proxy Port**: Use this field to enter the port number where the HTTP proxy is used to listen to both HTTP and HTTPS traffic. ▪ **HTTP Proxy User name**: Use this field to provide the username for the HTTP proxy. ▪ **HTTP Proxy Password**: Use this field to enter a valid password for the user that you specified in the **HTTP Proxy User name** field. **Note:** You can use the HTTP-related fields only when you want to run the following types of test assets:

Fields	Description
	▪ APISUITE ▪ APITEST ▪ APISTUB
Variables	Use this field to enter the name of the variable and its value if your test requires variables during the test run time. You must enter the variables in the following format: `name_of_the_variable=value_of_the_varibale` You can add multiple variables to the test run separated by a semicolon. For example, *varname1=value1;varname2=value2*

Note: In addition to optional fields, you can also use the following fields from Deploy to configure your test run:

- **Working Directory**
- **Precondition**
- **Post Processing Script**
- **Use Impersonation**
- **Auth Token Restriction**

You can accept the default values or change the values based on your requirements. For more information about these fields, see the related links.

c. Click **OK** to save the properties for the test.

9. Click **Save** in the design area.

Results

You have configured the process for the component in Deploy.

What to do next

You must create a resource in Deploy. See Creating a resource in IBM DevOps Deploy on page 1676.

Creating a resource in IBM® DevOps Deploy

You must create a resource to associate agents with components that you created in IBM® DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Resources**, and then click **Create Top-Level Group**.
   Result
   The **Create Resource** dialog is displayed.
3. Enter a name for the resource in the **Name** field.
4. Click **Save**.

Results

You have created the resource in Deploy.

What to do next

You must configure the resource. See Configuring the resource in IBM DevOps Deploy on page 1677.

Configuring the resource in IBM® DevOps Deploy

You must configure the resource to add an agent and associate the agent with the component in IBM® DevOps Deploy (Deploy).

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.
  - Created a resource in Deploy. See Creating a resource in IBM DevOps Deploy on page 1676.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Resources**.
   Result
   A list of resources that are available in Deploy is displayed.
3. Perform the following steps to add an agent to the resource:
   a. Click the resource from the list for which you want to add an agent.
   b. Click the **Actions** icon from the last column, and then click **Add Agent**.

c. Select the agent from the drop-down list.

Note: The **Name** field is auto populated with the name of the agent.

d. Click **Save**.

Result

The selected agent is added to the resource and you can view the status of the agent in the **Status** column.

4. Perform the following steps to add a component to the agent:

a. Click the agent from the list for which you want to add a component.

b. Click the **Actions** icon from the last column, and then click **Add Component**.

c. Select the component from the drop-down list.

Note: The **Name** field is auto populated with the name of the component.

d. Click **Save**.

Result

The selected component is added to the agent.

Results

You have configured the resource in Deploy.

What to do next

You must create an application. See Creating an application in IBM DevOps Deploy on page 1678.

Creating an application in IBM® DevOps Deploy

You must create an application in IBM® DevOps Deploy (Deploy) to fetch all the components together that you want to deploy.

Before you begin

- You must be familiar with working with Deploy.
- You must have been granted access to Deploy.

1. Log in to Deploy, if you are not already logged in.

Result

The Deploy dashboard is displayed.

2. Click **Applications**.
3. Click **Create Applications**, and then **New Applications**.
4. Enter a name for the application in the **Name** field.

Result

The **Environments** page for the application that you created is displayed.

Results

You have created the application in Deploy.

What to do next

You must configure the application. See Configuring the application in IBM DevOps Deploy on page 1679.

Configuring the application in IBM® DevOps Deploy

You must configure the application in IBM® DevOps Deploy (Deploy) to associate resources with environments and define processes to run test assets.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.
  - Created a process for the component in Deploy. See Creating a process in IBM DevOps Deploy on page 1671.
  - Configure the process for the component in Deploy. See Configuring the process in IBM DevOps Deploy on page 1672.
  - Created a resource in Deploy. See Creating a resource in IBM DevOps Deploy on page 1676.
  - Configured the resource in Deploy. See Configuring the resource in IBM DevOps Deploy on page 1677.
  - Created an application in Deploy. See Creating an application in IBM DevOps Deploy on page 1678.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Applications**.
   Result
   A list of applications that are available in Deploy is displayed.
3. Click the application that you want to configure from the **Name** column.
   Result
   The **Environments** page for the selected application is displayed.
4. Perform the following steps to create an environment for the application that you selected:

a. Click **Create Environment**.
b. Enter a name for the environment in the **Name** field.
c. Click **Save**.

5. Perform the following steps to configure resources to the environment:

   a. Click the environment that you created.

   b. Click **Add Base Resources**.
   Result
   A list of resources that are available in Deploy is displayed.

   c. Select the checkbox to add resources to the environment.

   d. Click **Save**.
   Result
   You can view the corresponding agent and the component that you added for the resource by using the **Expand** icon.

6. Perform the following steps to add the component to the application:
   a. Click **Applications**, and then select your application from the list.
   b. Click the **Components** tab, and then **Add Components**.
   c. Select the checkbox from the drop-down list to add components to the application.
   d. Click **Save**.
7. Perform the following steps to create a process for the application:

   a. Click the **Processes** tab, and then **Create Process**.

   b. Enter a name for the process in the **Name** field.

   c. Click **Save**.
   Result
   The **Design** tab for the process that you created is displayed.

8. Drag the component process listed under the **Component Process Steps** option from the left navigation pane and drop it into the design area.
9. Select the component process from the drop-down list in the **Operational (No Version Needed) Process** field.
10. Click **Save**.
11. Click the **Edit** icon, and then change the name of the properties.
12. Click **OK**, and then click **Save**.

Results

You have configured the application to run test assets from Deploy.

What to do next

You can run test assets from Deploy. See Running tests from IBM DevOps Deploy on page 1681.

Running tests from IBM® DevOps Deploy

You can run test assets from IBM® DevOps Deploy (Deploy) as a **Process** to test your application under test.

Before you begin

- You must be familiar with working with Deploy.
- You must have performed the following tasks:
  - Been granted access to Deploy.
  - Created a component in Deploy. See Creating a component in IBM DevOps Deploy on page 1670.
  - Created a process for the component in Deploy. See Creating a process in IBM DevOps Deploy on page 1671.
  - Configure the process for the component in Deploy. See Configuring the process in IBM DevOps Deploy on page 1672.
  - Created a resource in Deploy. See Creating a resource in IBM DevOps Deploy on page 1676.
  - Configured the resource in Deploy. See Configuring the resource in IBM DevOps Deploy on page 1677.
  - Created an application in Deploy. See Creating an application in IBM DevOps Deploy on page 1678.
  - Configured the application in Deploy. See Configuring the application in IBM DevOps Deploy on page 1679.
  - Started the Deploy agent. For more information, refer Starting agents.

1. Log in to Deploy, if you are not already logged in.
   Result
   The Deploy dashboard is displayed.
2. Click **Applications**.
   Result
   A list of applications that are available in Deploy is displayed.
3. Click the application that you configured for the test run.
4. Click the **Request Process** icon.
   Result
   The **Run Application Process** page is displayed.
5. Select the process that you created for the application which contains the test assets from the **Process** drop-down list.
6. Click **Submit**.
   Result
   The Deploy dashboard shows the progress of the process request.

Results

You have run the performance test assets as **Process** from Deploy.

What to do next

After the process completes, you can view the status of the process displayed as follows:

- **Success**: When the test run is successful
- **Failed**: When the test run is failed

You can view the details of the test run in the **Execution Log** section. The **Reports information** section on the Log file displays the names of the report along with its corresponding URLs.

Integration with IBM® Engineering Test Management

As a *Project Owner*, you can integrate Engineering Test Management as a quality management solution with Test . You can run test assets that are available in a project from Engineering Test Management.

The following topics provides more information about the integration of Test with Engineering Test Management.

Task flow for integration of IBM® Engineering Test Management

You must perform the following tasks in sequence to integrate Test with Engineering Test Management. For more information about the tasks, refer to the links provided in the table.

S/N	Tasks	More information
1	Create a project in Test.	Creating a project on page 1728
2	Install the required version of Engineering Test Management on your computer.	Engineering Lifecycle Management Documentation
3	Download the Engineering Test Management adapter, and then extract the contents of a compressed file. For more information about specific versions of plugin, see Integration plugin compatibility matrix on page 1639.	My HCLSoftware (MHS)
4	Add the adapter files that you downloaded to the installation directory of Engineering Test Management.	Adding the adapter files to IBM Engineering Test Management on page 1683
5	Configure the details of Engineering Test Management on Test.	Configuring IBM Engineering Test Management on DevOps Test on page 1684
6	Create a test script and a test case on Engineering Test Management to run the test assets.	Preparing test cases in IBM Engineering Test Management on page 1685

S/N	Tasks	More information
7	Run the test assets from Engineering Test Management.	Running tests from IBM Engineering Test Management on page 1687

Adding the adapter files to IBM® Engineering Test Management

You must add the adapter files to the installation directory to run test assets of Test from Engineering Test Management.

Before you begin

You must have completed the following tasks:

- Installed the latest version of Engineering Test Management from the Jazz portal on your computer. See System Requirements for DevOps Test 2026.06 (11.0.9).
- Downloaded the adapter (a compressed file) for Engineering Test Management from the My HCLSoftware (MHS).

  For more information about specific versions of plugin, see Integration plugin compatibility matrix on page 1639.

About this task

You must add the adapter files to the location where you installed Engineering Test Management to run test assets of Test.

1. Extract the compressed file that you downloaded.
2. Copy the `etm-adapter-updatesite` folder.
3. Go to the location where you installed Engineering Test Management on your computer.
4. Place the `etm-adapter-updatesite` folder in the `sites` folder of the installation directory of Engineering Test Management.
   For example, `D:\ELM\JazzTeamServer\server\conf\qm\sites`.
5. Copy the `dthub-profile.ini` file from the `provision_profiles` folder of the extracted package and place it in the `provision_profiles` folder of the Engineering Test Management installation directory.
   For example, `D:\ELM\JazzTeamServer\server\conf\qm\provision_profiles`.

Results

You have added the adapter files to Engineering Test Management.

What to do next

You must perform the following tasks:

- You must reset the Engineering Test Management server from the web console by using the **Request Server Reset** option.

  If you have administrator privileges, then you can access the **Request Server Reset** option from the following URL:

  ```
  https://<hostname>:<portnumber>/qm/admin?
  internal#action=com.ibm.team.repository.admin.serverReset
  ```

Note: You must replace the following values with the actual values in the URL:

- <hostname> with the hostname that you used when you installed Engineering Test Management.
- <portnumber> with the port number that is associated with an IP address of the hostname.

- Restart the Engineering Test Management server.
- Configure the details of Engineering Test Management on Test to establish a connection between the two products. See Configuring IBM Engineering Test Management on DevOps Test on page 1684.

Configuring IBM® Engineering Test Management on DevOps Test

You must configure Engineering Test Management on Test to establish a connection between the two products.

Before you begin

You must have completed the following tasks:

- Granted sufficient privileges to access **Project area** on Engineering Test Management.
- Created a project area in Engineering Test Management.
- Created a project in Test.

About this task

If you have multiple instances of Engineering Test Management, then you can configure all those instances on Test. If you have only one instance of Engineering Test Management, you can configure the same instance multiple times. However, you must choose a different **Project area** during the configuration of Engineering Test Management.

1. Log in to Test, if you are not already logged in.
2. Open a project from the team space.
3. Click **Manage > Integration**.
   The **Integration** page is displayed.
4. Click **Add IBM ETM Adapter** option within the **IBM Engineering Test Management (ETM)** section.
   The **Add IBM ETM Adapter** dialog is displayed.
5. Enter the following information in the **Add IBM ETM Adapter** dialog:

Fields	Actions
Server URL	Enter the URL of Engineering Test Management. For example, https://<hostname>:<portnumber>/qm
Username	Enter the username associated with Engineering Test Management.

Fields	Actions
Password	Enter the password associated with the username of Engineering Test Management.

6. Click **Validate**.
7. Select the project name that you created in Engineering Test Management from the **Project area** list.
8. Enter a name for the Engineering Test Management adapter in the **Adapter name** field.

   Note: You cannot provide an adapter name that already exists for the **Project area**.

9. Click **Save**.

Results

You have configured the details of Engineering Test Management on Test.

What to do next

You must create a test script and test case on Engineering Test Management to run the test assets of Test. See Preparing test cases in IBM Engineering Test Management on page 1685.

Preparing test cases in IBM® Engineering Test Management

You must create a test script and a test case on Engineering Test Management to run the test assets.

Before you begin

You must have completed the following tasks:

- Added the adapter files to the installation directory of Engineering Test Management. See Adding the adapter files to IBM Engineering Test Management on page 1683.
- Configured the details of Engineering Test Management on Test . See Configuring IBM Engineering Test Management on DevOps Test on page 1684.
- Generated an offline user token from Test. See Generating an offline token on page 1709.
- Copied the following values to be used during the preparation of a test script and a test case:
  - Branch name of the Git repository
  - Asset ID of the test that you want to run
  - **Optional**: Name of the environment if you want to run the API test suite.

1. Log in to Engineering Test Management, if you are not already logged in.
2. Open your project area from where you want to run the test assets.
3. Click **Construction**, and then click **Test Script** from the drop-down list.

4. Enter a name for the test script in the **Test Script** field.
5. Select **HCL DevOps Test Hub** from the **Type** drop-down list.
6. Enter the following test information:

Fields	Actions
Offline Token	Enter the offline token that you generated from Test.
Branch	Enter the name of the branch where your test assets are stored.
Asset ID	Enter an asset ID of the test asset that is available on the **Execution** page of Test. **Tip:** You can hover over the name of the test asset to view and copy the asset ID.
Environment	Enter a name of the API test environment. **Remember:** You must use this field only if you want to run the API test suites.

7. Click **Save**.
8. Perform the following steps to add a test script to a test case:

    a. Click **Construction > Test Case**.
    Result
    The **Test Cases** page is displayed.

    b. Enter a name for the test case in the **Test Case** field.

    c. Click **Test Scripts** from the left navigation pane.

    d. Click the **Plus** icon from the **Test Scripts** panel.
    Result
    The **Add Test Scripts** dialog is displayed.

    e. Select the checkbox to add the test script that you created to the test case, and then click **Add and Close**.

    f. Click **Save**.

Results

You have prepared Engineering Test Management.

What to do next

You can run the test assets of Test from Engineering Test Management. See Running tests from IBM Engineering Test Management on page 1687.

Running tests from IBM® Engineering Test Management

After you create a test case in Engineering Test Management, you can run the test. The test case includes the test scripts that contains test assets of Test .

Before you begin

You must have performed the following tasks:

- Prepared Engineering Test Management to run test assets of Test. See Preparing test cases in IBM Engineering Test Management on page 1685.
- Configured the details of Engineering Test Management on Test. See Configuring IBM Engineering Test Management on DevOps Test on page 1684.

1. Log in to Engineering Test Management.
2. Open the test case that you created in Engineering Test Management.
3. Click the **Play** icon , and then click **Run**.
   Result
   The **Run Test Case** dialog is displayed.
4. Click the **ChangeMachine** icon next to the **Machine** field to select the adapter that you configured on Test.
5. Select the required adapter name from the list, and then click **OK**.
6. Click **Finish** to start the test run.
   The Engineering Test Management dashboard displays the progress of the test case run.

   Note: If the dashboard does not display the progress of the test run correctly, then you must refresh the browser to view the correct status.

Results

You have run the test assets of Test from Engineering Test Management.

What to do next

You can perform the following tasks:

- Click **Show Result** to view information about the test results from Engineering Test Management when the test run is complete.
- Click **Link to Result** from **Results details** to view the test results from the **Results** page of Test. See Test results and reports on page 1501.

Deleting an IBM® Engineering Test Management adapter

You might want to delete an IBM® Engineering Test Management adapter when it is no longer needed.

Before you begin

You must have completed the following tasks:

- Been assigned the role of *Owner* of a project or *Owner* of the project in Test .
- Configured the details of Engineering Test Management on Test. See Configuring IBM Engineering Test Management on DevOps Test on page 1684.

1. Log in to Test and open the team space that contains your project.
2. Click **Manage > Integration**.
   The **Integration** page is displayed.
3. Go to the **IBM Engineering Test Management (ETM)** and within the **Configuration details of IBM ETM Adapters** section.

   You can view the Engineering Test Management adapters that are configured with the project on Test.
4. Identify the Engineering Test Management adapter that you want to delete, and then click the **Delete** icon .

   Note: If any of the test runs are in progress on Engineering Test Management, then those runs are aborted.
5. Click **Confirm** to delete the Engineering Test Management adapter from the project.

Results

You have deleted the Engineering Test Management adapter from the project on Test.

Integration with Jenkins

You can use the Test plugin to integrate Test with Jenkins. After you complete the integration, you can run tests assets that are available in a project of Test from a Jenkins server.

You must have installed Jenkins on your computer to install the Test Jenkins plugin. You can run the following command to start the Jenkins server to support UTF-8 character sets:

java -Dfile.encoding=UTF8 -jar jenkins.war

You can use either the Jenkins **Freestyle** project or the **Pipeline** project to run test assets from Jenkins. With **Freestyle** project, you can create build step from the Jenkins UI to run the test assets. Whereas the **Pipeline** project uses a simple text scripts based on the Groovy programming language. You can define pipeline scripts during the configuration of the **Pipeline** project by using any of the following methods:

- **Pipeline script**: In this method, you can directly enter a script in the field provided within the Jenkins UI or you can select a sample **Pipeline script** from the drop-down list.
- **Pipeline script from SCM**: In this method, you can create a script with a Groovy editor and then commit the script file into the Git repository.

For more information about the Jenkins Pipeline, refer to the Jenkins documentation.

Refer to the following topics to learn more about integrating Jenkins with Test.

Task flows for running test assets from Jenkins

You can perform certain tasks to run test assets from the Jenkins **Freestyle** project or the **Pipeline** project.

The following table lists the task flows for running test assets from the Jenkins **Freestyle** project:

Tasks	Go to...
Install the Test Jenkins plugin.	Installing the Test Jenkins plugin on page 1690
Import the CA certificate to your custom trust store.	Using a custom trust store on page 1691
Configure the **Freestyle** project.	Configuring the Freestyle project on page 1692
Run Test test assets on Jenkins.	Running tests from Jenkins on page 1702

You can perform the following tasks to run test assets from the Jenkins **Pipeline** project by using the sample script:

Tasks	Go to...
Install the Test Jenkins plugin.	Installing the Test Jenkins plugin on page 1690
Import the CA certificate to your custom trust store.	Using a custom trust store on page 1691
Create a pipeline script from the Jenkins UI.	Creating a pipeline script from Jenkins on page 1696
Configure the **Pipeline** project.	Configuring the Pipeline project by using the sample script on page 1700
Run Test test assets on Jenkins.	Running tests from Jenkins on page 1702

You can perform the following tasks to run test assets from the Jenkins **Pipeline** project by using the script from Source Code Management (SCM):

Tasks	Go to...
Install the Test Jenkins plugin.	Installing the Test Jenkins plugin on page 1690
Import the CA certificate to your custom trust store.	Using a custom trust store on page 1691

Tasks	Go to...
Create a pipeline script and commit the script to the Git repository.	For more information, refer to the Jenkins documentation.
Configure the **Pipeline** project.	Configuring the Pipeline project by using the script from SCM on page 1701
Run Test test assets on Jenkins.	Running tests from Jenkins on page 1702

Installing the Test Jenkins plugin

Before you can run the tests that are available in your Test project on the Jenkins server, you must install the Test Jenkins plugin on the Jenkins server.

Before you begin

You must have completed the following tasks:

- Installed Jenkins on your computer. For more information about installing Jenkins, refer to the Jenkins documentation.
- Downloaded the Test Jenkins plugin from the My HCLSoftware (MHS).

  For more information about specific versions of plugin, see Integration plugin compatibility matrix on page 1639.

1. Log in to the Jenkins server.
   Result
   The Jenkins dashboard is displayed.
2. Click **Manage Jenkins > Manage Plugins**.
3. Click the **Advanced** tab.
4. Click **Choose File** from the **Upload plugin** section to locate and **Open** the Test Jenkins plugin.
5. Click **Upload**.
   Result

   The Test Jenkins plugin is displayed in the **Installed** tab.

Results

You have installed the Test Jenkins plugin on the Jenkins server.

What to do next

You must import the CA certificate to your custom trust store to establish a trusted and secure connection between the Jenkins server and Test. See Using a custom trust store on page 1691.

Using a custom trust store

You must use a custom trust store in the Jenkins build to establish a trusted and secure connection between the Jenkins server and Test .

Before you begin

You must have completed the following tasks:

- Saved the Certificate Authority (CA) assigned to Test.

  Note: You can contact the administrator of Test if you do not have a copy of the CA.

- Installed Java on the computer from where you access the Test UI.

About this task

If the SSL certificate assigned to Test is signed by an internal CA, then you must download and import the CA to a custom trust store. You can then use the custom trust store in the Jenkins build step to establish a trusted and secure connection between the Jenkins server and Test.

Note: If the internal CA is already imported to the default trust store that is used by the Jenkins server, you need not use a custom trust store.

Restriction:

When you use Red Hat Enterprise Linux (RHEL) operating systems for Jenkins, you must run the Jenkins service with a user who has access to the custom trust store path to utilize the custom trust store feature. To change the Jenkins user, you must open the `/etc/sysconfig/jenkins` file and set the JENKINS_USER to the user who has access to the custom trust store path.

You can then run the following commands to set JENKINS_USER to another user who has access to the path of the custom trust store:

```
$JENKINS_USER= <username>
```

For example, `$JENKINS_USER= <user1>`

Note: You must ensure that the user account is available in the `/etc/passwd` file.

You can then run the following commands to change the ownership of the Jenkins folder:

```
chown -R username:username /var/lib/jenkins
```

```
chown -R username:username /var/cache/jenkins
```

```
chown -R username:username /var/log/jenkins
```

For example,

```
chown -R user1:user1 /var/lib/jenkins

chown -R user1:user1 /var/cache/jenkins

chown -R user1:user1 /var/log/jenkins
```

After the change of ownership is complete, you can run the following command to restart the Jenkins server:

```
/etc/init.d/jenkins restart
```

1. Locate the default trust store file (`cacerts` file) from the JRE directory.
   For example: `C:\Program Files\Java\jdk-18.0.1.1\lib\security`
2. Copy the `cacerts` file to a location of your choice on your computer.
3. Place the CA assigned to Test in the same location where you saved the `cacerts` file.
4. Run the following command from the command-line interface or terminal to import the CA of Test to custom trust store:

   ```
   keytool -import -trustcacerts -file {path to the downloaded CA with the file extension} -alias {label
    for the certificate} -keystore {path to the trust store cacerts file}
   ```

   For example,

   ```
   keytool -import -trustcacerts -file C:\Users\Desktop\cert\ca-master-hcl.crt -alias "otsca" -keystore C:
   \Users\Desktop\cert\cacerts
   ```

   Note: The default password of the trust store is *changeit*. It remains the same for the custom trust store. If you want to change the password, you can run the following command, and then enter the new password:

   ```
   keytool -storepasswd -keystore {path to the trust store cacerts file}
   ```

   For example, `keytool -storepasswd -keystore C:\Users\Desktop\cert\cacerts`

Results

You have successfully imported the downloaded CA to the custom trust store.

What to do next

You can run test assets either from **Freestyle** or **Pipeline** project from the Jenkins server.

Configuring the Freestyle project

You must configure a **Freestyle** project to add a build step, and then run tests that are available in your Test project from Jenkins.

Before you begin

You must have completed the following tasks:

- Installed the Test Jenkins plugin on the Jenkins server. See Installing the Test Jenkins plugin on page 1690.
- Created a Jenkins **Freestyle** project.
- Generated an offline user token from Test. See Access management for DevOps Test on page 1709.

1. Open your Jenkins **Freestyle** project from the list, and then click **Configure**.
2. Click the **Build** tab, and then click **Add build step**.
3. Select the **HCL DevOps Test Hub test** option from the drop-down list.
4. Provide the details about the test run for the fields in the following table:

   The following table lists the required fields that you must provide to run the test from Jenkins:

Fields	Action
Name	Enter a name for the Jenkins build step.
Server URL	Enter the URL of Test. The format of the URL is as follows: *https://hostname*.
Offline Token	Enter the offline user token that you generated from Test.

   The following table lists the optional fields that you can provide to run the test from Jenkins:

Fields	Descriptions
Asset Type	Use this field to select the test asset type that you want to run from the **Asset Type** drop-down list.
Branch	Use this field to select the branch of the Git repository from the drop-down list. The **Branch** drop-down list displays the branches that are available in the corresponding project of Test. **Note:** After you select the branch from the **Branch** drop-down list, if you want to change the URL of Test, offline user token, or the project in the **Build** step, then you must close the build step. Then you must click **Add build step**, select **Run HCL DevOps Test Hub test**, and then enter the details.
Datasets	Use this field to enter the path to the dataset if you want to replace the values of the dataset during a test run.

Fields	Descriptions
	You must ensure that both original and new datasets are in the same workspace and have the same column names. When you enter a value for the **Datasets** field, you must also include the path to the dataset. The path must be in the following format: `/project_name/ds_path/original_ds.csv:/project_name/ds_path/new_ds.csv` **Note:** You can override multiple datasets that are saved in a different project by adding multiple paths to the dataset separated by a semicolon.
Labels	Use this field to add labels to test results when the test run is complete. You can add multiple labels to a test result separated by a comma. For example, *label1, label2* After the test run is complete, then the values provided in the **Labels** field are displayed on the **Results** page of Test.
Project	Use this field to select a project from the drop-down list. The **Project** drop-down list displays the projects that are available in the corresponding team space of Test. **Note:** The **Project** drop-down list displays the projects where you are an *Owner* or a *member* of Test. You must be an *Owner* or a *Tester* of the project that is available in the team spaces to run the tests from the Jenkins server.
Secrets	Use this field to select the Secret from the **Classification** drop-down list if you created secrets for your project to use Secrets at test run time. The **Secrets** field is mandatory only if you select one of the following options in the **Asset Type** field: ◦ **APISUITE** ◦ **APITEST** ◦ **APISTUB** ◦ **POSTMAN** The following message is displayed when you select any other asset type than preceding list: `You can select Secrets only if you are running tests of type APISUITE, APITEST, APISTUB, or POSTMAN.`

Fields	Descriptions
Team Space	Use this field to select the name of the team space from the drop-down list. The **Team Space** drop-down list displays the names of the team spaces if you are an *Owner* or a *member* of the team space.
Test	Use this field to select the required test that you want to run from the drop-down list. The **Tests** drop-down list displays the available test assets from the corresponding branch in the following format: `Project_name [Path: the path of the test assets] [Repo: URL of the Git repository that the test belongs to]` **Note:** After you select the test details from the **Tests** drop-down list if you want to change the URL of Test, offline user token, or the project in the Jenkins **Build step**, then you must delete the build step and add a new build step.
Test Environment	Use this field to select an environment from the drop-down list. The **Test Environment** field displays the available test environments from Test. The **Test Environment** field is mandatory only if you select one of the following options in the **Asset Type** field: ◦ **APISUITE** ◦ **APITEST** ◦ **APISTUB** ◦ **POSTMAN** The following message is displayed when you select any other asset type than preceding list: `You can select Test Environment only if you are running tests of type APISUITE, APITEST, APISTUB, or POSTMAN.`
Use Custom Trust Store	Select this checkbox if you used an internal CA certificate and imported the certificate to the custom trust store. You can then enter the file path of your trust store followed by the file name in the **Custom Trust Store Path** field. Select the **Use Custom Password for the Trust Store** checkbox if you modified the trust store password, and then enter the new password in the **Custom Trust Store Password** field.

Fields	Descriptions
	Note: If you did not modify the trust store password, you must clear the **Use Custom Password for the Trust Store** checkbox.
Variables	Use this field to enter the name of the variable and its value if your test requires variables during the test run time. You must enter the variables in the following format: `name_of_the_variable=value_of_the_varibale` You can add multiple variables to the test run separated by a semicolon. For example, *varname1=value1;varname2=value2*
Fail the job if the test or any of the containing tests fail	Select the checkbox to mark the job as failed when the test or any child test within the test fails.

Note: You can run multiple tests sequentially in the same job by adding multiple build steps and providing details for the tests that you want to run.

5. Click **Save** to save the build step.

Results

You have configured the **Freestyle** project by adding the build step.

What to do next

You can run test assets from the Jenkins server. See Running tests from Jenkins on page 1702.

Creating a pipeline script from Jenkins

You must create a pipeline script to run test assets that are available in the Test project from the Jenkins **Pipeline** project.

Before you begin

You must have completed the following tasks:

- Installed the Test Jenkins plugin on the Jenkins server. See Installing the Test Jenkins plugin on page 1690.
- Generated an offline user token from Test. See Access management for DevOps Test on page 1709.
- Created a Jenkins **Pipeline** project.

1. Open your Jenkins **Pipeline** project from the list.
2. Click **Configure**, and then select the **Pipeline** tab.
3. Click **Pipeline Syntax** to generate a pipeline script.
4. Select the **step: General Build Step** option from the drop-down list in the **Sample Step** field.
5. Select the **Run HCL DevOps Test Hub test** option from the drop-down list in the **Build Step** field.
6. Provide the details about the test run for the fields in the following table:

   The following table lists the required fields that you must provide to run the test from Jenkins:

Fields	Action
Name	Enter a name for the Jenkins build step.
Server URL	Enter the URL of Test. The format of the URL is as follows: *https://hostname*.
Offline Token	Enter the offline user token that you generated from Test.

Field	Description
Asset Type	Use this field to select the test asset type that you want to run from the **Asset Type** drop-down list.
Branch	Select the branch from the drop-down list. The **Branch** drop-down list displays the branches that are available in the corresponding project of Test.
Datasets	Use this field to enter the path to the dataset if you want to replace the values of the dataset during a test run. You must ensure that both original and new datasets are in the same workspace and have the same column names. When you enter a value for the **Datasets** field, you must also include the path to the dataset. The path must be in the following format: `/project_name/ds_path/original_ds.csv:/project_name/ds_path/new_ds.csv`

Field	Description
	Note: You can override multiple datasets that are saved in a different project by adding multiple paths to the dataset separated by a semicolon.
Labels	Use this field to add labels to test results when the test run is complete. You can add multiple labels to a test result separated by a comma. For example, *label1, label2* After the test run is complete, then the values provided in the **Labels** field are displayed on the **Results** page of Test.
Project	Use this field to select a project from the drop-down list. The **Project** drop-down list displays the projects that are available in the corresponding team space of Test. **Note:** The **Project** drop-down list displays the projects where you are an *Owner* or a *member* of Test. You must be an *Owner* or a *Tester* of the project that is available in the team spaces to run the tests from the Jenkins server.
Secrets	Use this field to select the Secret from the **Classification** drop-down list if you created secrets for your project to use Secrets at test run time. The **Secrets** field is mandatory only if you select one of the following options in the **Asset Type** field: ◦ **APISUITE** ◦ **APITEST** ◦ **APISTUB** ◦ **POSTMAN** The following message is displayed when you select any other asset type than preceding list: `You can select Secrets only if you are running tests of type APISUITE, APITEST, APISTUB, or POSTMAN.`
Team Space	Use this field to select the name of the team space from the drop-down list. The **Team Space** drop-down list displays the names of the team spaces if you are an *Owner* or a *member* of the team space.

Field	Description
Test	Use this field to select the required test that you want to run from the drop-down list. The **Tests** drop-down list displays the available test assets from the corresponding branch in the following format: `Project_name [Path: the path of the test assets] [Repo: URL of the Git repository that the test belongs to]` **Note:** After you select the test details from the **Tests** drop-down list if you want to change the URL of Test, offline user token, or the project in the Jenkins **Build step**, then you must delete the build step and add a new build step.
Test Environment	Use this field to select an environment from the drop-down list. The **Test Environment** field displays the available test environments from Test. The **Test Environment** field is mandatory only if you select one of the following options in the **Asset Type** field: ◦ **APISUITE** ◦ **APITEST** ◦ **APISTUB** ◦ **POSTMAN** The following message is displayed when you select any other asset type than preceding list: `You can select Test Environment only if you are running tests of type APISUITE, APITEST, APISTUB, or POSTMAN.`
Use Custom Trust Store	Select this checkbox if you used an internal CA certificate and imported the certificate to the custom trust store. You can then enter the file path of your trust store followed by the file name in the **Custom Trust Store Path** field. Select the **Use Custom Password for the Trust Store** checkbox if you modified the trust store password, and then enter the new password in the **Custom Trust Store Password** field. **Note:** If you did not modify the trust store password, you must clear the **Use Custom Password for the Trust Store** checkbox.
Variables	Use this field to enter the name of the variable and its value if your test requires variables during the test run time.

Field	Description
	You must enter the variables in the following format: `name_of_the_variable=value_of_the_varibale` You can add multiple variables to the test run separated by a semicolon. For example, *varname1=value1;varname2=value2*
Fail the job if the test or any of the containing tests fail	Select the checkbox to mark the job as failed when the test or any child test within the test fails.

7. Click **Generate Pipeline Script** and copy the script that you created for the build step to use it in the sample script.

Results

You have created the pipeline script.

What to do next

You can configure the **Pipeline** project by using the **Pipeline script** option. See Configuring the Pipeline project by using the sample script on page 1700.

Configuring the Pipeline project by using the sample script

You can configure a **Pipeline** project directly from the Jenkins UI by using the sample pipeline scripts to run test assets from Jenkins.

Before you begin

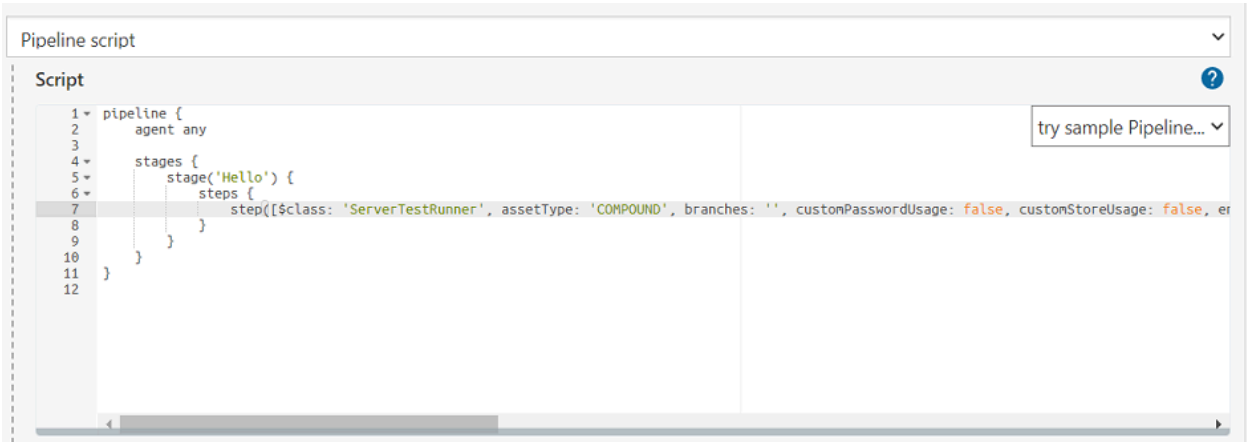
You must have completed the following tasks:

- Installed the Test Jenkins plugin on the Jenkins server. See Installing the Test Jenkins plugin on page 1690.
- Created a pipeline script. See Creating a pipeline script from Jenkins on page 1696.

1. Open your Jenkins **Pipeline** project from the list.
2. Click **Configure**, and then select the **Pipeline** tab.
3. Select the **Pipeline script** option in the **Definition** field.
4. Select the sample script from the drop-down list.

   For example, if you select `Hello Word` from the drop-down list, then the sample script is displayed as follows:

5. Specify the script that you created in place of *"echo 'Hello Word'"*.



Note: You can provide a different name for the `stage` in the script.

Results

You have configured the **Pipeline** project by using the **Pipeline script** option.

What to do next

You can run test assets from the Jenkins server. See Running tests from Jenkins on page 1702.

Configuring the Pipeline project by using the script from SCM

You can configure the **Pipeline** project to use the pipeline script from the Source Code Management (SCM), and then run test assets that are available in the Test project from the Jenkins **Pipeline** project.

Before you begin

You must have completed the following tasks:

- Installed the Test Jenkins plugin on the Jenkins server. See Installing the Test Jenkins plugin on page 1690.
- Created a pipeline script and committed the script to the Git repository. For more information, refer to the Jenkins documentation.
- Been granted administrator permission of the Jenkins server to add credentials into Jenkins.
- Added your GitHub credentials into Jenkins. For more information about adding global credentials, refer to the Jenkins documentation.
- Created a Jenkins **Pipeline** project.

About this task

If your pipeline scripts are complex, you can then write the script outside of Jenkins UI. You must commit that script file into your Git repository. During the **Pipeline** build process, Jenkins checks out the script file from the Git repository and runs your **Pipeline** project.

1. Open your Jenkins **Pipeline** project from the list.
2. Click **Configure**, and then select the **Pipeline** tab.
3. Select the **Pipeline script from SCM** option in the **Definition** field.
4. Select the **Git** option from the drop-down list in the **SCM** field.
5. Enter the URL of the Git repository in the **Repository URL** field where you stored your pipeline script.
6. Select the credentials of the Git repository from the drop-down list.
7. **Optional:** Enter the branch name of the Git repository in the **Branch Specifier** field.
8. Enter the path of the script that you stored in the Git repository in the **Script path** field.
9. Click **Save**.

Results

You have configured the **Pipeline** project by using the **Pipeline script from the SCM** option.

What to do next

You can run test assets from the Jenkins server. See Running tests from Jenkins on page 1702.

Running tests from Jenkins

You can run test assets either from the Jenkins **Freestyle** or the **Pipeline** project on the Jenkins server to test an application under test.

Before you begin

You must have completed the following tasks:

- Configured the **Freestyle** project, if you want to run test assets from the **Freestyle** project. See Configuring the Freestyle project on page 1692.
- Configured the **Pipeline** project either by using the **Pipeline script** or **Pipeline script from SCM**, if you want to run test assets from the **Pipeline script** project. See Configuring the Pipeline project by using the sample script on page 1700 or Configuring the Pipeline project by using the script from SCM on page 1701.
- Downloaded the latest **Test Results Analyzer** plugin from the Jenkinsci repository. For more information about the **Test Results Analyzer** plugin, refer to the Jenkins documentation.
- Installed the **Test Results Analyzer** plugin on the Jenkins server. For more information about installing the plugin, refer to the Jenkins documentation.

About this task

After the test run is complete, you can view the test results in a tabular format when you use the Jenkins **Test Results Analyzer** plugin. With a TRA-based report, you can filter the results based on the status of the build. The status of the builds can be PASSED, FAILED, and SKIPPED. You can also identify the failed build from the TRA-based report and take the required action to resolve the build errors. The TRA report also represents the build information in **Line**, **Bar**, and **Pie** graphs so that you can easily read the data.

1. Log in to the Jenkins server.
   Result
   The Jenkins dashboard is displayed.
2. Open your Jenkins **Freestyle** or **Pipeline** project from the list.
3. Click **Build Now** to run the test assets from Jenkins.

Results

You have run the test from the Jenkins server.

What to do next

You can view the build logs by clicking the build number from the **Build History** pane, and then selecting the **Console Output** option. You can also view the history of test results in a tabular format by clicking the **Test Results Analyzer** option.

You can access the report URLs to view the test run information at any point in time. You can also view the test reports and logs of the test that was run on the Jenkins server from the **Results** page on Test. See Test results and reports on page 1501.

Integration with Xray test management for Jira

When you use Jira as a change management system on Test and you use Xray as the test management application in Jira, you can integrate Xray with Test. With this integration, you can export the test results of the tests that run on Test to your Jira project. You can then view and use the test results in your project in Jira.

Prerequisites

Before you integrate Xray with Test, you must have completed the following tasks:

- Configured Jira as a change management system on Test. See Configuration of Atlassian Jira as a change management on page 1609.
- Installed the Xray test management app in Jira.

  Note: The Xray integration is supported only when the Xray test management application is installed on a Jira cloud.

- Ensured that you obtained the access and authentication details to Jira from the Jira administrator.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

Task flow

You can follow the tasks that are listed in the following table when you want to export test results to your Xray test project in Jira. The table also provides you the links to the information about the tasks.

Task	Go to...
Generate the Xray API keys for your username on Jira.	Generating API keys for the Xray app in Jira on page 1704
Use the generated Xray API keys to configure the Xray integration in Test.	Configuring the Xray integration on page 1705
Select an issue in your Xray project in Jira as a location to export the test results of a test run. You must select the issue while you configure a test run on Test.	Selecting a Jira Xray issue to export test results on page 1706

You can manage the Xray settings that you configured in Test. You can edit the saved configuration or you can delete the configuration. For more information, see Managing the Xray configuration on page 1708.

Generating API keys for the Xray app in Jira

You must generate API keys for the Xray app in Jira and use them to configure the Xray integration in Test . The Xray API keys are used by Jira to authenticate the requests from Test.

Before you begin

You must have completed the following tasks:

- Read about the prerequisite tasks in Prerequisites on page 1704.
- Verified that you can access Jira.

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.

1. Log in to Jira.
2. Click **Settings > Apps**.

   The apps that are installed in Jira are listed in the navigation pane.
3. Find the **Xray App** in the navigation pane, and then click the **API Keys** option.

   The **API Keys** page is displayed.
4. Click **Create API Key**.

   The **Create API Key** dialog is displayed.
5. Enter your username in the **User** field, and then select the username that is displayed.
6. Click **Generate**.

   The API keys are generated and displayed under the **Client ID** and **Client Secret** fields.
7. Click the **Copy** icon in the **Client ID** field to copy the key, and then paste the copied key into a text file.
8. Click the **Copy** icon in the **Client Secret** field to copy the key, and then paste the copied key into a text file.

Results

You have generated the Xray API keys in Jira.

What to do next

You must use the Xray API keys to configure the Xray integration in Test. See Configuring the Xray integration on page 1705.

Configuring the Xray integration

You can set up the Xray integration when you want to export test results from Test to an issue in your Xray project in Jira. You must configure the Xray integration in your project in Test before you select the Xray project in Jira as the location to export the test results after the test runs in Test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that you must have set up Jira as the Change Management system to add Jira Xray Integration.
- Generated the Xray API keys in Jira and saved the keys in a text file. See Generating API keys for the Xray app in Jira on page 1704.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.
4. Click **Add Jira Xray Integration** option within **Jira Xray Test Management** section.

   The **Add Xray Integration** dialog is displayed.
5. Perform the following steps:

   a. Enter the Xray API key that was generated for the **Client ID** in the **Client ID** field.

   b. Enter the Xray API key that was generated for the **Client Secret** in the **Client Secret** field.

   c. Click **Save**.

      The Xray configuration is saved and displayed under the **Jira Xray Test Management** pane.

Results

You configured the Xray integration on Test.

What to do next

You can perform the following tasks:

- View the following information on the **Jira Xray Test Management** that you used to configure the Xray integration:
  - The URL of the Jira server on which the Xray test management app is installed.
  - The project that you selected in Jira.
  - The Xray API key that is used as the Client ID.
- Select an issue in Jira as the location to which you can export the test results of a test run while you configure a run of the test on Test. See Selecting a Jira Xray issue to export test results on page 1706.

Selecting a Jira Xray issue to export test results

After you configure the Xray integration on Test , you can select a Jira Xray issue in Jira or create a new issue in Jira to export the test results. The test results are exported to the selected issue after the tests run on Test. You can then view and track the test results in your Jira project.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Configured the Xray integration by using the Xray API keys that are generated for your username. See Configuring the Xray integration on page 1705.
- Ensured that the **Execute test asset** dialog is displayed and you have configured the other settings for a test run in Test.

About this task

When you configure a test run in Test, you can select a Jira issue as the location where you want the test results to be exported. After the test is run, the results are exported to the Jira issue. You can then view and track the test results in the Jira issue from your project in Jira.

1. Click the **RESULTS** tab in the **Execute test asset** dialog.

   The **RESULTS** tab is displayed.

   Note: The **Export report options** field is enabled only if you configured the Xray integration with the Xray API keys that are generated for your username in Jira.

2. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: a. Select the **Jira Xray** option. The **Select issue** field is displayed. b. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project. c. Select the issue to which you want to export the test results. d. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: a. Select the **New Jira item** option. b. Continue with the next step.

Export options	Results in...	Actions
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ◦ You do not want to export the test results. ◦ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. a. Select the **None** option. b. Continue with the next step.

Results

You selected an issue in your Xray project or created an issue in Jira as a location to export the test results of a test run on Test.

What to do next

After the test run is completed, you can go to the **Results** page and expand the test result to view the Xray issue key to which the test results were exported. You can then click the Xray issue key link to open the issue and view the details of the issue in Jira.

Managing the Xray configuration

You can manage the configuration of the Xray integration that you set in Test when you want to modify the API keys configured or when you want to delete the existing Xray configuration.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that you obtained the access and authentication details to Jira from the Jira administrator.
- Configured the Xray API keys for the Xray integration on Test. See Configuring the Xray integration on page 1705.
- Regenerated the Xray API keys in Jira by following the steps to generate the Xray API keys in Generating API keys for the Xray app in Jira on page 1704.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Integration** in the navigation pane.
   The **Integration** page is displayed.

4. Go to the **Jira Xray Test Management** and within the **Configuration details of Jira Xray** section the details about the Xray integration is configured are displayed.
5. Perform any of the following actions when you want to update or delete the Xray configuration:
    - To update the Xray API keys that were set previously in the Xray configuration, go to Step 6 on page 1709.
    - To delete the Xray configuration, go to Step 7 on page 1709.
6. Perform the following steps to update the Xray API keys:

    a. Click the **Update Credentials** icon of the Xray integration that you want to manage.
    The **Update Xray Integration** dialog is displayed.

    b. Enter the Xray API key that was generated for the **Client ID** in the **Client ID** field.

    c. Enter the Xray API key that was generated for the **Client Secret** in the **Client Secret** field.

    d. Click **Update** to save the updated Xray API keys in the Configuration details of Jira Xray.

    The Xray configuration is updated and a confirmation message is displayed.
7. Perform the following steps to delete the existing Xray configuration:

    a. Click the **Delete** icon.
    The **Delete Xray configuration** dialog is displayed.

    b. Click **Confirm**.

    The Xray configuration is deleted and a confirmation message is displayed.

Note: The links to the issues that you created to export the test results are not deleted from the results panel in Test even after you delete the Xray configuration.

Results

You achieved the following results:

- Updated the Xray configuration.
- Deleted the Xray configuration.

Access management for DevOps Test

Desktop clients and third-party integrations use offline user tokens to connect to Test .

You can configure desktop clients and third-party integrations to access Test by using the offline user tokens generated from the server.

Note: Offline tokens remain valid indefinitely. However, if a token is unused for 30 days, it expires. When you use an offline token, it uses the permissions that are currently assigned to your user account.

You can use offline user tokens to perform the following tasks:

- Retrieve secrets configured on the server to be used in certain tests in HCL DevOps Test Integrations and APIs (Test Integrations and APIs).
- Enable publishing of test results and reports from desktop products that include Test Integrations and APIs, HCL DevOps Test Performance (Test Performance), or HCL DevOps Test UI (Test UI) to Test.
- Enable the Resource Monitoring Service in Test Performance to monitor a data source during a run on Test.
- Enable agents to connect with Test.
- Enable HTTP proxies to connect with Test.
- Enable third-party integrations.

See the following table for a list of integrations for which you can use the tokens.

Integrations	More information
Test Integrations and APIs with Test	See Test Integrations and APIs and Test.
Test Performance with Test	See Publishing test results to the server. See Enablement of Resource Monitoring services for a schedule.
Test UI with Test	See Publishing test results to the server.
Third-party integrations	See Integrations with other applications on page 1639.

Creating an offline user token in DevOps Test

You can create an offline user token, copy it, and then use that token to enable connections to be authenticated by Test .

Before you begin

You must have logged in to the Test with an active user account.

1. Click the **User** icon from the menu bar, and then select **Create Token**.

   The **Create Offline User Token** dialog is displayed with a token.

   Note: After you copy the token, it is no longer accessible because the dialog closes.

2. Click **Copy** to copy the token.

   The dialog closes.

3. Paste the copied token in a text file and save it for reference.
4. Use the token in the UI of the desktop products or in the application where this token is required.

Results

You have created an offline user token.

Deleting an offline user token in DevOps Test

You can delete all the offline tokens when you want to revoke server access or when the existing tokens are no longer required.

Before you begin

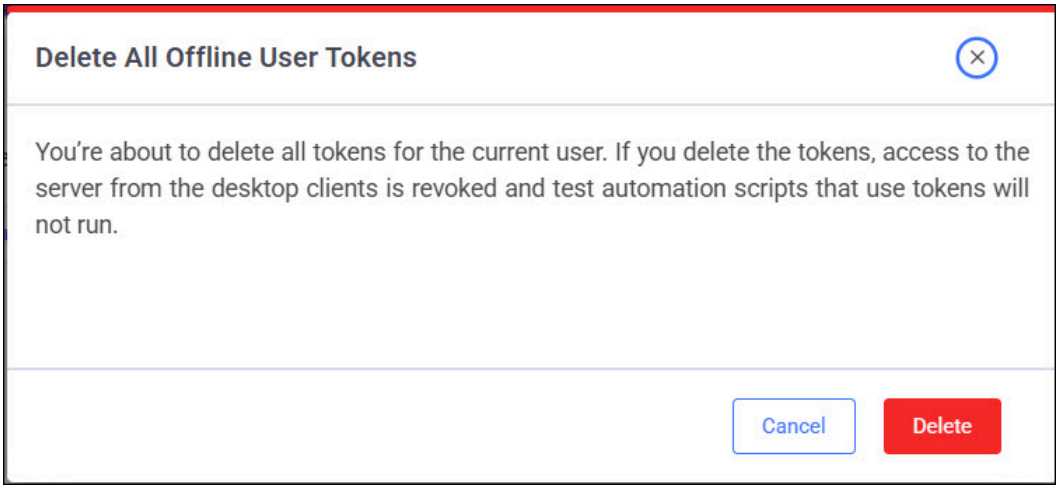
You must have logged in to Test with an active user account.

About this task

Offline tokens provide access for desktop clients and third-party integrations to connect to the server.

Warning: Deleting offline tokens invalidates all existing offline tokens. Any desktop client, automated agent, proxy, or third-party integration that currently uses these tokens will lose connection to the server and fail to authenticate until a new token is configured.

1. Click the **User** icon from the menu bar, and then select **Delete Tokens**.
   The **Delete All Offline User Tokens** dialog is displayed with a warning.



2. Click **Delete** to confirm deletion.
3. Perform any of the following necessary actions:
   - Inform the affected desktop client users that the existing tokens were deleted.
   - Update any test automation scripts that used the deleted tokens to prevent authentication failures.

What to do next

If you need to restore connections for desktop applications, agents, or integrations, you must complete the task to generate a new offline user token. See Creating an offline user token in DevOps Test on page 1710.

Working with DevOps Test REST services

When you want to use the REST APIs of Test in your test automation scripts, you can view the REST APIs that are exposed by Test. You can also run the APIs from within your project in Test.

All REST services are accessible from the base URL of Test and are defined by using Swagger. A navigable user interface lists the available set of APIs at `<Test_Hub_URL>/test/#/Initial/Admin/docs`. This Swagger file describes the individual APIs along with details of the parameters and response bodies.

You must be assigned the role of an administrator to be able to view or run the REST APIs.

After you log in to Test with your credentials that has administrator privileges, you must go to the following URL: `<Test_Hub_URL>/test/#/Initial/Admin/docs`

The Swagger docs that are available can be viewed from the drop down list.

You can select the Swagger documentation for the REST APIs that you want to view or use. For example, you can select the **Execution API (Public)** to view the APIs for the execution micro-service.

Note: Only the Execution API is public, and other APIs are internal and subject to change. The Swagger UI indicates whether an API is considered as public.

You can perform the following steps to view or run the API:

1. Expand the section to view the APIs that are available.
2. Expand each of the APIs to view the details such as the description, examples, parameters, and responses.
3. Click **Try it out**.
4. Enter the values for the required parameters.
5. Click **Execute** to run the API.

You can view the response after the API runs.

You can view the API doc for the execution micro-service that is extracted in this PDF document.

Related information

Running APIs in command line on page 1712

Running APIs in command line

You can run the APIs in the command line by adding a bearer access token to authorization header in every API call.

About this task

To generate the bearer access token, you must create an offline token.

1. Click the **User** icon , and select **Create Token** to obtain an offline token.

   Result

   The token is automatically generated and displayed in the **Create Offline User Token** dialog.
2. Click **Copy** to copy the token and save it in a secure location.

   You may assign the token to variable `OFFLINE_TOKEN` for using in the following steps.
3. Generate an access token by sending a POST request to `<baseUrl>/test/rest/tokens/` with the post data below:

   `refresh_token=$OFFLINE_TOKEN`

   Result

   The response JSON displays an 'access_token' field.
4. Add HTTP header Authorization with the access token in every API call:

   Authorization: `Bearer $access_token`

   The following example uses a bash command to start the execution:

```
TEST_HUB_URL=UNSET_URL
PROJECT_ID=UNSET_PROJECT_ID
BRANCH=UNSET_BRANCH
ASSET_PATH=UNSET_ASSET_PATH
if [ -n "$OFFLINE_TOKEN" ] && [[ "$PROJECT_ID" != *"UNSET"* ]] && [[ "$TEST_HUB_URL" != *"UNSET"* ]] &&
 [[ "$ASSET_PATH" != *"UNSET"* ]]; then \
  CURL_CMD="curl -k"; \
  echo "Getting access token from $TEST_HUB_URL/test/rest/tokens/"; \
  access_token=$($CURL_CMD -H "Accept: application/json" \
  -d refresh_token=$OFFLINE_TOKEN $TEST_HUB_URL/test/rest/tokens/ | grep -oP
 '"access_token"\s*:\s*"\K[^"]*'); \
  POST='{"testAsset": {"revision": "'$BRANCH'", "name": "'$ASSET_PATH'"},"offlineToken":
 "'$OFFLINE_TOKEN'"}'; \
  echo "Posting execution to $TEST_HUB_URL/test/rest/projects/$PROJECT_ID/executions/"; \
  execution_rsc=$($CURL_CMD -H "Content-Type: application/json" -H "Authorization: Bearer $access_token"
 \
        -d "$POST" $TEST_HUB_URL/test/rest/projects/$PROJECT_ID/executions/); \
  echo $execution_rsc; \
else \
  echo "OFFLINE_TOKEN env variable is not set (UI->Account->Create Token) or PROJECT_ID/ASSET_PATH is
 not set"; \
fi
```

Results

You ran APIs outside of the Swagger UI by using an offline token.

Test Manager Guide

This guide describes how to manage and track your overall test effort. This guide is intended for test managers.

Related information

Managing access to the server projects on page 1735

Managing team spaces

You might want to become a team space member, add members to your team space, change a user role in a team space, modify the team space, or delete a team space.

Each team space is associated with at least one *Team Space Owner*. You can assign multiple owners to your team space. Any user who becomes a member of a team space and can be assigned the role of a *Member*, *Project Creator*, *Architect*, or *Team Space Owner* of a team space, can access the team space.

As an owner of a team space, after you create a team space, you must configure the team space license. You can then add members to the team space and can assign different roles to each member of the team space. You can update or delete a team space. You can also add a repository to a team space to store a system model and edit the repository settings. Apart from adding a repository, you can add, update, or delete the Resource Monitoring agent if no longer required.

As an *Architect* of a team space, you can manage a team space repository and design a system model.

As a *Project Creator* of a team space, you can create a project in the team space.

You can view the configured agents or intercepts of your team space.

Viewing team spaces

After you log in to Test , you can view all the existing team spaces on the **Team Space Dashboard** page.

About this task

As a member of a team space, you can view your team spaces under **My Team Spaces**. You can also view the team spaces that are created by other users as the public team space and the Permissive team spaces under **Other Team Spaces**.

If the initial team space does not exist, then you can view the **Team Space Dashboard** without any navigation pane.

You as a member of a team space, when you want to use that team space immediately after you log in to Test, you can suffix the alias in the application URL.

For example, if the alias of the team space is `first`, then you must use the following Test URL in the address bar:

```
<server url>/#/first
```

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane, and then click **Join Team Space**.
   Result
   The **Team Space Dashboard** is displayed.

   You can view the team spaces in the following panels:

- **My Team Spaces**: You can view all the team spaces that you created. You can also view the team spaces in which you are a member. You can create a new team space by clicking **New Team Space** option.
- **Other Team Spaces**: You can view all the team spaces that are created by others.

Note: You cannot view the Restrictive private type team spaces.

Results

You have viewed the team spaces that are created by you and other users on the **Team Space Dashboard**.

What to do next

You can select a team space and can send a request to become a member of that team space. See Becoming a team space member on page 1720.

Adding members to a team space

When you create a team space to manage projects on Test , you must add users to your team space so that they can create and access the projects.

Before you begin

- As an administrator, you are assigned the default role of a *Team Space Owner*. If you log in to Test as another user, then you must have been assigned the role of a *Team Space Owner*.
- As an owner of a team space, you must have completed the following tasks:
  - Created a team space. See Creating a team space on page 745.
  - Configured a license for the team space. See Configuring licenses for team spaces.

You must have been assigned a role as a *Team Space Owner*. If you are a server administrator, then you are assigned with the default role of a *Team Space Owner*.

About this task

As an owner of a team space, you can add multiple users to your **Permissive** or **Restrictive** team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane.

   Note: If the initial team space does not exist, then you can view the **Team Space Dashboard** page without any navigation pane.

3. Identify the team space for which you want to add a member.
   You can either use the same team space where you choose to work or switch to any other team space.
4. Click **Manage > Configuration**.

5. Click **Add member** to add members in the initial team space.

   Result

   The **Add Member** page is displayed.
6. Enter a username in the **Add Members** dialog to add users.

   Result

   The list of users is displayed.
7. Select the user.
8. Assign a role to the selected user.

Note: All members are assigned the default roles of a *Project Creator* and *Architect*.

You can choose the role for the user based on its associated actions:

Roles	Responsibilities
Team Space Owner	◦ Create a team space. ◦ Update and delete a team space. ◦ Add members to a team space. ◦ Remove members from the team space. ◦ Assign the roles to the members. ◦ Modify the roles of the members. ◦ Create and modify a project. ◦ Add or update the system model. ◦ Add a repository to store a system model. ◦ Update and delete a repository in a team space. ◦ Configure or update agent and intercepts. ◦ Register, update, delete, and list Resource Monitoring sources in a team space.
Project Creator	◦ Create, update, and view a project ◦ Configure or update agent and intercepts.
Architect	◦ Create, update, delete, and view a repository in a team space. ◦ Create, update, and delete components in the system model. ◦ Configure or update agent and intercepts.
Member	◦ View the list of team spaces in the **Team Space Dashboard.** ◦ View the configuration of the team space. ◦ Configure or update agent and intercepts. ◦ View the registered agents, or intercepts. ◦ View the Resource Monitoring agents in a team space. ◦ View the registered Resource Monitoring agents. ◦ View components in the system model.

Notes:

- The members with the assigned role of a *Team Space Owner*, *Project Creator*, *Architect*, or *Member* of a team space can be assigned with any of the following project roles:
  - *Project Owner*
  - *Tester*
  - *Viewer*
- You can add or remove the role of a member by using the **Edit roles for members** icon next to each user in the **Members** list.

9. Repeat the applicable steps to add another user.

Results

You have added members with assigned roles to your team space. You can view the list of all added users on the **Team Space Configuration** page.

What to do next

You can reassign or remove the roles of users to one or more team spaces that you own. See Managing members and their roles in a team space on page 1721.

All users can request to be a member of another team space. See Becoming a team space member on page 1720.

Users added as members to the team space can view the team space in **My Team Spaces**.

Modifying the configuration of a team space

After you create a team space on Test , if you want to modify the details of the team space, add a repository to your team space, add or remove members of a team space or delete a team space, then you can perform these tasks from the **Team Space Configuration** page.

Before you begin

You must have been assigned the role of a *Team Space Owner*.

About this task

The **Team Space Configuration** page displays details of the team space.

As an owner of a team space, you can modify details of the team space, add members to your team space, and assign roles to the members of the team space on the **Team Space Configuration** page.

The *Team Space Owner* and *Architect* can add or remove a repository from the team space.

If the team space is no longer required, then the *Team Space Owner* can also delete that team space.

As a *Member*, *Project Creator*, or *Architect*, you can only view the configuration details of a team space on the **Details** tab of the **Team Space Configuration** page.

As a *Member*, and *Project Creator* you can only view the configuration details of a team space on the **Repository** tab of the **Team Space Configuration** page.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane.
3. Identify the team space for which you want to modify the configuration.
   You can either use the same team space where you are working or switch to any other team space.
4. Click **Manage > Configuration**.
   Result
   The **Configuration** page is displayed.
5. Perform the modifications on the following details of the **Configuration** page of the team space:

Fields	More information
Name	Displays the name of the team space.
URL alias	Displays an alias of the team space. You must suffix this alias in the application URL to access a specific team space after you log in to the application.
Member Access	Displays two options for Member Access:: ◦ Approval required to join the team space. ◦ Team space can be discovered by potential members.:
Description	Brief description of the team space.
Members	List of members in a team space.
Repositories	Displays the details of the repository that host the system model.

Results

You have modified the configuration details of the selected team space.

What to do next

You can add members and assign roles to each member of your team space.

Related information

Adding members to a team space on page 1715

Managing members and their roles in a team space on page 1721

Adding repositories to a server project on page 1729

Viewing the configuration of a team space

You can view the configuration of a team space as a member of any team space on Test . You can view the configuration details on the **Team Space Configuration** page.

Before you begin

You must be a member of a team space.

About this task

The **Team Space Configuration** page displays the configuration details of the team space.

As a member of a team space, if you want to access your team space immediately after logging into Test, then you must suffix the alias in the application URL. You can find details of the alias on the **Team Space Configuration** page. You can also view the list of members and their roles in that team space on the **Team Space Configuration** page.

1. Log in to Test.
2. Click the **Switch Team Space** icon from the left navigation pane.
3. Identify the team space for which you want to view the configuration.
   You can either use the same team space where you are working or switch to any other team space.
4. Click **Configuration** under **Manage** tab.
   Result
   The **Configuration** page is displayed.

   You can view the following details about the team space:

Fields	Tabs	More information
Name	**Details**	Displays the name of the team space.
URL alias	**Details**	Displays an alias of the team space. You must suffix this alias in the application URL to access a specific team space after you log in to the application.
Member Access	**Details**	Displays two options for Member Access::

Fields	Tabs	More information
		◦ Approval required to join the team space. ◦ Team space can be discovered by potential members.:
Description	**Details**	Displays a brief description of the team space.
Members	**Details**	Displays a list of members of the team space.
Repositories	**Details**	Displays the details of the repository that host the system model.

You have viewed the configuration details of the selected team space.

Becoming a team space member

After logging into Test , the licensed users must be a member of any team space to perform test activities in a project. As a licensed user, if you are not assigned the role of a member in any team space, then you can request the *Team Space Owner*to become a member of any existing team space.

Before you begin

You must be a licensed user.

About this task

If you want to become a member of a **Restrictive** team space, then only the owner of that team space can grant you the role of a member of a team space. If you request to become a member of a **Permissive** team space, then you automatically become a member of that team space.

Note: The server administrator can join any team space automatically without any approval and is assigned with a default role of *Team Space Owner*.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane, and then **Join Team Space**.
   Result
   The **Team Space Dashboard** is displayed.

   You can view the team spaces in the following panels:

- **My Team Spaces**: You can view all the team spaces that you created. You can also view the team spaces in which you are a member.
- **Other Team Spaces**: You can view all the team spaces that are created by others.

Note:

You can view only the public type of **Restrictive** team spaces and the **Permissive** team spaces. You cannot view the **Restrictive** private type team spaces.

3. Select the team space that you want to join from the list of other team spaces in the **Team Space Dashboard**.
4. Click the **Key** icon of the selected team space.
5. Confirm your request when prompted.

If you agree, then the *Team Space Owner* sees a notification about the request.

After opening the notification, the *Team Space Owner* can view the user who is requesting the access and can accept or decline the request. If the *Team Space Owner* accepts your request, you are added and assigned a *Member* role.

Notes:

- You can become a member of any team space only when the license of the selected team space is configured.
- If you are a server administrator, then the *Team Space Owner* role is the default role assigned.
- If you are a licensed user, then the *Member* role is the default role assigned and is restricted to specific actions.

You can then see the team space under **My Team Spaces** on the **Team Space Dashboard** page.

You might want to follow up with the *Team Space Owner* if your request is pending for some time.

Results

You have become a member of another team space.

What to do next

You can view the actions that you can perform based on your assigned role. See Adding members to a team space on page 1715.

Managing members and their roles in a team space

After you, as a *Team Space Owner* assign roles to the members of a team space onTest , you might want to remove a member from the team space or reassign the role to the existing members of your team space.

Before you begin

You must have been assigned the role of a *Team Space Owner*.

About this task

As a licensed user, you are assigned a role of a *Member* in any team space after the approval of the *Team Space Owner*.

As an owner of a team space, you can remove or reassign any member of your team space with the roles of a *Team Space Owner*, *Project Creator*, or *Architect*. You can also remove any member from the list of members of the team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane.
3. Select the team space for which you want to reassign the roles of the members or remove a member from the list of members.
   You can either use the same team space where you are working or switch to any other team space.
4. Identify the member from the list of **Members**.
5. Perform any one of the following operations to the identified member of the team space:
   Choose from:
   - Click **Remove member** to remove the identified member from the team space.
   - Click **Edit roles for member** and select the role that you want to assign or remove the assigned role for the identified member.

     You can choose multiple roles for the members based on the associated actions:

Roles	Actions
Team Space Owner	▪ Create a team space. ▪ Update and delete a team space. ▪ Add members to a team space. ▪ Remove members from the team space. ▪ Assign the roles to the members. ▪ Modify the roles of the members. ▪ Create and modify a project. ▪ Add or update the system model. ▪ Add a repository to store a system model. ▪ Update and delete a repository in a team space. ▪ Configure or update agent and intercepts. ▪ Register, update, delete, and list Resource Monitoring sources in a team space.
Project Creator	▪ Create, update, and view a project. ▪ Configure or update agent and intercepts.

Roles	Actions
Architect	▪ Create, update, delete, and view a repository in a team space. ▪ Create, update, and delete components in the system model. ▪ Configure or update agent and intercepts.
Member	▪ View the list of team spaces in the **Team Space Dashboard.** ▪ View the configuration of the team space. ▪ Configure or update agent and intercepts. ▪ View the registered agents, or intercepts. ▪ View the Resource Monitoring agents in a team space. ▪ View the registered Resource Monitoring agents. ▪ View components in the system model.

Note: The *Team Space Owner*, *Project Creator*, *Architect*, or *Member* of a team space can be assigned with any of the following project roles:

- *Project Owner*
- *Tester*
- *Viewer*

Similarly, you can remove the assigned role of any member of your team space.

Results

You have completed any of the following tasks in your team space:

- Reassigned the role of the members.
- Removed the assigned role of the members.
- Removed the members.

Adding members to a team space on page 1715

Deleting a team space

You might want to delete a team space on when it is no longer needed.

Before you begin

You must have been assigned the role of a *Team Space Owner* of Test .

About this task

As a *Team Space Owner*, you can delete a team space that you do not need. When you delete a team space, it is a permanent deletion. You cannot undo the delete action on a team space.

If you delete the initial team space, then you can only view the **Team Space Dashboard** page without any navigation pane.

After you delete the team space, you can use the name of the team space again.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane.
3. Identify the team space that you want to delete.
   You can either use the same team space where you are working or switch to any other team space.
4. Click **Manage > Configuration**.
   Result
   The **Configuration** page is displayed.
5. Click the **Delete Team Space** icon .
6. Confirm that you want to delete the team space when prompted.

   If you proceed, the team space is deleted including all of its projects and members.

Results
You have deleted the selected team space.

What to do next
You can view the available team spaces on the **Team Space Dashboard** page. See Viewing team spaces on page 1714.

After you delete a team space, the license that is used for that team space is released and is available to configure the other team spaces, if required. See Configuring licenses for team spaces.

Managing DevOps Test projects

Test projects manage access to your test assets, which are stored in a Git repository. Projects are maintained in a team space. Projects are either public by default or private. Private projects are not discoverable by other users. You can either add your own project or you can request to be a member of another public project.

All the licensed users are assigned with a default role of a *Project Creator*. As a *Project Creator*, when you create a project immediately after logging in the application, the project is created in the initial team space. If you want to create a project in any specific team space, then you must become a member of that team space. When you add your own project, you can configure it now or later. Configuring the project includes adding details about the project, adding one or more Git repositories, optionally adding secrets, classifying encrypted datasets, and adding a change management system. To

run test assets that are associated with an encrypted dataset, you must categorize the encrypted datasets by creating a classification. You can also add users to your project to access your test assets only if the users are the members of that team space. To use Jira to create defects for the tests available in your project, you must configure the Jira server for your project on Test.

Working with projects in a team space

After you log in to Test , you must have a project to perform the test activities. To work with projects, you must create and configure projects.

Before you begin

You must have logged into Test.

About this task

You must be assigned with the role of an *Owner*, *Tester*, or *Viewer* of a project.

1. Go to the **Projects** page from the **Initial Team Space** Home page. See Viewing active projects on page 1733.
2. Add a project. See Creating a project on page 1728.
3. Add a repository. See Adding repositories to a server project on page 1729.
4. Add secrets in a classification. See Secrets configuration on page 1732.
5. Encrypt the data set resources. See Managing an encrypted dataset on page 976.
6. Configure a change management system. See Configuration of a change management on page 1608.
7. Add members to a project and configure their roles. See Adding users to a project on page 1732.
8. Select a global branch in a project to view the test assets or resources maintained in the repositories. See Selecting the global branch in a project on page 1748
9. Perform the following tasks based on the type of test assets or resources that you want to run:

a. Add agents to your project, if you are using remote agents as a location to run certain tests. See Adding a performance agent to a project on page 1076.
b. Read the considerations that you must take into account before you configure a run or start a virtual service. See Prerequisites for running HTTP virtual services on page 1455.
c. Read the considerations that you must take into account before you configure a test run. See Prerequisites to running tests on page 1057.

10. Configure a run of the test asset or resource. See Test run configurations on page 1134.
11. View the progress of a test run. See Viewing the progress of running test assets on page 1444.
12. Manage a running test. See Management of running tests on page 1440.
13. View the results of a test run after the run is completed. See Test results on page 1499.
14. Review the test results and create defects for test runs from the Results page. See Creating Jira issues for the test results on page 1612.

Results

You have performed all the tasks with the projects.

Repository considerations for a server project

To collaborate with other project stakeholders, you can open test assets from a local clone of a remote repository, pull project test assets from the remote repository, and push changes made to your local test assets to the remote repository. Before you add a project and then add a repository to that project, you must consider some information about repositories.

Consider the following sections about version control systems that are used to manage remote repositories.

The following types of Git-based version control systems are supported:

- GitHub, which is an open-source product for storing and collaborating code.
- Azure Repos, which is part of a solution of Azure DevOps, and focuses on collaboration between DevOps professionals to develop private code.

Both these version control systems support Git repositories to store code.

You must be familiar with the various aspects of these version control systems to manage the application code that you want to test in Test .

You can learn more about installing, setting up, and using Git from the Git documentation.

You can learn more about installing, setting up, and using Azure Repos from the Azure Repos documentation.

Note: Git is the only tool that is supported to manage a repository in Azure Repos. Other tools, which can be used in Azure Repos, are not supported.

Git

You must install Git or upgrade to the supported version if you already have installed Git. See System Requirements for DevOps Test 2026.06 (11.0.9).

Repositories and user identities

After you install Git, you must set up your Git repository and set up access for members. You must ensure that the repository contains your test assets.

Optionally, you can use a command line utility or Git tool to access the repository, upload your test assets, fetch or pull from the repository, push to the repository, clone the repository, and other operations that you want to perform in Git.

Local and shared repositories

After you create a remote or shared repository in Git, you can create a local version of the repository by cloning the remote repository. You must ensure that your test assets are available in the remote repository and are also cloned to the local repository.

Alternatively, if your test assets are on your local system, you can set up a Git repository in the bare mode, add the project files to the local repository, and then commit and push from the local repository to the remote repository in Git by using your preferred method.

Note: While copying the test assets from your local system to the repository, you must ensure that you copy the entire project that contains the test assets.

User authentication for the Git repository

The administrator can set up different types of authentications for accessing the Git repository. Test supports the following authentication types:

- HTTP with username and password
- HTTP without username and password
- HTTPS with username and password
- HTTPS without username and password
- SSH with SSH key and passphrase
- SSH with SSH key and without a passphrase

Based on the authentication type that is set for a repository, you must provide the same authentication values in Test when you add a repository.

Test assets

You must complete the following tasks in the desktop products where you author your test before you check in and commit the test assets to the Git repository.

Test type	Task	More information
API suite in Test Integrations and APIs	Change the local stub to a remote stub.	See Test run considerations for API Suites or API tests on page 1059.
	Add the library files.	

Creating a project

You can create a project and enter its details.

Before you begin

To create and manage projects for your test assets, you must log in to Test by providing the application URL in a browser.

If you are a new user, and LDAP and Active Directory are not configured, then you must first sign up by filling out a form with your email, username, and password. You can then log in by using those details.

You must be a member of any licensed team space.

About this task

As a licensed user, you are by default assigned as both *Project Creator* and *Architect* role for the initial team space. You must select a team space to create a project.

You can view all the team spaces in the **Team Space Dashboard**. To create a project in any team space, you must be a member of that team space and assigned a *Team Space Owner* or *Project Creator* role in that team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **New Project** button on the **Projects** page.
   Result
   The **New Project** dialog is displayed.
3. Assign a name to your project.
4. **Optional:** Enter the description of the project.
5. Click **Create**.

Results

You have created a project.

What to do next

You can modify your project configuration. You can also add a repository to your project.

Related information

Default user administration

Changing the visibility configuration of a project on page 1734

Adding repositories to a server project on page 1729

Adding repositories to a server project

You can add a single repository individually or multiple repositories simultaneously to a server project to access assets and resources that are available in the repositories.

Before you begin

You must have completed the following tasks:

- Added a project on Test .
- Been granted permission and you must have set up your credentials to access the remote repositories in a repository domain.
- Created test assets and resources that are contained in either a single git repository or multiple git repositories.

About this task

As a project member with the role of a *Project Owner*, you can add a single repository or multiple repositories to your project.

Note: You can only add a single repository that is managed by using Git in Azure Repos. The addition of multiple repositories in Azure Repos is not supported.

You can use the information in the following table to decide the method for adding repositories to your project:

When...	Action...
You want to add any of the following repositories: • A single repository owned by you. • A single repository owned by other people. • The repositories that are in different domains.	You can add individual repositories one at a time. You must then provide the complete URL of the repository along with the required credentials to authenticate the connection to the repository from Test. For example, the URL to a single repository can be as `https://github.com/<user>/<repository>.git`. You must provide the *username* and *password* to access this repository.
You want to add any of the following repositories:	You can add all the repositories simultaneously that are in the same domain.

When...	Action...
• Multiple repositories that are owned by you and are contained in the same domain. • Multiple repositories that are owned by others and are contained in the same domain.	You must then provide the URL of the repository domain along with the required credentials to authenticate the connection to the repository from Test. For example, the URL of the repository domain can be `https://github.com`. You must select the platform and provide your *personal access token* to access the repositories.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the navigation pane or from the **My Projects** page.

   The **Overview** page of the project is displayed.
3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.
4. In the **Repositories** section, click **Add repository**.

   The **Add repository** dialog is displayed.

   You can either choose to add a single repository individually or multiple repositories simultaneously from a single domain.
5. Perform either of the following actions:
   - To add a single repository, go to Step 6 on page 1730.
   - To add multiple repositories from a domain, go to Step 7 on page 1731.
6. Perform the following steps to add individual repositories at a time:

   a. Enter the complete URL of the repository in the **Git URL** field.

      For example, the URL to a single repository can be as `https://github.com/<user>/<repository>.git`.

      The required authentication fields are displayed that depend on the protocol you specified in the URL.

If...	Then...
The repository URL contains *http* or *https*	The following fields for authentication are displayed: ▪ **Username** ▪ **Password**
The repository URL contains *git@*	The following fields for authentication are displayed:

If...	Then...
	▪ **SSH/Deploy Key** ▪ **Passphrase** You can add a Git repository by using git@ and SSH. For example: ▪ `git@github.com:account/testRepo.git` ▪ `ssh://git@10.111.111.333:2222/~/account/project.git`

Note: If you use SSH to connect to a remote repository and Test displays an `Auth Fail` error, you can resolve this error by regenerating your SSH keys by using the **-m PEM** option.

b. Enter the credentials to authenticate the connection to the repository.

c. Click **Add** to add the repository to your project.

You can add other individual repositories by specifying the URL and performing the actions in Step 6 on page 1730.

7. Perform the following steps to add multiple repositories simultaneously that are contained in the same domain:

Note: You can only add a single repository that is managed by using Git in Azure Repos. The addition of multiple repositories in Azure Repos is not supported.

a. Enter the URL of the repository domain in the **Git URL** field.

For example, the URL of the repository domain can be `https://github.com`.

b. Select the platform from the list under **Platform** where your repositories reside.

c. Enter your *personal access token* to authenticate your connection to the repository domain.

Note: If you do not have your *personal access token*, you can click **Generate** to generate your *personal access token* and use the token to authenticate your connection.

d. Click **Next**.

The connection to the repository domain is established and all the repositories that you own are listed. The time when the repository was last updated is displayed in the **Last updated** column.

e. Select the repositories that you want to add to your project.

f. Click **Add**.

Note: Depending on the size of the repository that you are adding, it can take a few to several minutes to add the repository to your project on the server.

All the repositories that you selected are added to your project and are listed on the **Repositories** page.

Note: If the repository is read-only, you will be able to add it and view its assets, but you will not be able to publish changes directly to it from Test Hub.

Results

You have added individual repositories or multiple repositories to your project on the server.

What to do next

You can perform the following actions on the repository that you added:

- Update the authentication credentials if they are changed in the Git repository configuration. See Updating the authentication credentials of the repository on page 1745.
- Delete a repository if it is no longer required. See Deleting a repository on page 1745.
- Refresh a repository to fetch and synchronize changes from the remote repository. See Refreshing repositories manually on page 1746.

Secrets configuration

If you are working with an API suite and the project test asset contains environment variables that are required for the test runs, you must configure the environment variables as secrets in a classification by using the **Add Secret** option in the **Security** page. Configuring secrets enable the API suite to run correctly on Test.

Related information

Protecting API test assets by using secrets on page 1749

Adding users to a project

You can add users to your project in Test so that they can access your test assets.

Before you begin

- You own a project.
- The users you want to add to your project must be the members of the team space of that project.

About this task

As a project owner, you can add other users to your public or private project. For example, if you have a large number of test assets that must be run, you might want your test team to help run them, and see the results.

1. Log in to Test.
   Result
   The **Projects** page of the Initial Team Space is displayed.
2. Select the project for which you want to add the users.
3. Click the **Configure Project** icon on the Project card.

   The **Configuration** page of the project is displayed.
4. In the **Project Members** section, click **Add Members**.

   The **Add Members** dialog is displayed.
5. Enter the name or email of the user in the search bar to find the user.
6. Select **Viewer**, **Tester**, or **Owner** role for the user that you want to add.

   The added user after logging in can see the owner's project in their list of **My Projects**.
7. Click **Add Members**.

   The newly added members are listed under the **Project Members** list.

Results

You have successfully added users to your project.

What to do next

You can add or remove roles to one or more projects that you own. All users can request to be a member of another public project.

Related information

Becoming a project member on page 1735

Managing access to the server projects on page 1735

Viewing active projects

After you log in to Test , you can view both active and archived projects in the **Initial team space**.

About this task

As a project owner, you can view your projects under the **My Projects** tab, and the projects that are created by other users as public projects are displayed under the **Other Projects** tab. You can view a list of all active projects that you created under **My Projects**. You can view a list of all archived projects by selecting the **Include Archived Projects** check box.

Log in to Test.

The **Projects** page is displayed.

You can view the following projects:

- The active projects that you created or added to as a member with either the *Tester* or *Viewer* role are displayed under the **My Projects** tab.
- The active projects that are created by others as public projects are displayed under the **Other Projects** tab.

Results

You have viewed the active projects that are created by you and other users in the team space.

What to do next

You can perform any of the following tasks:

- Create a project. See Adding details to a server project on page 1728.
- Request to become a member of a project that is displayed under the **Other Projects** tab. See Becoming a project member on page 1735.
- View the other pages in the team space and perform tasks on those pages. See Tasks in a team space on page 747.

Related information

Archiving or unarchiving server projects on page 1738

Changing the visibility configuration of a project

After you create a project in Test , you might want to change the visibility configuration of the project from the public, which is the default, to private.

Before you begin

You must have created a project.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Select the project from **My Projects** tab.
3. Click **Manage > Configuration**.
   Alternatively, select a project, and then click the **Configure project** icon on the project card.
   Result
   The **Configuration** page is displayed.
4. In the **Visibility** section, select **Private** as the visibility mode of the project.
5. Click **Save**.

Results

You have successfully changed the visibility configuration of a project.

What to do next

You can add a repository to your project.

Related information

Default user administration

Becoming a project member

You can request to be a member of another project. New users without any projects can also request to be a member of an existing project.

About this task

As a project owner, you can add users to your public or private projects. All users can request to become a member of a public project.

Note: A project owner can add a licensed user as a member of the project only if that user is the member of the team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Other Projects** tab and search for the project that you want to join.
3. Click the Project card or click **Join Project**.
   Only public projects are visible in the list of projects.
4. Confirm your request when prompted. If you agree, the project owner is notified.
5. The project owner sees a pending request **Notification** icon on their Project card.

   After opening the notification, the owner can see the user that is requesting access and can accept or decline it.

   If the project owner accepts your request, you are added as a member of the project with a **Viewer** role. A **Viewer** role is the default role assigned and is restricted to specific actions.

   You then see the project under **My Projects** tab.

   If the project owner declines your request, follow up with the project owner.

Results

You have sent a request to become a member of a project.

Managing access to the server projects

You might want to add or remove a project member role from your project.

About this task

As a project owner, you can assign access by specifying a role when you add a user to your project. You can also assign more access or remove access for a user. Roles enable users to perform tasks on project resources such as running tests and viewing test results.

1. Choose the role in a project based on its associated actions.

Option	Description
Owner of a project	◦ All Tester's actions ◦ Update, archive, list, and view a project ◦ Assign, update, delete, and list user roles for a project ◦ Accept new member requests ◦ Create, update, and delete a dataset classification in a project ◦ Add, update, and remove an encrypted dataset from a classification ◦ Update current row for a listed dataset in a project ◦ Delete, list and view a report ◦ Update, delete, and list a repository in a project ◦ Get the test assets from a repository in a project ◦ Create, update, delete and list secrets in a project ◦ Create, update, delete, and list resource monitoring sources in a project ◦ Get the content of a resource monitoring source in a project ◦ Register, update, delete, and list resource monitoring agents ◦ Create, configure, and delete the Jira change management system ◦ Create and update defects in the Jira change management system ◦ Create and update components in the system model
Tester of a project	◦ All Viewer's actions ◦ List repositories in a project ◦ Run a test and create a report ◦ Stop a test while running ◦ Get the test assets from a repository in a project ◦ Get a list of datasets in a project ◦ Get the content of a dataset

Option	Description
	◦ Update the current row for a listed dataset in a project ◦ Add, update, and remove an encrypted dataset from a classification ◦ Delete a report if you created the report ◦ Create and update defects in the Jira change management system ◦ Create and update components in the system model
Viewer of a project	◦ List your own roles on a project ◦ List running tests ◦ List and view a report ◦ List resource monitoring sources in a project ◦ Get the content of a resource monitoring source in a project ◦ List the resource monitoring agents ◦ View components in the system model ◦ View defects in the Jira change management system
Non-member of a project	◦ Request to be a member of a project

2. Open the project that you own.
   From the **Configuration** page, you can see a list of members in your project along with their roles and then you can modify their roles and add or remove the members from your project.
3. Click **Manage > Configuration** from the navigation pane.
   From the **Configuration** page, you can see a list of members in your project along with their roles and then you can edit their roles and add or remove the members from your project.
4. To edit the roles of the existing user, perform the following steps in the **Project Members** section:
   a. Hover over the user for whom you want to modify the role and then click the **Edit roles for members** icon.
   b. Select the new role for the user and then click the **Done editing members role** icon to save the modified role for the user.
5. To delete the roles of the existing user, perform the following steps in the **Project Members** section:
   a. Hover over the user for whom you want to modify the role and then click the **Remove member from the project** icon.
      The **Remove Member** dialog is displayed.
   b. Click **Yes** to remove the user from the project.

Archiving or unarchiving server projects

You can archive a project when that project is no longer needed but you want to retain it for future reference. If you do want to use an archived project, you can unarchive it.

About this task

As a project owner, you can archive inactive projects in Test . Archived projects are not visible to users or project members, but owners can show or hide their archived projects. You can view the list of all archived projects from the navigation pane. Archived projects can be unarchived.

- To archive a project:
  1. Log in to Test.
  2. Select your project from the **Projects** page.
  3. Click the **Configure project** icon on the project card.
     Result
     The **Configuration** page is displayed.
  4. Click the **Archive Project** icon.
     The **Archive Project** dialog is displayed.
  5. Click **Archive** to confirm that you want to archive the project.
     If you proceed, the project is archived and is hidden from **My Projects**.
- To view an archived project:
  1. Log in to Test.
     Result
     The **Projects** page of the initial team space is displayed.
  2. Select **Include Archived Projects** check box.
     Result
     A list of all the projects including archived projects that are associated with you is displayed under **My Projects** and the archived projects that are associated with others are displayed under **Other Projects**.
- To unarchive a project:
  1. Log in to Test.
     Result
     The **Projects** page of the initial team space is displayed.
  2. To view archived projects, check the box labeled **Include Archived Projects**.

3. Select your archived project, and then click the **Configure project** icon on the project card.
   Result
   The **Configuration** page is displayed.

4. Click the **Unarchive Project** icon.

   The **Unarchive Project** dialog is displayed.

5. Click **Unarchive** to confirm that you want to unarchive the project.
   If you proceed, the project is unarchived and is shown under **My Projects** tab.

Deleting server projects

You might want to delete a project when the project is no longer needed, and you want to free up disk space.

About this task

As a project owner, you can delete a project that you no longer want. When you delete a project it is permanent. You cannot undo the delete project action.

After you delete the project, you can use the project name again.

1. Open the project that you want to delete.
2. From the **Configuration** page, click the **Delete Project** icon.

   The **Delete Project** dialog is displayed.
3. Select the **I understand project deletion is permanent.** checkbox.

   Warning:

   If you proceed, the project is deleted including all of its test assets, results, repository and members.

4. Click **Delete** to confirm that you want to delete the project.

Results

You have deleted a project.

An overview of test assets, modifications, and scheduled runs

After you configure a project with one or more Git repositories and run some test assets, you can view statistics about those test assets.

From the **Overview** page, several cards display charts, sliders, and tables of the statistics of the test assets in your server project. You can click some of the charts, sliders, or tables to see more information, such as the progress of a scheduled

run or the results of a run. You can also review some statistics by date and see more details such as the proportion of test assets by type.

You can view a server project, which might contain multiple repositories and multiple branches, by selecting the name of the branch from the **Branch** drop-down list. For more information about selecting branches, see Selecting the global branch in a project on page 1748.

The **Members** area displays the total number of users who have access to the project. You can click the number to view the details of all the members. The **Owner** area displays the username of the project owner.

Test suites

This card displays a slider of the percentage of test suites by type. A test suite is a collection of tests, including schedules, Compound Tests, API Suites, and AFT Suites. You can hover over the slider and see the proportion of test suites by test suite type. The number of suites shown are relative to the selected branch.

Individual tests

This card displays a slider of the percentage of individual tests by type. You might have performances tests, API tests, or UI tests according to the desktop clients that you used to create the tests. You can hover over the slider and see the proportion of individual tests by type. The number of tests shown are relative to the selected branch.

Execution results

This card displays a chart of the proportion of test suites that were run by status and by date. If no date is selected, the card displays all the run results associated with the project since it was created. You can see the run results by clicking a test or Suite status. You can also hover over the chart and see the test or Suite status and the proportion of test assets. You can view statistics by tests or Suites that ran.

Notes:

- The results shown are generated from tests or Suites run.
- The statistics exclude canceled runs of tests or Suites.
- The number of Suites and individual tests that are associated with your project are shown on the **Home** page along with a verdict summary. You can see the run results by clicking a verdict. You can also see the last date and time when you ran one or more test assets.
- The number of suites shown are relative to the selected branch.

Last run

This card displays a table of the last three runs by date and time. You can see the run results by clicking each last run.

New or modified

This card displays a chart of new and modified test assets that were made in your Git repository for a week or for the last seven days based on a selected date range. You can hover your mouse over each bar in the chart and see the proportion of test assets by type. The data shown is relative to the selected branch.

Scheduled runs

This card displays a table of the next three scheduled runs by date and time. You can see the progress of a scheduled run by clicking each scheduled run.

Insights

This card displays a table of the insights on the supported parameters identified from the tests that were run in the project. The table lists the level of confidence with which the analysis of the specific parameter was done, the parameter analyzed, the name of the test asset, and the timestamp of the completed analysis. You can click any item in the row of a specific insight to view the details of that insight on the **Insights** page.

Managing DevOps Test projects on page 1724

Managing repositories

After you create a project in Test , you can add repositories that contain test assets and resources to the project. You can also change the repository details, update the user credentials of a repository, delete a repository, create a webhook for the configured repository.

Tasks in a repository

To add a repository in your project and work on the repository, you can perform the tasks listed in the following table:

Task	More information
Adding a repository	Adding repositories to a server project on page 1729
Updating the repository credentials	Updating the authentication credentials of the repository on page 1745
Refreshing a repository	Refreshing repositories manually on page 1746
Creating a webhook for the repository	Creating webhooks on page 1749
Selecting the global branch	Selecting the global branch in a project on page 1748
Deleting a repository	Deleting a repository on page 1745

Adding repositories to a server project

You can add a single repository individually or multiple repositories simultaneously to a server project to access assets and resources that are available in the repositories.

Before you begin

You must have completed the following tasks:

- Added a project on Test .
- Been granted permission and you must have set up your credentials to access the remote repositories in a repository domain.
- Created test assets and resources that are contained in either a single git repository or multiple git repositories.

About this task

As a project member with the role of a *Project Owner*, you can add a single repository or multiple repositories to your project.

Note: You can only add a single repository that is managed by using Git in Azure Repos. The addition of multiple repositories in Azure Repos is not supported.

You can use the information in the following table to decide the method for adding repositories to your project:

When...	**Action...**
You want to add any of the following repositories: • A single repository owned by you. • A single repository owned by other people. • The repositories that are in different domains.	You can add individual repositories one at a time. You must then provide the complete URL of the repository along with the required credentials to authenticate the connection to the repository from Test. For example, the URL to a single repository can be as `https://github.com/<user>/<repository>.git`. You must provide the *username* and *password* to access this repository.
You want to add any of the following repositories: • Multiple repositories that are owned by you and are contained in the same domain. • Multiple repositories that are owned by others and are contained in the same domain.	You can add all the repositories simultaneously that are in the same domain. You must then provide the URL of the repository domain along with the required credentials to authenticate the connection to the repository from Test. For example, the URL of the repository domain can be `https://github.com`. You must select the platform and provide your *personal access token* to access the repositories.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the navigation pane or from the **My Projects** page.

The **Overview** page of the project is displayed.

3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.

4. In the **Repositories** section, click **Add repository**.

   The **Add repository** dialog is displayed.

   You can either choose to add a single repository individually or multiple repositories simultaneously from a single domain.

5. Perform either of the following actions:

   - To add a single repository, go to Step 6 on page 1743.
   - To add multiple repositories from a domain, go to Step 7 on page 1744.

6. Perform the following steps to add individual repositories at a time:

   a. Enter the complete URL of the repository in the **Git URL** field.

      For example, the URL to a single repository can be as `https://github.com/<user>/<repository>.git`.

      The required authentication fields are displayed that depend on the protocol you specified in the URL.

If...	Then...
The repository URL contains *http* or *https*	The following fields for authentication are displayed: ▪ **Username** ▪ **Password**
The repository URL contains *git@*	The following fields for authentication are displayed: ▪ **SSH/Deploy Key** ▪ **Passphrase** You can add a Git repository by using git@ and SSH. For example: ▪ `git@github.com:account/testRepo.git` ▪ `ssh://git@10.111.111.333:2222/~/account/project.git`

Note: If you use SSH to connect to a remote repository and Test displays an `Auth Fail` error, you can resolve this error by regenerating your SSH keys by using the **-m PEM** option.

b. Enter the credentials to authenticate the connection to the repository.

c. Click **Add** to add the repository to your project.

You can add other individual repositories by specifying the URL and performing the actions in Step 6 on page 1743.

7. Perform the following steps to add multiple repositories simultaneously that are contained in the same domain:

Note: You can only add a single repository that is managed by using Git in Azure Repos. The addition of multiple repositories in Azure Repos is not supported.

a. Enter the URL of the repository domain in the **Git URL** field.

For example, the URL of the repository domain can be `https://github.com`.

b. Select the platform from the list under **Platform** where your repositories reside.

c. Enter your *personal access token* to authenticate your connection to the repository domain.

Note: If you do not have your *personal access token*, you can click **Generate** to generate your *personal access token* and use the token to authenticate your connection.

d. Click **Next**.

The connection to the repository domain is established and all the repositories that you own are listed. The time when the repository was last updated is displayed in the **Last updated** column.

e. Select the repositories that you want to add to your project.

f. Click **Add**.

Note: Depending on the size of the repository that you are adding, it can take a few to several minutes to add the repository to your project on the server.

All the repositories that you selected are added to your project and are listed on the **Repositories** page.

Note: If the repository is read-only, you will be able to add it and view its assets, but you will not be able to publish changes directly to it from Test Hub.

Results

You have added individual repositories or multiple repositories to your project on the server.

What to do next

You can perform the following actions on the repository that you added:

- Update the authentication credentials if they are changed in the Git repository configuration. See Updating the authentication credentials of the repository on page 1745.
- Delete a repository if it is no longer required. See Deleting a repository on page 1745.
- Refresh a repository to fetch and synchronize changes from the remote repository. See Refreshing repositories manually on page 1746.

Updating the authentication credentials of the repository

If the authentication credentials of the Git repository which was added to your project are changed, then you must update the credentials of the repository in Test .

Before you begin

You must have completed the following tasks:

- Been assigned a *Member* or *Project Creator* role in a team space.
- Been assigned the *Owner* role in the project with access permissions to edit repositories.

About this task

In Test, the repository is refreshed at regular intervals to pull the latest changes committed to the Git repository. After you update your authentication credentials of the repository, the repository is refreshed to ensure that you have access to the Git repository and to the latest assets in the repository.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the left navigation pane or from the **My Projects** page.
3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.

4. In the **Repositories** section, click the **Change...** icon under Actions column for the repository that you want to update.

   The **Edit Repository** dialog is displayed.

5. Enter the new credentials, and then click **Update**.

   The new credentials are updated and your access to the repository is retained.

Deleting a repository

You can delete repositories that you no longer require in your test environment.

Before you begin

You must have completed the following tasks:

- Configured the repository that contains the test assets in your project on Test .
- Been assigned a *Owner* role with access to delete repositories.

About this task

You can delete a repository that you have configured for your project.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the left navigation pane or from the **My Projects** page.
3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.
4. In the **Repositories** section, click the **Delete** icon under **Actions** column for the repository that you want to update.

   The **Delete repository** dialog is displayed.
5. Select the checkbox, and then click the **Delete** button.

   The repository is deleted and removed from the list.

Refreshing repositories manually

You can manually trigger the refresh activity for a repository to instantly fetch and synchronize the changes from the remote repository.

Before you begin

You must have completed the following tasks:

- Configured the repository that contains the test assets in your project onTest .
- Been assigned a *Member* or a *Project Creator* role.
- Been assigned a *Owner* role.

About this task

Every two minutes, the repository is refreshed automatically. You can also manually trigger the refresh activity for a repository.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the left navigation pane or from the **My Projects** page.
3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.

4. In the **Repositories** section, click the **Refresh** icon under **Actions** column for the repository that you want to update.

   The refresh activity is triggered.

   Note: The **Refresh** option is disabled when the refresh is in progress. After the refresh is completed, the **Refresh** option is enabled.

   The following table lists the icons and their description based on the status of the refresh activity:

Refresh icon	Description
	The last refresh activity was successful.
	The last refresh activity was successful but errors were found while processing some of the test assets. To view the error details of the test assets for a specific repository, you can click the arrow inline with the repository name. You can resolve the errors of these test assets in the Git server, and then refresh the server repository, if required. **Note:** The repository, which contains the branch that is selected in the **Branch** field, displays the unprocessed test assets for that branch. Other repositories display the unprocessed test assets for their default branch.
	The refresh activity was not successful due to any one of the following reasons: ◦ Internal error ◦ Connection issue ◦ Authentication failure ◦ Disk quota exceeded ◦ Repository unreachable

Results

You have manually refreshed the repository and the **Last Refreshed** field is updated with the following details:

- The time when it was last refreshed in the remote repository.
- Latest commit ID and message of the remote repository.

Selecting the global branch in a project

After you add one or more repositories to your project on Test , you can start accessing all branches in all repositories of that project. You can select only one branch as a global branch from the list of branches in the **Execution**, **Datasets**, and **Overview** pages.

Before you begin

You must have completed the following tasks:

- Been assigned a *Member* or *Project Creator* role in a team space.
- Added at least one repository in your project.

About this task

You can access all the branches contained in all the repositories, which are added to the project, by using the **Branch** field on the **Execution**, **Datasets**, and **Overview** pages.

After you select a branch from any of the repositories as the global branch, this selection is retained for you as the global branch unless you change the branch on any of the following pages: **Overview**, **Execution**, or **Datasets** pages.

Note:

- When you add the first repository to a project, the global branch is set to the default branch of the repository.
- Branches are arranged in an increasing order of their names in the list.
- When you change the branch in one of the pages, then the same branch is displayed as selected in the other pages and the contents of that page displays the assets from the selected branch.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the left navigation pane or from the **My Projects** page.

   The project **Overview** page is displayed.
3. Select a branch from the **Branch** field.

   The branch that you select on any of the following pages is reflected in the rest of the other pages and the test assets are filtered based on the global branch selection on each of these pages.:
   - **Overview**
   - **Execution**
   - **Datasets**

Results

You have selected a global branch in a project.

Creating webhooks

You can configure a webhook for a repository in the Git server to notify Test whenever there is a push event in the remote repository. Then, the refresh activity is triggered to fetch the latest changes to the server repository.

Before you begin

You must have completed the following tasks:

- Configured the repository that contains the test assets in your project.
- Been assigned a *Member* or *Project Creator* role in a team space.
- Been assigned the *Owner* role in the project.

1. Log in to Test and open the team space that contains your project.
2. Open your project either from the left navigation pane or from the **My Projects** page.
3. Click **Manage > Configuration** from the navigation pane.

   The **Configuration** page of the project is displayed.

4. In the **Repositories** section, click the **Webhook** icon under **Actions** column for the repository that you want to update.

   The **Webhook Configuration** dialog is displayed.

5. Copy the URL and the Secret of the repository that you want to configure.

   Note: The URL and the Secret details are specific to a repository.

6. Click the link of the repository for which you want to configure the webhook.

   The remote repository page is displayed.

7. Paste the details, which you copied from Test, in the appropriate fields of the remote repository.

Results

You have configured the webhook for a repository in the Git server. The changes of the remote repository are synchronized in the repository of your project.

Protecting API test assets by using secrets

Secrets are key-value pairs that are created for your project in Test under a classification. You can create classification for your project that enable you or members in your project to use secrets at test runtime either in Test or in HCL DevOps Test Integrations and APIs (Test Integrations and APIs).

The secrets in a project in Test maintains a separate access control list managed by the members with access to the secrets added to the classification. Controlling access to secrets means controlling access to applications and systems under test. The introduction of secrets under classification for a project simplifies managing access to separate environments. If a

member of a project does not have access to a secret, for example, *a server credential* then the member cannot accidentally or intentionally run tests against that server. For example, tests that must access the database server by using the server credentials to retrieve stored data can only be run by a member if the access to the secrets is granted.

Note: Secrets are applicable to test assets created in Test Integrations and APIs that facilitates running tests in defined environments. Secrets are not applicable to tests created in Test UI or Test Performance.

As a project member with the *Owner* or *Tester* role, you can add secrets to the classification in the project. You can grant or restrict access to the secrets that you added to the classification in the project.

Members with access to a secret classification can access, edit, or delete the secrets in Test and can view secrets, edit secrets, or delete secrets.

Members are granted Read access to the classification at the role level, while Read and Write access can be provided to specific members.

Members in the project with the *Owner* or *Tester* role and with access to the secrets can use the secrets in tests at runtime.

If you are configuring a project to run an API Suite with tests that refer to secret values, you must configure the secrets under a classification by using the **Add Secret** option in the **Security** page. You must complete the following tasks:

1. Create a classification. See Creating a classification on page 934.
2. Add secrets in the classification. See Creating a secret in a classification on page 1750.
3. Grant access to project members or member roles, who can access the secrets. See Granting access to members or member roles on page 1751.

Creating a secret in a classification

You must create secrets in the classifications that is set in your project so that the members of the project with access to the secrets can use them in specific during an API Suite run.

Before you begin

You must have completed the following tasks:

- Created a project on Test.
- Created a classification. See Creating a classification on page 934.
- You must be a member with access to the secrets in the classification. See Granting access to members or member roles on page 1751.

About this task

You can also configure secrets such that the secrets can be used across different test environments by members with access to the classification. Secrets correspond to the environment variables or tags that you create in a Test Integrations and APIs project specific to an environment.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification for which you want to add the secrets under the **Classification**.
5. Click **Add Secret**.
   Result
   The **Add Secret** dialog is displayed.
6. Enter a name for the secret as its *Identifier*, and then enter the `password` as the *Value* for the secret.

   For example, enter the name of the secret to access a database as `dbcred` and enter the `password` required to access the database as its value.
7. Click **Create**.

   A message is displayed that confirms the creation of the secret.

Results

You have created secrets in the selected classification for your project.

What to do next

- You can view, edit, or delete the secrets added to a classification any time you want.
- You can use the secrets in the tests that require these secrets during test runs.

Granting access to members or member roles

You can grant Read access to the secrets added to the classification in your project at the role level for members of a designated role. Additionally, you can provide Read and Write access to specific members. Without access to the classification, members cannot view, create, edit, delete, or use the secrets added to the classification.

Before you begin

You must be a project **Owner** and have completed the following tasks:

- Created a project in Test. See Managing DevOps Test projects on page 1724.
- Added one or more users to your project. See Adding users to a project on page 1732.
- Created at least one classification. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

The **Overview** page of the project is displayed.

3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification in the list under **Classification** to which the secrets are added and for which you want to grant the access.
5. Select any of the following methods to grant access to a member:
   Choose from:

   - Select the checkbox for the specific role under **Grant Read Only Access to roles** to grant read only access to the members of a specific role. For example, if you select **Tester**, then all members in the project with a tester role are granted read only access to the selected classification. You can select any role or all the roles listed.
   - Perform the following steps to grant read/write access to specific members:
     a. Click **Add Members** inline with **Members with Read/Write Access**.

        The **Additional Members** dialog is displayed.

     b. Enter the name or email ID to search the user or navigate through the list and select the member you want to grant access. You can select multiple members from the list.

        Important:

        Irrespective of the role that the member (**Owner**, **Tester** or **Viewer**) was assigned in the project, the access to the classification to which the secret is added must be specifically granted to the members from the **Security** page.

     c. Click **Add Members.**

        You granted the read/write access to the added members.
6. Select any of the following methods to revoke access to a member:
   Choose from:

   - Clear the checkbox for the specific role under **Grant Read Only Access to roles,** to revoke read only access to the members of a specific role. For example, if you clear the **Tester** checkbox then access for all members in the project with a tester role is revoked for the selected classification. You can select any role or all the roles listed.
   - Click the **Delete** icon inline with the member name to remove the specific members from the **Members with Read/Write Access** list.

Notes:

- Any member with access to the classification can remove access to other members specifically added or of all members with a specific role.
- Members with access to the classification can remove themselves from the access list provided that there is at least one member in the list. After removing themselves, members cannot add themselves back to the access list and must be added by any of the other members in the list.

Results

You have added members from your project or members with specific role to the access list of people who can access secrets in the selected classification, or you have removed specific members or members with specific role from the access list.

What to do next

You can add secrets to the classifications for your project.

Managing secrets

You can view, edit, or delete the secrets configured under a classification any time after you created secrets or after you were granted access to the secrets classification. You can change the value of the secret by editing the secret. You can delete secrets that you no longer require in your test environment.

Before you begin

You must have completed the following tasks:

- You must have created a project on Test and configured a secrets in your project.
- You must have created secrets in the selected classification or the classifications must contain secrets.
- You must be a member with access to the secrets classification.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Perform the following steps:
   a. Select the **Classification** from the list in the **Security** page.
   b. Optionally, select the classification that you want from the list if there are multiple classifications in the project.

   The secrets configured in the selected classifications are displayed.
5. Complete the steps for the task you want to perform as listed in the following table:

Task	Action
Viewing a secret value	Click the **View** icon inline with the secret to view the entered value. The value most likely is a password for the secret. The value configured for the secret is displayed.
Editing a secret value	Perform the following steps: a. Click the **Edit** icon inline with secret that you want to edit, The **Edit secret** dialog is displayed. b. Enter a `new value` for the secret as its *Value*. The value can be a password for the secret. **Note:** You can only change the value of the secret. c. Click **Save**. The value of the selected secret is changed.
Deleting a secret	Perform the following steps: a. Click the **Delete** icon inline with the secret that you want to delete. The **Delete secret** dialog is displayed. b. Click **Delete**. After you delete the secrets, the secrets listed in the classification is removed from the list.

Results

- You viewed the password configured of the secret under a classification that you created or were granted access.
- You changed the secret value of the secret under a classification in your project.
- You deleted and removed the secret from the selected classification in your project.

What to do next

You can use secrets in the tests that require these secrets during test runs.

Test run configurations on page 1134

Notification Management

Test provides a feature to display notifications for different events within the user interface (UI) of Test. You can configure Email notifications on Test to send out notifications about different events as emails to the subscribed users. You can also configure third-party applications as webhooks on Test when you want Test to send push notifications about the server events to the third-party applications in a preset template.

Test provides you the following features to receive notifications about server events:

Channels	Description
In-app	Notifications are displayed within the UI of Test.
Email	Notifications are sent in emails to subscribed users of Test by an SMTP server.
Webhooks	Notifications in a preset template are sent as push notifications by Test to the configured webhook of a third-party application, such as MS Teams, Slack, or others.

Managing notifications in the server UI

Viewing the in-app notifications or notifications in the server UI is a feature that is enabled automatically when you register as a user in Test.

When you register as a user in Test, the in-app notifications are automatically subscribed for you.

If you want to receive notifications about specific events and not all events, you can change the default subscriptions and modify your subscription for the server events. You can also view the in-app notifications that are displayed for you. See Managing in-app notifications on page 1756.

Managing Email notifications

You, as a *Server Administrator* or *Team Space Owner* can configure an existing Simple Mail Transfer Protocol (SMTP) server so that Test can send out notifications about the server events in emails to the registered users who have subscribed to the email notifications. See Configuring an SMTP server to manage email notifications on page 1761.

If you, as a registered user of Test want to receive the email notifications about specific events and not all events, you can change the subscriptions for the server events. See Managing email notifications on page 1759.

Managing webhook notifications

You, as a *Server Administrator*, *Team Space Owner*, or *Project Owner* can configure third-party applications as webhooks so that Test can send out push notifications about the server events to the third-party applications. See Configuration of a webhook on page 1762.

Managing in-app notifications

You can manage the in-app notifications by changing the subscriptions that are enabled by default for all the events that occur on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.

About this task

You can view the default notification subscription for all server events, and then choose to unsubscribe or change the subscription for any or all the events.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **User** icon on the menu bar.
3. Click **Account Settings**.

   Alternatively, click the **Notification** icon on the menu bar, and then click the **Settings** icon in the **Notifications** dialog.
4. Click the Expand icon and identify the server events for which you want to change the subscription.
   You can notice that for each of the server events, the in-app channel is displayed as selected, which is the default selection unless you have modified the subscription.
5. Perform the actions indicated in the following table to clear the subscriptions for server events that you do not want to be notified and to select the in-app subscription for the server events that you want to be notified.

When	Action	Result
You do not want to receive the in-app	Perform the following steps:	You have unsubscribed the in-app notifications for a specific server event and

When	Action	Result
notifications for a specific server event.	a. Identify the server event by expanding the channel list. b. Clear the checkbox in the **In App** row to unsubscribe. c. Click **Apply**.	the notification is not displayed for you when the event occurs.
You want to receive the in-app notifications for a specific server event.	Perform the following steps: a. Identify the server event by expanding the channel list. b. Select the checkbox in the **In App** row. c. Click **Apply**.	You have subscribed to the in-app notifications for the server event and the notification is displayed for you when the event occurs.
You want to subscribe to the in-app notifications for all server events.	Select the **In App** checkbox under **Channels**, and then click **Apply**.	The in-app channel is displayed as selected for all server events and notifications for all server events will be displayed.
You do not want to receive any in-app notifications for all server events.	Clear the **In App** checkbox, and then click **Apply**.	The in-app channel selections for all server events are cleared and no notifications will be displayed when the event occurs.

6. To change the notification language in which you want to receive the notifications from the default, select a language from the **Email Language** option in the **Notifications** pane and click **Apply**.

Results

You have modified the notification subscription for specific or all server events.

Viewing in-app notifications

You can view the notifications for the events that occur within the Test .

About this task

The in-app notifications are displayed in the server UI under the following categories for the server events that occur:

Category	Notifications displayed
User	Include information about actions performed by team space members in the team space.
System	Include information about actions performed by registered users at the server level.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Notifications** icon on the menu bar.

   The **Notifications** dialog is displayed.

   You can find the information about the default notifications that you can view based on your role in the server as in-app notifications in the **USER** tab and **SYSTEM** tab.

Category	Notification details	*Server Administrator* or *Team Space Owner*	*Project Creator* or *Project Owner*	*Tester*	*Viewer*
User notifications	Information about events at the server level or across team spaces performed by other team space owners.	✔	✔	✘	✘
	Information about events in the team space performed by other team space members.	✔	✘	✘	✘
	Information about events in the project performed by other project members.	✘	✔	✔	✘
	Information about events performed by you in a project.	✘	✘	✔	✔
System notifications	Information about events at the server level or across team spaces.	✔	✔	✘	✘

Category	Notification details	*Server Administrator* or *Team Space Owner*	*Project Creator* or *Project Owner*	*Tester*	*Viewer*
	Information about events in the team space performed by other team space members.	✔	✔	✘	✘
	Information about events in the projects at the team space level performed by other project members.	✔	✔	✘	✘

The notifications in the **USER** tab are displayed as the default option.

3. View the notifications in the **USER** tab.
4. View the notifications at the server level by clicking the **SYSTEM** tab.

Results

You have viewed the in-app notifications.

Managing email notifications

You can manage the email notifications by changing the subscriptions that are automatically enabled for you for all events that occur in Test .

Before you begin

You must have completed the following tasks:

- Ensured that the *Server Administrator* or *Team Space Owner* has configured a Simple Mail Transfer Protocol (SMTP) server. See Configuring an SMTP server to manage email notifications on page 1761.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.

About this task

After the SMTP server is configured on Test, you can view the server events that are subscribed in the **General Settings** page. You can either unsubscribe from the **Email** channel or change your subscriptions of the server events for which you do not want to receive email notifications.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **User** icon on the menu bar.
3. Click **Account Settings**.

   Alternatively, click the **Notification** icon on the menu bar, and then click the **Settings** icon in the **Notifications** dialog.

   The **General Settings** dialog is displayed.
4. Perform the actions indicated in the following table for the option you want for the email notifications:

When	Action	Results
You want to subscribe to email notifications for all server events.	Select the **Email** checkbox under **Channels** then click **Apply**.	The email channel for all server events is selected and you are subscribed to receive email notifications for all server events.
You do not want to receive any email notifications.	Uncheck the **Email** checkbox under **Channels**, then click **Apply**.	The email notification selection for all server events is cleared and you are unsubscribed from receiving email notifications for all the server events.
You want to receive temail notifications for a specific server event.	Perform the following steps: a. Expand the channel list in the row of the server event. b. Select the **Email** checkbox of the event you want to subscribe. c. Click **Apply**.	You have subscribed to the email channel to receive email notifications for the server event.
You do not want to receive email notifications for a specific server event, if you subscribed to it previously.	Perform the following steps: a. Expand the channel list in the row of the server event. b. Clear the checkbox for the **Email** channel option of the event you want to unsubscribe. c. Click **Apply**.	You have unsubscribed from the email channel for the server event, and you will not receive email notifications when the event occurs.

5. To change the language in which you want to receive the email notifications from the default, select a language from the **Email Language** list in the **Notifications** pane and click **Apply**.

   The default language is the language set on the computer that hosts Test.

Results

You completed the following tasks:

- Subscribed to the email channel for receiving email notifications for the selected server events.
- Unsubscribed from the email channel for selected server events that you subscribed previously.
- Subscribed to the email channel for receiving email notifications for all server events.
- Unsubscribed from the email channel for receiving email notifications for all server events.

Configuring an SMTP server to manage email notifications

Before you can receive email notifications about events that occur in Test , you need to configure an existing Simple Mail Transfer Protocol (SMTP) server in Test. Once configured, email notifications are sent to the registered users if they are subscribed to email notifications whenever events occur in Test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that an existing SMTP server is available to be connected to Test.

About this task

The configuration works for emails that are supported by the SMTP server. To use this capability, you must enable Test to connect to the SMTP server to send email notifications.

As a server administrator, you can configure email notifications so that other users can receive information about actions on the server projects.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Server administration page** icon from the menu bar.

   The **Global Settings** page is displayed.
3. Click **Add Configuration**.

4. Provide the following details to configure the SMTP server:
    - A name to the configuration.
    - The hostname and port number of the SMTP server.

      Note: The default configuration uses a local SMTP server that listens to the default port 25. This SMTP server does not require any authentication.

    - The email address of the sender. The email address is displayed in email notifications. The email notifications are sent to the users based on the notification settings.
    - The encryption type for secure communications is when the SMTP server is on an external network. You can enable either **STARTTLS** or **SSL/TLS**.

      Note: The SMTP server for the secure communication listens to the default port 465.

    - Login credentials are required if the SMTP server requires authentication.
5. Click **Add**.

Note: The SMTP configuration is added after a valid connection is established with the SMTP server.

Results

You configured an SMTP server to connect with Test and send out email notifications about the server events to users who have subscribed to email notifications.

What to do next

You can modify the default subscriptions for the email notifications, see Managing email notifications on page 1759.

Notification Management on page 1755

Configuration of a webhook

You can configure webhooks to send notifications to a messaging application such as Microsoft Teams, Slack, or any generic application that can receive an HTTP POST request when any of the events occur on Test . For example, when you add or remove a member from a team space or when you run a test.

A webhook is an HTTP custom callback that provides an application to send notifications to other applications. Webhooks help applications automatically communicate with other external applications.

The following table lists the tasks that you can perform and manage for the webhooks:

Task	Go to...
Configure a webhook template	Configuring a webhook template on page 1763
Configure a webhook	Configuring a project webhook on page 1774
Edit, clone, or delete a webhook template	Managing the webhook template configuration on page 1776
Edit, clone, or delete a webhook	Managing the webhook configuration on page 1779

Webhooks overview

Webhooks send a notification to the configured messaging applications when specific events occur on Test .

When the event occurs, Test automatically sends an HTTP POST request with event-related information in a JSON format or in plain text to the URL that you configured. You can define a template body or use the sample template that is set on Test. You must create a channel type, a template, and a webhook to send an HTTP POST request.

You can manage the webhook template configuration and webhook configuration on Test. You can identify the events and view the status of the events that are posted on the messaging application whenever an event occurs.

Configuring a webhook template

You can configure a project, team space and a server webhook template on Test to send notifications to the configured messaging application.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Ensured that you are familiar with Apache Velocity. See Apache Velocity Documentation.

About this task

You can create a template based on the channel type that you configured. You can select a generic template to send notifications to the generic application. You can also select a JSON sample template with specific fields defined to display event-related notifications in Microsoft Teams or Slack. You can use the sample template that is available for the messaging application or you can also define a JSON template to post the message about the events that occur on Test.

1. Select from the following actions you want to perform:
   - Configure a project webhook template. Go to Step 2 on page 1764.
   - Configure a team space webhook template. Go to Step 3 on page 1766.
   - Configure a server webhook template. Go to Step 4 on page 1768.
2. Perform the following steps to configure a project webhook template.

   a. Log in to Test.

      The **Projects** page of the initial team space is displayed.

   b. Click **My projects > *project_name*** to open the project that contains the test assets.

      The **Overview** page of the project is displayed.

   c. Click **Manage > Webhooks**.

      The **Templates** tab of Webhooks is displayed.

   d. Click **New Template**.

      The **New template** page is displayed.

   e. Perform the following actions on the **DETAILS** tab:
      i. Enter a unique name for the template.
      ii. Click the **Channel Type** option, and then select an existing channel type.
      iii. Alternatively, you can create a new channel type by clicking **Create new channel type ...** option if there are no channel types available in the drop-down list.

         The **New channel type** dialog is displayed.

      iv. Enter a unique name for the channel type, and then enter a description for the channel type.

      Note: You can also create a new channel type or edit a channel type from the **Channel Type** option available within the **Templates** tab.

   f. Perform the following steps if you want to select either a channel icon or a brand icon:
      i. Click **Create new channel type...**, and then click **Channel type** icon .

         The **Select icon** page is displayed.

      ii. View a list of icons that are displayed In the **GENERAL** tab.
      iii. Search for the icons by entering any text contained in the icon name in the **Search** field, and then select the required icon.

         The selected icon is displayed in the **Selected icon** box.

      iv. Click the **BRANDS** tab.

         View a list of icons that are displayed.

v. Search for the brands by entering any text contained in the brand name in the **Search** field, and then select the brand.

The selected brand is displayed in the **Selected icon** box.

vi. Click **Ok**.

The default icon is replaced with the selected icon.

g. Enter a description for the channel type, and then click **Apply**.

The channel type is created and added to the **Channel Type** list.

h. Enter a description for the template.

i. Perform the following steps to select an event:

i. Click **This template is suitable for events** and select All Events, or any of the subset events from the following list:

- All Events
- Team Space Events
- Project Events
- Execution Events
- License Events

ii. Search for the events by entering any text contained in the events name in the **Search** field, and then select the corresponding checkbox to select the specific event.

Note: All Events is the default event that is set for the webhook template.

j. Click the **Template** tab, and then perform any of the following actions:

- Perform the following steps to insert a generic template:

i. Click the **cloud** icon to insert a velocity text processing template in the **Template body**.

A message is displayed about the action that inserts a text in the template body.

ii. Click **Ok**.

The text is inserted in the **Template body**.

- Perform the following steps to insert a Microsoft Teams sample template:

i. Click the **Microsoft Teams** icon to replace a template with a Microsoft Teams template.

A message is displayed about the action that replaces the content of the template body with a Microsoft Teams template.

ii. Click **Ok**.

A Microsoft Teams sample template is inserted in the **Template body**.

- Perform the following steps to insert a Slack sample template:

i. Click the **Slack** icon .
ii. A message is displayed about the action that replaces the content of the template body with a Slack template.
iii. Click **Ok**.

A Slack sample template is inserted in the **Template body.**

- Perform the following steps to insert a DevOps Velocity sample template:

i. Click the **infinity** icon .
ii. A message is displayed about the action that replaces the content of the template body with a DevOps Velocity template.
iii. Click **Ok**.

A DevOps Velocity sample template is inserted in the **Template body.**

k. Click **Apply**.

The template is created and added to the **Templates** tab.

3. Perform the following steps to configure a team space webhook template:

a. Log in to Test.

The **Projects** page of the initial team space is displayed.

b. Click **Initial Team Space > Manage Team Space > > Webhooks**.

The **Templates** tab of Webhooks is displayed.

c. Click **New Template**.

The **New template** page is displayed.

d. Perform the following actions on the **DETAILS** tab:
i. Enter a unique name for the template.
ii. Click the **Channel Type** option, and then select an existing channel type.
iii. Alternatively, you can create a new channel type by clicking **Create new channel type ...** option if there are no channel types available in the drop-down list.

The **New channel type** dialog is displayed.

iv. Enter a unique name for the channel type, and then enter a description for the channel type.

Note: You can also create a new channel type or edit a channel type from the **Channel Type** option available within the **Templates** tab.

e. Perform the following steps if you want to select either a channel icon or a brand icon:

i. Click **Create new channel type...**, and then click **Channel type** icon .

The **Select icon** page is displayed.

ii. View a list of icons that are displayed In the **GENERAL** tab.

iii. Search for the icons by entering any text contained in the icon name in the **Search** field, and then select the required icon.

The selected icon is displayed in the **Selected icon** box.

iv. Click the **BRANDS** tab.

View a list of icons that are displayed.

v. Search for the brands by entering any text contained in the brand name in the **Search** field, and then select the brand.

The selected brand is displayed in the **Selected icon** box.

vi. Click **Ok**.

The default icon is replaced with the selected icon.

f. Enter a description for the channel type, and then click **Apply**.

The channel type is created and added to the **Channel Type** list.

g. Enter a description for the template.

h. Perform the following steps to select an event:

i. Click **This template is suitable for events** and select All Events, or any of the subset events from the following list:

- All Events
- Team Space Events
- Project Events
- Execution Events
- License Events

ii. Search for the events by entering any text contained in the events name in the **Search** field, and then select the corresponding checkbox to select the specific event.

Note: All Events is the default event that is set for the webhook template.

i. Click the **Template** tab, and then perform any of the following actions:

- Perform the following steps to insert a generic template:

i. Click the **cloud** icon to insert a velocity text processing template in the **Template body**.

A message is displayed about the action that inserts a text in the template body.

ii. Click **Ok**.

The text is inserted in the **Template body**.

- Perform the following steps to insert a Microsoft Teams sample template:
  i. Click the **Microsoft Teams** icon to replace a template with a Microsoft Teams template.

  A message is displayed about the action that replaces the content of the template body with a Microsoft Teams template.

  ii. Click **Ok**.

  A Microsoft Teams sample template is inserted in the **Template body**.

- Perform the following steps to insert a Slack sample template:
  i. Click the **Slack** icon .
  ii. A message is displayed about the action that replaces the content of the template body with a Slack template.
  iii. Click **Ok**.

  A Slack sample template is inserted in the **Template body.**

- Perform the following steps to insert a DevOps Velocity sample template:
  i. Click the **infinity** icon .
  ii. A message is displayed about the action that replaces the content of the template body with a DevOps Velocity template.
  iii. Click **Ok**.

  A DevOps Velocity sample template is inserted in the **Template body.**

j. Click **Apply**.

The template is created and added to the **Templates** tab.

4. Perform the following steps to configure a server webhook template:

a. Log in to Test.

The **Projects** page of the initial team space is displayed.

b. Click the **Settings** icon on the menu bar.
c. Click **Webhooks**.

The **Templates** tab of Webhooks is displayed.

d. Click **New Template**.

The **New template** page is displayed.

e. Perform the following actions on the **DETAILS** tab:

i. Enter a unique name for the template.
ii. Click the **Channel Type** option, and then select an existing channel type.
iii. Alternatively, you can create a new channel type by clicking **Create new channel type ...** option if there are no channel types available in the drop-down list.

The **New channel type** dialog is displayed.

iv. Enter a unique name for the channel type, and then enter a description for the channel type.

Note: You can also create a new channel type or edit a channel type from the **Channel Type** option available within the **Templates** tab.

f. Perform the following steps if you want to select either a channel icon or a brand icon:

i. Click **Create new channel type...**, and then click **Channel type** icon .

The **Select icon** page is displayed.

ii. View a list of icons that are displayed In the **GENERAL** tab.
iii. Search for the icons by entering any text contained in the icon name in the **Search** field, and then select the required icon.

The selected icon is displayed in the **Selected icon** box.

iv. Click the **BRANDS** tab.

View a list of icons that are displayed.

v. Search for the brands by entering any text contained in the brand name in the **Search** field, and then select the brand.

The selected brand is displayed in the **Selected icon** box.

vi. Click **Ok**.

The default icon is replaced with the selected icon.

g. Enter a description for the channel type, and then click **Apply**.

The channel type is created and added to the **Channel Type** list.

h. Perform the following steps to select an event:

i. Click **This template is suitable for events** and select All Events, or any of the subset events from the following list:

- All Events
- Team Space Events
- Project Events
- Execution Events
- License Events

ii. Search for the events by entering any text contained in the events name in the **Search** field, and then select the corresponding checkbox to select the specific event.

Note: All Events is the default event that is set for the webhook template.

i. Click the **Template** tab, and then perform any of the following actions:

- Perform the following steps to insert a generic template:
  i. Click the **cloud** icon to insert a velocity text processing template in the **Template body**.

  A message is displayed about the action that inserts a text in the template body.

  ii. Click **Ok**.

  The text is inserted in the **Template body**.
- Perform the following steps to insert a Microsoft Teams sample template:
  i. Click the **Microsoft Teams** icon to replace a template with a Microsoft Teams template.

  A message is displayed about the action that replaces the content of the template body with a Microsoft Teams template.

  ii. Click **Ok**.

  A Microsoft Teams sample template is inserted in the **Template body**.
- Perform the following steps to insert a Slack sample template:
  i. Click the **Slack** icon .
  ii. A message is displayed about the action that replaces the content of the template body with a Slack template.
  iii. Click **Ok**.

  A Slack sample template is inserted in the **Template body.**
- Perform the following steps to insert a DevOps Velocity sample template:
  i. Click the **infinity** icon .
  ii. A message is displayed about the action that replaces the content of the template body with a DevOps Velocity template.
  iii. Click **Ok**.

  A DevOps Velocity sample template is inserted in the **Template body.**

j. Click **Apply**.

The template is created and added to the **Templates** tab.

Results

You have configured and created a project, team space and a server webhook template on Test.

What to do next

You must configure a webhook to push the events from Test to the messaging application. See Configuring a project webhook on page 1774.

Configuring a server webhook

You can configure a server webhook to send notifications to a messaging application whenever an event occurs on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role of a *Server Administrator*. See Managing access to the server projects on page 1735.
- Ensured that you have access to the messaging applications.
- Created a channel type.
- Configured your messaging application.
- Copied the URL of the external communication application. See Creating an incoming webhook.
- Created a webhook template. See Configuring a webhook template on page 1763.

About this task

When you configure a webhook on Test, you must copy the URL of the communication application in the **Webhook URL** field and paste the outgoing URL, and then select the events. You can select either all events or a subset of events.

You can be notified of the following types of events:

- All Events
- Team space Events
- Project Events
- Execution Events
- License Events

You can configure the webhook resume policy by selecting either the Queue old messages or Discard old messages option. When a server webhook is disabled due to communication failures or network issues, the server event notifications are not delivered to the configured webhook, and you receive a notification that the webhook is disabled. By configuring the queue old messages, you can ensure that the event notifications are not lost and are delivered to the configured webhook after the server webhook is enabled again.

If you configure the Discard old messages for a server webhook, the event notifications are discarded from the moment the webhook is disabled. Only server events that occur after the webhook is re-enabled are sent to the configured webhook.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Settings** icon on the menu bar, and then click **Webhooks**.
   The **Templates** tab of Webhooks is displayed.
3. Click the **Webhooks** tab, and then click **New Webhook**.

   The **New Webhook** page is displayed.
4. Enter a name for the webhook and paste the URL that you copied in the **Webhook URL** field.
   You must copy the URL while you configure your communication application.
5. Click the **Webhook resume policy**, and then select a resume policy option from the drop-down list. You can select any of the following options:
   a. Queue old messages
   b. Discard old messages
6. Click the **Channel Type**, and then select a channel type from the list.
7. Enter a description for the webhook, and then select a template from the drop-down list.
   A corresponding event that you configured for the template is displayed in the **Events** field.
8. Click the **Templates** icon Template, to add the templates that are configured for the channel type.

   Note: If you want to change the events, then click the events option and select the required events.
9. You can perform any of the following steps:
   a. Click move the template to a higher priority icon to move the template to a higher priority.
   b. Click move the template to a lower priority icon to move the template to a lower priority.
10. Click **Apply**.
    The webhook is created and added to the **Webhooks** tab.

Results

You have configured and created a server webhook on Test.

What to do next

You can perform any of the following tasks:

- You can duplicate or delete the template that you created on Test. See Managing the webhook template configuration on page 1776.
- You can duplicate or delete the webhook you created on Test. See Managing the webhook configuration on page 1779.

Configuring a team space webhook

You can configure a team space webhook to send notifications to a messaging application whenever an event occurs on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you have access to the messaging applications.
- Created a channel type.
- Configured your messaging application.
- Copied the URL of the external communication application. See Creating an incoming webhook.
- Created a webhook template. See Configuring a webhook template on page 1763.

About this task

When you configure a webhook on Test, you must copy the URL of the communication application in the **Webhook URL** field and paste the outgoing URL, and then select the events. You can select either all events or a subset of events.

You can be notified of the following types of events:

- All Events
- Team space Events
- Project Events
- Execution Events
- License Events

You can configure the webhook resume policy by selecting either the Queue old messages or Discard old messages option. When a team space webhook is disabled due to communication failures or network issues, the team space event notifications are not delivered to the configured webhook, and you receive a notification that the webhook is disabled. By configuring the queue old messages, you can ensure that the event notifications are not lost and are delivered to the configured webhook after the team space webhook is enabled again.

If you configure the Discard old messages for a team space webhook, the event notifications are discarded from the moment the webhook is disabled. Only team space events that occur after the webhook is re-enabled are sent to the configured webhook.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Initial Team Space > Manage team space**, and then click **Webhooks**.
   The **Templates** tab of Webhooks is displayed.
3. Click the **Webhooks** tab, and then click **New Webhook**.

   The **New Webhook** page is displayed.
4. Enter a name for the webhook and paste the URL that you copied in the **Webhook URL** field.
   You must copy the URL while you configure your communication application.

5. Click the **Webhook resume policy**, and then select a resume policy option from the drop-down list. You can select any of the following options:
    a. Queue old messages
    b. Discard old messages
6. Click the **Channel Type**, and then select a channel type from the list.
7. Enter a description for the webhook, and then select a template from the drop-down list.
   A corresponding event that you configured for the template is displayed in the **Events** field.
8. Click the **Templates** icon , to add the templates that are configured for the channel type.

   Note: If you want to change the events, then click the events option and select the required events.

9. You can perform any of the following steps:
    a. Click move the template to a higher priority icon to move the template to a higher priority.
    b. Click move the template to a lower priority icon to move the template to a lower priority.
10. Click **Apply**.
    The webhook is created and added to the **Webhooks** tab.

Results

You have configured and created a team space webhook on Test.

What to do next

- You can duplicate or delete the template that you created on Test. See Managing the webhook template configuration on page 1776.
- You can duplicate or delete the webhook you created on Test. See Managing the webhook configuration on page 1779.

Configuring a project webhook

You can configure a project webhook to send notifications to a messaging application whenever an event occurs on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Ensured that you have access to the messaging applications.
- Created a channel type.
- Configured your messaging application.

- Copied the URL of the external communication application. See Creating an incoming webhook.
- Created a webhook template. See Configuring a webhook template on page 1763.

About this task

When you configure a webhook on Test, you must copy the URL of the communication application in the **Webhook URL** field and paste the outgoing URL, and then select the events. You can select either all events or a subset of events.

You can be notified of the following types of events:

- All Events
- Team space Events
- Project Events
- Execution Events
- License Events

  You can configure the webhook resume policy by selecting either the Queue old messages or Discard old messages option. When a project webhook is disabled due to communication failures or network issues, the project event notifications are not delivered to the configured webhook, and you receive a notification that the webhook is disabled. By configuring the queue old messages, you can ensure that the event notifications are not lost and are delivered to the configured webhook after the project webhook is enabled again.

  If you configure the Discard old messages for a project webhook, the event notifications are discarded from the moment the webhook is disabled. Only project events that occur after the webhook is re-enabled are sent to the configured webhook.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Webhooks** in the navigation pane.
   The **Templates** tab of Webhooks is displayed.
4. Click the **Webhooks** tab, and then click **New Webhook**.

   The **New Webhook** page is displayed.
5. Enter a name for the webhook and paste the URL that you copied in the **Webhook URL** field.
   You must copy the URL while you configure your communication application.
6. Click the **Webhook resume policy**, and then select a resume policy option from the drop-down list. You can select any of the following options:
   a. Queue old messages
   b. Discard old messages

      The Queue old messages is selected as the default option.

7. Click the **Channel Type**, and then select a channel type from the list.
8. Enter a description for the webhook, and then select a template from the drop-down list.
   A corresponding event that you configured for the template is displayed in the **Events** field.
9. Click the **Templates** icon, to add the templates that are configured for the channel type.

   Note: If you want to change the events, then click the events option and select the required events.

10. You can perform any of the following steps:
    a. Click move the template to a higher priority icon to move the template to a higher priority.
    b. Click move the template to a lower priority icon to move the template to a lower priority.
11. Click **Apply**.
    The webhook is created and added to the **Webhooks** tab.

Results

You have configured and created a project webhook on Test.

What to do next

You can perform any of the following tasks:

- You can duplicate or delete the template that you created on Test. See Managing the webhook template configuration on page 1776.
- You can duplicate or delete the webhook you created on Test. See Managing the webhook configuration on page 1779.

Managing the webhook template configuration

You can manage the webhook template configuration that you set on Test when you want to edit, duplicate, delete the existing webhook templates, or create new templates. Before you create a webhook, you can view the templates created at server, team space, and project levels. Additionally when you create a project, team space or server webhook you can utilize the corresponding templates associated with them.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Project Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Configured a webhook template. See Configuring a webhook template on page 1763.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Webhooks** in the navigation pane.

   The **Templates** tab of Webhooks is displayed.
4. Perform the tasks indicated in the following table:

Task	Action
Configuring a webhook template	Click the **New Template** option to configure a webhook template. See Configuring a webhook template on page 1763.
Viewing webhook templates	View the following details about the project, team space and server templates: a. The **Show all levels** checkbox selected. b. The following icons that display the server, team space, and project webhook templates in the **From** column. ▪ Project template icon ▪ Team space template icon ▪ Serve template icon As a project owner, you can view project, team space, and server templates on the project template page. Similarly, as a team space owner, you can view only team space and server templates on the team space template page. Perform the following steps to view project or team space templates: a. Clear the **Show all levels** checkbox. You can only view project webhook templates, if you are on the project template page, and you can only view team space templates, if you are on the team space template page. b. Click the **Action** icons to edit, duplicate view or delete the templates. **Note:** As a *Project Owner*, you can edit the project webhook templates; however, you can only view and clone the details of server webhook templates or team space webhook templates. If you are a *Team Space*

Task	Action
	Owner you can edit the team space templates; however, you can only view and clone the details of server webhook templates. If you clone a webhook template, then you can edit or delete a webhook template.
Editing a webhook template	Perform the following steps to edit the webhook template: a. Click the **Edit template** icon . The **Edit template** page is displayed. b. In the **Details** tab, you can enter a new name for the webhook template, or select any other value for the options. c. In the **Templates** tab, you can also edit or select a template based on the channel type you selected on **Details** tab. d. Click **Apply**. The edited template is saved to the **Templates** tab.
Cloning a webhook template	Perform the following steps to duplicate the webhook template: a. Click the **Duplicate template** icon . The **Duplicate template** page is displayed. b. In the **Details** tab, you can edit or modify the values by entering a new name for the webhook template, by selecting a Channel Type, or Events. c. In the **Templates** tab, you can edit or select other webhook template based on the channel type you selected on **Details** tab. d. Click **Apply**. The cloned webhook template is added to the **Templates** tab.
Deleting a webhook template	Perform the following steps to delete the webhook template: a. Click the **Delete Template** icon . The Delete template confirmation dialog is displayed. b. Select the **I understand template deletion is permanent** checkbox, and then click **Delete**. The webhook template is removed from the template list.

Results

You achieved the following results:

- Edited and saved a webhook template configuration.
- Cloned a webhook template configuration.
- Deleted a webhook template configuration.

Managing the webhook configuration

You can manage the webhook configuration that you set on Test you want to edit, duplicate, delete the existing webhook configurations, or create a webhook.

Before you begin

- Ensured that you are assigned a role of a project *Owner* in the project. See Managing access to the server projects on page 1735.
- Ensured that you configured a webhook. See Configuring a project webhook on page 1774.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Webhooks** in the navigation pane.
   The **Templates** tab of Webhooks is displayed.
4. Click the **Webhooks** tab.
5. Perform the tasks indicated in the following table:

Task	Action
New Webhook	Click the **New Webhook** option to configure and create a webhook. See Configuring a project webhook on page 1774.
Editing a webhook	Perform the following steps to edit the webhook: a. Click the **Edit Webhook** icon . The **Edit webhook** page is displayed. b. Enter a new name for the webhook. c. Replace the webhook URL by pasting a different URL of another messaging channel you configured. d. Select another channel type to post the notification of an event. e. Select a different template, and then select events from the **Events** list. f. Click **Close**.
Cloning a webhook	Perform the following steps to clone the webhook: a. Click the **Duplicate webhook** icon . The **Duplicate webhook** page is displayed.

Task	Action
	b. Enter a new name for the webhook, and then click **Apply**. The cloned webhook is added to the **Webhooks** tab.
Deleting a webhook	Perform the following steps to delete the webhook: a. Click the **Delete Webhook** icon . The **Delete Webhook** confirmation dialog is displayed. b. Select the **I understand webhook deletion is permanent** checkbox, and then click **Delete**. The webhook is removed from the webhook list.

Results

You achieved the following results:

- Edited and saved a webhook configuration.
- Cloned a webhook configuration.
- Deleted a webhook configuration.

Enabling a webhook

You can enable a webhook when push notifications about events occurring on Test are not delivered to the configured webhook due to communication failures or network issues, and you receive a notification that the webhook is disabled.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned the role of a *Server Administrator*, *Team Space Owner* or a *Project Owner*. If you are a server administrator, you can have three roles-server admin, team space owner, and project owner.
- Configured a webhook. See Configuring a project webhook on page 1774.

About this task

When a webhook is disabled due to communication failure or network issues, you are notified about the disablement of the webhook. Consequently notifications for the events are not delivered to the configured webhook and instead be queued for sending after you re-enable the webhook. You have the option to either send the queued messages or discard the queued messages.

1. Select from the following actions that you want to perform:
   - Enable a project webhook. Go to Step 2 on page 1781.
   - Enable a team space webhook. Go to Step 3 on page 1781.
   - Enable a server webhook. Go to Step 4. on page 1781
2. Perform the following steps to manually enable a project webhook:

   a. Log in to Test.

      The **Projects** page of the initial team space is displayed.

   b. Click **My projects >** ***project_name*** to open the project that contains the test assets.

      The **Overview** page of the project is displayed.

   c. Click **Manage > Webhooks**.

      The **Templates** tab of Webhooks is displayed.

   d. Click the **Webhooks** tab, and then click the **Disabled** webhook option to enable a webhook that is disabled.

   The event notifications that were queued when the webhook was disabled are delivered to the configured webhook or discarded by Test.This setting is based on the resume policy configuration that you set for the specific project webhook.
3. Perform the following steps to manually enable a team space webhook:

   a. Log in to Test.

      The **Projects** page of the initial team space is displayed.

   b. Click the **Settings** icon on the navigation pane, and then click **Manage team space**.
   c. Click **Webhooks**.

      The **Templates** tab of Webhooks is displayed.

   d. Click the **Webhooks** tab, and then click the **Disabled** webhook option to enable a webhook that is disabled.

   The event notifications that were queued when the webhook was disabled are delivered to the configured webhook or discarded by Test. This setting is based on the resume policy configuration that you set for the team space webhook.
4. Perform the following steps to manually enable a server webhook:

   a. Log in to Test.

      The **Projects** page of the initial team space is displayed.

   b. Click the **Settings** icon on the menu bar, and then click **Webhooks**.

      The **Templates** tab of Webhooks is displayed.

   c. Click the **Webhooks** tab, and then click the **Disabled** webhook option to enable a webhook that is disabled.

   The event notifications that were queued when the webhook was disabled are delivered to the configured webhook or discarded by Test. This setting is based on the resume policy configuration that you set for the server webhook.

Results

You enabled the webhook on Test to push notifications of the events that failed to be delivered to the configured webhook.

Management of events

When an identified event occurs on Test , a webhook sends an HTTP POST request to the URL that you configured for the webhook. The request contains the message associated with the event, in JSON format or plain text. Each event corresponds to a set of actions that occur. For example, when a member is added to a Team space or when a Test failed with an error.

The following tables describe different events that are identified on Test.

Table 622. Main

Event	Description
All Events	When any of the events occur, a webhook sends a notification.

Table 623. Team Space Events

Event	Description
Team Space Management	When events occur at the team space management level, a webhook sends a notification.
Team Space Created	When a team space is created, a webhook sends a notification.
Team Space Deleted	When a team space is deleted, a webhook sends a notification.
Team Space Updated	When a team space is updated, a webhook sends a notification. Following are the subsets of the team space events: **Event** / **Notification sent** Team Space URL alias Updated / When the team space URL alias is updated. Team Space Renamed / When the name of the team space is changed. Team Space Becomes Permissive / When the team space is accessible. Team Space Becomes Private / When an access to the team space is not shared.

Table 623. Team Space Events (continued)

<table>
<tr><th>Event</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Team Space Becomes Public</td><td>When all members are provided access to the team space.</td></tr>
<tr><td>Team Space Becomes Restrictive</td><td>When access to the team space is limited.</td></tr>
</table>
</td></tr>
<tr><td>Team Space Repositories</td><td>When an event occurs in the team space repositories, a webhook sends a notification.

Following are the subsets of the team space repository events:
<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Team Space Repositories Created</td><td>When the team space repositories are created.</td></tr>
<tr><td>Team Space Repositories Deleted</td><td>When the team space repositories are deleted.</td></tr>
</table>
</td></tr>
<tr><td>Team Space Member</td><td>When an event occurs in the team space, a webhook sends a notification.

Following are the subsets of the team space member events:
<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Team Space Member Added</td><td>When a member is added to the team space.</td></tr>
<tr><td>Team Space Member Removed</td><td>When a member is removed from the team space.</td></tr>
<tr><td>Team Space Member Role Added</td><td>When a specific role for a member is added.</td></tr>
<tr><td>Team Space Member Role Removed</td><td>When a specific role of a member is removed.</td></tr>
</table>
</td></tr>
<tr><td>Team Space Role Request</td><td>When a request is sent to join a team space, a webhook sends a notification.

Following are the subsets of the team space role request events:</td></tr>
</table>

Table 623. Team Space Events (continued)

Event	Description
	Event / **Notification sent** Team Space Role Requested — When a member sends a request to get a role in the team space. Team Space Role Request Accepted — When the request of the member for a role in the team space is accepted. Team Space Role Request Rejected — When the request of the member for a role in the team space is rejected.

Table 624. Project Events

Event	Notification sent
Project Management	When events occur at the project level, a webhook sends a notification. The Following are the subsets of project management events: **Event** / **Notification sent** Project Archived — When a project is archived. Project Created — When a project is created. Project Renamed — When a project is renamed. Project Deleted — When a project is deleted. Project Unarchived — When a project is unarchived.
Project Repositories	When an event occurs in the project repositories, a webhook sends a notification. Following are the subsets of the project repositories events: **Event** / **Notification sent** Project Repository Created — When a project repository is created. Project Repository Deleted — When a project repository is deleted.

Table 624. Project Events (continued)

Event	Notification sent
Project Member Role	When the role of a member of a project is changed, a webhook sends a notification. Following are the subsets of the project member role events: **Event** / **Notification sent** Project Member Role Added — When a project member role is added to the project. Project Member Role Removed — When a project member role is removed from the project.
Project Member Role Requests	When a request is sent to add a member role to the project, a webhook sends a notification. Following are the subsets of the project member role requests events: **Event** / **Notification sent** Project Member Role Requested — When a member sends a request to join a project. Project Member Role Request Accepted — When a request of the member to join a project is accepted. Project Member Rejected — When a request of the member to join a project is rejected.

Table 625. Execution Events

Event	Description
Test and Suite Status	Webhook sends notifications about the status of the test and test suite. Following are the subsets of the test and test suite status events: **Event** / **Notification sent** Execution Started — When you start to run a test or a test suite. Execution Stopped Manually — When the test run is manually stopped.

Table 625. Execution Events (continued)

<table>
<tr><th>Event</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Execution Completed with Verdict Pass</td><td>When the test run is completed with a pass verdict.</td></tr>
</table>
</td></tr>
<tr><td>Test and Suite Status Errors</td><td>Webhook sends notifications about the error status of the test and test suite.

Following are the subsets of test and test suite status error events:

<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Execution Completed with Verdict Fail</td><td>When the test run is completed with a fail verdict.</td></tr>
<tr><td>Execution Completed with Verdict Error</td><td>When the test run is completed with an error status.</td></tr>
<tr><td>Execution Completed without any Verdict</td><td>When the test run is completed without any results.</td></tr>
<tr><td>Execution Launch Failed</td><td>When the test launch fails.</td></tr>
<tr><td>Execution Stopped with Error</td><td>When the test run stops with an error.</td></tr>
<tr><td>Execution Stopped Automatically</td><td>When automatically the test run stops.</td></tr>
<tr><td>Execution Incomplete</td><td>When the test run is not completed.</td></tr>
</table>
</td></tr>
<tr><td>Virtual Service Status</td><td>Webhook sends notifications about the status of the virtual services.

Following are the subsets of the virtual service status events:

<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Virtual Service Started</td><td>When a virtual service is started.</td></tr>
<tr><td>Virtual Service Stopped Manually</td><td>When a virtual service is manually stopped.</td></tr>
</table>
</td></tr>
<tr><td>Virtual Service Errors</td><td>Webhook sends notifications about the errors that occur in the virtual services.

Following are the subsets of the virtual service error events:

<table>
<tr><th>Event</th><th>Notification sent</th></tr>
<tr><td>Virtual Service Launch Failed</td><td>When a virtual service launch fails.</td></tr>
<tr><td>Virtual Service Stopped with Error</td><td>When a virtual service is stopped with an error.</td></tr>
<tr><td>Virtual Service Stopped Automatically</td><td>When a virtual service is automatically stopped.</td></tr>
</table>
</td></tr>
</table>

Table 626. License Events

Event	Notification sent
License Failure	When a valid license is not obtained.

Troubleshooting

This guide describes how to analyze and resolve some of the common problems that you might encounter while you work with Test .

Known issues are documented in the Release document and the link is in the Release Notes under the Known issues section. See Defect fixes and known issues.

You can contact HCL Support if you are unable to troubleshoot the problem. Gather all the required background information and provide the details to HCL Support for investigation. For more information, see HCL Customer Support.

Troubleshooting issues

You can find information about the issues or problems that you might encounter while working with Test . Details about issues, their causes and the resolutions that you can apply to fix the issues are described.

The troubleshooting issues are presented to you in the following tables based on where or when you might encounter these issues on Test.

- Table 627: Troubleshooting issues: installation on page 1787
- Table 628: Troubleshooting issues: server administration on page 1789
- Table 629: Troubleshooting issues: configuring test runs on page 1790
- Table 630: Troubleshooting issues: test or stub runs on page 1792
- Table 632: Troubleshooting issues: Jira and Xray integrations on page 1796

Table 627. Troubleshooting issues: installation

Problem	Cause	Solution
On Ubuntu, when you are installing Test and you encounter errors in the scripts that are running.	At times, scripts might not appear to be running due to any of the following reasons: • Slow connection speeds. • Insufficient CPU, memory, or disk resources. • A firewall that was configured incorrectly is already enabled.	You can complete any of the following tasks: • To identify the issue, you can perform a diagnostic check by running the following command: `journalctl -u k3s` This command displays the log that you can use to check for the problem.

Table 627. Troubleshooting issues: installation (continued)

Problem	Cause	Solution

		• Run the following command to see which pods are running and which pods are not running:
		`kubectl get pods -A`
		Run the following command to get details about a specific pod:
		`kubectl describe pod -n <namespace> <pod name>`
		• Follow the on-screen instructions to resolve the errors.
		• Some issues can be solved by re-running the following script:
		`sudo ./k3s-init.sh`

On Ubuntu, DNS is not working as expected.		The DNS configuration that is used by the cluster can be displayed by using the following command:
		`kubectl get cm -n kube-system coredns -ojsonpath="{.data.Corefile}"`
		The **forward** setting displays the *nameservers* that are used. For example, you might see the following in the `corefile`:
		`.:53 { : forward . 8.8.8.8 9.9.9.9 : }`
		A script (`ubuntu-set-dns.sh`) is supplied for managing these values.

Table 627. Troubleshooting issues: installation (continued)

Problem	Cause	Solution

		For example, to set the DNS values for the values shown in the previous example:
		`sudo ./ubuntu-set-dns.sh --server 8.8.8.8 --server 9.9.9.9`
		Note: If you do not use sudo in the command, the script runs but the configuration might be lost if the cluster is restarted.
		To learn more about the behavior of the script, run the following command:
		`sudo ./ubuntu-set-dns.sh --help`

When running helm install the created pods keep crashing, and the logs contain: ACCESS_REFUSED when trying to connect to RabbitMQ	In some instances, the RabbitMQ password is not automatically setup correctly.	Manually apply the necessary password: `kubectl exec -n <namespace> <release-name>-rabbitmq-0 -- rabbitmqctl change_password user \ "$(kubectl get secret -n <namespace> <release-name>-rabbitmq -o jsonpath='{.data.rabbitmq-password}' | base64 --decode)"`

Table 628. Troubleshooting issues: server administration

Problem	Cause	Solution
When a user is assigned an additional role, the change in the permissions is not observed in the browser.		You must log out of the session and log in again for the changed role to take effect.
You see the following message displayed on Test:	You requested to join an project that no longer has an owner. Orphaned	Ask an administrator to take ownership of the project, and then add you as a member.

Table 628. Troubleshooting issues: server administration (continued)

Problem	Cause	Solution
`You can't request to join a project that has no owners`	projects occur when the project owners are deleted. This can occur, for example, when the person leaves the organization.	

Table 629. Troubleshooting issues: configuring test runs

Problem	Cause	Solution
When you configure a run of a schedule that matches the following conditions: • The schedule has two user groups configured to run on static agents when the schedule was created in Test Performance 10.1. • One of the user groups is disabled and the asset is committed to the remote repository. Both the static agents are displayed as available for the test run in the **Location** tab of the **Execute test asset** dialog when only one agent that is configured for the user group must be available.	The cause might be because of the following reasons: • The schedule was created in Test Performance 10.1. • The user group that is disabled is not removed or deleted from the test resources. • The agent configured on the disabled user group is already added as an agent to the server project and is available for selection.	To resolve the problem, select from either of the following methods: • By using Test Performance 10.1.1. Perform the following steps: 1. Open the schedule in Test Performance 10.1.1. 2. Save the schedule and the project. 3. Commit your test asset to the remote repository. 4. Proceed to configure a run for the schedule on Test 10.1.1. • By using Test Performance 10.1. Perform the following steps: 1. Select the disabled user group. 2. Click **Remove**. 3. Save the schedule and the project.

Table 629. Troubleshooting issues: configuring test runs (continued)

Problem	Cause	Solution
		4. Commit your test asset to the remote repository. 5. Proceed to configure a run for the schedule on Test 10.1.1.
You have added a remote repository to your project that contains the test assets or resources of the following types: • Postman • JMeter • JUnit The test assets or resources are not displayed on the **Execution** page for you to select the asset for a run.	This problem occurs if the server extension is not enabled. Although the extension was enabled at the time of installation of Test, it was disabled subsequently by the server administrator.	You must verify if the server extension is enabled and running by running the following command: kubectl get pod -n devops-system, where *devops-system* is the namespace that you created to install Test. The server extensions that are running are displayed. If the server extension that you want is not running implying that the server extension is not enabled. You must enable the server extension. Contact the server administrator to enable the server extension.
When you run AFT Suites in Test, the test run finishes with the `Completed with error` message in the **Status** column. On hover over this status, the `Pod failed reason OOMKilled` message is displayed.	The test run fails because of the higher memory consumption.	To resolve this issue, perform one of the following steps: • Increase the Execution Pod memory to 8Gi if you run the test in a container environment: `execution.template.resources.limits.memory: 8Gi` For details on the Helm parameter, see Set memory limit. • Decrease the number of tests in the AFT Suite if you want to run the test without an agent. Edit the `.xml` file of the AFT Suite in HCL DevOps Test UI (Test UI) to reduce the number

Table 629. Troubleshooting issues: configuring test runs (continued)

Problem	Cause	Solution
		of tests, and then commit the changes. • Use an agent to run the test if you cannot decrease the asset size of the AFT Suite. You can perform one of the following steps: ◦ When running the test, in the **LOCATION** tab, select an agent in the **Override** column. ◦ Edit the `.xml` file of the AFT Suite in Test UI to specify an agent in the locations section, and then commit the changes.

Table 630. Troubleshooting issues: test or stub runs

Problem	Cause	Solution
You encounter any of the following issues: • When many tests are run simultaneously on the default cluster location and you observe the following issues: ◦ Out of memory errors. ◦ Observe that the test runs are slow with a high CPU usage. ◦ The Kubernetes pods are getting evicted.	The issue is seen when any of the following events occur: • Many tests are run in parallel. • The memory that is used by the tests during the test run exceeds the allocated default memory of 1 GB. • The default memory of the container is not adequate for the test run. • Pods are evicted due to low node memory.	To resolve the problem, you can increase the resource allocation for test runs by using the arguments listed in Table Table 631: Increasing resource allocation on page 1794. You can enter arguments in the **Additional configuration options** field in the **Advanced** settings panel of the **Execute test asset** dialog when configuring a test run. **Important:** The memory settings that you configure for a

Table 630. Troubleshooting issues: test or stub runs (continued)

Problem	Cause	Solution
• When you run an AFT suite that contains multiple Web UI tests and you observe the following issues: ◦ Error stating that the browser might not be installed or the browser version is unsupported. ◦ Error stating multiple random time-outs or an internal error. • When you run VU schedules that contain multiple Web UI test or large number of virtual users or a combination of Web UI, performance, and API tests, and you observe the following issue: ◦ The test run hangs and the inadequacy of memory can be inferred as the cause in the logs.		test run is persisted for the test when ever you run it. You must use this setting judiciously. Configuring all tests for an increased memory limit might affect subsequent test runs or cause other memory issues when tests run simultaneously. In addition, in the **JVM Arguments** field under the **Advanced** settings you can set the maximum heap size for the test run time. For example, adding the JVM argument **-Xmx3g** sets the maximum heap size to *3Gi*.
You are not able to run Web UI tests on a remote agent that runs on Linux because the browser fails to launch.	Browser launch is prevented when the remote agent runs as *root* or *sudo*.	To resolve this issue, you must perform the following steps after you have installed the remote agent: 1. Stop the agent. 2. Start the agent as the logged in user by performing the following steps: a. Open a terminal on Linux. b. Enter the following commands: cd / opt/HCL/DevOpsTest/Majordomo/

Table 630. Troubleshooting issues: test or stub runs (continued)

Problem	Cause	Solution
		sudo ./MDStop.sh ./MDStart.sh

Note: You can refer to the Kubernetes documentation for information about the different units that can be used for resources in the **Additional configuration option** fields.

Table 631. Increasing resource allocation

Requirement	Configuration option name	Default value, if no value is set	An example value	Result of using the example value
Specifying the memory limit of the *init container*.	`init.resource.memory.limit`	*1024Mi*	*2048Mi*	Increases the memory limit of the *init container* from the default value to *2048Mi*.
Configuring a larger memory request for the *init container* to avoid pod eviction.	`init.resource.memory.request`	*64Mi*	*1024Mi*	Increases the initial memory request for the *init container* from the default value to *1024Mi*.
Specifying the cpu request for the *init container*.	`init.resource.cpu.request`	*50m*	*60m*	Increases the cpu request for the *init container* from the default value *60m*.
Specifying the memory limit of the container used for the test run.	`resource.memory.limit`	The larger of *3Gi* or *maximum heap size + 1Gi*	*4Gi*	Changes the memory limit of the main container from the default value to *4Gi*.

Table 631. Increasing resource allocation

(continued)

Requirement	Configuration option name	Default value, if no value is set	An example value	Result of using the example value
Note: If the memory limit you set is more than the default limit, you must run the following command to increase the allotted limit to 8 GB or any other value above the default value of 3 GB, at the time of installing the server or anytime later: `--set execution.template.resources.limits.memory=8Gi` You must be a server administrator to run this command.				
Specifying the memory request for the container used by the test run.	`resource.memory.request`	*1024Mi*	*2048Mi*	Increases the memory request for the main container from the

(continued)

Requirement	Configuration option name	Default value, if no value is set	An example value	Result of using the example value
				default value to *2048Mi*.
Specifying the cpu request for the main container used by the test run.	`resource.cpu.request`	*50m*	*70m*	Increases the cpu request for the main container from the default value to *70m*.

Table 632. Troubleshooting issues: Jira and Xray integrations

Problem	Cause	Solution
You are not able to create Jira work items in Jira. You are also not able to view the created work items in Jira that you created in HCL OneTest™ Server 10.5.4 or earlier.	The cause can be due to the change in the authentication method used to connect to Jira in Test 11.0.0 or later.	Reconfigure Jira as a change management system in Test 11.0.0 or later. See Configuration of Atlassian Jira as a change management on page 1609.
You are not able to export results to the Xray project. You are also not able to view the results exported to the Xray project that you created in HCL OneTest™ Server 10.5.4 or earlier.	The cause can be due to the change in the authentication method used to connect to Jira in Test 11.0.0 or later.	Reconfigure the Xray project after you reconfigure Jira Test 11.0.0 or later. See Integration with Xray test management for Jira on page 1703.

Failed to install DevOps Test Runtime on Windows 11 25H2

When you attempt to install DevOps Test Runtime on Windows 11 version 25H2, the standard installation might fail with an error message.

The installer might display the following error message:

```
There is a problem with this Windows Installer package. A program required for this install to
 complete could not be run. Contact your support personnel or package vendor.
```

Resolution

To work around this issue, you must install the `devops-test-runtime.msi` file by using a command prompt as an administrator.

Note: You must ensure that the file name of the MSI package does not contain any spaces. For example, if you download the file multiple times, your browser might save it as `devops-test-runtime (1).msi`. Running the installation commands with spaces in the file name causes the command to fail and triggers an error dialog. To avoid this issue, you must rename the downloaded file to remove any spaces before you run the commands.

Perform the following steps:

1. Open a command prompt as an administrator.
2. Navigate to the directory where the `.msi` file is available.
3. Enter the following command in the command prompt:

   ```
   msiexec /i MSI_PATH
   ```

   The installation window with the progress bar is displayed.
4. Click **Proceed** to accept the download of the proprietary certificate if prompted.

   You have installed DevOps Test Runtime by using the command-line interface.

Related information

Recording a Web UI test on page 771

Failed to load the extension in Google Chrome while recording

When you select the Chrome browser to record a Web UI test in Test , you might get the Failed to load extension message.

Resolution

You must install the DevOps Test browser extension for Chrome that is available on the Chrome Web Store at DevOps Test Chrome extension.

You have an option to install the extension in the default profile of Chrome or use one of the other profiles available. If you use a different profile, then you must add an environment variable in your system with the following values:

- **Variable name**: DEVOPS_TEST_CHROME_PROFILE_NAME
- **Variable value**: <profile_name>

Perform the following steps:

1. Open Google Chrome.
2. Switch to the Chrome profile for which you want to add the extension by clicking the profile on the toolbar. On a Mac system, you must run the following command to create a new temporary profile by cloning the existing profile:

- mkdir -p "$HOME/Library/Application Support/devops-test-runtime/chrome-temp-profile" && cp -R "$HOME/Library/Application Support/Google/Chrome/Default" "$HOME/Library/Application Support/devops-test-runtime/chrome-temp-profile/"

And then open Chrome with the cloned profile.

3. Go to the Chrome Web Store.

   The extensions page is displayed.

4. Click **Add to Chrome**.

   The **Add "DevOps Test"?** dialog is displayed.

5. Click **Add extension**.

   A confirmation message is displayed.

6. Close all the Chrome browsers.

   Additionally, you can check and terminate any active browser processes in the background.

7. Open Test in the Edge or Firefox browser.
8. Record a test by choosing the Chrome browser from the **Browser** drop-down list.

Release

Release standardizes and automates the software release lifecycle with the DevOps Loop, moving applications smoothly from preproduction to production. It provides predictable scheduling, integrates changes from planning tools, and gives stakeholders clear visibility into plans and milestones.

Introduction to releases and pipelines

A release represents the delivery of multiple applications through one or more phases of a life cycle. A typical release includes many deployments to test environments and a small number of highly orchestrated deployments to staging and production. Release managers can define milestones that lead up to the release, as well as a plan to deliver participating applications to each phase of the life cycle.

Releases can represent all kinds of events, from major events in the life of your company to comparatively minor events, like recurring maintenance. You assign the applications, which are business-meaningful pieces of a system or software that can be independently deployed to the release. You create deployment plans, which define the tasks that must be completed when a deployment runs, for your release.

Pipelines automate releases. Pipeline stages organize inputs and jobs as your code is built, deployed, and tested. Stages accept input from either Source control management (SCM) repositories or other external applications, such as HCL DevOps Deploy (Deploy). Stages and jobs run serially and enable flow control for your work.

Home page

Use the **Home** page to view value streams, releases, and insights defined in your environment.

Access the **Home** page and user interface using the URL provided by your administrator. To access the user interface, the administrator must authenticate your credentials. After logging into Measure, the **Home** page is displayed. From the **Home** page, you can view value streams, releases, and insights.

The Home page task bar allows you to access details and work with value streams, releases, and insights. Click **Value Streams**, **Releases**, or **Insights** to view respective home pages where you can manage value streams, govern software releases, and view real-time report information for your DevOps process.

If you have administrator privileges, there are several functions available. Click **Settings** ( ) on the task bar to perform the following tasks.

- Setup the calendar
- Perform integrations and install plugins
- View license management details
- Manage user authorization
- Manage user authentication
- Configure email server
- View your profile and create User access keys (UAKs)

The **Home page** displays all recently viewed value streams and releases with each represented in respective card views. Click the required card to work with value streams and releases. Click **View all** to access the **Value Streams** and **Releases** pages.

Administering

Configuring Measure

A default Measure administrator ID is included as part of Measure. It is used to install and complete initial configuration tasks.

The Measure administrator can perform the following tasks from the administrator user interface:

- Integrations
- User authentication
- Environment mapping
- Line of business mapping

Users who are part of the Deploy system team can perform the following tasks:

- Environment mapping
- Line of business mapping

Security considerations

To ensure user data security, specify a **logout url** when authenticating users. This ensures that the user is logged out of the system and prevents another person to access their account through the cached browser data.

Configuring an email server

Configuring an email server

Before you begin

To send email, you must define an SMTP (Simple Mail Transfer Protocol) server.

This task requires that you are an Measure administrator.

About this task

You can set up a mail server for sending notifications and email.

1. On the Measure dashboard, click **Settings > Email Server**.
2. Click **Configure email server**.
3. In the **Email server** window, in the **Mail server host** field, enter the mail server URL.
   For example, `smtp.gmail.com`.
4. In the **Port** field, enter the mail server port number.
5. **Optional:** If you want to secure your email communication, check **Secure mail server connection**.
6. In the **Mail server user name** field, enter the email user account name.
7. In the **Mail server password** field, enter the user account password.
8. In the **Mail server sender name** field, enter the mail server sender name.
9. In the **Mail server address** field, enter the mail server address name.
10. Click **Save**.

Note: To delete the email settings, click **Delete Settings**.

Configuring calendar settings

Use the **Calendar Settings** page to manage the appearance of calendar events.

About this task

This task requires that you are an Measure administrator.

Use the **Calendar Settings** page to add, remove, and set the presentation style such as color for events displayed in the calendar. You can define presentation order of events for days with multiple event types. Events types include the following.

- Release events and activities
- Financial blackouts, maintenance windows, release opportunities
- Holidays

The **Preview** portion of the page displays all the defined events.

1. To access the **User authentication settings** page, click the Settings icon ( ) at the top right of the user interface. Click **Calendar**.
2. To create an event, click **Add event type** for the type of event to be added.
   There is an **Add event type** for each event type. Type the name of the event and click the check mark icon.
   a. To change the presentation style and color, place the cursor over the default style created and right-mouse click. Optionally, click the edit icon ( ).
   b. Use the left and right arrow to set the priority for the event.
      The left arrow moves the event up and the right arrow moves it down.
3. To remove an event, move the cursor to the event and click the delete icon ( ).
4. To modify an event, move the cursor to the event and click the edit icon ( ).
   There are separate edit icons for changing the event name and presentation style.

Configuring security settings

The Measure security model is organization- and team-based. The organization is the base element; teams belong to organizations. Team members manage releases, events, and deployments. Administrators manage teams and assign users to them.

The team-based security model means that teams manage releases, reports, pipelines, events, and run deployments. Only team members can create or modify team-managed objects. Users can be assigned to more than one team. Users are identified by email address. The administrator manages the security system and manages teams and users.

After Measure is integrated with HCL DevOps Deploy on page 1885, Deploy teams and applications can be imported into Measure. When a team is imported, all team members are imported. Users are identified by email address. Administrators can also create users.

Roles and permissions

A number of roles are defined in the product that can be assigned to a user or group. Roles set boundaries on activities that a user or group member can perform.

Roles are assigned to users and groups within the team context. Users or groups are assigned to a team with a specific role. The role assigned to a user is only for the team that the user is a member. A user can be a member of multiple teams and have a different role on each.

The interlocking concept of teams, roles, and permissions ensures that users have the appropriate permissions to perform their work and not affect processes outside of their assigned scope. The interaction of these three concepts provides the mechanisms to create an infrastructure that is secure and flexible.

There are two types of roles, global and team. Global roles provide permissions to access all resources of the product. Team specific roles provide permissions to access team specific resources of the product. Users with team specific roles can view only the resources associated with that team.

You can customize the roles using the following procedure.

1. On the Measure dashboard, click **Settings** , and then click **Authorization > Roles**.
2. On the **Roles** page, click **Create role**.
3. In the **Name** field, enter the name for the role.
4. In the **Description** field, enter the description for the role.
5. In the **Scope** field, select the scope for the role.

   Note: The possible values for the scope of the roles are global and team.

6. In the **Permissions** field, select the required action under each resources.
7. Click **Save**.

Note: The users with **Team manager (global)** and **Product administrator** role can create roles.

You can assign members to global roles using the following procedure.

1. Click to assign members to roles.
2. In the **Members** field, enter or select the member to assign the roles.
3. Click **Save**.

You can use to edit roles and to delete roles.

The roles with label **Custom** are customized roles. The roles with label **static** are system generated roles. **Static** roles cannot be modified or deleted.

Note: Until new users are assigned to teams, they are automatically assigned to the Default team with no assigned role. Administrators grant users elevated permissions when they assign them to roles such as Lead Developer or Release Manager.

Note: When you create a custom role and provide permissions to the deployment plan and deployment template, you must also add group view permissions.

The following tables show the available roles.

Note: For each of the roles, the underlying resources and permissions are also scoped as team or global.

Role mapping limitation

In Loop, Measure uses Keycloak groups to map roles. You can refine the permissions by using the authorization features. Measure supports the following roles:

- Product administrator
- Non-admin user

These roles define the baseline access level. You can extend this baseline access by using authorization within Measure.

Role mapping matrix for Measure

Keycloak group	Loop role	Supported	Notes
User group	Product administrator	No	Users in the Keycloak user group cannot be directly assigned product administrator priviliges in Measure.
User group	Non-admin user	Yes	Standard user access is supported.
Admin group	Non-admin user	No	Admin grup users cannot be downgraded to non-admin user via Loop role mapping.
Admin group	Product administrator	Yes	Administrator access is correctly mapped from Keycloak.

Authorization behavior in Measure

You can elevate permission for users in the Keycloak non-admin user group by using the authorization feature in Measure.

When configuring these settings, note the following behavior:

- You can grant non-admin users additional access rights directly at the Measure level.
- You can manage these permissions independently of Keycloak group role mapping.
- Authorization controls what actions a user can perform within Measure, but it does not change the user's Keycloak group.
- Role mapping changes in Measure do not synchronize back to Keycloak groups.

Note:

- Keycloak mapping supports only product administrator and non-admin user roles.
- Keycloak defines baseline access, while Measure authorization extends these permissions for non-admin users.
- Role mapping does not synchronize back to Keycloak groups.

Managing users and authentications

Use **Authorization** and **Authentication** to manage users and authentication.

Users can be created, modified, or removed in Measure.

Users can be authenticated from the systems detailed in the following table:

Table 651. User authentication methods

Authentication method	UI	API
Local on page 1812	Supported	Not supported
LDAP on page 1813	Supported	Not supported
OpenID Connect (OIDC) on page 1817	Supported	Not supported
SSO on page 1817	Supported	Not supported
User access key (UAK) on page 1820	Not supported	Supported

API authentication

UAK is the recommended method through the API. An example for UAK is:

```
curl -X POST -k -H 'Content-Type: application/json' -H 'Authorization: UserAccessKey xxxxxxxxxxxxxxxxxxxx'.
```

Details for configuring UAKs are found here on page 1820.

Managing users

Use the **Users** page to create, edit, or remove users.

About this task

This task requires that you are an Measure administrator.

Users can be created, edited, or removed from **Authorization** on the **Settings** page.

To create a user, complete the following steps:

1. Click **Settings > Authorization > Users > Create user** to display the **Create user** window.
2. Complete the required fields.
3. Click **Save**.

What to do next

To modify or remove a user, click **Settings > Authorization > Users** and perform the following steps.

- To modify a user:
  - Click the overflow menu ⋮ and select **Edit** for the required user.
  - Change the required fields in the **Edit user** window.
  - Click **Save**.

- To remove a user, click the overflow menu ⋮ and select **Delete** for the required user.

  Note: Users are deleted from all teams and groups. Users' access keys are also deleted. You can use a deleted user email address to create a new user. The new user is created with default permissions. The user cannot retain previous roles and permissions after deletion.

Note: Additional user authorization topics include teams, groups, and user access keys.

Authenticating users with LDAP

Use the **User authentication settings** page to manage user authentication.

Before you begin

You must have the URL of the external LDAP server that you intend to authenticate users. This task requires that you are an Measure administrator.

About this task

An LDAP realm identifies users and groups and defines rules how to search users and groups. When unknown users attempt to log on, an external LDAP server authenticates them by using the realm parameters that you configure. To configure an LDAP authentication realm, you identify the URL of the LDAP server, and define valid searches.

To create an LDAP realm, complete the following steps:

1. From the Measure dashboard, page, click **Settings > Authentication**.
2. Click **Configure LDAP** .
3. On **LDAP** page, in the **Name** field, enter a name for the realm configuration.
   The value is an arbitrary label that does not effect the other settings.
4. In the **LDAP URL** field, enter the URL for the LDAP that you use for authentication.
   Separate multiple servers by commas.
   Example
   For example, `ldap://ldap_server.my_domain.com:389,ldap://ldap_server.my_domain2.com:389`.
5. Specify whether anonymous searches are allowed by completing one of the following options:
   Choose from:
   - If the LDAP server allows anonymous searches, select **Search Anonymously**.
   - For authenticated searches, clear the **Search Anonymously** check box, and then enter the **Bind DN** and **Bind credentials**. Velocity uses these fields to authenticate users when it connects to the LDAP server. For example, `cn=velocity,ou=applications,dc=mydomain,dc=com`.
6. **Optional:** In the **Scope when searching LDAP users** area, specify a search scope by selecting one of the following options:
   Choose from:

- **Subtree**. Select this option when user entries are direct children of the **Search base**.
- **One level**. Select this option if all user entries are direct grandchildren of the **Search base**.
- **Base**. Select this if option if user entries are two or more levels below the **Search base**.

The scope is relative to the **Search base** selected in the next step. It is a good practice to make the scope as narrow as possible.

7. In the **Search base** field, enter the user search base.
   Example
   The starting directory for the search, such as `ou=employees,dc=mydomain,dc=com`.
8. In the **Search filter** field, enter the search filter.
   Example
   The LDAP filter expression that is used when searching for user entries. The user name replaces the *{{username}}* variable in the search pattern, for example, `uid={{username}}`.
   If the value is not part of the DN pattern, enclose the value in parenthesis, for example, `(mail={{username}})`. For more information, see the help information for your LDAP server and look for information about creating user search filters.
9. **Optional:** In the **Bind property** field, enter a search expression.
   Example
   This is the name of the LDAP attribute that contains the **Bind DN** specified earlier. The default value is `dn`.
10. **Optional:** In the **Name attribute** field, enter the LDAP user name.
    This is the name of the LDAP attribute that contains the user's full name. Examples are `cn` and `displayName`.
11. In the **Email attribute** field, enter the user email address.
    This is the name of the LDAP attribute that contains the user's email address. For example, `mail`.
12. In the **Role definition** area, specify a role by completing one of the following options:

    a. Select **Role in LDAP reference their members** if you want to find group membership by searching roles, and then define the **Group search filter**.

    Note: The **Group search filter** is the LDAP filter expression that is used when you search for user entries. The user name replaces the {1} variable in the search pattern and the full user distinguished name (DN) replaces the {0} variable, for example, `(&(uniqueMember={dn})(cn=BSO*))`. The user name replaces the `{username}` variable in the search pattern and the full user distinguished name replaces the `{dn}` variable.

    a. Select **User roles are defined as an attribute on that user** if you want to find group membership by using this attribute, and then define the **Group DN Attribute** and **User Group Attribute** fields.
    The **Group DN Attribute** is the name of the LDAP attribute on group entries, whose value is the group's distinguished name. For example, `dn`. The **User Group Attribute** is the name of the LDAP attribute on user entries, whose value is the distinguished name of a group of which the user is a member. For example, `memberOf`.

13. In the **Group search base** field, enter the directory that is used for group searches.
    Example
    For example, `ou=employees,dc=mydomain,dc=com`.

14. In the **Group name attribute** field, enter the name of the entry that contains the users' group names in the directory entries that are returned by the group search.
    If this entry is not specified, no group search runs, for example, `cn`.
15. On the **Search group subtree** box, subtrees (if any) are searched. If the item is not selected, the search is limited to the **Group search base**.
16. Click **Save**.
17. Click **Import users** to verify the **LDAP** configuration settings. For the valid **LDAP** configurations, user import status is successful. For the invalid **LDAP** configurations, user import fails with the error message.

Results

The first time an unknown user attempts to log on, LDAP authorization realms are searched in an attempt to identify the user. If the user is found, a corresponding user ID is created in Measure. In addition, if the user is part of an LDAP group, that group is imported too.

When new users log on to the server and use their LDAP credentials, they are listed on the `Users` page. In most cases, do not manage user passwords or remove users from the list. If an active user is removed, they are still able to log on to the server while their LDAP credentials are valid.

Copying DevOps Deploy authentication and authorization realms into Measure

Transfer authentication and authorization realm settings from DevOps Deploy to Measure.

Before you begin
You must have both the authentication and authorization realms created in Deploy before you can copy them into Measure. This task requires that you are an Deploy and Measure administrator.

1. From the Deploy home page, click **Settings > Authentication (Users)**, and then click the required authentication realm.
2. Click the arrow to the left of **Edit** to display the authentication realm fields to be copied into the Measure fields.
3. From the Measure home page, click **Settings > User Authentication**.
4. Copy information from the DevOps Deploy authentication realm fields to the Measure fields, as described in the following table.

Table 652. Copying authentication realm fields

Deploy authentication realm field	Measure field
Name	**Name**
Description	**Description**
LDAP URL	**LDAP URL**
Search Anonymously	**Search Anonymously** Note: Match selection to Deploy field.
Search Connection DN	**Bind DN**

Deploy authentication realm field	Measure field
Search Connection Password	**Bind credentials**
User Search Base	**Search base**
User Search Filter	**Search filter** Note: Do not copy the **User Search Filter** field. In the **Search filter** field, enter `mail={{username}}`.
Name Attribute	**Name Attribute**
Email Attribute	**Email Attribute**

5. Match the **Search User Subtree** selection with the **Scope when searching LDAP users** selection.
   If **Search User Subtree** and **Subtree** are not selected, follow these guidelines for making a selection in the **Scope when searching LDAP users** field:

Options
One level indicates that only the immediate children of the entry that is specified as the search base are considered. The base entry itself is not considered, nor any descendants of the immediate children of the base entry.
Base indicates that only the entry that is specified as the search base is considered. None of its subordinates are considered.

6. From the Deploy home page, click **Settings > Authorization (Groups)**, and then click the required authorization realm.
7. Click **Edit** for the required authorization realm to display the fields to be copied into the Measure fields.
   For the following steps, you will be copying information from the Deploy authorization realm fields displayed in the **Create Authorization Realm** fields to the Measure fields.
8. Copy information from the Deploy authorization realm fields to the Velocity fields, as described in the following table.

Table 653. Copying authorization realm fields

Deploy authorization realm field	Measure field
Group Search Base	**Group Search Base**
Group Search Filter	**Group Search Filter** Note: Do not copy the **Group Search Filter** field, enter `member={{dn}}`
Group Name	**Group Name Attribute**
Search Group Subtree	**Search Group Subtree** Note: Match selection to Deploy field.
User Group Attribute	**User Group Attribute**

9. Click **Save** on the **User authentication** page in Measure.
10. Click **Import users** to verify the **LDAP** configuration settings. For the valid **LDAP** configurations, user import status is successful. For the invalid **LDAP** configurations, user import fails with the error message.

Authenticating users with OpenID Connect (OIDC)

Use the **Authentication** page to manage user authentication with **OpenID Connect**.

Before you begin

To configure the **OIDC** authentication, you must have Measure administrator permission and privileges.

About this task

OpenID Connect is an authentication method which you can use to authenticate users.

To configure an **OIDC** authentication, complete the following steps:

1. From the Measure page, click **Settings > Authentication > OIDC**.
2. Click **Configure OIDC** .
3. On **OIDC** page, in the **Name** field, enter a name for the **OIDC** configuration.
4. In the **Description** field, enter a description for the **OIDC** configuration.
5. In the **OIDC Issuer** field, enter the issuer for **OIDC** authentication.
6. In the **Authorization URL** field, enter the URL of **OIDC** authorization provider .
7. In the **Token URL** field, enter the URL for token request with **OIDC** provider.
8. In the **User info URL** field, enter the URL for user information request with the **OIDC** provider.
9. In the **Client ID** field, enter the client ID that is registered with the **OIDC** provider.
10. In the **Client Secret** field, enter the client secret that the **OIDC** provider issues upon registration.
11. Click **Save**.
    Result

    You have successfully configured **OIDC** authentication. You can log in to Measure using **OIDC** configuration.
12. On the Measure login page, click **Login with OIDC** to log in using OIDC configuration.
    The **Authorization URL** page opens to validate the user for accessing the Measure
13. On the **Authorization URL** page, enter the username in **Username** field and password in **Password** field.
    You have successfully logged in to the Measure.
14. On the **Settings > Authentication > OIDC** configuration page, click **Delete configuration** to delete the **OIDC** configuration.

Results

You have successfully configured the **OIDC** authentication. You can log in to Measure using the **OIDC** authentication.

Creating a header-based SSO authentication integration

A header-based single sign-on (SSO) authentication realm uses an external server for authentication.

1. On the Measure dashboard, click **Settings > User authentication > SSO > Configure SSO**.
2. In the required fields, specify the following parameters:

Table 654. SSO properties

Field	Description
Name	The name for the integration.
Full name header name	The user name on the SSO server that contains the list of users.
Email header name	The user email on the SSO server that contains the list of users. Note: For **Email header name**, there is a change to lower case in the Measure database.
Logout URL	The SSO server's logout URL.

Note: Measure supports header-based SSO and can integrate with other SSO mechanisms, such as Security assertion markup language (SAML). It is the responsibility of the user to modify the SSO scheme in use to transmit the headers to authenticate with Velocity Measure and then block the login page. The aforementioned method is different for every SSO product and mechanism.

3. Click **Save**.
   Result
   Setting up an SSO user does not automatically add the user on page 1812 to the Measure database and is explained in further detail below.

Results

When users log on to an SSO-configured Measure instance, their **Email header name** SSO credential is compared to the SSO server's user list. If the email address matches an existing user in the Measure database, a user will automatically be created in the database and listed as **SSO** in the **User Type** field.

Note: Once the SSO setup is completed properly by the admin user and that user logs out of Velocity, there is a loss of admin access privileges because of the inability to log back in as the admin. New users created via the SSO login only have the Viewer and Release participant permissions by default and the admin cannot change the permissions as stated previously. Possible solutions for this scenario include the following:

1. Set the Measure server to allow direct access from specific IPs that will allow the admin to login.
2. Create an SSO user with the Measure admin email address of `admin@admin.com`.
3. Perform an SSO login with a different browser while the local Measure admin navigates to **Settings > User authentication > Teams** and grants full admin privileges to the SSO user.

As a guideline, Item 3 is the recommended method for preserving admin access privileges to Measure.

To delete a current SSO configuration after it was created, click the **Delete Configuration** button on the **Settings** page for **SSO**.

Managing user groups

You can combine users into groups. When you grant permissions to the group, you simultaneously grant them to the group members. When you assign a group to a team, all group members are simultaneously assigned to the team.

About this task

Note: Groups cannot be imported from DevOps Deploy.

To create a group, complete the following steps:

1. On the Measure dashboard, click **Settings** , and then click **User authorization > Groups**.
2. On the Groups page, click **Create Group** and in the Add New Group window, enter a name for the group, and then click **Save**.
3. With the group selected, click **Add user**.
4. In the **User** list, select a user, and then click **Save**. The user is added to the **Members** list. You can add a user by typing the user's email address. The email address is used as the user name.

What to do next

If you configure an LDAP server, groups can be imported when new users log on for the first time.

Password management

Password management details how you can change the administrator password and retrieve the RabbitMQ password from Kubernetes on page 1820 and OpenShift on page 1820.

Changing the Administrator password

Use the **Users** page to change the administrator's password.

About this task

The admin user is the Measure super user. You set the initial admin password during installation. To change the admin password, complete the following steps.

Note: This task requires that you are an administrator.

1. Click **Settings > User authorization > Users** to access the **User authentication settings** page.
2. Click the **Change password** action for the admin user, and then enter your own password.

3. Enter the new password.
4. Click **Save**.

Retrieving the RabbitMQ™ password in Kubernetes™

Accessing the RabbitMQ password from Kubernetes.

1. From a command line window, run the following command to retrieve the data contained in the secret.

   ```
   kubectl get secret velocity-rabbitmq -o yaml
   ```

2. On the `password` line, copy the password.
   The password is Base64 encrypted.
   Result
   The screen capture for copying the password is shown in the following illustration.
3. Use a Base64 decoder to decode the password.

   a. For a Linux shell, run the following command to decode the password:
      Paste the password in the command line.
      Example

      ```
      echo -n '<password>' | base64 --decode
      ```

   b. The decoded password is displayed in the shell.

Retrieving the RabbitMQ™ password in OpenShift™

Accessing the RabbitMQ password from OpenShift.

About this task

To retrieve the RabbitMQ password in the OpenShift Container Platform application, use the following procedure.

1. Navigate to the OpenShift Web Console UI.
2. Navigate to the list of secrets (**Resources > Secrets**).
3. Navigate to the **velocity-rabbitmq**.
4. Click on **Reveal Secret** to display the value in the **password** field.

Managing User access keys (UAKs)

Create a key that you can use to authenticate API calls.

About this task

Until new users are assigned to teams, they are automatically assigned to the Default team in the Viewer and Participant roles. Users in these roles can view objects, such as releases and value streams, but they cannot create or edit them. Additionally, users in these roles can auto-generate user access tokens and access API endpoints with GET requests. Administrators grant users elevated permissions when they assign them to roles such as Lead Developer or Release Manager.

1. On the Settings page, click **My Profile**.
2. Click the **Create user access key** button.
3. In the **Name** field, enter the name for the user access key.
4. Click the **Create** button.
5. In the **User access key created** window, click to copy the **Access key** to the clipboard.
6. Save the key to a secure location.

   Note: It's important to save the key because it will not be accessible after you close the **Access key created** window.

7. Click **x** to close the **User access key created** window.

What to do next

You can use the key whenever you use plugins or external clients to integrate tools into Measure.

Integrations support the capability to auto-generate the required user access keys that is implemented on a plugin by plugin basis.

Note: Plugins are not updated at the same time and you can refer to the plugin documentation page for the latest updates. The update status of existing integrations only change when you edit the integration.

The auto-generated user access key process is detailed in the following:

1. On the Measure **Home** page, click **> Integrations > Plugins**.
2. Click the **Add integration** button for the required plugin integration to display the **Add Integration** modal window.
3. The **User Access Key** field is displayed if the plugin is not updated.

   Note: The **User Access Key** field is not displayed if the plugin is updated.

4. Fill in the required fields for the plugin.
5. Click the **Show Hidden Properties** check box to display the auto-generated properties for the integration.

   Note: In the Measure **User Access Key** field, you can enter a user access key if you have one, but it is not required.

6. Click the **Add** button.

7. Click **User Authorization > User Access Keys** to locate the plugin in the **Name** field with the format of **Integration Name** - AutoGen.

   Note: Any existing plugin integrations that are edited and saved automatically auto-generate user access keys in the aforementioned manner.

You can review the issued user access keys on the **User access key management** page, **Settings > User authorization > User access keys**. If you have administrator permissions, you can delete user access keys from that page.

Configuring log level settings

Control the amount of detail sent to log files.

About this task

Log files contain information about the data that your plugin integrations use or create. You can control the amount of information kept in the log files by setting the logging levels. You set the logging level separately for each integration.

The following list contains the logging levels:

- `ALL`
- `TRACE`
- `DEBUG`
- `INFO`
- `WARN`
- `ERROR`
- `FATAL`
- `OFF`

Each level contains less information than the level that precedes it in the list. To keep the most verbose information, select `ALL`. The default logging level is `INFO`.

1. On the **Settings** page, click **Integrations**, and then select the **Edit** action for the integration that you want to change.

   Note: You can also set the logging level when you create an integration.

2. On the **Add Integration** page, select the logging level from the **Logging Level** list.
3. Click **Update**.

What to do next

To see a log file, use the **View log** action associated with the integration.

If you want to troubleshoot an integration, setting the logging level to `DEBUG` is a good place to start.

Configuration of data retention policy

Data retention policies in Measure help you manage the lifecycle of data objects by archiving or deleting resources based on scope, retention rules, and execution schedules.

Data Retention is an administrative governance feature available only for Velocity 5.2.5 or later, which allows you manage the lifecycle of data objects over time automatically. By establishing automated retention policies, Product Administrators can systematically archive or permanently delete versions and their linked resources, such as builds, inventory, and deployments that are no longer required for active operations.

You can create a data retention policy by providing the details, such as **Name**, **Description**, **Retention days**, and **Resource type**. You can also select the following policy **Mode**, which defines the action applied to the resource:

- Archive mode: This mode provides a temporary cleanup step. When resource types, such as versions, reach their archival time threshold, the system moves them out of your daily workspace. The data is removed from the active user interface so it stops cluttering your daily view. The data is still available in the backend and the administrator can still retrieve this data whenever required. The archived data continue to appear in reports such as Pipeline Snapshot, Deployment Audit, and Release Readiness reports.
- Delete mode: In this mode, the system removes the resource data permanently from the system's hard drives and databases. Because Measure maintains data integrity, deleting an object (such as a software version) will also cascade to delete all of its tightly coupled background data (such as its specific builds and deployment history). The deleted resources do not appear in reports such as Pipeline Snapshot, Deployment Audit, and Release Readiness reports.

Both archive and delete operations are soft and hard lifecycle controls, respectively, from a UI perspective, but neither operation preserves full recoverability through bulk restore. Bulk restore is not supported. However, archived resources can be restored manually.

If a resource is shared across multiple teams or applications, the system does not delete or archive the resource until all associated teams and applications are included in the selected scope. This process ensures that shared resources are not removed prematurely.

You can define the policy scope using the **Scope** field. The available scopes are as follows:

- Global: The policy is applied to all the resources across all users.
- Team: The policy is applied to only selected teams. You can select multiple teams for a single policy.
- Application: The policy is applied to only selected applications. You can select multiple applications for a single policy.

You can manage data retention policies from the **Settings > Policies > Data retention policy** page. Available actions include edit, delete, execute, and view logs. You can view the execution details by using **Audit Logs** to track policy runs and results.

You must take a database backup before creating the policies, because the reports, value stream, and insights metrics will be impacted. The linked resources of the Versions are as follows:

- Builds
- Deployments
- Inventory

Adding data retention policy

You can add a data retention policy to archive or delete resources in Measure based on defined scope and retention rules.

Before you begin

You must have the product administrator role. For more information about the roles, see Roles and permissions on page 1801.

1. On the Home page, click the **Settings** icon.
2. On the **Settings** page, select **Policies > Data retention policy**.
3. Click **Add policy**.
4. Enter the following details in the given fields:
    - Name: Add the name of the data retention policy.
    - Description: Add the description about the policy.
    - Retention days: Add the number of days for data retention.
5. Select **Mode** from the drop-down list:
    - Archive: The resource data is removed from the active user interface, so it stops cluttering your daily view.
    - Delete: The resource data is removed from the system.
6. Select **Resource** type, Version, from the drop-down list.

    Note: Currently, only the **Version** resource type is supported.

7. Select **Scope** from the drop-down list:
    - Global: This policy scope is applied to all resources across all users.
    - Team: This policy scope is applied to only selected teams.
    - Application: This policy scope is applied to only selected applications.
8. Click **Create policy**.

    The data retention policy is created as is in a disabled state, which is the default state. To enable the policy, follow the steps:

    a. Select the toggle button under the **Disable / Enable** field.
    b. Review the impacted policy records preview.
    c. Enter the policy name again to confirm enable, and then click **Confirm**.

    The policy is enabled and completed. The policy is scheduled to run every 24-hour interval.

Results

You have added the data retention policy.

What to do next

Click the icon to expand and view the following details about the data retention policy:

- Policy ID
- Resource
- Scope
- Mode
- Last execution detail
- Executed by
- Affected count
- Cutoff time

Managing data retention policy

You can edit, delete, run, and view policies from the policy page.

Before you begin

You must have the product administrator role with at least one data retention policy.

1. On the Home page, click the **Settings** icon.
2. On the **Settings** page, select **Policies > Data retention policy**.
   A list of available data retention policies is displayed.
3. Click the icon adjacent to your data retention policy to select any of the following options:

Options	Description
Edit	Update Name, Description, Retention days, Mode, Scope, or Resource, and click **Save policy**.
Delete	Click **Confirm** to delete the policy. **Note:** The deleted policy cannot be recovered.
Execute	Review the impacted policy records preview. Enter the policy name again to confirm execution and click **Confirm**. A product administrator can use this option to run the policy manually.
View logs	You can review the execution log and details of the data retention policy. Click **Download log file** to download the file.

Viewing the execution history of the data retention policy

You can view the execution history of data retention policies from the Audit Logs page.

Before you begin

You must have the Global viewer role. For more information about the roles, see Roles and permissions on page 1801.

1. On the Home page, click **Settings > Audit Logs**.
2. Filter or search for the policy that is executed as Data Retention category.
3. Review execution status and details.

Results

The system displays the execution details as follows:

- Name: Name of the policy
- Category: Category as DATA_RETENTION
- Operation: Mode of the policy, Archive or Delete
- Resource: Resource type is Version
- Scope: Scope of the policy, Global, Team, or Application
- Records affected: Number of records affected by this data retention policy
- Status: Status of the policy as completed or failed
- Triggered by: Who executed the policy
- Completed at: Timestamp of the data retention policy execution

Measure MCP Server - Tech Preview

A Model Context Protocol (MCP) server provides a structured way for GenAI clients to access tools, data, and actions through a consistent, secure interface. When you connect a GenAI client that supports MCP to the Measure MCP server, you can use natural-language requests to retrieve information from your Measure.

Disclaimer:

This release contains access to the MCP server feature in Velocity Measure as a Tech Preview and can be enabled by passing the `betaFeature=mcp` parameter while running the installer. The Tech Preview is intended for you to view the capabilities of MCP server offered by Velocity, and to provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL® provides the information without obligation of support and "as is" without warranty of any kind.

The Velocity Measure MCP server exposes predefined queries that let you view Value Stream Management data, metrics, build and deployment details, workflow gate statuses, and information about teams, applications, and workspaces. This capability provides a simple, conversational way to obtain operational insights without requiring navigation of the Measure interface or creation of API requests.

The Measure MCP server offers the following tools:

- applicationById
- builds
- deployments
- latestWorkflowGateChecks
- metrics
- teamsForCurrentUser
- teamspacesForTenant
- workflow
- workflowsForTenant
- workflowStatsByIdQuery

To use the Measure MCP server, you must enable the MCP server feature flag when you run the installer. See Prerequisites to connect with the MCP server in Measure on page 1827.

You can currently connect to the Measure MCP server using the following GenAI clients:

- Claude Desktop. See Connecting to the DevOps Velocity MCP server in Claude Desktop on page 1828
- GitHub Copilot in Visual Studio Code. See Connecting to the Measure MCP server by using GitHub Copilot in Visual Studio Code on page 1829.

The MCP deployment is enabled, and the MCP pod is running in the default configuration. To reduce resource consumption, you must disable the MCP deployment when the MCP server is not in use. See Disabling the MCP Deployment in DevOps Velocity.

Prerequisites to connect with the MCP server in Measure

You can find information about the requirements and setup steps needed before connecting to the MCP server in Measure.

Before connecting to the MCP server, you must complete the following prerequisites:

1. Install **Keycloak 26.5.6**.
2. Download and run the script to create the necessary clients for the Velocity application and MCP server.

   Note: Download the compressed file from here: keycloak-setup script. Refer to the `README.md` file included in the bundle for instructions to run the script.

3. Install or upgrade the Velocity instance by providing the Keycloak URL, client secret, and JWKS URL for MCP.

   Here is a sample command to install or upgrade Velocity with the MCP configuration:

```
helm upgrade --install velocity -n <custom_namespace_name> \
                ./accelerate-<version>-helm.tgz \
                --set license=accept \
                --set url.domain= <domain_name or I.P address>\
                --set access.key=<access_key>\
                --set mongo.url=<mongodb url>\
                --set secret.tls=<tls_secrete_name>\
```

```
                --set rabbitmq.nodePort=31672 \
                --set loglevel=ALL \
                --set externalKeycloak.url=https://<keycloak_hostname>/realms/devops-velocity \
                --set
 externalKeycloak.jwksUrl=https://
<keycloak_hostname>/realms/devops-velocity/protocol/openid-connect/certs \
                --set mcp.secretValue="<mcp-velocity-client-secret>"
```

Note: `--set jwksUrl=externalKeycloak.jwksUrl=https://<keycloak_hostname>/realms/devops-velocity/protocol/openid-connect/certs` is required only for Velocity 5.2.4 and earlier versions.

Before running the Helm command, you must replace the following placeholder values with your actual configuration:

- **<keycloak_hostname>**: Replace with your Keycloak server hostname or IP address.
- **<mcp-velocity-client-secret>**: Replace with the secret value configured for the **mcp:velocity** client in Keycloak.

These parameters ensure that Velocity can authenticate users via Keycloak and connect to the MCP server securely.

For more information about installation and upgrading, refer to the following related topics:

- Installing on Kubernetes
- Installing on OpenShift
- Installing on Google Kubernetes Engine
- Upgrading Kubernetes-based installations
- Upgrading an OpenShift installation using Helm charts

Connecting to the DevOps Velocity MCP server in Claude Desktop

You can connect to the Measure Model Context Protocol (MCP) server by using the Claude Desktop application to interact with Velocity and retrieve the necessary data and insights.

Before you begin

You must have completed the following tasks:

- Installed Velocity and configured Key cloak. See Prerequisites to connect with the MCP server in Measure on page 1827.
- Configured OIDC authentication in Velocity. See Authenticating users with OpenID Connect (OIDC) on page 1817
- Obtained the MCP Server URL. For example: `https://<velocity_hostname>/mcp`
- Ensured that Claude Desktop is installed.

1. Open the **Claude Desktop** application.
2. Navigate to **Settings > Connectors**.
3. Click **Add custom connector**.
   The **Add custom connector** window is displayed.
4. Enter the name of the connector. For example: Velocity MCP server
5. Enter the Velocity MCP server URL in the **Remote MCP server URL** field.

6. Click **Add**.
   The MCP server is now added and listed on the **Connectors** page.
7. Click the **Connect** button next to the newly added Velocity MCP server entry.

   Claude Desktop redirects you to the **DevOps Loop** login page.
8. Sign in using the Velocity OIDC user credentials.

   A consent screen is displayed requesting access to MCP tools, Velocity APIs that are used internally for tool execution, and basic profile and role information.
9. Click **Yes** to approve and complete the connection.

   After successful authentication, Claude Desktop displays the list of available MCP tools provided by the Velocity MCP Server.

   Note: The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session expires and you are required to re-authenticate.

Results

You have successfully connected to the Velocity MCP server by using Claude Desktop.

What to do next

You can run prompts related to Velocity to confirm a successful connection.

Connecting to the Measure MCP server by using GitHub Copilot in Visual Studio Code

You can connect to the Measure Model Context Protocol (MCP) server by using GitHub Copilot in Visual Studio (VS) Code to interact with Measure and retrieve the necessary data and insights.

Before you begin

You must have completed the following tasks:

- Installed Measure and configured Key cloak. See Prerequisites to connect with the MCP server in Measure on page 1827.
- Configured OIDC authentication in Measure. See Authenticating users with OpenID Connect (OIDC) on page 1817
- Obtained the MCP Server URL. For example: `https://<velocity_hostname>/mcp`
- Ensured that you have installed VS Code and the GitHub Copilot extension.

1. **Optional:** Open the terminal and enter the following command to allow the self-signed certificates if you are using a self-signed certificate during the Measure installation.

   ```
   export NODE_TLS_REJECT_UNAUTHORIZED=0
   ```
2. Enter the following command to open VS Code.

   ```
   code .
   ```

3. Open the **Command Palette** by pressing the keys Ctrl+Shift+P or Cmd+Shift+P.
4. Search and select **MCP: Add Server**.
5. Choose **HTTP** as the server type, when prompted for the transport type.
   The Velocity MCP Server uses HTTP-based transport.
6. Enter the **MCP Server URL** in the **URL** field.
   VS Code automatically generates the required `mcp.json` configuration.
7. Enter a name for the server. For example: Velocity MCP Server.
8. Select **Workspace**, when VS Code prompts you to choose where to save this configuration.
   - **Global** – used for all VS Code workspaces
   - **Workspace** – used only in the current folder/project

     Note: When **Workspace** is selected, a `.vscode` folder is automatically created, and an `mcp.json` file is generated within it.

     A sample `mcp.json` file is as shown below:

     ```
     {
      "servers": {
       "velocity-mcp-server": {
        "url": "<velocity_mcp_server_url>",
        "type": "http"
       }
      },
      "inputs": []
     }
     ```

Property	Description
<velocity_mcp_server_url>	Specifies the full Velocity MCP server URL. For example: `https://<velocity_hostname>/mcp`

   Result

   The `mcp.json` file is opened.
9. Click **Start** for the added MCP server.
   Result
   A prompt appears to authenticate via OAuth.
10. Click **Allow**.
    Result
    The following prompt is displayed:

    ```
    Do you want code to open the external website?
    ```

11. Click **Open**.

Result

The OIDC login page is displayed.

12. Sign in using the Measure OIDC user credentials.

    Result

    A consent screen is displayed requesting access to MCP tools, Measure APIs (used internally for tool execution), and basic profile and role information.

13. Click **Yes**.

    You are automatically redirected to VS Code or you can also close the browser and switch to VS Code.

14. Verify the connection.

    The Measure MCP Server must display **Running** as the status.

> **Note:** The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session expires and you are required to re-authenticate.

Results

You have successfully connected to the Measure MCP server by using GitHub Copilot in VS Code.

What to do next

You can run prompts related to Measure to confirm a successful connection.

Releasing Software

A release is a repeatable plan that is used to drive deployments.

Releases are the organizing focus of software deliveries. Releases can represent any software-development-related event, from major milestones in the life of the company to comparatively minor events, like recurring maintenance. You can schedule a release at any point in your development-operations lifecycle. You can automate release schedules or manually run deployments.

A release contains deployment plans and events that are related in some business-meaningful way. For example, the deployment plans might represent the phases in a software development lifecycle, such as development, QA, and production. An event might represent a blackout that affects the release.

Every value stream has a corresponding pipeline generated for it, and every pipeline has deployment plan templates. The tight relationship between pipelines and deployments makes it easy to use pipelines to drive deployments. You can start by creating a release and adding deployment plans and events to it. Or you can start with value streams and pipelines and then join them to a release. You can run deployments directly from a pipeline or from a deployment plan.

You can coordinate several releases into a single event, which ensures that all release stakeholders can participate. If you add events to a release, you can use the calendar to organize releases and deployment plans.

Managing a release

Use the release details page to view details about a specific release.

This page contains the calendar and list of tasks. When viewing tasks you can select to view only your tasks or all tasks.

You can also use this page to access and work with release templates.

Use this page to view and work with archived releases removed from the calendar and list of tasks.

When you access a release from the **Releases** page, you can create a deployment plan and display overview details about the release, such as the deployment plans associated with the release with related details. From the **Overview** section of the **Releases** page, you can view the following release details for specific releases:

- **Plans** displays the plans associated with the release and task status, team, and date that the task is scheduled. You can access additional details for specific plans.
- **Task progress** displays the associated tasks that are not completed and contains information such as type of task, task owner, start and end time, duration, and task dependencies.
- **Approvals** list the approvals with the status of the approval and approver.
- **Change requests** displays a list of ServiceNow™ change requests.

The **Properties** section displays properties defined in the plan and property value.

Managing releases

Release management is the process of planning, scheduling, and controlling software deliveries.

About this task

The **Releases** page displays information about releases. This page provides access to the calendar, tasks, events, release activities, and related details.

The page contains the calendar or list of tasks. Click **Calendar** to view the calendar. To hide the calender and task bar, click . To view tasks, click **Tasks**. When viewing tasks, you can select to view only your tasks or all tasks. To view events, click **Events**. To create an event, click .

Release activities are displayed in a tile or list () format. Using the search bar on the top of the page, you can limit the amount of information displayed by typing a filter to narrow the search results. Additionally, click the filter ( ) to limit the list of displayed release activities to: **Complete**, **In progress**, or **Scheduled**. Click an item in the **Release activities** list to view specific release details.

Click the tag ( ) to toggle on or off the display of tags associated with the release activity.

To create a new release, click **Create release**.

To import the releases and events, click **Import Release**.

You can also use this page to access and work with release templates by clicking **Templates** on the page.

Click **Archived** to view and work with releases removed from the **Releases** page and the calendar.

You can view release details, such as deployment plans associated with the release, by clicking **Overview**. This page will display headings that include: **Plans**, **Task progress**, **Approvals**, and **Change requests**.

- Plans associated with the release an be viewed by clicking **Plans**. The number above the **Plans** heading is the total number deployment plans related to this release.
- Tasks details can be viewed by clicking **Task progress**. The number above the **Task progress** heading displays the number of associated tasks not completed and total number of tasks. Click the task for additional task information.
- Click **Approvals** to display approvals details. The number above the **Approvals** heading is the total number of approvals. Click the approval name for details about a specific approval.
- Click **Change requests** to display a list of ServiceNow™ change requests. The number above the Change requests heading is the total number of ServiceNow™ change requests.

Click **Properties** to display a properties defined in the plan and property value. You can add or change the property value by double-clicking the **VALUE** property field. Click the check mark to save the value.

To create a new deployment plan, click **Create deployment plan**.

Creating releases

1. On the **Releases** page, click **Create release**
2. In the **Create release** window, type a name for the release in the **Name** field.
   This field can be referenced with the `${sys:release.name}` system property. A name is required.
3. In the **Tags** list, select one or more events or tags. You can also create a tag by typing the name of the new tag in the field.
   If you want the event to appear on the calendar, select an event that is created on the **Configure Calendar** page. Tags that you create with the **Create release** window are not displayed on the calendar, which can prevent calendar clutter.
4. In the **Description** field, type a description of the release. This field can be referenced with the `${sys:release.description}` system property.
5. In the **Deployment plan templates** field, select one or more templates to add to the release.
   Each template that you select, adds a deployment plan to the release with the name **Copy of *template_name***. You can convert any deployment plan into a template. If the selected templates have user-defined properties, you are prompted to provide values for them when you save the release.
6. In the **Start Time** field, select a starting date and time. This field can be referenced with the `${sys:release.start}` system property. Starting times are required for all releases.
7. In the **End Time** field, select the ending date and time. This field can be referenced with the `${sys:release.end}` system property.
8. In the **Team** list, select a team to manage the release. You can add deployment plans from other teams to the release event, not just the team that manages the release. All the teams that you belong to are available. A team is required.
9. If the selected templates have properties, click **Next**, and then provide values for the properties. Otherwise, click **Save** and view details to save the release and open the **Releases** details page. If you added templates to the release, a

deployment plan for each template is created and displayed. If you didn't select any templates, an empty deployment plan is added to the release with the name **Plan: *release_name***.

To display the release in the **Activities** list, ensure that the date range includes dates within the release's start or end times.

What to do next

After the release is created, you can add deployment plans, events, and tags to it.

Archiving releases

You can archive a release to remove it from the list of releases.

About this task

Although you cannot delete a release, you can store it in the archives. Archived releases are not displayed on the **Releases** page.

To archive a release, click the overflow ( ) and then select **Archive**.

Repeat this action for each release to be archived.

You can view archived releases and restore them by clicking **Archived** on the **Releases** page.

Events and tags

An event represents a release-related activity that you manage with the calendar. A tag is a label that you can add to a release or an event. You can use tags to filter the `Activities` list on the **Releases** page. Tags do not appear on the calendar.

Events are organized into general categories that include releases, holidays, and maintenance windows. You can add events to releases or use them independent of releases. When an event is assigned, it is represented on the calendar by an icon appropriate for the event category. You can use the icons to filter the **Releases** page and select releases for any affected date or range of dates.

Tags are assigned to releases and can be used to filter the **Releases** page. Assigned tags appear in Releases page but they do not appear on the calendar. You can use tags to avoid calendar clutter.

Restoring archived releases, plans, and templates

You can restore archived releases, deployment plans, and templates.

About this task

A restored release retains all of its original deployment plans.

1. On the **Releases** page, click **Archived**.
   The **Archive** page lists all archived items. The **TYPE** column displays whether the item is a release, plan, or template.

2. Locate the item to be archived.
   Using the search bar, you can limit the amount of information displayed by typing a filter to narrow the archive search results. Filters can contain keywords, teams, tags, or name. You can also click on some of the table headers to sort the table in ascending or descending order based on the heading selected. For example, clicking **ARCHIVED DATE**, list the items from earliest archive date to current. Click the tag ( ) to toggle on or off the displaying of tags associated with the release activity.
3. If an item needs to be restored, click the overflow ( ) and then select **Restore**.
   Repeat this step for each release to be restored.
4. Click **Releases** to return to the **Releases** page.

Results

- Restored releases are displayed in the list of releases.
- Restored releases retains all of its original deployment plans.
- Restored deployment plans have a status of **draft**.

Deployment plans

A deployment plan is a container for tasks. Tasks define the activities that your team runs to complete a software deployment.

You create a deployment plan by assigning a team to manage it and then adding tasks to the plan. Team members add tasks to the plan and run the tasks during deployments. The managing team also determines which HCL DevOps Deploy (Deploy) applications are available. After an integration is configured, all applications that are managed by the team in Deploy are available.

When you use the Pipeline feature, releases and deployment plans are automatically generated as you add stages and applications to the pipeline. You can start deployments directly from the pipeline, or open the deployment plan and start the deployment by running an eligible task.

The tasks define the activities that the team performs to complete a deployment. You can create new tasks, copy tasks from other deployment plans or import tasks from CSV files. When you are satisfied with the plan, you can schedule a deployment. You can also run a deployment at any time by starting one of the plan's tasks.

Tasks are displayed on individual rows in deployment plans. Each row contains information that identifies the task and provides its status. Each row also contains action icons that are used during deployments, such as **Start** task or **Skip**.

You can run the tasks sequentially or parallely beginning with the first task, or topmost task, in the plan. After the first task finishes, the second task is eligible to run, and so forth. The order in which tasks are eligible to run is called the execution order.

The execution order can be modified by combining tasks into groups. When you create a group on page 1849, you set the group's execution pattern, which can be sequential or parallel. If a group has a sequential execution pattern, its tasks run sequentially starting with the first task. If a group has a parallel execution pattern, tasks in the group can be started in any

order and they can run simultaneously. If a plan consists entirely of parallel tasks, you can start any task regardless of its position in the list.

Task eligibility can also be effected by task dependencies. If a task has any prerequisites on page 1848, it cannot start, even if it is otherwise eligible, until all prerequisite tasks are resolved.

Some tasks start automatically as soon as they are eligible to run, while other tasks are started manually. Whether a task starts automatically or not depends on its type. Manual tasks, as the name implies, are started manually. Deploy and Delayed-type tasks automatically start as soon as they are eligible.

Eligible tasks display a **Start Task** button. To start a deployment, you start one of a plan's eligible tasks. Scheduled deployments start automatically at the scheduled time if an eligible task is of a type that can start automatically, such as Deploy.

Managing deployment plans

You can change existing deployment plans and view current status from the **Deployment Plan** details page.

About this task

The **Deployment Plan** details page displays a list of tasks, properties, versions, and the change history associated with the plan.

- Click **Tasks** to work with the tasks in the plan. You can add tasks, schedule tasks, skip a task, and reopen a completed task.
- Click the **Properties** to view properties and their value.
- Click the **Versions** to view versions.
- Click the **Change history** to view a list of the changes, revision number, user who made the revision, and date. You can also restore a plan to a specific version by clicking restore ( ).

From this page you can modify and archive the plan, change the name of the plan, make a copy of the plan, and create a template from the plan. Access these features from the overflow menu ( ) at the top right corner of the page.

- Click **Import tasks** to incorporate tasks into the deployment plan from various file sources including spreadsheets, project management tools, or IBM® DevOps Release.
- Click **Estimate task times** for approximating task durations.
- Click **Edit** to modify the deployment plan. With this option, you can add events and tags to the release event.
- Click **Copy** to copy a deployment plan. A copy of the selected plan is added to the release.
- Click **Copy as template** to create a template based on this plan.
- Click **Archive plan** to remove the deployment plan from the release. Removed plans are not permanently deleted and can be added to another release.

Creating deployment plans

You can start with a blank plan that has no defined tasks, copy an existing plan, or start with a plan template. You can also auto-create them by assigning applications to pipelines. When you copy a plan or use a template, many tasks are already defined.

About this task

Complete the following steps to create a deployment plan:

1. On the **Releases** details page, click **Create Deployment Plan**.
2. On the Create Deployment Plan window, in the **Deployment plan template** list, specify the template that you want to base the plan on. The default value is **None**.
3. In the **Plan name** field, enter the plan name.
4. In the **Description** field, enter the description.
5. In the **Team** list, select a team to manage the plan. All teams that you are a member of are available. Team members can modify the plan and manage tasks. The HCL DevOps Deploy applications that are managed by the team in Deploy are available to assign to Deploy type tasks.
6. To schedule a deployment for the plan, click **Start time**, and then select a date and time for the deployment. Scheduled deployments automatically start at the scheduled time if the plan contains eligible auto tasks. You can schedule a deployment for any future time.
7. In the **Tags** list, select tags that you want to add to the plan.
8. Click **Save**. If you created the plan on a **Releases** details page, the plan is part of the selected release. After you save the plan, click **Edit** to modify plan details.

Note: You can create one deployment plan as a primary linked to many secondary deployment plans. Deployment is executed only from primary deployment plan.

Importing tasks into deployment plans

You can import tasks that are defined in comma-separated values (CSV) files into a deployment plan.

About this task

You can import tasks from CSV files that are exported from IBM® DevOps Release or another application capable of creating CSV files. When you import a deployment plan from Release, segments are converted into groups with the same execution pattern as the original segments. Segment tasks are bracketed by note-type Start Segment and End Segment tasks. Task dependencies are preserved during import. Segment dependencies are represented by dependencies to End Segment tasks.

To learn about deployment plans exported from Release, download the `SamplePlan.csv` file from the Import Tasks dialog.

Note: When you import tasks, tasks that are already defined in the deployment plan are overwritten and replaced by the tasks in the CSV file.

The following table contains the fields that define a task in an Release deployment plan. The first row in the CSV file contains the column headers, which correspond to the table's Field column. The rows after the first row contain task data, one task per row. The order of the columns does not matter.

Note: If you are creating tasks in a CSV file, you must include the required fields that are identified by the asterisk character (*) in the following table.

Table 655. Release deployment plan fields

Field	Description
segmentName*	The name segment. Required field.
name*	The name of the deployment task. Required field.
type*	Task type. Possible values are note, waitfortimetask, ucdtask, or manual. During import, if the field contains an unrecognized value, the task is assigned the manual type.
description	Description of the deployment plan.
property:processId	The process ID in HCL DevOps Deploy (Deploy) that corresponds to the task.
property:task-environments	Application environments available to the task.
property:mailRecipients	Email addresses of users who receive email messages when notifications are sent.
taskTagNames	The names of the tags that are associated with the task.
taskPrequisiteIds	A comma-separated list of IDs for tasks that must complete before this task can start.
segmentPrerequisiteIds	A comma-separated list of IDs for segments with which the current segment has dependencies.
taskPrequisiteNames	A comma-separated list of names for tasks that must complete before this task can start.
segmentPrerequisiteNames	A comma-separated list of names for segments with which the current segment has dependencies.
assignedUserEmail	Email address of the user who is assigned to the current task.
executorGroup	User group assigned to the current task.

Table 655. Release deployment plan fields (continued)

Field	Description
segmentPattern	Execution pattern of the selected segment.

Complete the following steps to import tasks into a deployment plan:

1. On the **Deployment Plan** details page, click **Import Tasks**.
2. In the Import Tasks dialog, click **Choose File**, and then select the CSV file in addition to confirming the choice in the dialog box. You can also drag a file onto the field.
3. Click **Import**. The tasks are added to the deployment plan. If the import process is unsuccessful, click **View Report** to display the error log.

Copying deployment plans

You can duplicate deployment plans by copying them.

About this task

The status of a copied or promoted plan is `draft` even if the original plan has a status of `done` or `in progress`.

1. **Optional:** To copy a plan, click the overflow icon ( ) and select **Copy plan** from the drop-down on the **Releases** details page. When you copy a plan, a new plan with the name "Copy of `plan_name`" is inserted into the **Releases** details page. The copied plan contains all the tasks that are defined in the original plan. If HCL DevOps Deploy (Deploy) tasks are in the plan, the applications, versions, and environments that are selected in the original are also selected in the copied plan. Applications, versions, and environments are displayed on the **Versions** tab on the Deployment Plan Detail page.
2. **Optional:** To create a template from a plan, click the overflow icon ( ) and select **Copy as template** from the drop-down on the **Releases** details page. When you copy a plan as a template, a new plan with the name "Copy of `plan_name`" is inserted into the **Templates** page. The copied plan contains all the tasks that are defined in the original plan. If Deploy tasks are in the plan, the applications, versions, and environments that are selected in the original are also selected in the template.

Managing deployment plan templates

You can convert deployment plans to create deployment plan templates.

About this task

To create a template, click the overflow icon ( ) and select **Copy as template** from the drop-down on the **Releases** details page. When you create a template, a new plan with the name "Copy of plan_name" is inserted into the **Templates** page. The status of a template is `template` even if the original plan has a status of `done` or `in progress`. The template contains all the tasks that are defined in the original plan. If HCL DevOps Deploy (Deploy) tasks are in the plan, the applications selected in the original are also selected in the template.

You cannot run deployments with templates. To use a template for a deployment, first copy or promote it and then use the copied or promoted plan.

Archiving deployment plans

You can remove deployment plans from releases by archiving them.

About this task

Deployment plans cannot be permanently deleted, but can be archived. When you archive a deployment plan, it has a status of **Archived** and is not displayed in the list of plans on a **Releases** details page.

You can view archived deployment plans and restore them by clicking **Archived** on the **Releases** page.

1. Click **Plan** for a release to view a list of associated deployment plans.
2. On the line of the plan to be archived, click the overflow menu icon ( ) and select **Archive this plan**.
   Repeat this step for each plan to be archived.

Running deployments

Complete deployments by resolving the tasks in a deployment plan.

A deployment starts when one of the plan's eligible tasks starts. A scheduled deployment starts automatically at the scheduled time if one of its eligible tasks is an auto task, such as HCL DevOps Deploy (Deploy) tasks. Otherwise, begin a deployment by starting one of the plan's eligible tasks. If the plan contains several eligible tasks, you can start any of them. You can manually start a deployment at any time. You can manually start a scheduled deployment before its scheduled time.

The deployment plan's execution pattern determines when tasks are eligible to start. If the plan has the sequential execution pattern, which is the default pattern, tasks become eligible in the order in which they are listed in the plan, starting with the first task. After the first task resolves, the second task becomes eligible. Start eligible manual tasks by clicking the task's **Start** button. Auto tasks, such as Deploy tasks, start automatically as soon as they become eligible.

The tasks in a group with a parallel execution pattern become eligible simultaneously. Tasks in parallel groups can be started in any order. Nested groups and tasks with ad hoc dependencies can affect the execution pattern.

You can modify a deployment plan after you start a deployment. You can add, delete, and modify tasks.

After all tasks are resolved, the deployment is complete. A task is resolved if it has a status of `Complete`, `Failed`, or `Skipped`. If you reopen a task or add a task after the deployment is complete, the deployment's status changes to `In Progress`.

Starting deployments manually

Starting deployments manually

About this task

You can start a deployment manually at any time, including deployments that are scheduled to start later.

Tasks in a deployment plan might be inapplicable for deployment. HCL DevOps Deploy (Deploy) tasks are inapplicable if no version or environment is specified for the tasks. When you create Deploy tasks, you can delay selecting the environment and version by using the **Use Version** option. Before the deployment starts, ensure that all Deploy tasks are applicable for the upcoming deployment.

You can deliberately exclude tasks from a deployment. You can make tagged tasks inapplicable by excluding their tags from the deployment. Tasks with excluded tags are inapplicable for deployment.

Inapplicable tasks have the status of `Not Applicable`. Tasks with the `Not Applicable` status cannot be started. If an inapplicable task is a prerequisite for an active task, the dependency is ignored.

To start a deployment, complete the following steps:

1. On the **Releases** details page, click the deployment plan that you want to use for the deployment. The **Deployment Plan** details page is displayed.
2. **Optional:** To make tagged tasks inapplicable for the current deployment, click **Versions**, and then in the **Tags** area, clear the tags. If a task has more than one tag, clear all of them.
3. To select the version or environment for any inapplicable Deploy tasks, click **Versions**, and then select the environment and version. You can also change your choices for tasks that have their environments and versions already selected.
4. **Optional:** Click **Hide Not Applicable Tasks** to remove inapplicable tasks from the displayed task list. Hidden tasks are not removed from the deployment plan.
5. Click the **Start** action for one of the plan's eligible tasks. If more than one task is eligible, you can start any of them. Only eligible tasks display the start button. A started task has the status of `In Progress` until it is resolved.
   Result
   After a deployment starts, the plan's status changes to `In Progress`. The status remains `In Progress` until all tasks are resolved. When all tasks are resolved, the plan's status changes to `Done`.

Resolving tasks

Complete a deployment by resolving the tasks in the deployment plan.

About this task

A started task is resolved when its status changes to `Complete`, `Failed`, or `Skipped`.

You resolve manual tasks by using the appropriate status action. Auto tasks, such as HCL DevOps Deploy (Deploy) tasks or Jenkins®, change status automatically as conditions change. However, you can manually resolve auto tasks. For example, you might manually fail an Deploy task that is taking too long to complete.

To resolve a started task, apply one of the following statuses:

- Click **Complete** to finish the task. `Complete` means that the task finished with the expected results.
- Click Skip to skip the task for the current deployment.

- Click **Fail** to end the task. `Fail` means that the task did not finish or finished with unexpected results.
- Click **Task Reopen** to open a resolved a task. If all tasks are completed, reopening a task reopens the deployment.

Importing tasks into deployment plans

You can import tasks that are defined in comma-separated values (CSV) files into a deployment plan.

About this task

You can import tasks from CSV files that are exported from IBM® DevOps Release or another application capable of creating CSV files. When you import a deployment plan from Release, segments are converted into groups with the same execution pattern as the original segments. Segment tasks are bracketed by note-type Start Segment and End Segment tasks. Task dependencies are preserved during import. Segment dependencies are represented by dependencies to End Segment tasks.

To learn about deployment plans exported from Release, download the `SamplePlan.csv` file from the Import Tasks dialog.

Note: When you import tasks, tasks that are already defined in the deployment plan are overwritten and replaced by the tasks in the CSV file.

The following table contains the fields that define a task in an Release deployment plan. The first row in the CSV file contains the column headers, which correspond to the table's Field column. The rows after the first row contain task data, one task per row. The order of the columns does not matter.

Note: If you are creating tasks in a CSV file, you must include the required fields that are identified by the asterisk character (*) in the following table.

Table 656. Release deployment plan fields

Field	Description
segmentName*	The name segment. Required field.
name*	The name of the deployment task. Required field.
type*	Task type. Possible values are note, waitfortimetask, ucdtask, or manual. During import, if the field contains an unrecognized value, the task is assigned the manual type.
description	Description of the deployment plan.
property:processId	The process ID in HCL DevOps Deploy (Deploy) that corresponds to the task.
property:task-environments	Application environments available to the task.
property:mailRecipients	Email addresses of users who receive email messages when notifications are sent.
taskTagNames	The names of the tags that are associated with the task.

Table 656. Release deployment plan fields (continued)

Field	Description
taskPrequisiteIds	A comma-separated list of IDs for tasks that must complete before this task can start.
segmentPrerequisiteIds	A comma-separated list of IDs for segments with which the current segment has dependencies.
taskPrequisiteNames	A comma-separated list of names for tasks that must complete before this task can start.
segmentPrerequisiteNames	A comma-separated list of names for segments with which the current segment has dependencies.
assignedUserEmail	Email address of the user who is assigned to the current task.
executorGroup	User group assigned to the current task.
segmentPattern	Execution pattern of the selected segment.

Complete the following steps to import tasks into a deployment plan:

1. On the **Deployment Plan** details page, click **Import Tasks**.
2. In the Import Tasks dialog, click **Choose File**, and then select the CSV file in addition to confirming the choice in the dialog box. You can also drag a file onto the field.
3. Click **Import**. The tasks are added to the deployment plan. If the import process is unsuccessful, click **View Report** to display the error log.

Running scheduled deployments

A scheduled deployment starts automatically at its scheduled time if any of its auto tasks are eligible to start.

About this task

If a deployment plan does not contain any eligible auto tasks, start the deployment by manually starting one of the eligible tasks. If the deployment plan belongs to a pipeline-generated release, you can start the deployment directly from the pipeline.

You can manually start a scheduled deployment at any time even if the plan has eligible auto tasks.

Tasks

A task represents a business-meaningful activity that is associated with a software deployment. Each task is defined on a separate row in a deployment plan. During a deployment, you run tasks defined in the deployment plan to complete the deployment.

Most tasks have a starting and ending point, and a measurable duration. A task can have other attributes depending on its type. A task can be of one of following types:

Ansible

Automation tool used for configuration management, application deployment, intraservice orchestration, and provisioning tasks.

Delayed

Represents a critical event that happens at a specific time.

Email

Sends an email message.

Header/Note

an organizational element. For example, you might use a header task to identify a task group.

Jenkins®

Runs a Jenkins® job or pipeline.

Manual

Represents any activity that is associated with a software deployment, such as taking a server offline or updating a database. Users assigned manual tasks can be sent email notifications when their tasks start or fail.

Run a Shell Script

Shell script tasks are used to execute a sequence of commands. The shell is the command line interface (CLI) for the operating system (OS) used to interpret the sequence of commands communicating with the software interface.

Run another plan

Runs deployments for other deployment plans participating in the same release event. This is an experimental task type.

ServiceNow™

Creates and manages ServiceNow tickets.

HCL DevOps Deploy (Deploy) (requires Deploy integration)

Use this task to run an Deploy application process.

Deploy Status (requires Deploy integration)

Use this task to add a status to all component versions contained within an Deploy snapshot.

Wait for approval

Pauses a deployment until the designated users approve the task.

You can add tasks to deployment plans by one of the following methods:

- Create a new task
- Import from CSV files that are created by Deploy or another application
- Copy tasks from other deployment plans

Additionally, tasks are auto-created when you add an application to a pipeline on page 3127.

Managing tasks

A list of associated tasks can be viewed from a **Deployment Plan** details page. The list of tasks include details about the task. You use action icons to change the task's status during a deployment, such as start or skip a task.

About this task

Each task in a deployment plan is contained in a separate row. Click ( ) to show or hide associated tasks from the list.

Click ( ) show or hide tags.

The information that is displayed for each task is described in the following table.

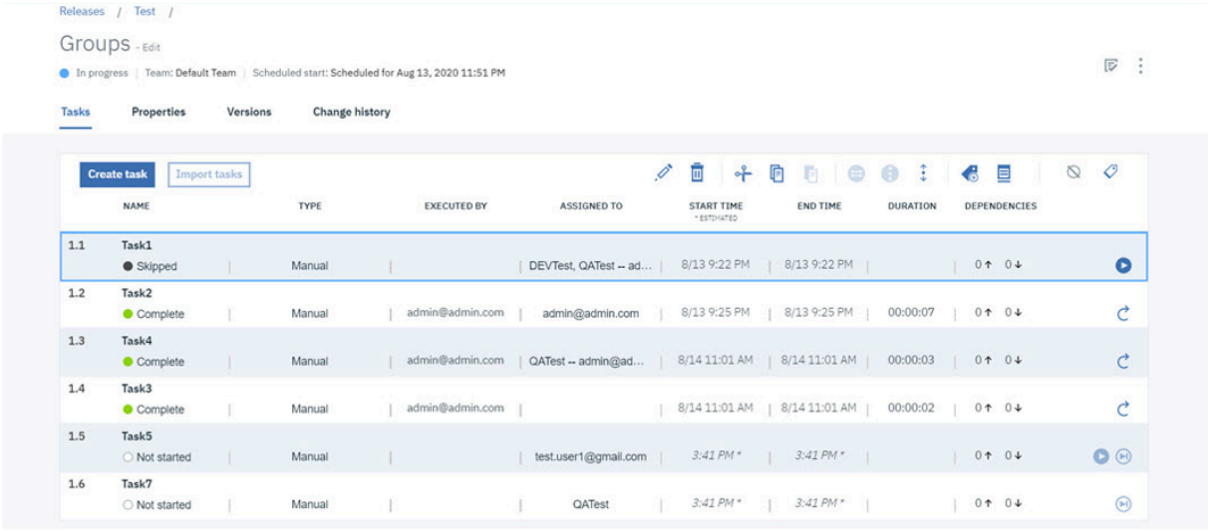

Table 657. Task properties

Property	Description
Name	Task name
Status	Task status: Not started, complete, failed, skipped, not applicable

Table 657. Task properties (continued)

Property	Description
Type	Type of task: Delayed, Deployment Risk Analysis, Email, Header/Note, Jenkins®, Manual, Run another plan, ServiceNow™, HCL DevOps Deploy, and Wait for approval.
Executed by	Person who executes the manual task
Assigned to	Groups and users designated as the task owner
Start time	Start time or expected start time based on scheduled start, or estimated duration of other tasks
End time	Time that the task resolved
Duration	Length of time in minutes from task start to task resolution.
Dependencies	Indicates the number of tasks that are prerequisites for the task, and dependent on the task
Action icons	One or more actions used to change the status of the task during a deployment

Tasks are listed in the order that they run. The order of the tasks can be changed by selecting one or more tasks and dragging to the new location.

At the end of each row are applicable actions associated with the task. Depending on the task you can perform one or more of the following actions.

- Start task ( )
- Skip task ( )
- Re-run task ( )
- Complete task ( )
- Fail task ( )

You can manage the tasks in a deployment plan from the task bar above the table. When a task is selected, the task bar displays and you can perform the following actions:

- Click ( ) to edit the task.
- To copy a task or group, select one or more tasks and click , and then place the cursor where you want to insert the copied task and click to paste the selection.
- To cut a task or group from a deployment plan, select the task and click .
- To delete a task, select the task and click . The task is removed from the deployment plan.
- To create a group of tasks that can run simultaneously, select the tasks and click . The group must consist of at least two tasks.
- To create a group of tasks that are to consecutively run, select the tasks and click . This is the default execution pattern.
- To add or remove tasks that must complete first, select the task and click . In the dialog box, select or type the prerequisite task to be added. Click **X** next to the prerequisite to be removed. When finished, click **Save**.
- To add or remove tags, select the task and click . In the dialog box, type or select tags to add. To remove a tag, click **X** next to the tag to be removed. When finished, click **Save**.
- To view information about when the task started, completed, and errors, click .

Creating tasks

By default, new tasks are inserted at the bottom of the deployment plan. After a task is created, you can move it, or copy it and paste it into another deployment plan. You can also create dependencies with other tasks on page 1848.

About this task

Tasks can be added to a deployment by creating a new task or importing an existing task.

After you save a task, actions are displayed for the task. You use actions to change the task's status during a deployment.

All tasks have the skip action. Other actions, such as the start action, are displayed when the context is appropriate for them.

1. From the **Deployment Plan** details page, click **Create task** to create one or more tasks.
2. Select a task type.

   Note: The availability of task types will depend on your version of HCL DevOps Deploy (Deploy) and integrations.

   Possible task types include:
   - Ansible
   - Delayed
   - Deployment Risk Analysis
   - Email
   - Header / Note
   - Jenkins
   - Manual
   - Run a Shell Script (requires shell script plugin)
   - Run another plan
   - ServiceNow™
   - Deploy (requires Deploy integration)
   - Deploy Status (requires Deploy integration)
   - Wait for approval
3. Provide information in required and optional fields displayed according to the task type selected.
4. Click **Save and create another** to create additional tasks. Click **Save** when finished.

Managing task dependencies

You can make a task a prerequisite for other tasks. If a task is a prerequisite, dependent tasks cannot start, even if they are otherwise eligible, until the prerequisite task is resolved.

About this task

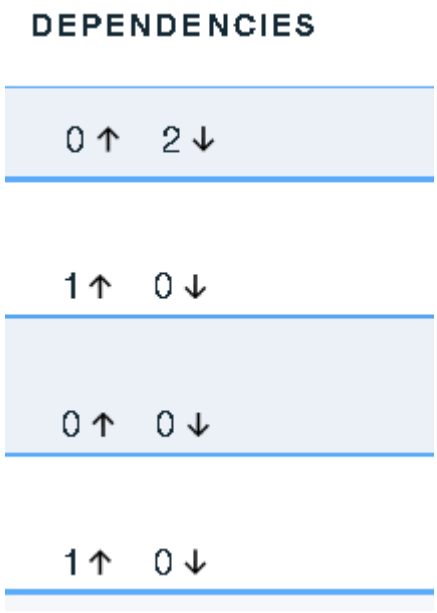
A task can have multiple dependent tasks and multiple prerequisite tasks. You can define dependencies for a task with any other task in the deployment plan. However, you cannot create circular dependencies. You cannot, for example, make a task dependent on a task that itself depends on the first task. By controlling task dependencies, you can ensure that events occur in their expected order.

To make a task a prerequisite for other tasks, complete the following steps:

1. On the **Deployment Plan** details page, select a task or task group, and then click . You can select multiple tasks and groups.
2. In the **Manage prerequisites for selected tasks** dialog box, in the **Prerequisite tasks for selected tasks** drop-down list, select the prerequisite task.
3. Click **Save**.

Result

Task dependencies are shown in the **DEPENDENCIES** column on the **Deployment Plan** details page. Up arrows indicate task prerequisites; down arrows indicate task dependencies. In the following figure, the first task does not have any prerequisites and has two tasks dependent on it. The second task has one prerequisite task and there are no tasks dependent on it.



What to do next

To review or modify dependencies, select the task and then click . Use the **Manage prerequisites for selected tasks** dialog box to modify or remove dependencies.

Creating task groups

You can combine two or more tasks into a task group. When you create a group, you define the whether the group task are executed sequentially or in parallel.

About this task

Tasks can run in a parallel or sequential pattern. When you create the task, you decide the execution pattern. Tasks without dependencies can execute in any order or simultaneously which is *parallel* execution. Tasks that must execute in specific order are *sequential* execution. Tasks are done in list-order starting with the first or top-most task.

You can embed groups within other groups. A sequential-pattern group can be embedded within a parallel-pattern group, and vice versa; however, you cannot embed a sequential-pattern group within another sequential group, or a parallel-pattern group within another parallel group.

1. On the **Deployment Plan** details page, select two or more tasks.
2. Depending on the type of group you want to create, complete one of the following.
   Choose from:
   - To create a parallel group, click the Parallel icon)). If you cannot create a parallel group with the selected tasks, the icon is disabled. For example, you cannot create a parallel group if all the selected tasks are already in a parallel group.
   - To create a sequential group, click the Sequential icon ( ).

   Result
   The group is formed and a group select bar is added to the deployment plan. If you selected discontiguous tasks, the tasks form a contiguous list starting with the topmost selected task.

Managing task groups

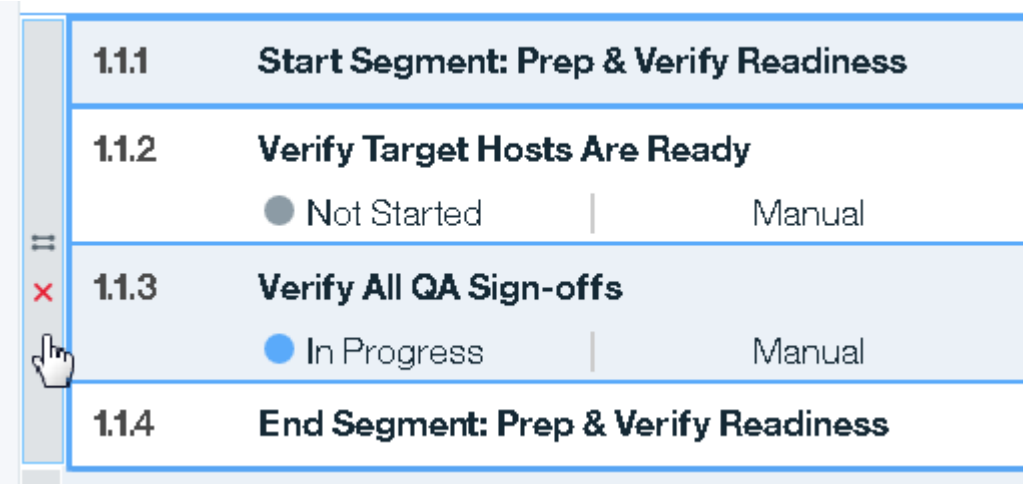
You can combine two or more tasks into a task group. When you create a group, you define the whether the group task are executed sequentially or in parallel.

About this task

You can recognize task groups in the list of task, there is a bar connects the grouped tasks and contains an icon to identify if it is a parallel or sequential group.

- parallel
- sequential

The following image shows a parallel group.



You can manage task groups in several ways:

- To move a group, select the group select bar or click anywhere on the group, and then drag it to a new location.
- To copy a group, select the group and click , and then place the cursor where you want to insert the copied group and click .
- To cut a group, select the group and click .
- To ungroup a group, select the group and click the **Ungroup** icon on the group select bar.
- To delete the tasks in a group, select the group and click . The tasks are removed from the deployment plan.

Managing task tags

Tags are organizing elements that you can add to tasks. You can filter deployment plans by tag. For example, during a deployment to a production environment, you might disable tasks with the `DEV_only` tag, which is intended to be used only in development environments.

About this task

To add a tag to a task, complete the following steps:

1. On the **Deployment Plan** details page, select a task or task group, and then click . You can select multiple tasks and groups.
2. In the **Manage Tags for Selected Tasks** dialog box, in the **Tags** drop-down list, select tags. You can create a new tag by typing a name in the list's text box.
3. Click **Save**.
   Tags are displayed on the task rows in the **Deployment Plan** details page. In the following figure, the Deploy WAR task has two tags assigned to it, `Deployment`, and `Critical`.

   The tags used by a deployment plan are displayed on the **Deployment Plan** details page by clicking **Versions**. To render tasks with a specific tag `Not Applicable` for a deployment, clear the tag. Tasks with the `Not Applicable` status cannot be started.

Creating run another plan tasks

A run another plan task runs a deployment for another deployment plan.

About this task

The targeted plan can be created from a template or a tag. If you use a template, the template and the targeted plan must be in the same release as the run another plan task.

To create a run another plan task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create task**. If you want to insert a task at a specific position in the plan, select a task before you use the **Create task** action. The new task is inserted before the selected task.
2. In the **Create task** dialog box, in the **Type** drop-down list, select **Run another plan**.
3. In the **Name** field, enter a name for the task.
4. In the **How do you want to choose another plan** area, select an option.
   If you choose, **By template**, the template and associated deployment plan must be in the same release as the task's parent plan. If you choose, **By tag**, the tagged deployment plan must be in the same release as the task's parent plan as demonstrated in this example on page 1852 of creating a primary and secondary template.
5. In the **Run plans created from this template** list, select a deployment plan template. The template and associated deployment plan must be in the same release as the task's parent plan.
6. In the **Run plans with this tag** list, select the tag associated with the template to the task.
   You can select multiple tags. To create a tag, type the tag name in text box.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When the task runs, a deployment starts for the deployment plan that was created from the selected template or tagged plan. If multiple plans in the release event are eligible, deployments start for all of them. While the other deployments run, status information is provided by the run another plan task. Expand the task to see the status information. You can open the other deployments by using links on the task. While the other deployments run, the run another plan task has a status of **In Progress**.

Creating run another plan tasks: Example

A run another plan task runs a deployment for another deployment plan.

About this task

This example is a targeted plan that is created from a tag. The tagged deployment plan must be in the same release as the task's parent plan.

To create a targeted plan that is created from a tag, complete the following steps:

1. Create the primary template.
    a. On the **Releases** page, click **Templates > Create template**.
    b. In the **Plan template name** field, enter the name for the primary template.
    Accept the default values for the remaining fields.
    c. Click **Save**.
    d. Click the name of the primary template.
2. Referring to the Creating tasks on page 1847 page, create independent and dependent tasks for the primary template by using field values that are detailed in the following tables for each task:

Table 658. Manual task

Create task field	Value
Type	Select **Manual**.
Name	Enter the name for the manual task.
Description	Default value.
Duration (minutes)	Default value.
Tags	Default value.
Assigned groups and users	Default value.

Table 659. Run another plan task

Create task field	Value
Type	Select **Run another plan**.
Name	Enter the name for the secondary task.
How do you want to choose another plan?	**By tag**
Run plans with this tag	Select a tag or create a new tag by typing a name in the field. The primary deployment plan will find any other plan with this tag name when it runs.
Tags	Default value.

3. Create the secondary template.
    a. On the **Releases** page, click **Templates > Create template**.
    b. In the **Plan template name** field, enter the name for the secondary template.
    Accept the default values for the remaining fields.

c. Click **Save**.

d. Click the name of the secondary template.

4. Referring to the Creating tasks on page 1847 page, create independent and dependent tasks for the secondary template by using field values that are detailed in the following tables for each task:

Table 660. Wait for approval task

Create task field	Value
Type	**Wait for approval** or any task that starts automatically.
Name	Enter the name for the task.
Approval prompt	Default value or enter a prompt message.
Approvers	Select the name of the approver. You can select multiple approvers.
Required Approver	Select **Any approver can approve** or **All approvers must approve**

Table 661. Manual task

Create task field	Value
Type	**Manual**
Name	Enter the name for the task.
Description	Default value.
Duration (minutes)	Default value.
Tags	Default value.
Assigned groups and users	Default value.

5. Referring to the Creating releases on page 1833 page, create a release with the primary and secondary templates by using field values that are detailed in the following table:

Table 662. Create release

Create release field	Value
Name	Enter the name for the release.
Tags	Select the name for the required tag.
Description	Default value.
Deployment plan templates	Select the name of the primary template that you created.

Create release field	Value
Start time	Default value.
End time	Default value.
Team	Default value.

6. On the **Releases** page, click the name of the release.
7. Click the primary plan to display the independent task and dependent task with a tag in the template.
8. At the top of the page, click the link to go back to the release.
9. Create the deployment plan.
    a. Click **Create deployment plan**.
    b. In the **Deployment plan template** list, select the name of the secondary template that you created.
    c. In the **Tags** field, select the name for the required tag.
    d. Click **Save**.

    Note: You can create one deployment plan as a primary linked to many secondary deployment plans. Deployment is executed only from primary deployment plan.

10. Click the primary plan to display the independent and dependent tasks.
    The dependent task is now ready to run with the independent task being a manual type.

    a. On the manual task, click **Start task** to start the task.

    b. On the manual task, click **Approve task** to complete the task.
    The manual task displays the status as `Complete`, and the dependent task displays `In progress`.

    c. On the dependent task, click the arrow to the left of **In progress**.

    d. Click **Go to** to go to the dependent task.

    e. On the "Wait for approval" task, click **Approve task** to approve the task.

    f. On the "Manual" task, click **Start task** to start the task.

    g. On the "Manual" task, click **Complete task** to complete the task.

    h. At the top of the page, click the link to go back to the release.

The **Manual** and **Run another plan** tasks are both displayed as completed in the secondary plan.

i. At the top of the page, click the link to go back to the primary plan to display the plans in the release that are completed.

Creating delay tasks

Delayed-type tasks represent milestones or critical events during a deployment. With delayed tasks, you can ensure that important tasks start at the expected time. Typically, delayed tasks are prerequisites for other important tasks.

About this task

A delayed task starts as soon as it is eligible to run, and it finishes at a user-specified time. A started delayed-type task has a status of `In Progress` until it reaches its planned-for time, when it then changes its status to `Complete`. When a delayed tasks completes, auto tasks that are dependent on it start running.

Complete the following tasks to create a delayed task:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Delayed**.
3. In the **Name** field, enter a name for the task.
4. In the **Delay type** field, select the method used to determine the length of the delay.
   If you select **Delay by selecting a time and time zone**, use the **Delay until time** and **Time zone** fields to specify when the task will complete. If you select **Delay by using a date and time property**, use the **Delay property** field to enter a property name. The property value can be set at run-time when the deployment starts. Refer to the Properties reference for information about properties:

   ```
   /docs/services/UCCR/UCCR_property_ref.html#property_overview
   ```

   Otherwise, if you select **Delay by selecting a number of minutes**, use the **Minutes** field and enter the number of minutes between tasks.
5. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating email tasks

An email task sends an email message when the task runs. You specify the email's recipients and message when you create the task. Email tasks are auto tasks and run as soon as they are eligible.

Before you begin

Before using email tasks in your deployments, setup an email server. on page 1800

About this task

To create an email task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Email**.
3. In the **Name** field, enter a name for the task.
4. In the **Recipients** field, enter or select the email's recipient.
   The list of available recipients includes the users and groups who are members the team that manages the task. You can also type the email addresses of non-team members. You can specify multiple recipients.
5. In the **Email subject** field, enter the email topic.
   You can use properties in this field.
6. In the **Email message** field, enter or paste the email message.
   You can use properties in this field. For example, you might notify email recipients that a release is started by using a message similar to this one, "The `` `${sys:release.name}` `` release has started." See the Properties reference for information about properties on page 1871.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When the task runs, the recipients receive an email with the subject you specified when you created the task.

Creating header/note tasks

Header tasks represent organization elements that you can add to deployment plans. If you create a task group, you might identify the group with a header task. Header tasks can have dependencies like any other task.

About this task

You can organize task groups with header/note tasks. You can create a note by adding information about a group or task. When you import a deployment plan from IBM® DevOps Release, segment tasks are bracketed by note-type Start Segment and End Segment tasks. Segment dependencies are represented by dependencies to End Segment tasks.

To create a header task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Header / Note**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter or paste a description.
   You might enter a note, a reminder, or other instructions in the field.
5. Click **Save**.

Result

The task is inserted into the deployment plan.

Creating Jenkins (Legacy) tasks

A Jenkins (Legacy) task runs a job in your integrated Jenkins instance.

Before you begin

Before using Jenkins (Legacy) tasks in your deployments, add the plugin to your Jenkins instance and configure an integration. on page 1886 After integrating Measure to Jenkins, you can add Jenkins jobs to you pipelines and releases.

About this task

To create a Jenkins (Legacy) task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Jenkins (Legacy)**.
3. In the **Name** field, enter a name for the task.
4. In the **Jenkins Job or Pipeline** field, select a job or pipeline.
5. In the **Duration (minutes)** field, enter an estimate for the length of the task.
6. In the **Tags** list, select an item to attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating manual tasks

Manual tasks represent some activity that is associated with a software release. Manual tasks have a start point, end point, and a measurable duration.

About this task

To create a manual task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Manual**.
3. In the **Name** field, enter a name for the task.
4. In the **Duration (minutes)** field, enter the number of minutes that you expect the task to run until it is completed.
   The estimated duration is used to calculate expected deployment times.
5. In the **Tags** list, select an item to attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.

6. In the **Assigned groups and users** list, select the task owner.
7. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

Once the manual task is executed, you can select the task on the deployment plan details page on page 1845, click to display the **Edit task** window, and view who executed the task in the **Executed By** field.

Creating run shell script tasks

Shell script tasks are used to execute a sequence of commands.

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create task** dialog box, in the **Type** list, select **Run a Shell Script Task**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter or paste a description.
   You might enter a note, a reminder, or other instructions in the field.
5. In the **Shell Script** field, enter or paste the shell script code. An example shell script code is the following:

```
echo "Hello World"
sleep 2
"Do some stuff..."
sleep 2
echo "Task finished"
```

6. Click **Save**.
   Result
   The task is inserted into the deployment plan.

Creating ServiceNow tasks

A ServiceNow™ task can create and update ServiceNow™ change requests.

Before you begin

ServiceNow task prerequisites:

- ServiceNow tasks work with Internet-accessible instances of ServiceNow, such as `my_instance.service-now.com`.
- ServiceNow tasks work with the Jakarta® release of ServiceNow, and references the current API version.
- The user supplying credentials for the task must have access to the ServiceNow API, and permission to see and modify all change request fields. At a minimum, the user must be in a ServiceNow role that has the Create Change permission.

About this task

A ServiceNow task can perform one of the following actions:

- **Create** creates a ServiceNow change request. You can set the values for all request fields, and pass the request ID to update, and wait tasks.
- **Update** can update the values for any request field.
- **Wait** waits for a particular value in a specific field. The field can be any field on the change request.

A ServiceNow task can include ServiceNow properties and Measure properties. ServiceNow properties have the following syntax: `propertyName=value`.

This short video describes how to use ServiceNow with Measure.

To create a ServiceNow task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **ServiceNow**.
3. In the **Name** field, enter a name for the task.
4. In the **Tags** list, attach a tag to the task.
   You can select multiple tags. To create a tag, type the tag name in list's text field.
5. In the **Connection settings** area, enter the URL of the ServiceNow instance, and the user ID, and password of the ServiceNow user.
6. In the **Action** list, select the action type for the task.
   The action types are defined in this list:
   - The **create** action creates a ServiceNow change request with the properties defined in the task.
   - The **update** action modifies properties in change request.
   - The **wait** action waits for a specific value in a change request field.
7. Complete the action-specific parameters, as described in the following tables:

Table 663. Create action

Create action	Description
Request type	You can use the ServiceNow default types or a user-created type. Default types are normal, emergency, and standard. Normal requests pass through all stages

Create action	Description
	of the ServiceNow state model. Standard types are pre-authorized and skip the Assess and Authorize states. Emergency types skip the Assess state.
Short description	The text you enter is displayed in the Short description field of the ServiceNow change request.
Assignment group	The ServiceNow agent or group responsible for resolving the change request. Possible assignees include agents and groups available to the ServiceNow instance.
Additional properties	The ServiceNow properties set by this task. Each property must be on its own line. For example, a simple request might include the following fragments: `approval=requested`.
Output property	Measure property that contains the change request ID. For example, if you specify `service_now_stage_ticket_id`, you can use the property with update and wait actions to identify the ticket.

Table 664. Update actions

Update action	Description
System ID	The ID of the ServiceNow change request. If you capture the ID with a create action **Output property** field, you can use it here. For example, if you specify `service_now_stage_ticket_id` in the **Output property** field of a create action, you can use the ID by specifying `${service_now_stage_ticket_id}`. See the Properties reference for information about properties on page 1871.
Additional properties	The ServiceNow properties set by this task. Each property must be on its own line. For example, to update the state of the change request, you can specify or `state=-1`.

Table 665. Wait actions

Wait action	Description
System ID	The ID of the ServiceNow change request. If you capture the ID with a create action **Output property**

Wait action	Description
	field, you can use it here. For example, if you specify `` `service_now_stage_ticket_id` `` in the **Output property** field of a create action, you can use the ID by specifying `` `${service_now_stage_ticket_id}` ``.
Field	The name of the affected field in the ServiceNow change request. The value in the field is checked for updates by the interval defined by the Check request interval field. For example, if you are checking the **approval** field, you might specify `` `approval` ``.
Value	The value expected in the ServiceNow field as defined by the **Field** property. For example, if you are checking the **approval** field, you might specify `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` ``, the task completes successfully.
Check request interval	The value defines how frequently ServiceNow is checked for updates. The value represents minutes. The default value is `1`, which mean ServiceNow is polled every minute.

Result

When the task starts, it has the status of **In progress**. The status changes to **Complete** when the related ServiceNow action is resolved.

What to do next

The ServiceNow change request life cycle is referred to as the state model. As a change request is used, it progresses through the various states of model. The state of a closed request is 'closed', for example.

In Measure, ServiceNow tasks are frequently used to change the state of a request. To modify a request state, you use the ServiceNow `state` property. For example, to change the state of a request to Review, you can specify **`state=0`** in the **Additional properties** field of an Update action.

The following table provides the values for the default states for the normal request type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 666. ServiceNow normal request state model

State	Value
New	-5
Assess	-4
Authorize	-3

Table 666. ServiceNow normal request state model (continued)

State	Value
Scheduled	-2
Implement	-1
Review	0
Closed	3
Canceled	4

Creating ServiceNow task using Service Now plug-in

A ServiceNow™ task can create and update ServiceNow change requests and the change tasks within the change request. You can also create a ServiceNow - Wait Change Request task which will wait for the specified value to appear in a specific field of a change request in ServiceNow.

Before you begin

You must have completed the following tasks:

- Ensured that you have internet-accessible instances of ServiceNow, such as `my_instance.service-now.com`.
- Created an integration with ServiceNow plug-in. For more information, refer to ServiceNow plug-in documentation.

Note: Ensure that the credentials used for the plug-in integration must have access to the ServiceNow API and permission to see and modify all change request fields. At a minimum, the user must be in a ServiceNow role that has the Create Change permission.

About this task

You can create the following automation tasks with which you can perform the actions in ServiceNow directly from Measure:

- **ServiceNow - Create Change Request and Change Task**

  This task creates a change request, change task or both in ServiceNow.

- **ServiceNow - Update Change Request and Change Task**

  This task updates the value in any change request, change task, or both in ServiceNow.

- **ServiceNow - Wait Change Request**

  This task waits for specified value to appear in a specified field of a change request in ServiceNow. The task will be completed when the provided value appears in the ServiceNow change request. The field can be any field of a change request.

- **ServiceNow - Wait Change Task**

  This task waits for specified value to appear in a specified field of a change task in ServiceNow. The task will be completed when the provided value appears in the ServiceNow change task. The field can be any field of a change task.

1. Click **Releases** on the left navigation pane.
   Result
   The **Releases** page is displayed.
2. Click any deployment plan.
   Result
   The **Deployment Plan** details page is displayed.
3. Click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
   Result
   The **Create Task** dialog is displayed.
4. In the **Type** list, select any one of the following options based on the action that you want to perform in ServiceNow:
   - **ServiceNow - Create Change Request and Change Task**
   - **ServiceNow - Update Change Request and Change Task**
   - **ServiceNow - Wait Change Request**
   - **ServiceNow - Wait Change Task**
5. In the **Name** field, enter a name for the task.
6. In the **Description** field, enter the description for the task.
7. In the **Integration** field, select the integration which you have created for ServiceNow.
8. Based on the task type you selected, enter the details in the task specific parameters, as described in the following tables:

Table 667. ServiceNow - Create Change Request and Change Task

ServiceNow - Create Change Request and Change Task type	Description
Short description for change request	Enter the text that you want to display in the Short description field of the ServiceNow change request.
Request type	Enter the ServiceNow request type. you can use the ServiceNow default types or a user-created type. Default types are normal, emergency, and standard. Normal requests pass through all stages of the ServiceNow state model. Standard types are pre-authorized and skip the **Assess** and **Authorize** states. Emergency types skip the **Assess** state.

ServiceNow - Create Change Request and Change Task type	Description
Assignment group for change request	Enter the ServiceNow agent or group responsible for resolving the change request. Possible assignees include agents and groups available to the ServiceNow instance.
Additional properties for change request	Enter the ServiceNow properties that you want to update by this task while creating the change request. For example, a simple create change request might include the following fragments: {"approval:requested"}.
Create change task	Enter the ServiceNow properties that you want to update by this task while creating the change task within the change request. You can create multiple change task by separating each change task properties object by a comma. For example, a simple create change task might include the following fragments:[{"short_description":"createtask","change_task_type":"planning","description":"changetask"}]
Output property	Enter the system ID of the created change request.

Table 668. ServiceNow - Update Change Request and Change Task

ServiceNow - Update Change Request and Change Task type	Description
Change Request Number	Select the Change Request Number of the ServiceNow change request that you want to update. See the Properties reference for information about properties on page 1871.
Change request properties	Enter the ServiceNow properties that you want to update by this task while updating the change request. For example, to update the state of the change request, you can specify or `{"state:-1"}`.
Update change task	Enter the ServiceNow properties that you want to update by this task while updating the change task within the change request. You can update multiple change task by separating each change task properties object by a comma. For example, to update the state of the change task, you can specify or `[{"state:3"}]`.

Table 669. ServiceNow - Wait Change Request

ServiceNow - Wait Change Request type	Description
Change Request Number	Select the Change Request Number of the ServiceNow change request. See the Properties reference for information about properties on page 1871.
Field	Enter the name of the field for which the task should check for a match in the ServiceNow change request. The value in the field is checked for updates in a regular interval. For example, if you want to check for a match in the **approval** field, you might specify `` `approval` ``.
Value	Enter the value expected in the ServiceNow field defined in the **Field** property. For example, if you are checking the **approval** field, you can specify a value `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` `` in ServiceNow, the task completes successfully.

Table 670. ServiceNow - Wait Change Task

ServiceNow - Wait Change task type	Description
Change task system id from property reference.	Enter the system ID of the change task.
Change Request Number	Select the Change Request Number of the ServiceNow change request. See the Properties reference for information about properties on page 1871.
Change request system id from property reference.	Enter the system ID of the change request.
Field	Enter the name of the field for which the task should check for a match in the ServiceNow change request. The value in the field is checked for updates in a regular interval. For example, if you want to check for a match in the **approval** field, you might specify `` `approval` ``.
Value	Enter the value expected in the ServiceNow field defined in the **Field** property. For example, if you are checking the **approval** field, you can specify a value `` `approved` ``. In this example, when the value in the **approval** field changes to `` `approved` `` in ServiceNow, the task completes successfully.

9. Click **Save** or **Save and create another** to add the task or add the task and create another task respectively.

Result

When the task starts, it will have the status of **In progress**. The status changes to **Complete** when the action mentioned in the task is performed in ServiceNow.

Example

Additional Information

The ServiceNow change request life cycle is referred to as the state model. As a change request is used, it progresses through the various states of model. For example, the state of a closed request is 'closed'.

In Measure, ServiceNow tasks are frequently used to change the state of a change request and change task.

To modify a request state, you use the ServiceNow `state` property. For example, to change the state of a change request to **Review**, you can specify "state:0" in the **Change request properties field** of a **ServiceNow - Update Change Request and Change Task** type and to change the state of a change task to **In progress**, you can specify "state:2" in the **Update change task** field of a **ServiceNow - Update Change Request and Change Task** type.

The following table provides the values for the default states for the normal change request type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 671. ServiceNow normal change request state model

State	Value
New	-5
Assess	-4
Authorize	-3
Scheduled	-2
Implement	-1
Review	0
Closed	3
Canceled	4

The following table provides the values for the default states for the normal change task type. For more information, see the configure dictionary for the state property in the ServiceNow documentation.

Table 672. ServiceNow normal change task state model

State	Value
pending	-5
open	1
in progress	2
closed	3
canceled	4

Creating DevOps Deploy tasks

Use DevOps Deploy tasks to run DevOps Deploy applications.

Before you begin

Before you can use DevOps Deploy tasks in pipelines and deployment plans, you must first configure DevOps Deploy integration on page 1885.

The applications that are available to a deployment plan depend on the team that is assigned to the plan. The applications that are managed by the team in DevOps Deploy are also available in Measure.

About this task

To create this task type, specify the application's process, version, and environment. You can set the version and environment at design time or select them at run time. When you run this task, the application runs in the integrated DevOps Deploy instance. During deployments, DevOps Deploy tasks start automatically when they become eligible to run.

To create a DevOps Deploy task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **DevOps Deploy**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, provide the description of the task.
5. In the **Integration** drop-down list, select the plugin integration.
6. Select the **Assigned group or user** from the drop-down list.
7. In the **Application** drop-down list, select an application.
8. In the **Process** drop-down list, select or enter an application process.

Processes that belong to the selected DevOps Deploy application are available.

9. In the **Version** drop-down list, select an application version.
   Versions refer to DevOps Deploy application snapshots. Versions that belong to the selected application are available. To postpone selecting a version, select **Use Version Tab**. If the application process does not require a version, select **No version items exist**. You might select this last option if you are running a configuration-type process that does not require components.
10. In the **Environment** drop-down list, select or enter an application environment.
    Environments that belong to the selected DevOps Deploy application are available. To postpone selecting an environment until you are ready to run the deployment, click **Versions** on the **Deployment plan** details page.
11. In the **Deploy Request Properties** box, enter the properties that you want to pass to the IBM DevOps Deploy (Legacy) application.
    Properties are name-value pairs. You can enter multiple properties. Put each property on a separate line. The following graphic provides an example of property definitions:
    Figure 4. property definitions

12. Select the snapshot display from the **On Failure** and **On Success** drop-down list.
13. Click **Save**.
    Result
    The task is inserted into the deployment plan.

Results

After the task is created, the plan's **Versions** page is updated with information about the application. If you selected **Only Changed Versions** for the application environment and version on the **Create Task** dialog box, use the **Versions** page to set those options before running the deployment.

Creating Ansible tasks

Create an Ansible® task.

Before you begin

In your Ansible® instance, create a user token. You use the token to authenticate your Measure user to Ansible®.

About this task

Create an Ansible® task to manage Ansible® jobs.

To create an Ansible® task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Ansible**.
3. In the **Name** field, enter a name for the task.
4. In the **Description** field, enter a name for the task.
5. In the **Instance URL** field, enter the location of your Ansible® installation..
6. In the **Access Token** field, paste the token that you generated in your Ansible® instance.
7. In the **Job ID** field, enter the Ansible® job identification number..
8. **Optional:** In the **Extra Variables** box, enter any parameters that you want to pass to the Ansible® job.
   The parameter format is JSON. For example:

   ```
   {
    "environment": "DEV"
   }
   ```

   example,
9. Click **Save**.
   Result
   The task is inserted into the deployment plan.

What to do next

When you run the task, a webhook is created that uses the Ansible® API to run the job. While the job is running, you can accesses Ansible® logs by using a link in the deployment plan. When the Ansible® job is finished, the Measure task status is updated.

Creating wait for approval tasks

A Wait for approval task pauses a deployment until a designated user provides approval. Email notifications are sent to users when the task starts.

Before you begin

Before using email tasks in your deployments, setup an email server. on page 1800

About this task

To create a wait for approval task, complete the following steps:

1. On the **Deployment Plan** details page, click **Create Task**.
   If you want to insert a task at a specific position in the plan, select a task before using the **Create Task**. The new task is inserted above the selected task.
2. On the **Create Task** dialog box, in the **Type** list, select **Wait for approval**.
3. In the **Name** field, enter a name for the task.
4. In the **Approval prompt** field, enter the text that you want to include in the email message.

The text is displayed in the **Task Details** section of the email.

5. In the **Approvers** list, select the users or groups designated to approve the task.
   Team members and groups are available to choose.
6. In the **Required approver** area, specify whether all the approvers must approve the task, or a single approver is sufficient.
7. Click **Save**.
   The task is inserted into the deployment plan.

Results

When the task runs, email notifications are sent to the selected approvers. The deployment plan cannot progress until the task is approved or skipped. Approval is granted by completing the task in the deployment plan.

Note: For information on pipeline notifications, see this page on page 3149.

Approving wait for approval task

You can approve the wait for approval task using the received email notifications.

About this task

Designated approval user receives the email notification for approving the wait for approval tasks. The email notification contains the task information for which the wait for approval task needs to be approved.

You can click **Approve** or **Reject** for approving or rejecting the wait for approval task.

By default, designated users can approve the task or share the email notification to any user for approving. You can prevent the latter functionality by enabling the `authorized-approval` feature flag.

To activate this security feature, enter the feature name `authorized-approval` under `featureFlags` . After enabling `authorized-approval` feature flag , only designated users can approve or reject the wait for the approval task. To approve or reject, the user must login Measure. Not designated users are not authorized to approve or reject the wait for approval task using the email notification.

Using properties

A deployment plan can contain user-defined properties. Properties values can be defined at design- or run-time.

Tasks can reference properties defined in their parent deployment plan. In addition to the properties that you create, system properties are available to all plans.

Creating properties

Creating properties

About this task

You define properties with the **Deployment Plan** details page by clicking **Properties**. You can create a property before you use it, or you can create a property by first referencing it in a task, and then later defining its attributes. If you create a property by reference, it appears as text-type property on the **Properties** tab.

To create a property, complete the following steps:

1. On the **Deployment Plan** details page, click **Properties**, and then click **Add**.
2. On the **Add property** window, in the **Name** field, enter the name. Property names cannot contain white spaces, `{}`, or `:`.
3. In the **Label** field, enter the label that appears in the user interface.
4. In the **Type** list, select the property type.
   The available types are described in this list:
   - `Text`
   - `Textarea`
   - `Password`
   - `Select`
   - `Boolean`
   - `Date and time`. Values are replaced by a string with the following format `day, month, year, time`. For example, `Thursday, January 1st 1970, 12:00 am UTC`.

     Note: When a date and time property is used in a ServiceNow® task, the value is replaced with the date and time format expected by ServiceNow®.

5. In the **Value** field, you can enter an initial value for the property.
6. In the **Default Value** field, enter a value for the property.
   This value is used unless the user sets the value. You can leave this field blank.
7. If you want users to supply a value for the property when they create a release, check **Prompt for this property at release creation at the specified sequence position**.
8. In the **Display sequence position** list, select a position for the property.
   This selected value affects the property's position on the **Properties** tab
9. Click **Save**.
   Result
   The property is displayed on the deployment plan **Properties** page.

What to do next

After the release is created, you can add deployment plans, events, and tags to it.

Using properties

You can use properties in deployment plans, REST API endpoints, and external systems, such as ServiceNow®.

Property examples

Use the following syntax to reference a property: `` `${propertyName}` ``. To escape the syntax pattern, use two dollar-sign symbols, `$${...}`. You set property values with the deployment plan's **Properties** page, REST API endpoints, or external systems, such as ServiceNow®.

The following table describes how to properties with task types.

Task type	Usage
ServiceNow	You can use the ServiceNow on page 1863 **Output property** field in a create change request action to store the change request ID in a property, for example, `'service_now_prod_ticket_id'`. Then, with another task, update the change request by referencing the property in the **System ID** field like this, `'${service_now_prod_ticket_id}'`.
Email	You can reference a system property in the email task on page 1856 **Subject** field, for example, `'${sys:release.name}' is complete!`.
Delayed	You can reference a delay task on page 1856 property in the **Delay property** field, for example, `'${prodTarget}'`. In this example, the task delays until the value in the `'${prodTarget}'` property is reached.

System properties

System properties enable you to access information about the parent release of a deployment plan. System properties can be referenced by any property-enabled task that is part of a release.

The following table contains the available system properties:

Table 673.

Property	Description
`${sys:release.name}`	The value in the release's **Name** field.
`${sys:release.description}`	Contains the content of the release's **Description** field.
`${sys:release.start}`	Release's **Start time**.
`$${sys:release.end}`	Contains the content of the release's **End time** field.

In the **Email message** field of an email-type task, you can reference system properties like this example:

```
Deployment for release `${sys:release.name}` - `${sys:release.description}` is complete.
```

You can reference a system property in a ServiceNow task's **Short description** field like this example:

`Staging deployment `${sys:release.name}``.

Extending Product Functions

Learn how to extend the function of Velocity Measure

Measure is designed to be easily extended. You can enhance existing functions or add entirely new ones by configuring plugin integrations. Plugins are software add-ons that extend Measure functionality by integrating with external tools. In general, each plugin manages one external application. The HCL DevOps Deploy (Deploy) plugin, for example, enables you to run Deploy applications.

If you cannot find a plugin for your environment, you can create plugins by using the plugin software development kit (SDK) on page 1884.

Measure supports several plugin types:

- Value stream plugins are supported by default. To create an integration with these plugins, you simply configure an integration in the value stream JSON file.
- Quality data plugins integrate test and metrics data into reports and value streams on page 1893. To create an integration with these plugins, you use external clients to post data to Measure API endpoints.
- Dedicated plugins provide external data to value streams, pipelines, and releases. Plugins of this type include: Deploy on page 1885, and Jenkins on page 1886. Use the Integrations page to configure integrations for these plugins.
- Task-based integrations provide external data to deployment plans. Use ServiceNow tasks to manage ServiceNow change requests on page 1887.

Introducing plugins

Extend Measure by configuring plugin integrations to external tools.

Measure uses a containerized microservices architecture. This means that plugins are not run directly from Measure but from containerized instances managed by a containerization platform. Runtime instances are created from images on the Docker Hub™ repository. Measure retrieves images from this repository and creates instances as needed.

For Kubernetes-based installations such as OpenShift™, Measure uses Kubernetes™ as its containerization platform. An Argo Workflow Engine manages plugin workflow. A Kubernetes pod starts when a plugin task is requested and sends the results to Measure. When complete, the container containing the plugin ends.

Plugins are categorized by data collection and communication methods. Generally, plugins are designed to use one of the following communication methods.

- **Webhook**. These plugins use webhooks to communicate with a defined Measure API endpoint. The webhook is used to trigger data collection events. Examples include the AppScan™, and SonarQube plugins.
- **Poller**. These plugins are based on an event defined by the plugin. Queries are performed to determine when to send and update data from the external service. Examples include the GitHub™, and Rally plugins.
- **Parser**. These plugins integrate functions to parse a specific file type and create a metric document that Measure can display with other value stream management and portfolio views. Examples include the JUnit, and OneTest plugins.

Available plugins are stored at HCL plugin database.

If you cannot find a plugin for your environment, you can create plugins by using the plugin software development kit (SDK) on page 1884.

If a metrics plugin is not available for your tool, you can upload custom metrics using Measure API endpoints.

To use a plugin, you configure an integration. "Integration" refers to a user-configured instance. You might use the GitHub plugin to configure an integration with the Service A repository, and then configure another integration with your Service B repository. Although both integrations use the GitHub plugin, each integration provides a unique set of data to Measure. You manage each integration separately.

Some integrations are termed "native integrations," and are not technically plugin derived. Native integrations are used with deployment plans by defining tasks of a specific type on page 1885. You can use DevOps Deploy data with your deployments and pipelines, for example, by defining DevOps Deploy-type tasks.

Some plugins might have a corresponding plugin in the external tool. To integrate Jenkins, for example, you install the " Measure" plugin into Jenkins™ using the Jenkins plugin manager. Then you configure a corresponding Jenkins integration in Measures. The two integrations operate in tandem.

Preventing plugins installs in unsupported server versions

Plugin versions incompatible with Measure are prevented from installing.

About this task

Based on the your installed version of Measure, plugins not compatible with that version are prevented from installing in the product. If the installed version of Measure is equal or greater than the product version that the plugin supports, the installation of the plugin is possible.

Notifications for incompatible plugins versions prevented from installation are displayed in each of the following three scenarios:

Scenario 1: Installing plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Plugins** tab.

3. Locate the required plugin in the list and click **Install**.
4. The error **Plugin <name> is only supported on** Velocity **versions equal to or greater than x.x.x** is displayed on the right side of the **Status** field for that plugin.

Scenario 2: Loading plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Plugins** tab.
3. Click **Load plugin**.
4. In the **Load a custom plugin** window, click in the **Plugin Image** field and enter the required plugin.
5. Click **Submit**.
6. The error **Plugin <name> is only supported on** Velocity **versions equal to or greater than x.x.x** is displayed in the **Load a custom plugin** window.

Scenario 3: Upgrading plugin

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click the **Integrations** tab.
3. Locate the required plugin and then click on the overflow menu and select **Upgrade**.
4. In the **Status** field for the plugin, **Upgrade failed** is displayed.

Creating plugin integrations

Defining integration allows you to communicate with external tools.

Before you can create an integration, ensure you have the user credentials and connection information required by the external tool, such as URLs, and API endpoints. To create an integration with HCL DevOps Deploy (Deploy), for example, you need a user token generated by Deploy, and the URL where the server is located. Ensure that you have all the necessary connection information before starting.

Credentials and other connection properties vary among individual plugins. You can find property descriptions and use cases for all plugins on the product website.

A plugin is a software add-on designed to communicate with external services and applications. Each plugin defines an expected record type and communication method. Communication can be uni-directional or bi-directional. To use a plugin, you must install and configure an integration.

To view the plugin in Measure, on the **Home** page, click **Settings > Integrations**.

The **Integrations** page has three tabs:

1. Integrations on page 1877
2. Installed Plugins on page 1877
3. Available Plugins on page 1878

Integrations

The **Integrations** tab lists all plugins that are configured for integration. Click the right-angle bracket to view the details of the configured plugin. All integrations are listed regardless of how they are created.

You can use search to find configured plugin integrations. The search query finds matches in the **Name** and **Type** fields. On the **Integrations** tab, you can sort by the **Name**, **Status**, **Type**, and **Last sync** fields in ascending or descending order by clicking a table header.

Click **Show Archived** to see the archived plugin integrations. The following table details the fields on the **Integrations** tab:

Field	Description
Name	The name of the plugin. Click the right-angle bracket to view details of the plugin integration. Click to view plugin documentation.
Status	The working status of the configured plugin integration. Possible values are **Online** and **Failed**. The **Online** status is displayed for working plugin integrations. The **Failed** status is displayed for plugin integrations that are not working. Disrupted communications or inaccurate integration configurations can cause the integration to fail.
Type	The type of the plugin.
Last sync	The last plugin synchronization time.
Disable/Enable	Set to disable or enable the plugin integration.
	Click to **Edit**, **Upgrade/Downgrade**, **View logs**, and **Archive/Delete** plugin integrations.

Installed Plugins

The **Installed Plugins** tab displays all plugins that are installed by default with the Measure installation. The installed plugins are ready to configure for integration.

You can search for installed plugins. The search query finds the matches in the **Name** field. On the **Installed Plugins** tab, you can sort the **Name** field in ascending or descending order by clicking the header.

The following table details the fields on the **Installed Plugins** tab:

Field	Description
Name	The name of the plugin. Click to view all installed versions of the plugin. Click to view plugin documentation.
Version	The version of the installed plugin.
Image	The image of the plugin.
Release Date	The release date of the installed plugin.
Actions	Click **Add integration** and provide details to configure the integration. All the integrations are enabled by default. To create a disabled plugin integration perform the following the steps: • In the **Add integration** window, click **Show hidden properties**, and then clear **Enabled** to create a disabled plugin integration. Click and select **Delete** to delete the installed plugin.

The latest version for Parser plugins are installed with the **Non-Configurable** status.

Available Plugins

The **Available Plugins** tab displays all supported plugins for Measure.

You can search for the supported plugins. The search query finds matches in the **Name** field. On the **Available Plugins** tab, you can sort the **Name** field in ascending or descending order by clicking on the header.

The following table details the fields on the **Available Plugins** tab:

Field	Description
Name	The name of the plugin. Click to view all versions of the plugin. Click to view plugin documentation.
Version	The version of the available plugin.
Image	The image of the plugin.
Release Date	The release date of the available plugin.

Field	Description
Actions	Click **Install** to install the required version of the plugin.

Advanced usage

You can configure integrations for some plugin types by adding an integration definition to a value stream JSON file on page 3078. Using a text editor, define an integration object in the `integrations` array of the `value_stream_name-vsm.json` file. The following code example illustrates a Jira integration.

```
{
     "_id": "velocity-generated-id",
     "type": "ucv-ext-jira",
     "tenant_id": "velocity-generated-id",
     "name": "my-JIRA",
     "disabled": false,
     "properties": {
       "baseUrl": "http://my-jira-url",
       "username": "admin",
       "password": "****",
       "jiraProjects": [
         "My-Project"
       ]
     }
   },
```

Integrations created by the value stream method are displayed on the **Integrations** page along with integrations created by the other methods.

Additional Measure product features requiring you to perform plugin installation before use include the following:

1. Handlebars Reporter
2. Bottleneck detection
3. Parser

The integration is listed on the **Integrations** page. The **Integrations** page is where you manage integrations. on page 1881

Integrations start providing data when successfully configured. For some integration types, such as quality-data types on page 3165, you can start using their data without additional configuration. For example, you can create dashboard charts that contain quality data when the integration is added. For example, JUnit is a quality-type plugin.

Other integration types require additional configuration before you can start using the associated data. Native integrations require that tasks are added to deployment plans. on page 1885 Value stream integrations, such as GitHub™, require a reference in the value stream JSON file. If you define an integration on the **Plugins** tab, add a reference to the integration name in the JSON file. If you define an integration directly in a JSON file described in Step 3, no additional configuration is required.

Github plugin integration example

Github plugin integration example

About this task

To configure the Github plugin integration, complete the following steps:

1. In the **Integration Name** field, enter a name for the integration, such as "Git tutorial."
   Such as GitHub tutorial. Later, we use this name to associate the integration to our value stream.
2. In the **Url** field, enter the URL for the GitHub project that you configured earlier .
   The URL is similar to this example, `https://github.com/myGitHubID/myGitHubProject`.
3. In the **Name** field, enter the name of the GitHub repository.
   Using the example URL from the preceding step, the name is `myGitHubProject`.
4. In the **Owner** field, enter the GitHub account that owns the repository.
   Using the example URL, the owner is `myGitHubID`.
5. In the **Token** field, enter your Github personal access token to authenticate with the Github repository.
   In GitHub, to generate a personal access token, go to **Settings**>**Developer settings**>**Personal access tokens** then click **Generate new token** and select the scope **repo** which allows to access repositories.
6. In the **API URL** field, enter the GitHub API URL.
   For enterprise Github account, use GitHub API URL `https://example.com/api/v3`.
   For public Github account, use GitHub API URL `https://api.github.com`.
7. Select the **Show Hidden Properties** check box.
   Result
   The hidden fields are displayed.
8. Enter the custom time for the plugin job in the **Plugin Job Timeout** field.

   Note: The default time is 1h, you can specify the maximum time a plugin job should be allowed to run before being automatically canceled in the following format:
   - 30m for 30 minutes
   - 1h for one hour
   - 1d for one day

9. **Optional:** Select the **Interval** time to set the frequency to run the schedule event.

   Note: If you do not want to change the interval time of the schedule event while creating the integration, the default sync intervals defined in the plugin are applied.

10. Click **Add**.

Results

The integration is listed on the **Integrations** page. If the integration is successful, the **Status** field displays `Online`. If the status is not `Online`, use the **View log** option to troubleshoot the integration. You can increase the logging level in the integration configuration if you need more troubleshooting information.

Managing integrations

You can manage the existing configured integrations.

About this task

After an integration is successfully configured, it periodically communicates with the external tool to synchronize the data flow.

The default communication interval when scheduled event integrations run can be configured by the `PLUGIN_INTEGRATION_RUN_INTERVAL` environment variable on the reporting-consumer service to a valid integer for the minutes between each run.

To manage an integration, perform the following steps:

1. On the Measure **Home** page, click **Settings > Integrations**.
   Result

   The **Integrations** page lists all configured integrations. All integrations are listed regardless of how they are created. You can use search functionality for searching the integration in the **Integrations** tab. The search query finds the matches in **Name** and **Type** fields. On the **Integrations** tab, you can sort the **Name**, **Status**, **Type**, and **Last sync** fields in ascending or descending order by clicking on the required table header field.
2. **Optional:** To modify an integration definition, click overflow menu ⋮ **> Edit**, and then modify the integration definition properties.
3. **Optional:** To view the integration log file, click overflow menu ⋮ **> View logs**.
   This action displays the integration's last execution log.
4. **Optional:** To upgrade or downgrade the plugin used by the integration, click overflow menu ⋮ **> Upgrade/ Downgrade**.
5. **Optional:** To sync with the external tool, click overflow menu ⋮ **> Resync**.
   This action attempts to communicate with the external tool immediately. You might do this when you want to run tests before the next communication interval. You can also select the time line from when you want to resync the data from the external tool.

   Note:

Not all integration types support this action. All scheduled event plugins such as Jira, GitHub, GitLab, Azure DevOps, and HCL DevOps Deploy are supported with the resync functionality.

6. **Optional:** To archive an integration, click overflow menu **> Archive/Delete**.

   Note: Select the **Delete the integration data** checkbox to delete the integration data.

7. **Optional:** To disable or enable an integration, click the **Disable/Enable** field of the integration.
   Result
   Communication with the external tool stops until re-enabled. You might do this if you want to stop data delivery during testing.
8. **Optional:** To disable or enable multiple integrations, select the required integrations and then **Select Actions** appears. Click the drop-down list of **Select Actions** and select **Disable** or **Enable**.

Defining an initial sync date for plugins

For scheduled events plugins, you can specify an initial sync date.

About this task

For scheduled events plugins, you can specify an initial sync date by performing the following steps:

1. On the **Settings** page, click **Integrations**.
2. In the **Integrations** page, click **Plugins** tab.
3. Locate the required plugin and then click **Add integration**.
4. In the **Add Integration** window, click the **Show hidden properties** check box.
5. Click **Initial Sync Date** field to specify the date to pull data for initial run.
6. Fill the remaining required fields in the **Add Integration** window.
7. Click **Add**.

Note: If the plugin does not support the sync feature, the **Initial Sync Date** field is not displayed when you click the **Show hidden properties** check box in the **Add Integration** window.

Archiving integrations

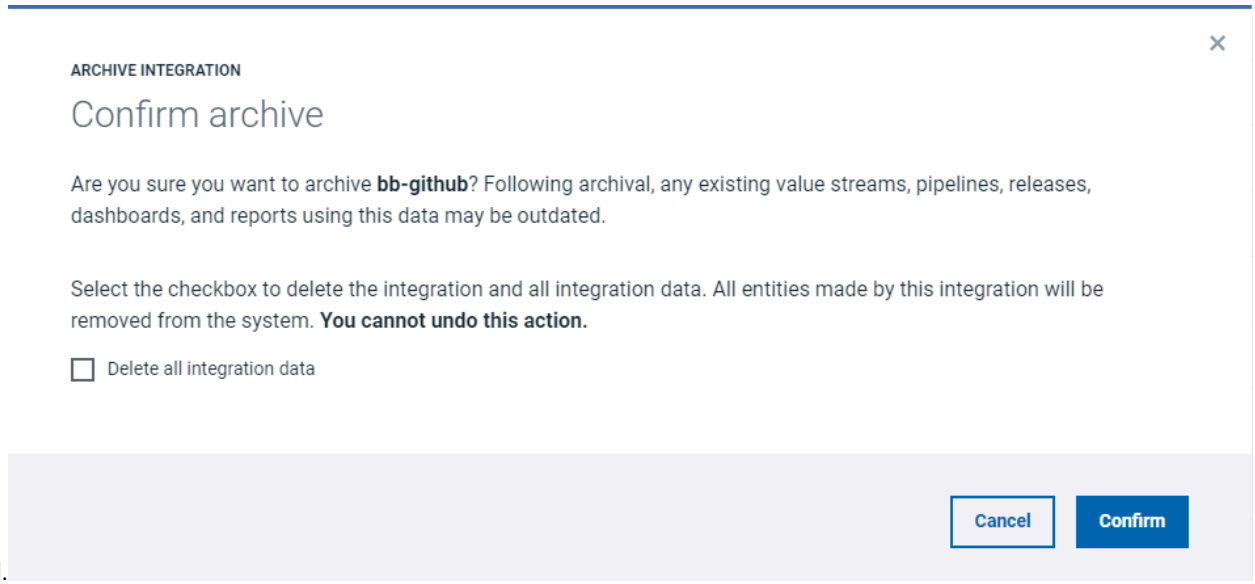
Archive the no longer needed integrations.

About this task

This topic describes the procedure for archiving integrations.

To archive integration, complete the following steps:

1. On the **Home** page, click **Settings > Integrations > Configured**.
   Result
2. Select **Archive/Delete** from the overflow menu (⋮) of the plugin integration which you want to archive.
3. The archive confirmation modal window is displayed.



4. Select **Delete all integration data** checkbox to delete all integration data and click **Confirm**.
   You can view all archived integrations by clicking **Show Archived**.

Note: You can restore the archived integrations by clicking the overflow menu and select the **Restore**.

Upgrading and downgrading integrations

You can upgrade or downgrade the integration versions based on the plugin's compatibility with Measure.

Before you begin

You must have installed the required plugin. See Creating plugin integrations on page 1876.

1. On the **Home** page, click **Settings > Integrations**.
   The **Plugin and Integrations** page is displayed.
2. Click **Integrations**.
3. Select the toggle button under the **Disable/Enable** field to disable the plugin integration for which you want to upgrade or downgrade the version.
   You can avoid a partial data synchronization issue by disabling the integration before the upgrade.
4. Select **Upgrade/Downgrade** from the overflow menu (⋮) .

Note: The plugin version must be compatible with the Velocity version. For more details about the compatibility matrix, see the specific plugin documentation.

5. Select the version from the drop-down list.
6. Click **Upgrade**.

Note: If you select a lower version of the plugin from the drop-down list, the integration downgrades to the lower version.

7. Select the toggle button under the **Disable/Enable** field to enable the plugin integration.

Results

You have upgraded or downgraded the integrations.

Creating plugins with the plugins SDK

You can create your own plugins and install them in Measure. After installing custom plugins, you can integrate them in your releases, reports, and value streams.

Measure provides a SDK that contains the tools, including local dependencies and wrappers, that you need to create your own plugins. The plugin SDK provides a sample plugin that you can use to get started, and JavaScript templates that you can customize for your own plugins.

To create a plugin, your development environment must include the following items:

- Node.js version 12 or later
- NPM version 6 or later
- Docker
- Measure version 2.0 or later

To get started with the plugin SDK, complete the following steps:

1. Download the plugin SDK. On the Measure **Plugins** tab, click **Download plugin sample**. After the download is finished, extract the compressed file.
2. Build the sample plugin. In the `ucv-ext-sdk-template` folder, run the following commands. Additional instructions are provided in the SDK `Readme.md` file.

```
 npm install
npm run dist-runnable
docker build . -t name:tag
```

The `name` value can be any value that you want. The `tag` value must represent the latest image version, or some other valid semantic version. For example, `docker build . -t testplugin:0.1`.

3. Upload the sample plugin. On the Velocity **Plugins** tab, click **Load plugin**, and then select the Docker image that contains your plugin. To upload the image from the previous step, you specify `testplugin:0.1`.
4. Create an integration by using the sample plugin. On the **Plugins** tab, click **Add integration**.

Plugins are categorized by data collection and communication methods. Generally, plugins are designed to use one of the following communication methods.

- **Webhook**. These plugins use webhooks to communicate with a defined Measure API endpoint. The webhook is used to trigger data collection events. Examples include the AppScan™, and SonarCube plugins.
- **Poller**. These plugins are based on an event defined by the plugin. Queries are performed to determine when to send and update data from the external service. Examples include the GitHub™, and Rally plugins.
- **Parser**. These plugins integrate functions to parse a specific file type and create a metric document that Measure can display with other value stream management and portfolio views. Examples include the JUnit, and OneTest plugins.

The plugin SDK provides JavaScript templates for each type. For example, the template `ucv-ext-sdk-templates/src/endpoints/SampleEdnpoint.js` defines the properties that you need to create an endpoint-type plugin.

Managing native integrations

Native integrations add external functionality to releases, deployment plans, and pipelines.

Native integrations are available for the following applications or services:

- IBM DevOps Deploy
- Jenkins™
- ServiceNow™
- Ansible™

Configuring DevOps Deploy integrations

Use DevOps Deploy applications in your deployments and pipelines.

Before you begin

- Obtain a token from your DevOps Deploy server. When you create the DevOps Deploy token, specify **admin** as the user.

  This task requires that you are an Measure administrator.
- You must install the DevOps Deploy plugin, see Github plugin integration example on page 1880.

Note:

You must not integrate the same instance of Deploy using UrbanCode Deploy (Legacy) and Deploy (ucv-ext-ucd) plug-in in Measure. Integrating the same Deploy instance using UrbanCode Deploy (Legacy) and Deploy plug-in in Velocity can result in data corruption.

About this task

After you configure an integration, create tasks to run DevOps Deploy applications during your deployments on page 1868. You can also add applications to your pipeline stages and run them that way.

1. Click **Settings > Integrations**.
   The **Plugin and Integrations** page is displayed.
2. Click **Installed Plugins**, and click **Add Integration** for **DevOps Deploy**.
3. In the **Add DevOps Deploy Integration** window, enter a name for the integration, and in the **URL** field, specify the URL. The format is `HTTPS://hostname:port`. For example, `HTTPS://sampleUCD:8443`.

   Note: If you are running DevOps Deploy locally, you can substitute `HTTPS://host.docker.internal:port` in place of `localhost`.

4. In the **Access Token** field, paste the token from DevOps Deploy.
5. Click **Add**.

   Note: The initial synchronization includes four months of data. Depending on the amount of data, the synchronization process can take some time.

What to do next

Synchronization occurs every fifteen minutes but you can synchronize any time by clicking **Actions > Resync** on the **Integrations** page. To prevent synchronization, select the toggle button under **Disable/Enable** field on the **Integrations** page.

Configuring Jenkins integrations

Manage Jenkins™ jobs with your deployments and pipelines.

Before you begin

Obtain the Measure plugin and install it in your Jenkins instance. On the Jenkins Plugin page search for `velocity`. Complete the integration by pasting the Measure credentials into Jenkins.

Note: Ensure the following requirements are met prior to installation of the plugin.

- You must have admin privileges in Jenkins.
- Upgrade the Jenkins plugin version to 2.1.0 in order to upgrade the Velocity version to 2.1.0 and later. Velocity version 2.0.6 will be the last version to support the previous Jenkins plugin version of 2.0.6 and earlier.

Note:

You must not integrate the same instance of Jenkins using Jenkins (Legacy) and Jenkins (ucv-ext-jenkins) plug-in in Measure. Integrating the same Jenkins instance using Jenkins (Legacy) and Jenkins plug-in in Velocity can result in data corruption.

About this task

This configuration makes Jenkins jobs available to pipelines and deployment plans. You can run Jenkins jobs with Measure and use the output in later tasks. After you configure an integration, add Jenkins tasks to deployment plans on page 1858 and pipeline stages.

1. Click **Settings > Integrations > Plugins**.
   A list of defined integrations with current information about each integration is displayed in a table.
2. Click **Add Integration** for **Jenkins**.
3. In the **Add Jenkins Integration** window, in the **Name** field, enter a name for the integration and click **Create**.
4. In the **Integration ID** field, click to copy the ID and then paste it into the corresponding field in your Jenkins instance, **Manage Jenkins > Configure System > DevOps Velocity**.
5. In the **Integration token** field, click to copy the token and then paste it into the corresponding field in Jenkins.
6. Click **Save**.
   Depending on the amount of data,the initial integration can take some time.
   Result
   Synchronization occurs every minute. To prevent synchronization, click the **Disable/Enable** field on the **Integrations** page.

What to do next

After the initial integration, you can add Jenkins tasks to deployment plans and select any of the integrated jobs. Similarly, you can add Jenkins jobs to pipeline stages.

Integrating with ServiceNow

Create and manage ServiceNow™ change requests with Measure. Update change requests with Measure tasks and then react to status changes. Control deployment progress with change request updates.

ServiceNow integrations are managed on the task level. You configure an integration when you add a ServiceNow task to a deployment plan on page 1859. After an integration is configured, other ServiceNow tasks can use the same instance.

Migrating integrations

Migrate the legacy plug-in integrations to external plug-in integrations.

You can migrate the following (Legacy) plug-in integration to external plug-in integrations:

Migrating integration of Jenkins (Legacy) to Jenkins

Migrating integration of Jenkins (Legacy) to Jenkins.

Before you begin

You must have completed the following tasks:

- Back up the database, see instructions in this page.
- Ensure that you have added the version parameter to all applicable jobs in Jenkins server. The Jenkins plugin search for jobs with version parameter as reference.

About this task

To migrate the integrations of Jenkins (Legacy) to Jenkins, complete the following steps:

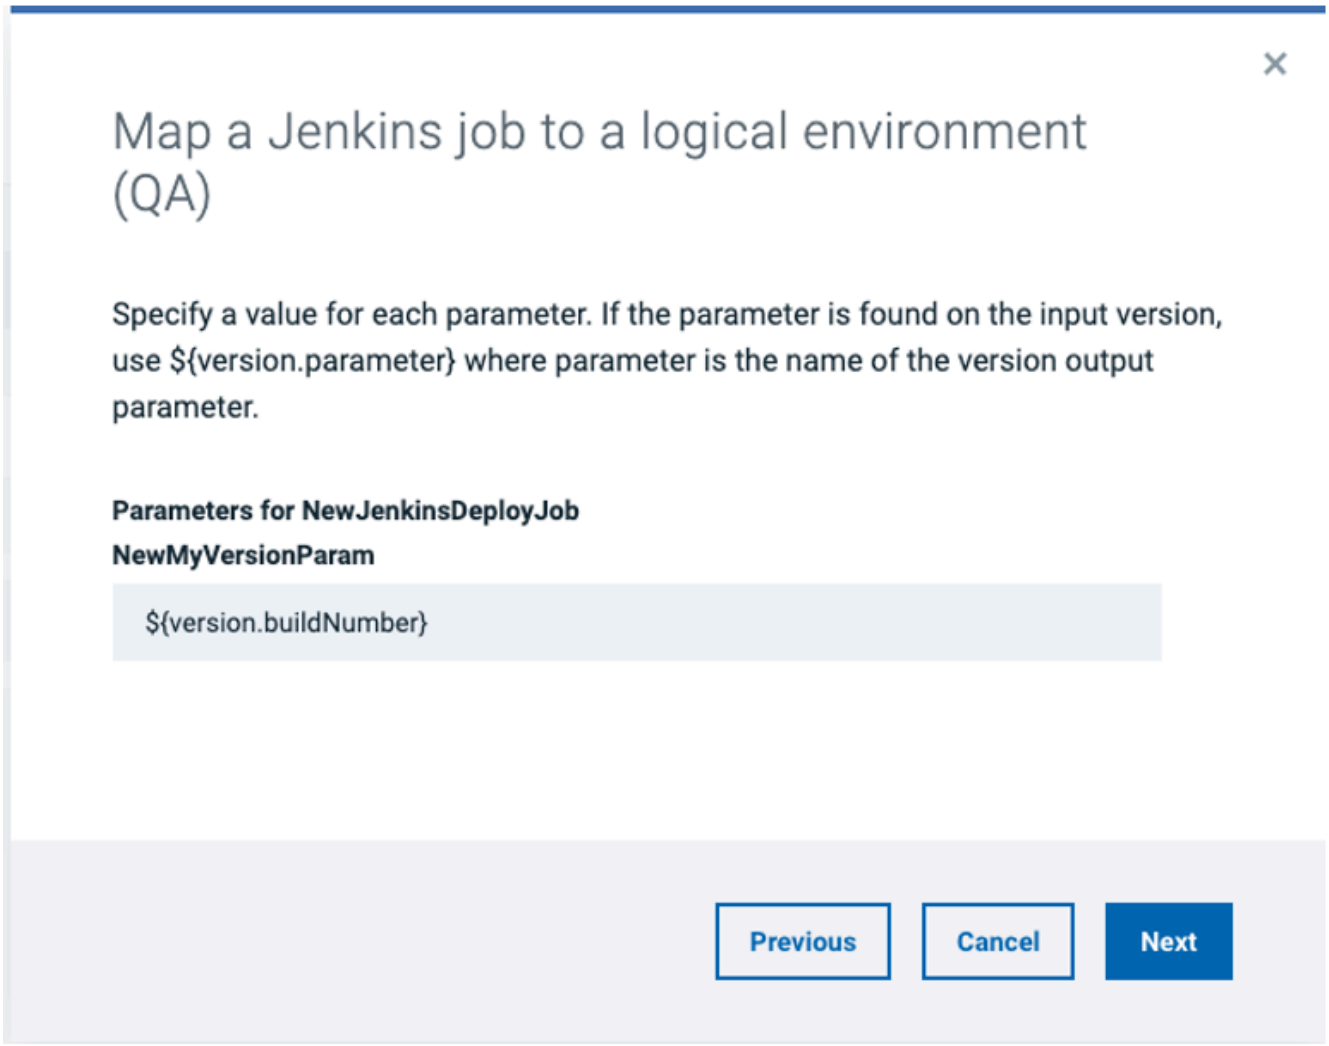
1. From the Measure page, click **Settings > Integrations > Configured**.
   A list of all configured integrations are displayed.
2. Click overflow menu for configured **Jenkins (Legacy)** plug-in and then click **Migrate**.
   The **MIGRATE JENKINS INTEGRATION** window is displayed. You can view the road-map of migration process. Before you begin the migration process, ensure that you have taken the backup of database.
3. On the **MIGRATE JENKINS INTEGRATION** window, click **Continue**.
   The **Add Jenkins Integration** window is displayed.
4. On the **Add Jenkins Integration** window, enter the value for all required fields to create new integration of **Jenkins** and then click **Add** to add the integration details.
   The migration process starts automatically and it reaches to **complete** step of migration process.
5. Click **Close** to close **Migrate Jenkins Integration window**.
   You have successfully migrated integration of **Jenkins (Legacy)** to **Jenkins**.

Results

You can see the **Jenkins** integration data in Velocity.

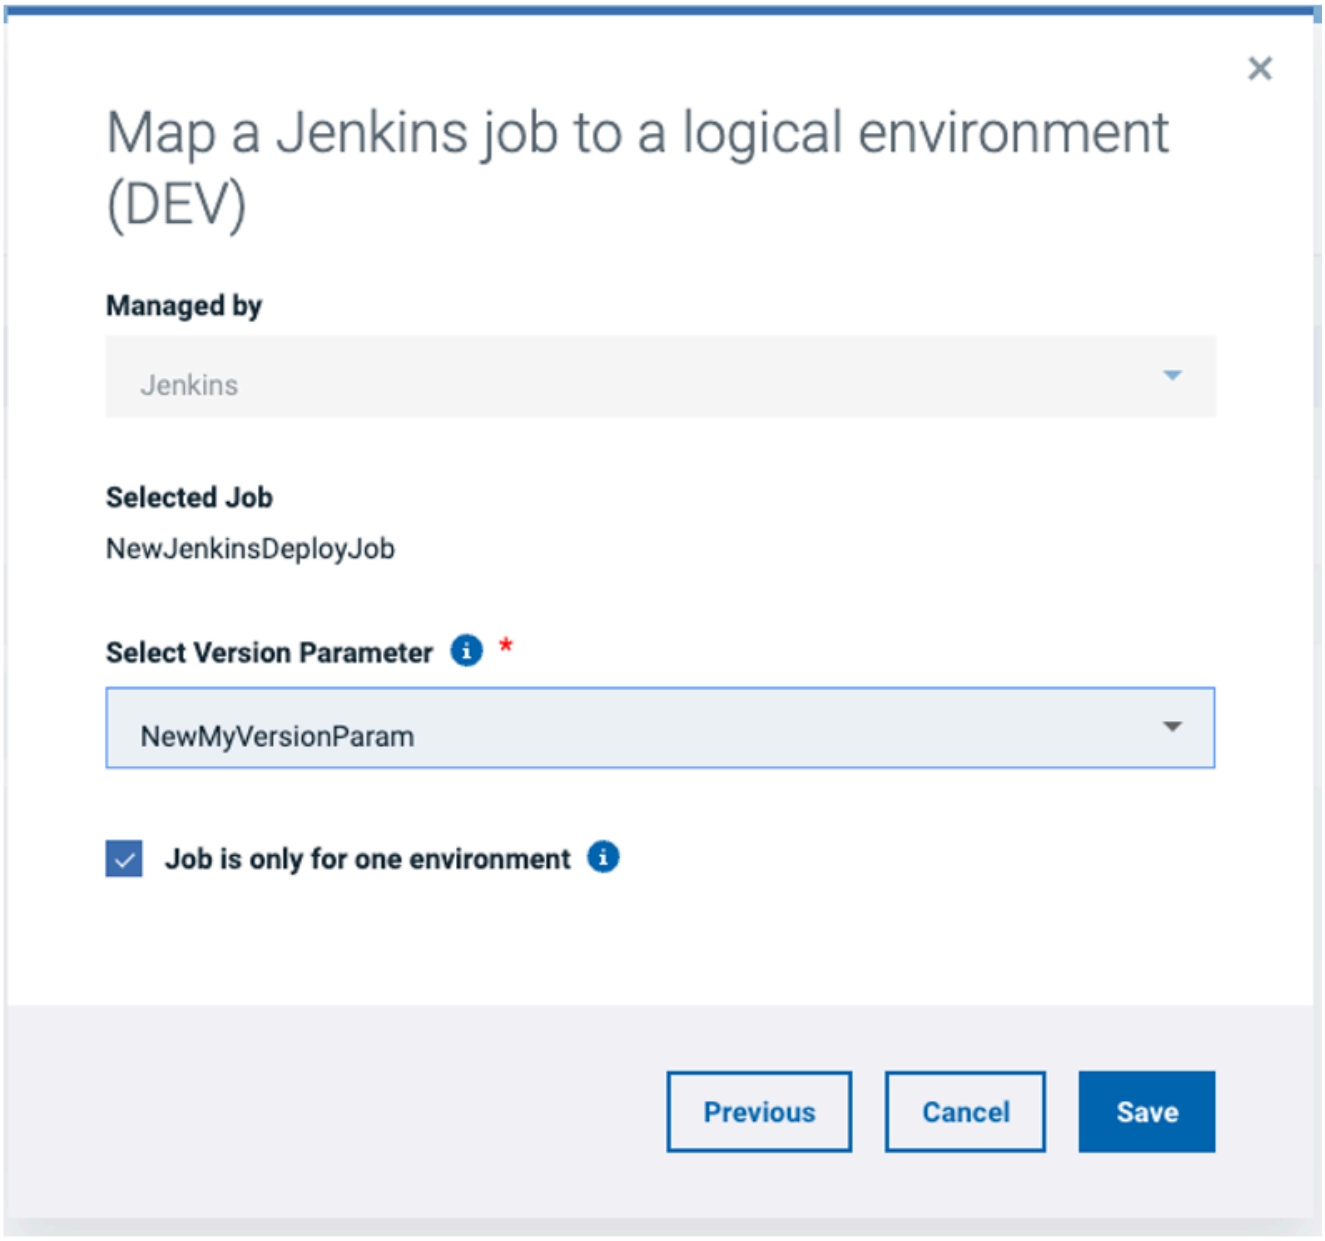
What to do next

Go to pipeline of any value stream and add Jenkins application. While configuring the Jenkins job to logical environment ensure that you use `${version.buildNumber}` parameter.



Map a Jenkins job to a logical environment (QA)
Specify a value for each parameter. If the parameter is found on the input version, use ${version.parameter} where parameter is the name of the version output parameter.
Parameters for NewJenkinsDeployJob
NewMyVersionParam
${version.buildNumber}
Previous
Cancel
Next

Choose the required parameter in **Select Version Parameter**



field.

Migrating integration of UrbanCode Deploy (Legacy) to HCL DevOps Deploy (Deploy)

Migrating integration of UrbanCode Deploy (Legacy) to DevOps Deploy.

Before you begin

You must have completed the following tasks:

- Ensured that you have taken Back up the database, see instructions in this page.
- Ensured that there is no **Releases** with **UrbanCode Deploy (Legacy)** task is **In progress** or **Scheduled** for later.
- Ensured that there is no **UrbanCode Deploy (Legacy)** deployment is **In progress** or **Scheduled** for later.

About this task

To migrate the integrations of UrbanCode Deploy (Legacy) to DevOps Deploy, complete the following steps:

1. From the Measure page, click **Settings > Integrations > Configured**.
   A list of all configured integrations are displayed.
2. Click overflow menu for configured **UrbanCode Deploy (Legacy)** plug-in and then click **Migrate**.
   The **MIGRATE URBANCODE DEPLOY(HCL LAUNCH) INTEGRATION** window is displayed. You can view the stages of the migration process.
3. On the **MIGRATE URBANCODE DEPLOY(HCL LAUNCH) INTEGRATION** window, click **Continue**.
4. The **URBANCODE DEPLOY (Legacy)** integration is migrated to DevOps Deploy integration. The integration name is changed by appending **--migrated-EXT**.
   The migration process automatically installs latest available version of the DevOps Deploy plugin. If any version of DevOps Deploy plugin is already installed, the migration process uses that version of the plugin for migrating the integration.

Results

All **URBANCODE DEPLOY (Legacy)** task type changes to DevOps Deploy task in templates.

What to do next

You can schedule the deployment for DevOps Deploy applications by using the migrated DevOps Deploy integrations.

Uploading a build to a pipeline

builds/apiDriven

```
curl -k -X POST 'https://localhost/api/v1/builds/apiDriven' \
    -H 'Authorizat1on: UserAccessKey <User Access Key>' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":"<Version Name>",
        "application":{"externalId":"efecb73f-dclc-4d3d-b3bb-
        38339445e892"},
        "url":"<Build URL>",
        "revision":"<Commit SHA>"
    }'
```

Table 674. builds/apiDriven parameters

Parameter	Type	Required	Description
UserAccesKey	string	false	User access key
version	string	true	JSON object with either 'externalId' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})

Table 674. builds/apiDriven parameters (continued)

Parameter	Type	Required	Description
application	object	false	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
url	URL	false	URL link to build in external tool
revision	string	true	SHA of the commit linked to the build

Example

Example

```
curl -k -X POST 'https://localhost/api/v1/builds/apiDriven' \
    -H 'Authorizat1on: UserAccessKey 3b3ec6cc-1e37-4353-bc3a-46b493eed4e6' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":"1.0",
        "application":{"externalId":"b900ff5b-1fff-44ab-bcc6-9d39d5937026"},
        "url":"https://test.com",
        "revision":"12345678"
    }'
```

Uploading deployment status

deployments/apiDriven

```
curl -k -X POST 'https://localhost/api/v1/deployments/apiDriven' \
    -H 'Authorizat1on: UserAccessKey <User Access Key>' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":{"name":"<Version Name>",
        "application":{"externalId":"efecb73f-dclc-4d3d-b3bb-
        38339445e892"},
        "url":"<Deployment URL>",
        "environment":{"name":"DEV"}
    }'
```

Table 675. deployments/apiDriven parameters

Parameter	Type	Required	Description
UserAccesKey	string	false	User access key

Table 675. deployments/apiDriven parameters (continued)

Parameter	Type	Required	Description
version	object	true	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
application	object	true	JSON object with either 'externalid' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})
url	URL	false	URL link to build in external tool
environment	object	true	JSON object with either 'externalId' or 'name' (Examples: {"name": "apidrivenjenkinsjob"} or {"name": "application id in external tool"})

Example

Example

```
curl -k -X POST 'https://localhost/api/v1/deployments/apiDriven' \
    -H 'Authorization: UserAccessKey 324adfe9-cc97-43fa-81c6-e248ceeb726a' \
    -H 'Content-Type: application/json' \
    -d \
    '{
        "version":{"name":"1.0",
        "application":{"externalId":"f2262e67-6516-4597-92a6-cfe537abdd00"},
        "url":"http://example.com",
        "environment":{"name":"DEV"}
    }'
```

Getting started with GraphQL in Measure

You can use GraphQL Playground in explore and test APIs interactively before using them in real scenarios. This GraphQL playground provides a convenient environment to use queries and mutations, that helps you understand the available data and how to structure requests effectively.

GraphQL is a flexible and efficient query language for APIs that allows you to request exactly the data you need. Unlike traditional REST APIs that return fixed data structures, GraphQL helps you define the shape of the response, fetch related data in a single request, and interact with data using queries (to read data) and mutations (to create or update data).

With GraphQL in Measure, you can use queries to retrieve value stream data, such as work items, deployments, commits, and other DevOps artifacts, and use mutations to create or manage resources.

Setting up GraphQL with API endpoints

Before you begin, you must create a user access key. See Managing User access keys (UAKs) on page 1820.

Follow the steps to set up and authenticate the GraphQL Integrated Development Environment (IDE) in DevOps Velocity:

1. Navigate to the Velocity instance GraphQL interface using `https://my_velocity:port/graphiql`.
2. Click the Set Headers icon.
3. Enter **Authorization** in the **Header key** field.
4. Enter the user access key in the **Value** field.

After the authentication is complete, you can start using different GraphQL APIs to validate responses and refine your queries. The GraphQL Playground also provides built-in documentation for each query and mutation, allows you to easily explore available fields, input parameters, and response structures.

After testing, you can use these APIs in your applications or leverage them to create and manage resources in Measure for bulk operations or automation scenarios without using the UI.

Mutations

Mutations are used to create new data, update existing data, and delete existing data.

Here are a few examples of mutations that you can use in Velocity.

- Create a Value Stream

  A Value Stream represents the flow of work items through a pipeline. It helps you visualize how work items move from one stage to another across various tools in the pipeline. To create a new value stream, you can use the following GraphQL mutation:

  ```
  mutation {
    createValueStream(
      name: "string"
      description: "string"
      tenantId: "_____"
      team: { id: "string", name: "string" }
      workflow: "_____"
    )
  }
  ```

- Add an environment to a pipeline

  A pipeline defines the series of steps required for deploying software, while stages represent the different phases of the pipeline (for example, build, deploy, test). To add a new stage to a pipeline, you can use the following GraphQL mutation:

  ```
  mutation {
    addPipelineStages(
      pipelineId: "Pipeline_ID",
      stages: [{ name: "<Stage_name>", type: "<Stage_type>" }]
    ) {
      _id
      name
      type
      description
      planId
      triggers {
  ```

```
      _id
      name
    }
    gates {
      _id
      name
    }
    cf_space_id
    promoteTo
    latestAutopromotionStatus
    deploymentModes
    defaultDeploymentMode
    groupsAndUsers
    solutionVersionId
  }
}
```

- Add an application to a pipeline

  To add an application to a pipeline, you can use the following mutation:

```
mutation {
  addApplications(
    pipelineId: "_____"
    applications: [{ name: "string" }]
    processes: [{ name: "string" }]
    type: "string"
  ) {
    _id
    name
    tenant_id
    description
    stages {
      _id
      name
      type
      description
      planId
      triggers
      gates
      cf_space_id
      promoteTo
      latestAutopromotionStatus
      deploymentModes
      defaultDeploymentMode
      groupsAndUsers
      solutionVersionId
      solutionVersion
    }
    applications {
      _id
      name
      type
      description
      processes
      source
      inputJobId
      stages
      subApplications
```

```
      children
      level
      external_id
      selectedChildren
      versionRegEx
    }
    synchronize
    team {
      id
      name
      tenantId
    }
    created
    stats {
      leadTime
    }
  }
}
```

Queries

You can access detailed information from Measure by using GraphQL queries.

The following are some example queries that demonstrate how to retrieve various types of data.

- Get application data by using the application ID

  You can retrieve detailed information about a specific application by using its ID and the following query:

```
{
  applicationById(id: "<Application_ID>", tenantId: "<Tenant_ID>", loadChildren: true) {
    _id
    id
    external_id
    tenant_id
    integration_id
    name
    alphaNumericName
    active
    createdAdHoc
    json_data
    type
    version
    level
    childrenIds
    children {
      _id
      id
      external_id
      tenant_id
      integration_id
      name
      alphaNumericName
      active
      createdAdHoc
      json_data
      type
```

```
      version
      level
    }
  }
}
```

- Retrieve the application environment details by tenantID

  To retrieve all unique application environment details for a given tenantID, you can use the following query::

```
{
  applicationEnvironmentsByTenantId(tenantId: "TenantID") {
    _id
    id
    external_id
    tenant_id
    name
    app_id
    external_app_id
    active
    json_data
    type
    version
    inventory {
      external_version_id
      components
    }
  }
}
```

- Retrieve application environment name by tenantID

  To retrieve all unique application environment names for a given tenantID, you can use the following query:

```
{
  uniqueApplicationEnvironmentNamesByTenantId(tenantId: "_____") {
    name
  }
}
```

How to

The topics in this section describe how to work with Measure features. Tutorials and workbooks are available for users of all experience levels.

Creating reports

Use the **Home** page to create one of the following reports.

About this task

- Custom
- Delivery Transformation
- Recent Activity

- Team Performance
- Audit

1. From the **Home** page, click **Insights > Reports**.
2. Click to **Add report**.
3. On the **New report** page, in the **Type of report** field, select the type of report from the list.
4. Enter the name of the report in the **Report name** field.
5. Enter a report description in the **Description** field.
6. Select an icon for the report in the **Icon** field.
7. Click **Add**.
   After the report is created you can immediately run, edit, and share the report with other users.

Sharing reports

You can share reports with others in your organization and who are authenticated to Measure. By default, you see only the reports that you create.

About this task

When you share a report, the users you are sharing the report with are able to access the report from their Home page. Depending on the access level that you provide, they can modify the report or only view report data.

Note: The data users can view is restricted to data from the teams of which they are a member.

You can remove access at any time by clicking the delete icon next to the email address on the **Share Report** page.

1. From the **Insights > Reports** page, select the report that you want to share.
2. Click

to copy the URL link for sharing the report.
3. Share the URL of the report to required users.

   Note: The user must be authenticated for accessing the reports.

Glossary

This glossary provides terms and definitions for the Measure software and products.

The following cross-references are used in this glossary:

- *See* refers you from a non-preferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

A

activity

Activities include releases, events, and deployment plans that you develop, start, and complete with the product.

agent

A program that runs on a remote computer and communicates with the Measure server. Agents run processes on deployment target systems.

agent relay

A communication proxy for agents that are located behind a firewall or in another network location.

API

An interface that allows an application program that is written in a high-level language to use specific data or functions of the operating system or another program.

Application

One or more computer programs or software components that provide a function in direct support of a specific business process or processes. See also application server.

application environment

A user-defined collection of resources that hosts an application. These application environments refer to environments that are created to be in the product.

application process

A process that is associated with an application. Unlike a component or generic process, an application process is created from application-level steps. Typically, an application process invokes component processes, and orchestrates multi-component deployments. See also component process on page 1900, generic process on page 1901, process on page 1903.

artifact

A deployable item such as a file, image, database, configuration material, or anything else that is associated with a software project. By default, artifacts are stored in CodeStation repository.

authentication realm

An authentication realm manages users and determines user identity. It retrieves information from sources such as LDAP servers and Keystone identity services.

auto task

A task that starts automatically they are eligible to run. Examples of auto task types are HCL DevOps Deploy, Continuous Delivery pipeline, email, and Slack.

B

blackout

A setting that prevents deployments and snapshots from being scheduled. Blackouts solely affect the environment and application that they are applied to.

C

change

An artifact that represents a generalized notion of a development work product, such as a task, defect report, or enhancement request. See also initiative on page 1901.

component

A representation of deployable items and the user-defined processes that operate on them, usually by deploying them.

component process

A process defined for the deployment of components.

component version

See version on page 1904.

D

dashboard

A displayed collection of user-defined data filters and metric charts. Dashboards are used to analyze project data for their quality and efficiency.

dependent task

A task depends on another task to finish before it starts. The task that a dependent task waits for is called a prerequisite task. Dependent tasks cannot start until all its prerequisite tasks are resolved. Dependent tasks are used to ensure that tasks run in the specified order.

deployment

The activities used to deliver a software project to a deployment target. Typically, you run deployments for each stage of your release lifecycle, ending with the production stage when the software becomes generally available. The activities that are performed during a deployment, called tasks, are defined in deployment plans. You start a deployment by starting one of the plan's eligible tasks. You complete a deployment by resolving all the tasks in the deployment plan.

dots

A value stream unit of work, such as a pull request, build, or deployment. Units of work can be combined, such as commits and pull requests, which significantly enhances the data quality of value streams.

duration

The time a task takes to run. Duration is measured from the time a task starts until it is resolved. When you create some task types, you can estimate its expected duration. Duration is reported in minutes.

E

environment

A collection of resources that identify the components that can be deployed by the parent application and the agents that do the work.

events

Release-related activities that are applied to releases and tracked with a calendar. You can use events to organize your releases and other time-dependent activities, such as holidays and blackouts.

execution pattern

The order in which tasks in a deployment plan become eligible to run. By default, a plan's execution pattern is sequential. Sequential tasks run in order beginning with the first task in the plan. You can combine tasks into groups and assign the parallel execution pattern to the group. Parallel tasks can run in any order and run simultaneously.

G

gate

A requirement that must be met before an application can move on to the next stage.

generic process

Processes that are designed to run outside typical component or application processing. See also application process on page 1899, component process on page 1900, process on page 1903.

group

A logical container that serves as a mechanism to grant permissions to multiple users.

I

initative

An action to take for the change occurred.

insights

A set of related features such as metric data dashboards, reports, and the application portfolio.

integration

Regular communication between Measure and external products and services. Communication with integrated products can be bidirectional.

L

lifecycle

The phases in a release. A lifecycle is a template for the stages of work in a release.

lock

A means of preventing changes being made to a release.

logical environment

A collection of physical environments on page 1902.

M

manual task

A release related task that users must manually complete. See also auto task on page 1899.

metric data

Tools, such as charts and graphs that are applied to project data to assess project quality and progress.

metric definition

A JSON object that defines expected value types and chart default settings.

milestone

A significant event in a project or process that is used to determine progress toward goals.

P

particles

See dots on page 1900.

phase

An organizational segment within a value stream containing the stages, such as "Planning," or "Development,", that define process flow within that group.

physical environment

An actual deployable location, server, hardware, and so on.

pipeline

A sequence of stages that retrieve input and run applications and jobs, such as builds, tests, and deployments.

plugin

A separately installable software module that adds function to an existing program, application, or interface.

portfolio

A collection of application information in one location where you can analyze the data with metric charts and graphs.

process

In Measure, processes define automation activities, such as deploying components.

property

A variable that specifies a value that is provided during process deployment and is associated with a specific Measure object. An individual property's value can be accessed only by certain types of related objects, such as environments, processes, and components.

Q

quality

A user-defined attribute that serves as a gate for applications to enter phases.

R

release

The delivery of multiple applications through one or more phases of a lifecycle.

resource

A user-defined construct that is based on the architectural model of Measure. A resource represents a deployment target.

role

A job function that identifies the tasks that a user can perform and the resources to which a user has access. A user can be assigned one or more roles.

S

segment

A period of time in a deployment plan. Deployment plans can group tasks into segments to specify when tasks are run relative to each other.

snapshot

A collection of specific versions of components. Typically, a snapshot represents a set of component versions that are known to work together.

stage

In the value stream, a subset of a phase that contains data from integrated tools.

swim lane

A representation of value stream data in tabular form where the columns represent value stream stages, and the rows represent users.

T

tag

A label that you can apply to tasks or releases. When applied to tasks, tags can determine task applicability for a given deployment. When applied to releases, tags can be used to organize and filter releases.

task

Represents a business-meaningful activity that has starting and ending points and a measurable duration. Durations are used to estimate deployment times. You add tasks to deployment plans. When you run a deployment, you complete the tasks in the plan

task group

A combination of two or more tasks that are associated into a group. When you form a group, you define the group's execution pattern as sequential or parallel.

team

A team is a collection of users and groups.

token

A particular message or bit pattern that signifies permission or temporary control to transmit over a network.

U

user

A representation of an account on the server. Users can be members of teams and groups. User can be created in Velocity Measure server or import users from an external authentication realm, including an LDAP, Active Directory, or SSO provider.

V

value stream

A representation of the objects. The value stream provides a strategic window into your project workflow.

version

A representation of an Deploy application snapshot.

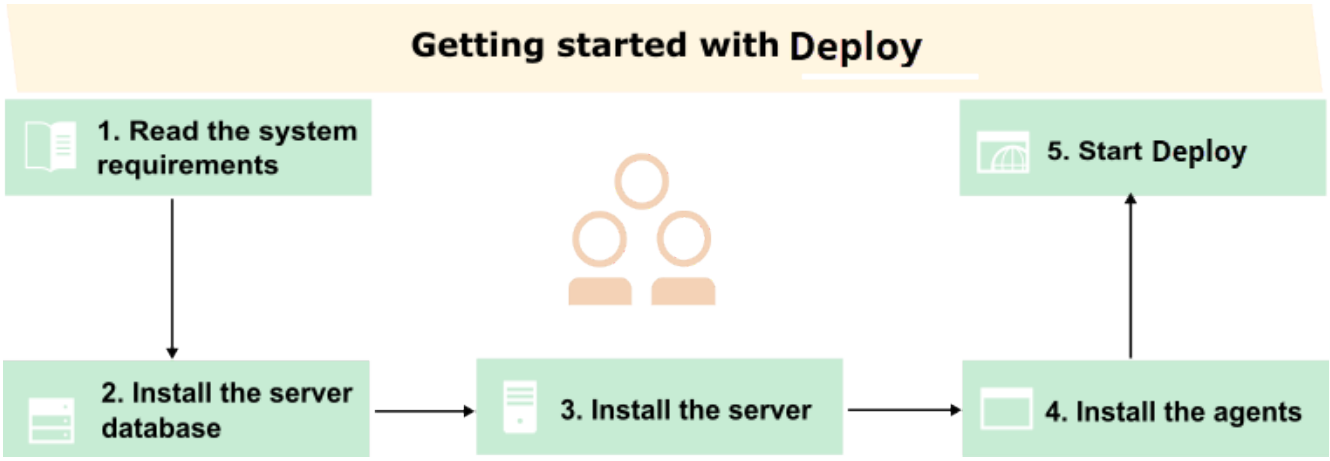
Deploy

Deploy standardizes and simplifies the rollout of software components across environments within the DevOps Loop. Its release automation tools improve deployment speed and reliability, providing visibility into multi-tiered deployments and orchestrating complex processes across environments and approval gates.

Getting Started

Quickly become productive with HCL DevOps Deploy (Deploy).

The following diagram outlines the steps that are required to get started with Deploy.



Read the system requirements

For supported platforms and requirements, see the System Requirements topic.

Install and start the server

To download the product, visit the HCLSoftware download portal website.

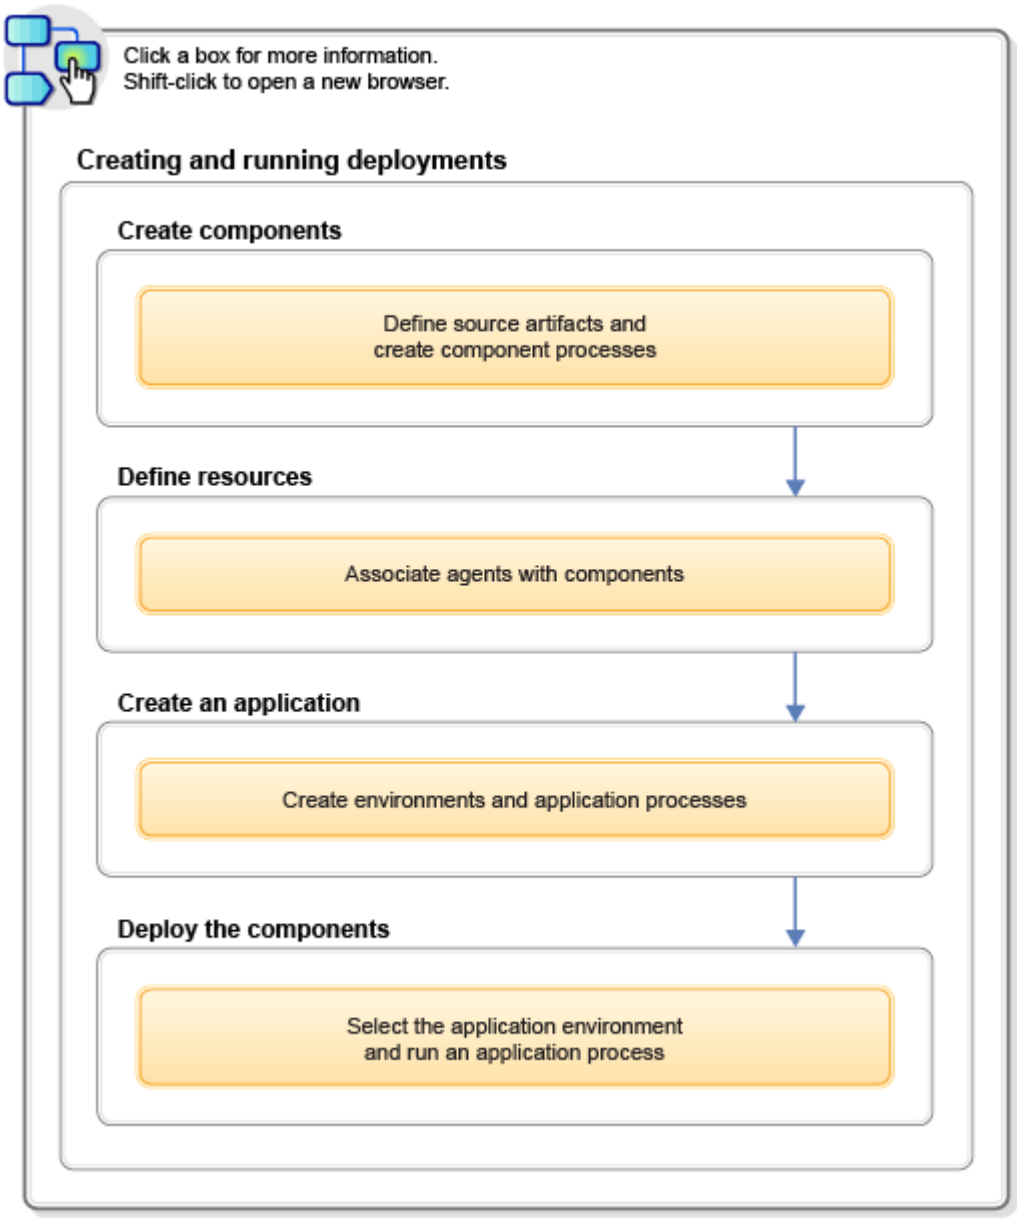
See the Installing topic for installation details.

For information on installing licenses, see Applying HCL licenses to agents on page 2115

Using Deploy

The following diagram outlines the minimum steps that are required to create and run a deployment. Each box describes a core activity and, taken together, they illustrate the product's primary function. The fastest way to become productive is to work through these steps and understand what each does and how each interrelates with the others.

From the **Welcome** page, you can work through a wizard that shows you the basic steps to deploying artifacts with Deploy. Click the **Welcome** tab, and then click **Let's creat an application**. The wizard guides you step-by-step and provides brief explanations of the entire process for creating a deployment. If you do not see the **Welcome** tab, click the help menu icon that is located in the upper-right corner of the window. Then, click **Welcome**. See Setting up the wizard for new users on page 2119 for configuration information.



1. Click this area for information about creating components. on page 2252
2. Click this area for information about creating resources. on page 2313
3. Click this area for information about creating applications. on page 2345
4. Click this area for information about running deployments. on page 2525

Overview of DevOps Deploy

Use HCL DevOps Deploy (Deploy) to standardize and simplify the process of deploying software components to each environment in your development cycle.

Deploy helps you meet the challenge of deploying software throughout your enterprise by providing tools that improve both deployment speed and reliability. The release automation tools in Deploy provide complete visibility into n-tiered

deployments. Use the tools to model processes that orchestrate complex deployments across every environment and approval gate.

By using plug-ins in Deploy, you integrate the server with your existing middleware and organize code from your existing code repositories into components. You design processes to deploy your code by using steps that run each required task. Then, you organize your components into applications and create environments for each stage of your release process. Finally, you create an application process to set the deployment order of your components and deploy your application to an environment.

Systems and topology overview

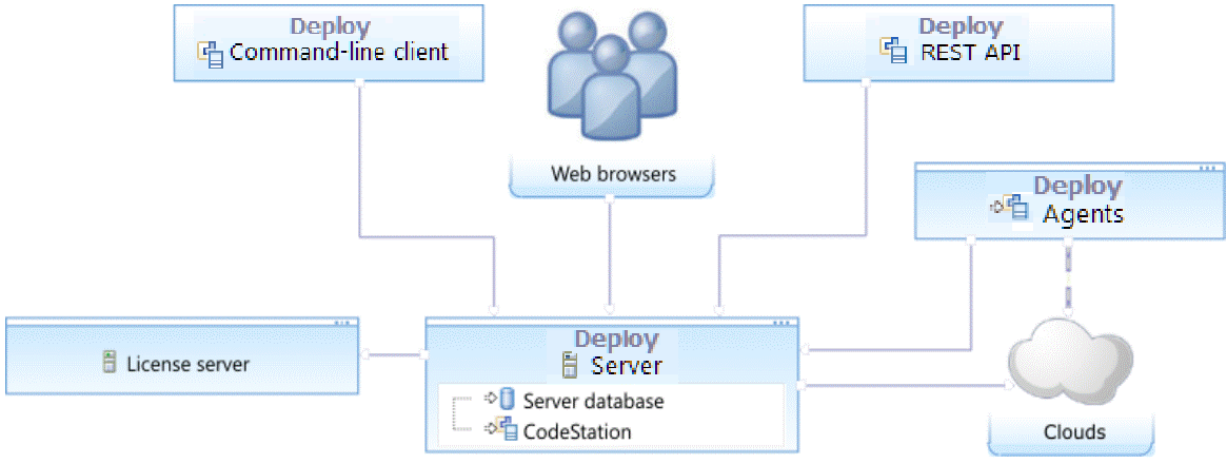
HCL DevOps Deploy (Deploy) includes several systems, including a server and one or more agents. You can configure multiple topologies, including ones that use high availability, disaster recovery, and so on, to meet your needs.

The following system topologies, including diagrams, are shown. For explanation of the system components, see the Description of systems on page 1911.

- Core topology on page 1907
- Multi-region topology on page 1908
- High-availability clustered topologies on page 1909
- Disaster recovery topologies on page 1909
- Default ports on page 1910
- Description of systems on page 1911

Core topology

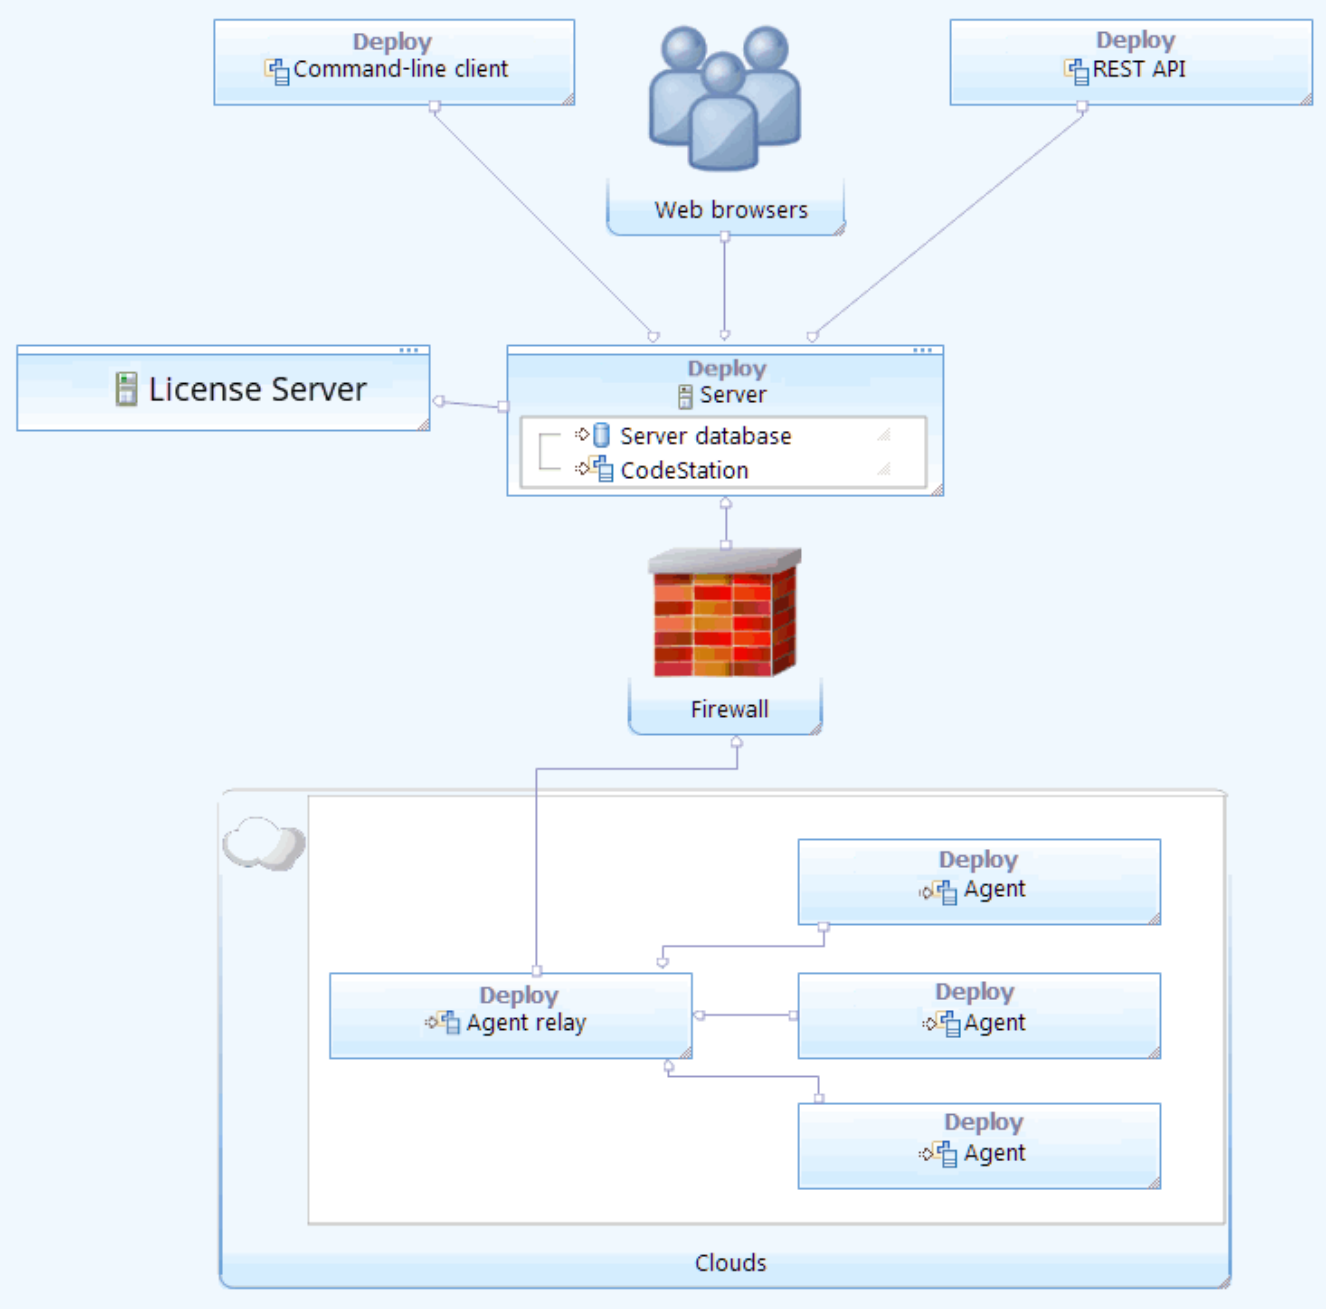
The core installation of Deploy includes a server, agents, and a license server. Clients access the server through web browsers, the REST API, or the command-line client. Agents can be installed on cloud environments, virtual machines (VMs), containers, or physical systems; the agents are shown on cloud systems in the following diagrams, but they can be installed on many different systems.



To install the core components, see Installing DevOps Deploy.

Multi-region topology

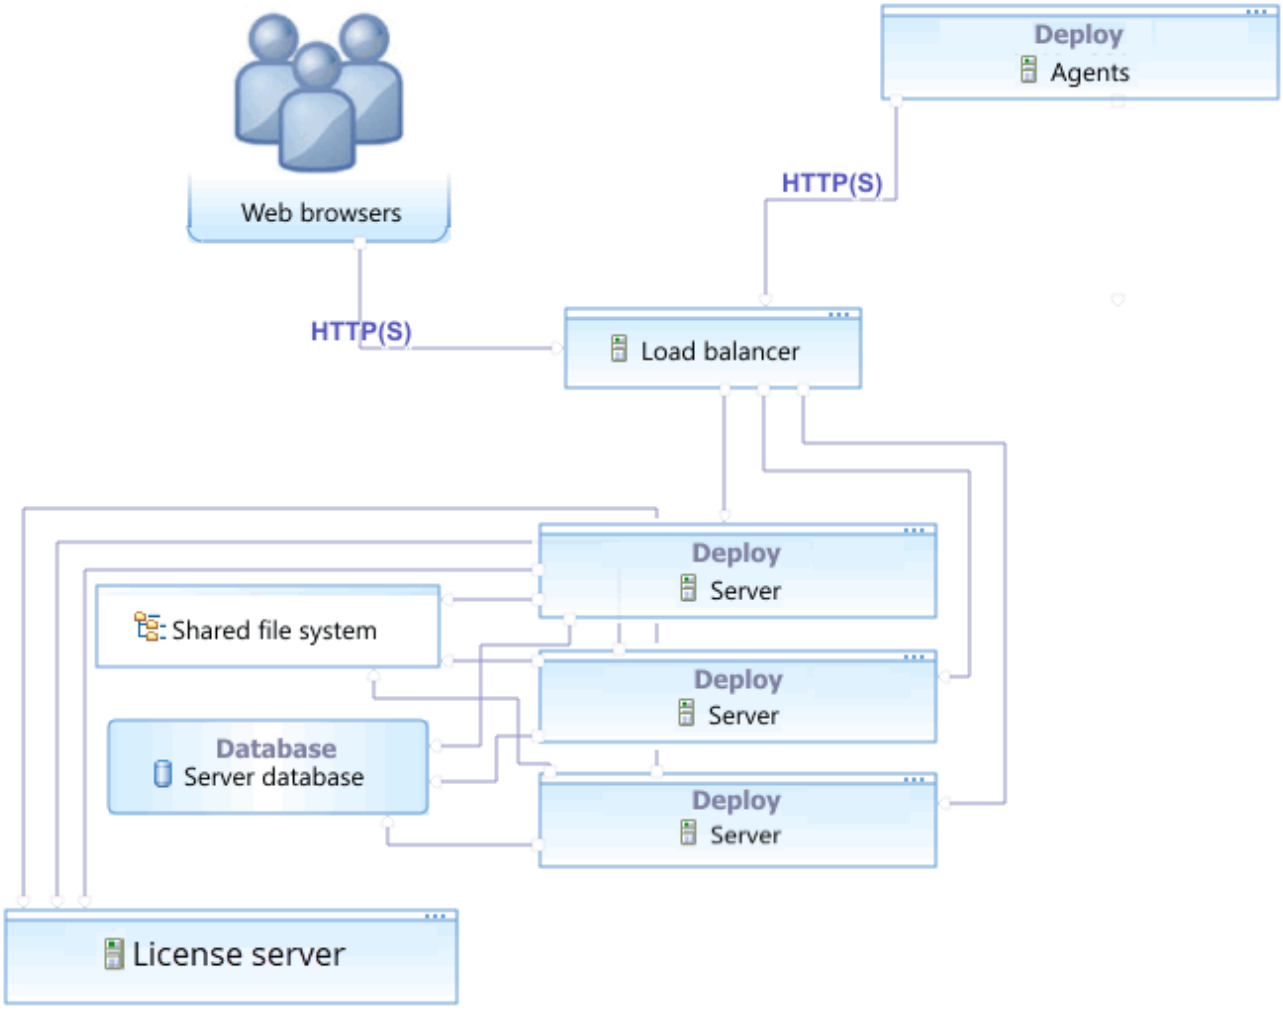
If your environment has multiple security zones that are divided by firewalls, you can use agent relays to connect agents to the server through the firewalls. For example, if your Deploy server is within a firewall, but your target environments are outside the firewall, the agents on those target environments cannot connect directly to the server. In this case, you install an agent relay outside the firewall to allow the agents to connect to the server through the firewall, as shown in the following diagram.



To install and configure an agent relay, see Installing agent relays.

High-availability clustered topologies

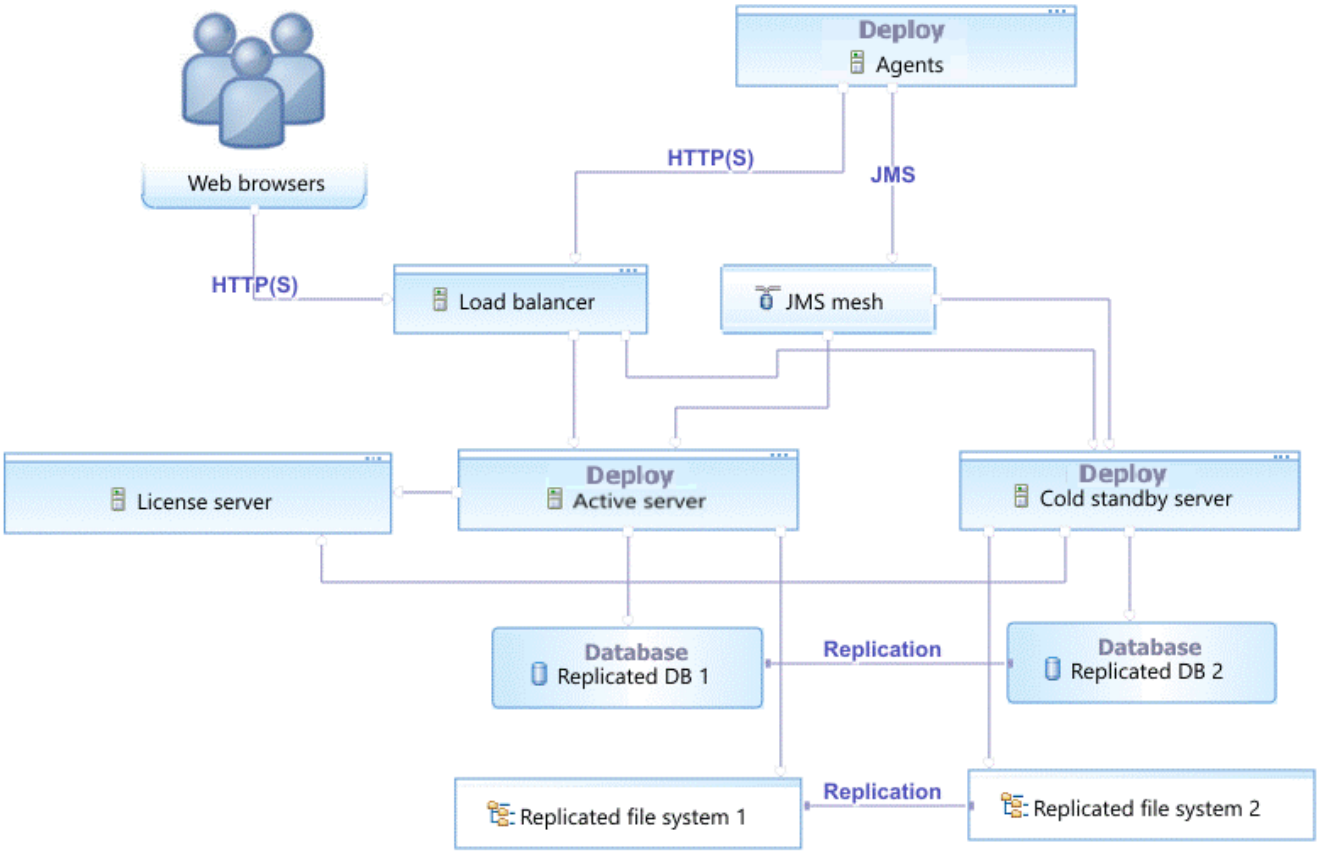
High-availability topologies use multiple servers. These servers can all be running at the same time to share the load (as in a clustered topology), or they can be waiting for another server to fail (as in a cold standby topology). The following diagram shows a clustered topology in which a load balancer distributes connections to three servers. Users connect directly to the load balancer, which sends them to an active server. Agents connect via HTTP and HTTPS to the load balancer. The servers store their files on a shared database and file system.



To configure a cluster of servers, see Setting up clusters of servers on page 2063.

Disaster recovery topologies

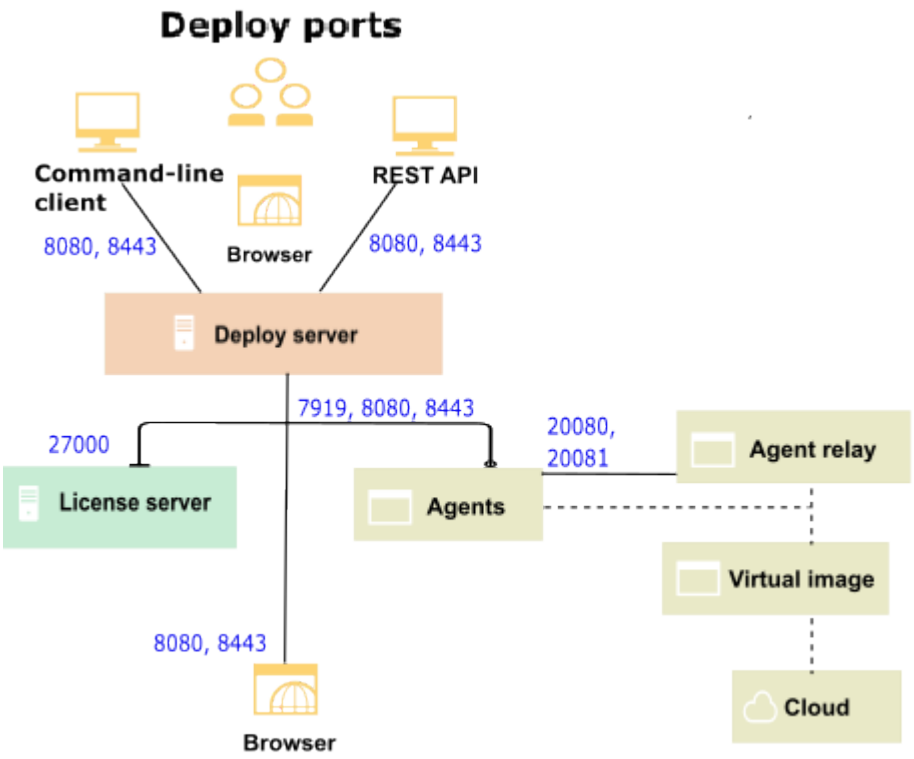
One way to prepare for disaster recovery is to have a cold standby system, including a stopped server and a replicated copy of the database and file system. The following diagram shows a simple topology with a cold standby server and related resources on standby.



To configure a cold standby system for the server, see Adding cold standby servers on page 2068.

Default ports

The following diagram shows the default port numbers that Deploy uses for communication. Most of these ports can change depending on your choices at installation time. The following diagram is only a summary of the defaults.



For more information about ports, see System requirements and performance considerations.

Description of systems

Deploy server

The Deploy server stores components, processes, and other elements with which you model automated application deployments. You run automated deployments from the server.

Web browsers

Web browsers are the main way that users interact with the server. The Deploy browser-based GUI is a Rich Internet Application (RIA) that maintains much of its functionality in the browser. Clients interact with RESTful (representational state transfer) services on the server as needed.

Command-line client

The command-line client provides access to the server through the command line. It can automate functions on the server, such as creating components and applications, and provides most of the features that are found in the browser-based GUI. The command-line client is also built on top of RESTful services. See Command-line client (CLI) reference on page 2591.

REST API

The REST API provides access to the server through HTTP. Like the command-line client, it can automate functions on the server, such as creating components and applications.

Agents

The agents run processes on target systems. Agents can run on physical computers, virtual systems, or cloud systems. See Agents on page 2336.

Agent relays

An agent relay is a communication proxy for agents that are located behind a firewall or in another network location. See Agent relays on page 2341.

License server

The license server provides licenses to the server.

Clouds

The clouds host virtual resources. For more information, see Connecting to clouds through Deploy.

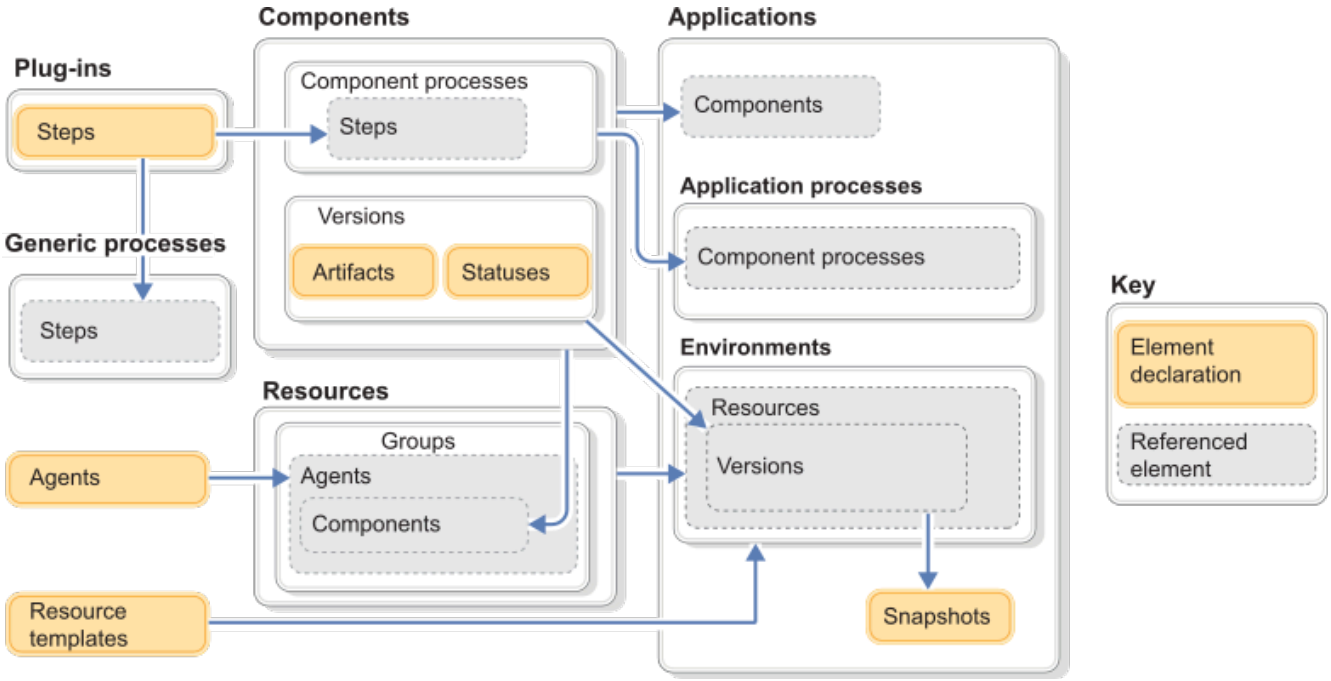
CodeStation

CodeStation stores component versions and artifacts. It is part of the Deploy server.

Elements overview

The HCL DevOps Deploy (Deploy) elements that you use to model software deployments include applications, environments, and components.

This graphic shows the relationships between different elements on the server, such as applications, environments, and components. Each element is described in the following text.



Components

Software components are central to Deploy. Components represent deploy-able items, also called artifacts, which can be files, images, databases, configuration materials, or anything else that is associated with a software project. Each time that you import new files that are associated with a component, a new component version is created. The server keeps copies of these component version artifacts, and you specify which component version to use each time you deploy. You can also apply statuses, such as `Selenium tests passed` to component versions and use the statuses in processes to control deployment behavior.

You create component processes, processes that usually contain all the steps that are necessary for the server to deploy the component to an environment. These steps describe all actions, such as starting a Tomcat server or updating files in a database. Many process steps are available by default, and you can obtain more steps from plug-ins.

Plug-ins

Automation plug-ins are the most common type of plug-in, and they provide more steps for component processes. For information about specific plug-ins, see the HCL Plug-ins site.

Resources

Resources are represented in a tree throughout Deploy to represent the relationships between components, the agents that deploy the components, and the target deployment environments. You create groups to represent target servers and environments, attach the agents that deploy to the environments, and attach components to the agents that run their processes.

The most common resource is an agent, a software program that facilitates communication between the component's host and the server. The agent runs the processes that deploy components.

To replicate a section of the resource tree, create a resource template. Resource templates describe a small section of the resource tree and can be applied to environments through a blueprint.

Applications

An application is a logical group of components that are deployed together. Applications have processes, but their steps usually start processes or modify resources. An application contains environments, which describe all the deployment locations that are needed in your deployment process, and you run application processes to deploy components to environments.

Deploy provides you with tools to ensure consistent deployments, like snapshots. Snapshots record the component versions that are deployed to an environment, and you can use a snapshot to select the component versions that are applied during a deployment.

Generic processes

You create a generic process to run any automated task that is not tied to a specific component or application. You can use any process step that is available for component processes when you create generic processes. You can create generic processes to set up new target servers or to perform audit tasks.

Learning

Tutorials and instructions for all experience levels.

The Tutorial section contains tutorials for users of all experience levels. If you are new to Deploy, the HelloWorld tutorial on page 1915 introduces the most-used product features in an easy-to-follow way. You do not need additional resources to complete the tutorial.

The How to section provides short, directed instructions for a variety of product features, such as how to configure web hooks.

Additional information about the product including descriptions of key features, tool integrations, and to schedule a demo, see the HCL DevOps Deploy product page. You can **Join Webinar** to view recorded videos about the product.

Visit the blogs page to learn more about the product features. Use the **Filter by** to see only Deploy topics.

Tutorials

Tutorials are available for every experience level.

This section contains tutorials for users of all experience levels. If you are new to Deploy, the HelloWorld tutorial on page 1915 introduces the most-used product features in an easy-to-follow way. You do not need additional resources to complete the tutorial.

After HelloWorld, the next step is the JPetStore on page 1934 tutorial that shows you how to deploy a data-driven web application. In addition to providing more in-depth topics, the JPetStore tutorial is also used by other tutorials.

If you are an experienced user, you can find tutorials that cover particular use cases, such as the Blue-Green Deployment tutorial on page 1984, or particular product features, such as how to use snapshots on page 1970.

Some tutorials provide a head-start by including resources that you can download, or that build on other tutorials. The JPetStore tutorial, for example, is used by several tutorials.

If you have topics that you would like covered by a tutorial, add a comment and describe your topic.

Basic tutorials

Tutorials for new users.

The tutorials in this section introduce the most-used product features. The HelloWorld tutorial on page 1915 is ideal for new users.

Create a simple helloWorld deployment

In this tutorial, you create a simple application with HCL DevOps Deploy (Deploy). You use standard plug-ins to create a component and define an application that deploys the component to an environment.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a component and add a user-defined property to it.
- Import artifacts to create a component version.
- Create a component process.
- Create an application and application process.
- Configure an environment with resources and apply a user-defined tag to it.
- Run the application process to deploy the component.

Time required:1 hour

Introduction

In this tutorial, you create a simple application with HCL DevOps Deploy (Deploy). You use standard plug-ins to create a component and define an application that deploys the component to an environment.

The deployment that you create in this tutorial, although simple, introduces you to the most-used product features. The `helloWorld` deployment that you create in the tutorial deploys a component by moving some files on the local file system to another location on the file system, presumably a location that is used by an application server.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a component and add a user-defined property to it.
- Import artifacts to create a component version.
- Create a component process.
- Create an application and application process.
- Configure an environment with resources and apply a user-defined tag to it.
- Run the application process to deploy the component.

Time required:1 hour

Time required

This tutorial takes approximately 1 hour to finish. If you explore other concepts that are related to this tutorial, it might take longer to complete.

System requirements

To run this tutorial, you must have an installation of Deploy.

Prerequisites

To complete this tutorial, you must have installed the Deploy server and at least one agent. Typically, the agent is installed on a computer or system other than the one where the server is located. However, for simplicity, the agent can be installed on the same system where the server is installed.

Configure the helloWorld tutorial system

To deploy the tutorial component, or any component, you must have an *agent*. An agent is a lightweight process that runs on a target computer and does the actual work of deploying components.

Before you begin

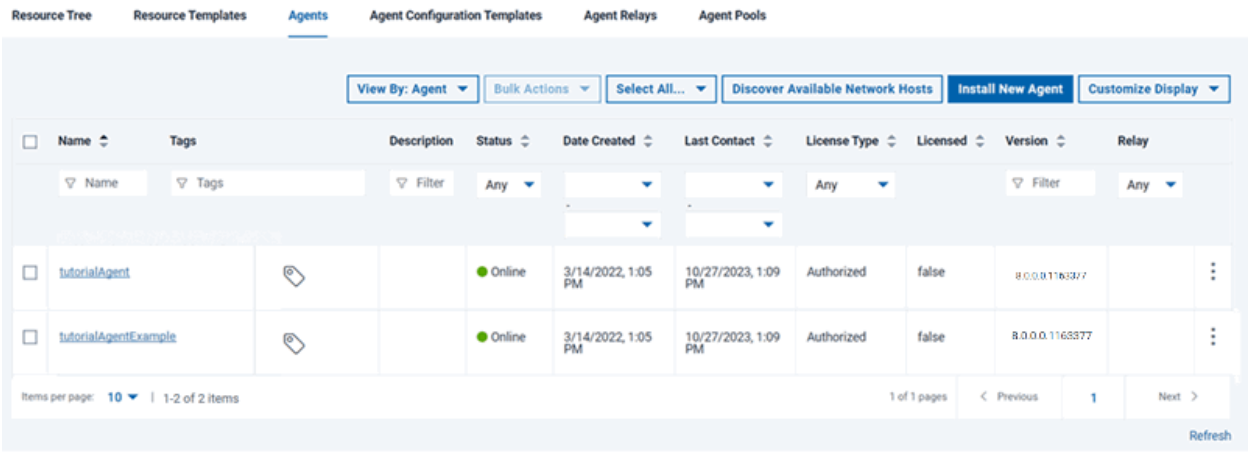
Before you begin the tutorial, make sure that you completed the Prerequisites on page 1916.

About this task

To complete the tutorial, you must have an agent that is running on a target computer system. This target computer can be a virtual image, or a physical computer, including the one where the server is installed. You must have access to this computer and be able to install the agent on it. In addition, you must create several directories on the file system where the server is located. These directories contain the artifacts that you deploy.

To prepare the tutorial system:

1. Provision a computer for use as the target computer.
2. Install an agent on the target computer.
   You can install the agent from the HCL DevOps Deploy (Deploy) web interface as described in Installing agents remotely. You can install the agent from the command line as described in Installing agents from the command line.
3. Designate the agent for importing versions.
   By default, one system-wide agent is designated to import component versions. If you skip this step or if another agent is already designated, you can still use the new agent when you import your component version. To designate the agent, see System settings on page 2086.
4. On the Deploy server, verify that the agent is installed by clicking **Resources > Agents**. Your agent must be included in the list of agents with a status of `Online`, as shown in the following figure:



5. Add the agent as a resource:

    a. To the left of the **Agents** tab, click the **Resource Tree** tab.

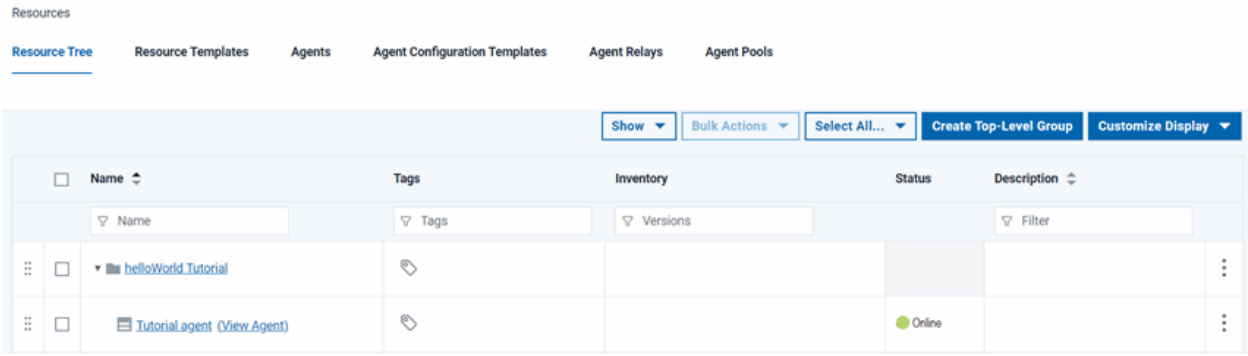
    b. Click **Create Top-Level Group**, give the new group a name such as `helloWorld Tutorial` and click **Save**.
    This group is a container for resources, such as agents and components.

    c. On the same line as the resource group, click ⋮ **Actions > Add Agent**, as shown in the following figure:

    d. In the **Create Resource** window, select the agent in the **Agent** list, and click **Save**.

Result

The agent is displayed as a child of the resource group.



6. On the computer where you installed the agent, add files that represent deployable artifacts to the file system.

    a. Create a directory and give it a name such as `helloWorld` on the file system where the agent is located.

    b. In the `helloWorld` directory, create a subdirectory that is named `1.0`.
    The source configuration the tutorial uses treats each subdirectory in the target directory as a different component version.

    c. In the `1.0` directory, place several files with any name and extension.
    The files represent the artifacts that the agent deploys by using the processes that you create. For the exercise, the number of files and their type is irrelevant, but, for best performance, limit their number and size.

    Note: If z/OS® is used on your target computer, convert text-type files that are used for artifacts to IBM®-1047 encoding.

Results

The server and agent are configured for the tutorial, and the files that represent artifacts are ready to use. If you installed the agent on a remote system, you must know the credentials and locations that you specified.

Lesson 1 Create the helloWorld component

Components contain *artifacts* and *processes*. Artifacts include runnable files, images, databases, configuration instructions, and anything else that is associated with a software project. Processes define the activities that components can perform.

Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the helloWorld tutorial system on page 1916.

About this task

In many cases, artifacts are added to a component by connecting the HCL DevOps Deploy (Deploy) server to a computer system that hosts the artifacts. The server can import artifacts from build systems, source-code management systems, and file systems. Imported artifacts are stored in CodeStation, the artifact repository. The artifacts for the helloWorld component come from the file system where the Deploy agent is located. For more information about creating components, see Creating components on page 2248.

1. To create the helloWorld component:
    a. Click the **Components** tab and then click **Create Component**.
    In the window that opens, you define the component and specify the location of the artifacts for it.
    b. In the **Name** field, type `helloWorld`.
    c. In the **Source Configuration Type** list, select **File System (Versioned)**.
    This parameter defines the type of artifacts the component uses. All artifacts in a component share the source type. The File System (Versioned) type looks for the artifacts on the file system.

    Note: The None type can be used for configuration-type or operational-type deployments. For more information about deployment types, see Creating component processes on page 2425.

    d. In the **Base Path** field, specify the location of the `helloWorld` folder that you created earlier, such as `/home/user1/artifacts/shared/helloWorld`.
    The File System (Versioned) source type considers directories in the specified folder as representations of component versions. For this reason, make sure that you specify the `helloWorld` directory and not the `helloWorld/1.0` directory.
    e. Accept the default values for the other fields on the page.
    The **Preserve Execute Permissions** and **Import Versions Automatically** check boxes are cleared and the **Copy to CodeStation** check box is selected. The **Default Version Type** is set to **Full**.
    f. Click **Save**.
2. Create a component property.
    A property is user-defined parameter that can be set at design time or run time. Properties can be defined for components, processes, applications, environments, and other product elements. Here you set the property on the

component, but in situations where multiple components share the property, you might set the property value on the environment instead of setting it on every component.

a. On the "**Component: helloWorld**" page, click the **Configuration** tab and then click **Component Properties**.

b. Click **Add Property**.

c. In the **Edit Property** window, name the property something like `helloHome`.

d. In the **Value** field, type the name of the directory that you created to hold the component artifacts, for example `c:\helloWorld`.
The component process uses this property later to identify the target location for the component artifacts.

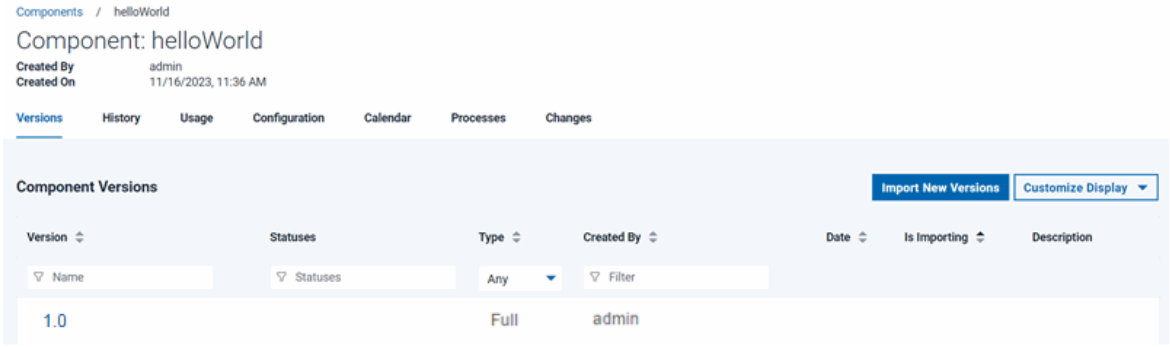
e. Click **Save**.

3. Import the component version:

a. Click the **Versions** tab.

b. Click **Import New Versions**.
Result
The server creates a version of the component that is based on the folder in the `helloWorld` folder, and imports the files in the `helloWorld/1.0` directory. In this case, the server creates a single version of the component that is based on the `helloWorld/1.0` folder. If other folders were in the `helloWorld` directory, they too would be imported and versions would be created from them.

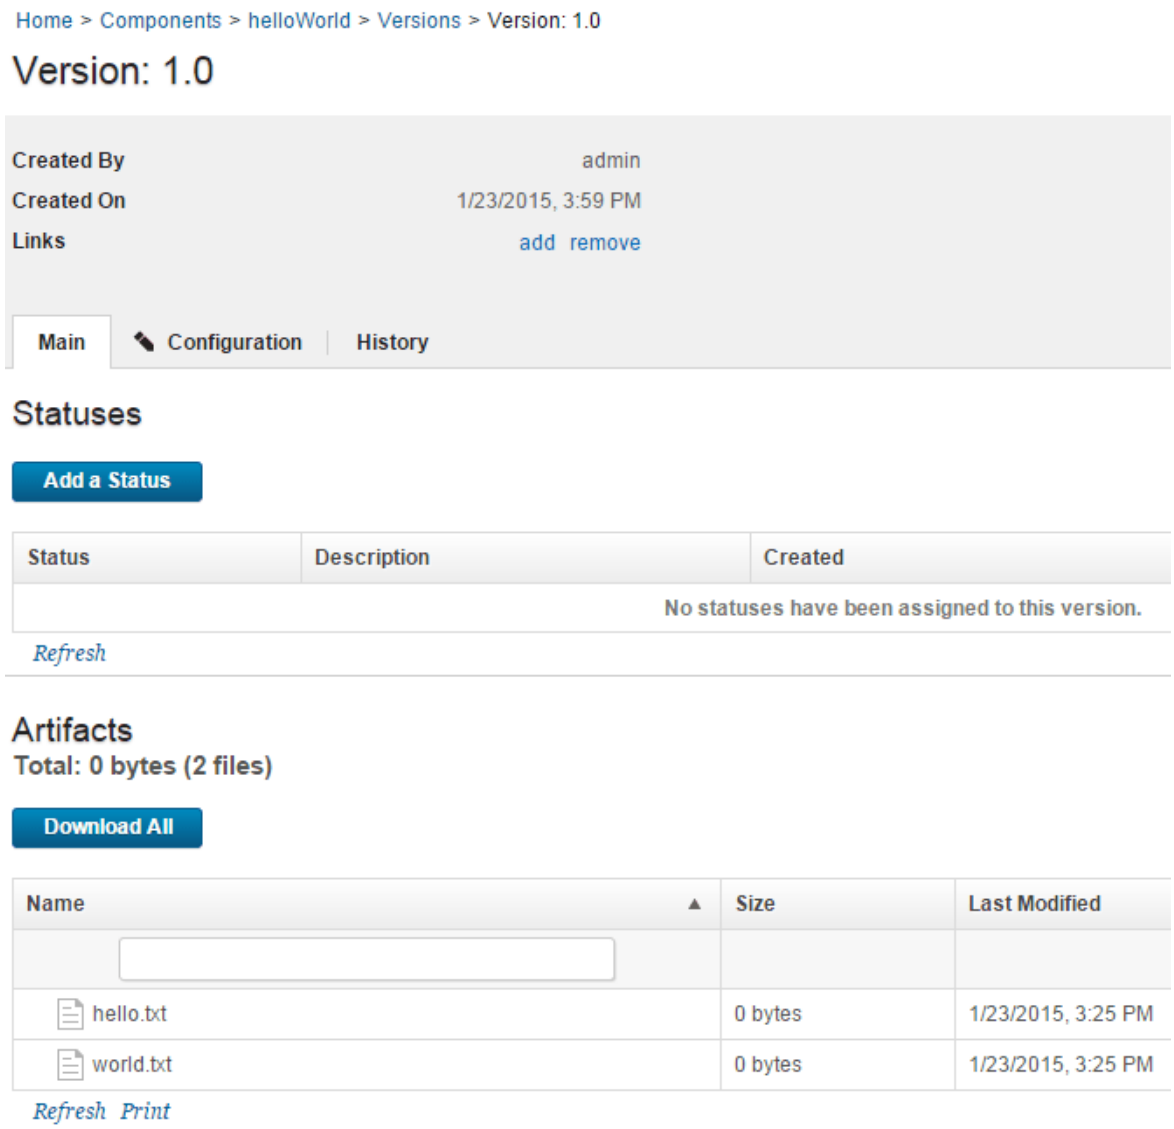
c. Verify that the list of versions includes version 1.0 of the component, as in the following figure:
Result



d. Click the version name, **1.0**.

e. Verify that the list of artifacts includes the files in the `helloWorld/1.0` directory, as in the following figure:

Result



Result

The helloWorld component is ready to use.

Results

In this lesson, you created a component that is based on files in the file system, and imported the initial version into CodeStation, the artifact repository. On the **helloWorld Component** page, you have the initial version, 1.0, listed.

What to do next

Component processes describe different ways to use a component, such as how to deploy it, install it, update it, or do other tasks with it. In the next lesson, you create a process that defines how to deploy the component. For more information about creating components, see Creating components on page 2248.

Lesson 2 Create a component process

Component processes are user-defined tasks that operate on components.

About this task

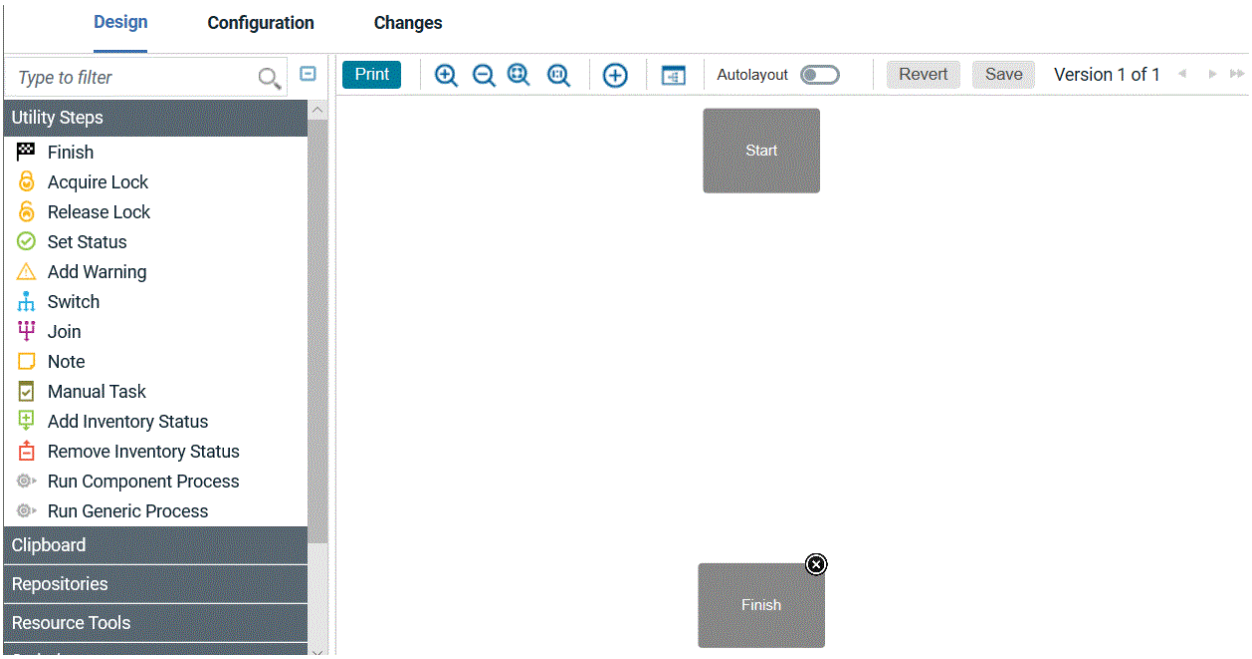
A component process is a succession of commands that are called *steps*. Steps can manipulate files, run system commands, set properties, pass information to other steps, and run programs. Steps are provided by *automation plug-ins*. Processes are designed with the drag-and-drop process editor where you drag plug-in steps onto the design editor and configure them as you go. Several plug-ins come with the product and others are available, which work with many different types of software. In this tutorial, you use two plug-ins, both of which come with the product: **FileUtils** and Deploy Versioned file storage. A component can have any number of processes defined for it, but a component must have at least one process.

In this lesson, you create a deployment process for the helloWorld component. Later, you create an application process that uses the component process to deploy the component.

To create the component process:

1. Define the component process:
    a. On the "**Component: helloWorld**" page, click the **Processes** tab, and then click **Create Process**.
    b. In the **Create Process** window, type `helloProcess` in the **Name** field.
    c. Accept the default values for the other fields, and click **Save**.
    The **Default Working Directory** field becomes the folder that the agent uses to do its work, such as downloading artifacts and creating temporary files. For the tutorial, the value becomes `\agent_install \var\work\helloWorld`.

    Result
    The process is listed on the **Processes** pane.
2. Open the **helloProcess** process editor and go to **Design**.
    Result
    The process editor lists plug-ins and steps. The required **Start** and **Finish** steps represent the beginning and the end of the process and are automatically placed on the design area. You add steps to the process by dragging them onto the design area and arranging them between the **Start** and **Finish** steps.



3. Add a step that removes files from the working directory.
   To ensure that the agent works with the most recent files, remove files that remain from previous work:

   a. In the **Step Palette** pane, click **Utilities**.

   b. Click and drag the **Delete Files and Directories** step to the process editor.
      Result

      Click the edit properties icon , and the **Edit Properties** window opens, showing the properties for the step. Some of these properties are unique to the step, and others are the same for all steps.

   c. In the **Name** field, specify a name, for example, `Clean work space`.

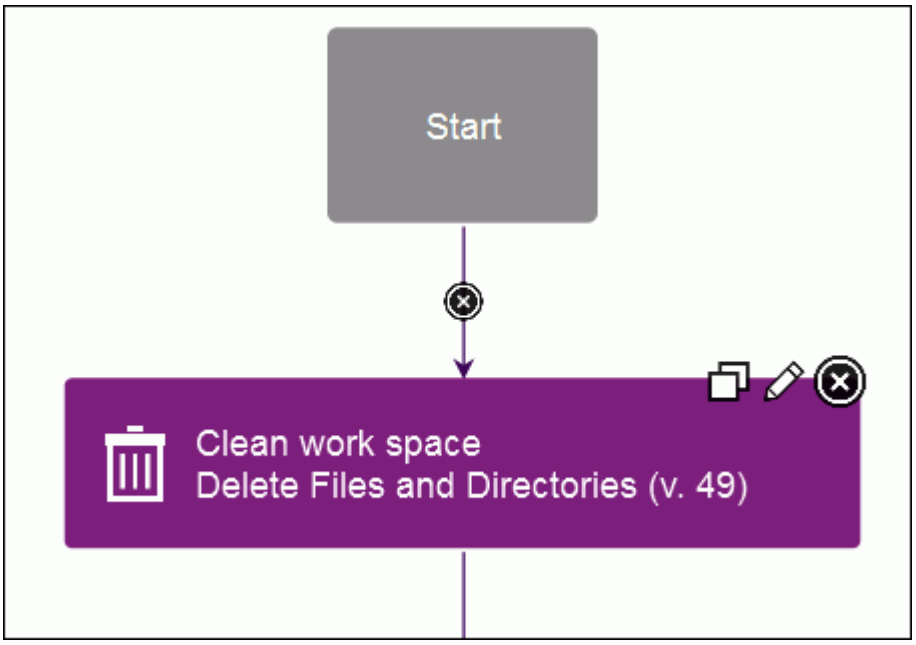
   d. In the **Base Directory** field, specify a single period (`.`).
      This value resolves to the folder that you specified as the agent working directory, such as *<DEPLOY_AGENT_HOME>*`/var/work`.

   e. Click the **Include** field, and in the **Edit Text** box, specify an asterisk (`*`); then, click **Save**.
      This parameter instructs the agent to remove all files in the working directory.

   f. Accept the default values for the other properties, and then click **OK**.

Result

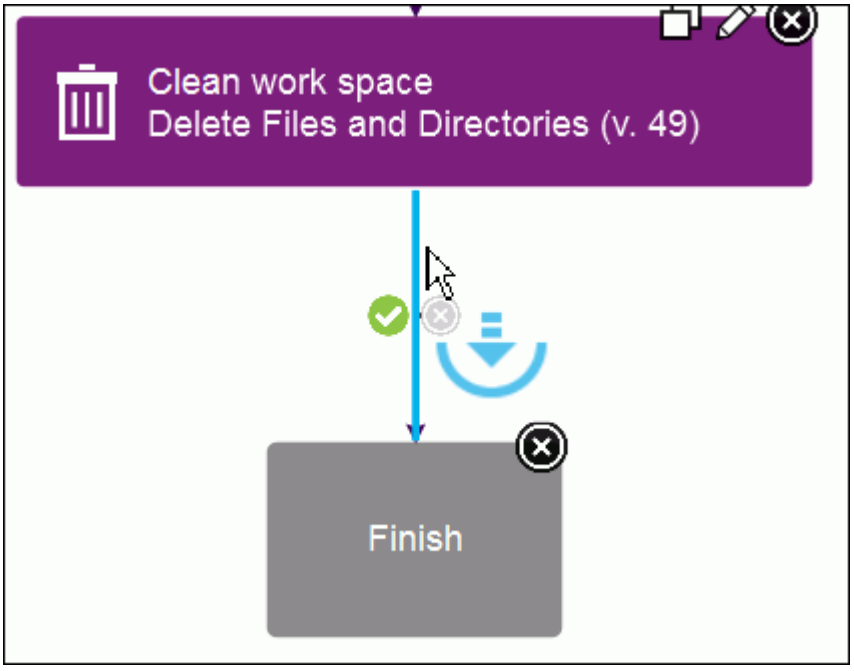
The new step is displayed in the design area. Each step has two icons at the upper-right corner of the step. Click the **Edit** icon to reopen the **Edit Properties** window where you can modify the step properties. Click the **X** icon to delete the step and connections to or from it.



The **Start** and **Finish** steps are automatically connected to the step.

4. **Optional:** If the process step became disconnected from the **Start** and **Finish** steps, connect the **Start** step to the **Clean work space** step. Beginning with **Start**, the connections between steps determine the process flow. You can define connections as you place steps or later.
5. Add a step to download the latest version of the component artifacts from the CodeStation repository.
   The **Download Artifacts** step is used in most deployment-type processes. This step downloads the specified version of the component artifacts to the agent's recently cleaned working directory. When you run the process, specify which version of the component artifacts to use.

a. Click **Repositories**, and under **Artifact/Deploy** drag the **Download Artifacts** step to the process editor. Be sure to highlight the connection arrow when you drag the step to the process editor so that connection arrows are automatically inserted from the previous step to the Finish step. See the highlighted connection arrow in this illustration:



b. Click the **Edit** icon , and in the **Edit Properties** window, accept the default values; then, click **OK**.

c. **Optional:** If you didn't highlight the connection arrow when you dragged the step to the editor, complete these steps:

   i. Delete the connection arrow between the **Clean work space** step and the **Finish** step.

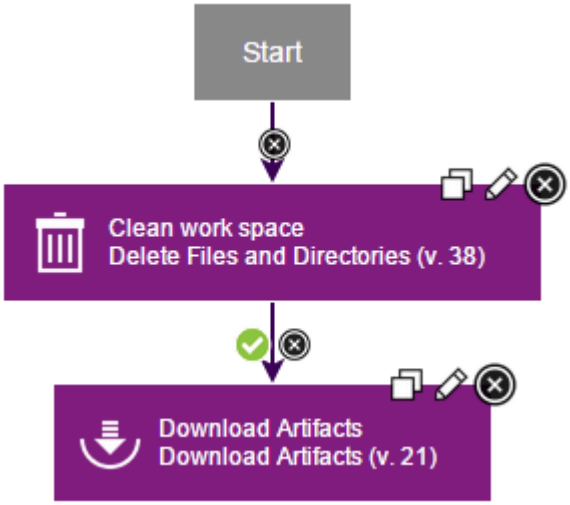
   ii. Draw a connection from the **Clean work space** step to the **Download Artifacts** step, and then connect the **Download Artifacts** step to the **Finish** step.

Tip: To manually connect steps, move the mouse over one step. The arrow icon is displayed, as the following figure shows. You use this icon to connect steps to one another.

. Click and drag the arrow icon over the subsequent step. The direction of the arrow defines the direction of the process flow.

Except for connections from **Start**, each connection has a *conditional flag*. The conditional flag represents the process status that is required before the connection can be followed. The connection is followed only if the originating step is complete, and the specified condition is met. The possible conditions are as follows: success, failure, or either. The default condition is success, which is represented by a green check mark, as

the following figure shows. In this example, the **Download Artifacts** step is started only if the **Clean work space** step finishes with a success condition. You can change the conditional flag by clicking the icon.



6. Add a step to create a compressed file.
   In this example, the compressed file contains the files that were downloaded in the previous step.

   a. Click **Utilities**, and under **FileUtils**, drag a **Create .zip File** step to the process editor.

   b. In the **Edit Properties** window, specify the name: `Compress artifacts`. (To open the **Edit Properties** window, the click the **Edit** icon .)

   c. In the **.zip File Name** field, type `helloWorld.zip`.

   d. In the **Base Directory** field, type a single period (`.`).
      The compressed file is created in the agent working directory.

      Note: If you specify the final destination directory instead of the agent working directory, the following step would be unnecessary. However, in addition to moving the file, the following step demonstrates how to use the property that you created earlier.

   e. In the text editor that opens for the **Include** field, type an asterisk (`*`); then, click **Save**.
      The compressed file contains all the files that were downloaded from the repository.

   f. Accept the default values in the other fields, and click **OK**.

   g. Verify that there is a connection from the **Download Artifacts** step to the **Compress artifacts** step. If the steps are not connected, manually connect them.

7. Add a step to move the artifacts.
   This step moves the compressed file to the target folder. For simplicity, the tutorial moves the file to a directory in the `\helloWorld` folder.

a. Expand **Utilities**, and under **FileUtils**, drag a **Move Directory** step to the process editor.

b. In the **Edit Properties** window, specify the name `Deploy artifacts`.

c. In the **Source Directory** field, type a single period (`.`).

d. In the **Destination Directory** field, type the following value: `${p:helloHome}/target`.
The `${p:helloHome}` value refers to the property that you created earlier. The `/target` directory is relative to the property value. If, for example, you defined the property value as `/home/user1/artifacts/shared/helloWorld`, the file is moved to `/home/user1/artifacts/shared/helloWorld/target`. For information about using properties, see Properties on page 2500.

e. In the text box that opens for the **Include Files** field, type: `*.zip`; then, click **Save**.

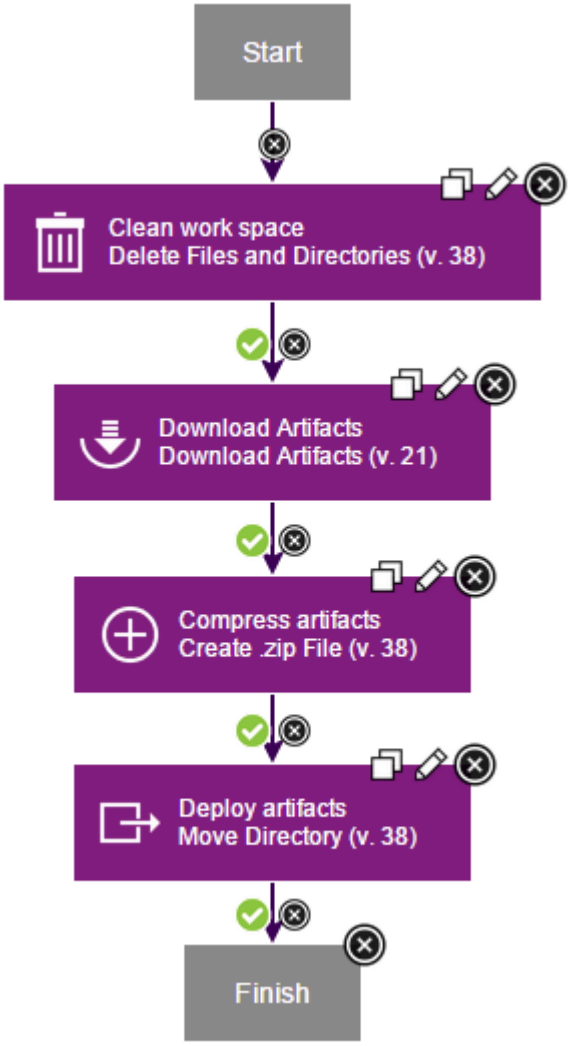
f. Accept the default values in the other fields, and click **OK**.

g. Verify that there is a connection from the **Compress artifacts** step to the **Deploy artifacts** step.

8. Verify that there is a connection from the **Deploy artifacts** step to the **Finish** step.
9. Save the process by clicking **Save** .

Results

The complete process for the helloWorld component looks like the following figure:



In this lesson, you created a component process to deploy the helloWorld component.

You can use component processes to automate many tasks on components. Later in this tutorial, you create an application process to deploy the component.

Lesson 3 Create an application

Applications manage components, typically by deploying them into environments.

About this task

To create an application, you identify the components that it manages; define at least one environment into which the components are deployed; and create a process to do the work. An environment maps components to agents and handles inventory, among other things. An application process is similar to but not identical to a component process. Application processes are primarily intended to direct underlying component processes and orchestrate multi-component deployments. In this lesson, you create an application and assign the helloWorld component to it.

1. Click the **Applications** tab, and then click **Create Application**.
2. Name the new application something like `hello Application`.
3. Accept the default values for the other fields, and click **Create**.
   For the tutorial, the default value for the **Notification Scheme** is fine. HCL DevOps Deploy (Deploy) integrates with LDAP and email servers, which enables the product to send event-based notifications. For example, the `default notification scheme` sends an email (if an email server is configured, see System settings on page 2086) when a deployment finishes. Notifications can also play a role in deployment approvals. See Managing Security on page 2149 for information about security roles.
4. Add the helloWorld component to the application:

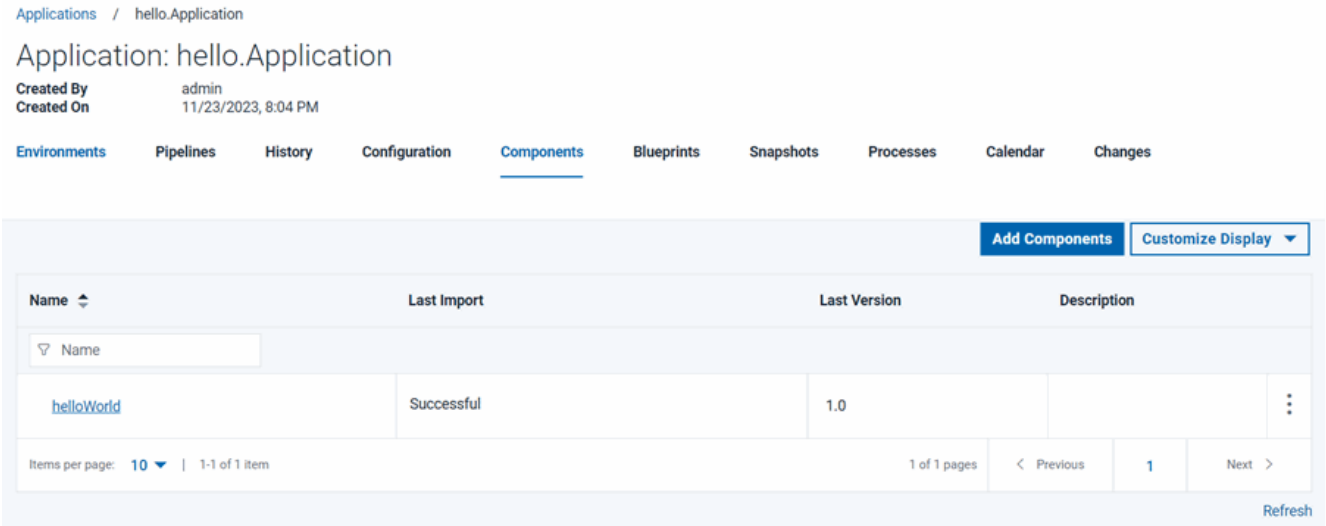
   a. From the **Application: hello Application** page, click the **Components** tab. This is the **Components** tab that is associated with the application, not the **Components** tab at the top of the page.

   b. Click **Add Component**.

   c. In the **Add a Component** window, select the **helloWorld** component, and then click **Save**.
   An application can deploy only components that are added to it.

Results

The application includes the helloWorld component, as shown in the following figure. Applications can have any number of components, and components can be included in any number of applications.



In this lesson, you created an application and assigned the helloWorld component to it. On the **Components** tab, you have the component that is managed by the application listed.

What to do next

For more information about creating applications, see Creating applications on page 2346.

Lesson 4 Configure an application environment

When you create an environment, you map resources to it that define where the parent application can run deployments.

About this task

An environment is a user-defined collection of resources that identify the components that can be deployed by the parent application, along with the agents that do the work.

1. Define the environment:
    a. On the **Application: hello Application** page, click **Environments**.
    b. Click **Create Environment**.
    c. Specify the name to be something like `helloDeploy`.
    d. Accept the default values in the other fields in this window, and click **Save**.
2. Add the resource group that contains the agent you created earlier to the environment.
   When you set up the agent, you added the agent as a resource to a resource group.

    a. Click the environment name.

    b. Using the **Resources** tab for the environment, click **Add Base Resources**.
    Result
    The **Add Resource to Environment** window shows all available resources.

    c. Select the check box next to resource group that you created earlier, `helloWorld Tutorial`, and then click **OK**.
    When you select the resource group, you automatically select the resources that are associated with it, such as the agent that you assigned to the group. Selecting an agent-type resource identifies the location, usually a computer, where deployments can occur.

3. Map the helloWorld component to this agent resource.

    a. As you hover the mouse over the row with the agent resource, click **Actions > Add Component**.

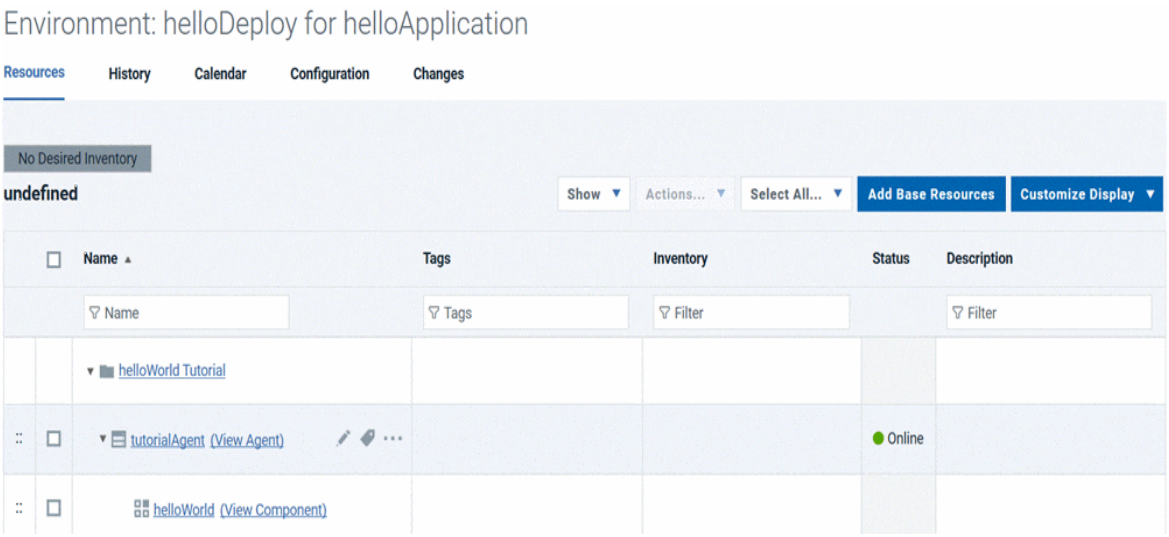
    b. Select the **helloWorld** component and then click **Save**.
    Only components added to the parent application are available to be mapped to the agent resource.

    Note: In order for a component to be deployed by an application, it must be added to the application and also mapped to an agent-type resource. A component that is added to an application but not mapped to an agent resource, cannot be deployed by that application. Similarly, a component that is mapped to an agent resource but not added to an application, cannot be deployed by that application.

4. Add a tag to the helloWorld component resource.
   User-defined tags can identify resources and be referenced in application processes.

    a. Click the check box for the **helloWorld** component.

    b. On the same row as the **Add Base Resources** push button, click **Actions > Add Tag**.
    The **Add Tag** selection is shown in the following figure:

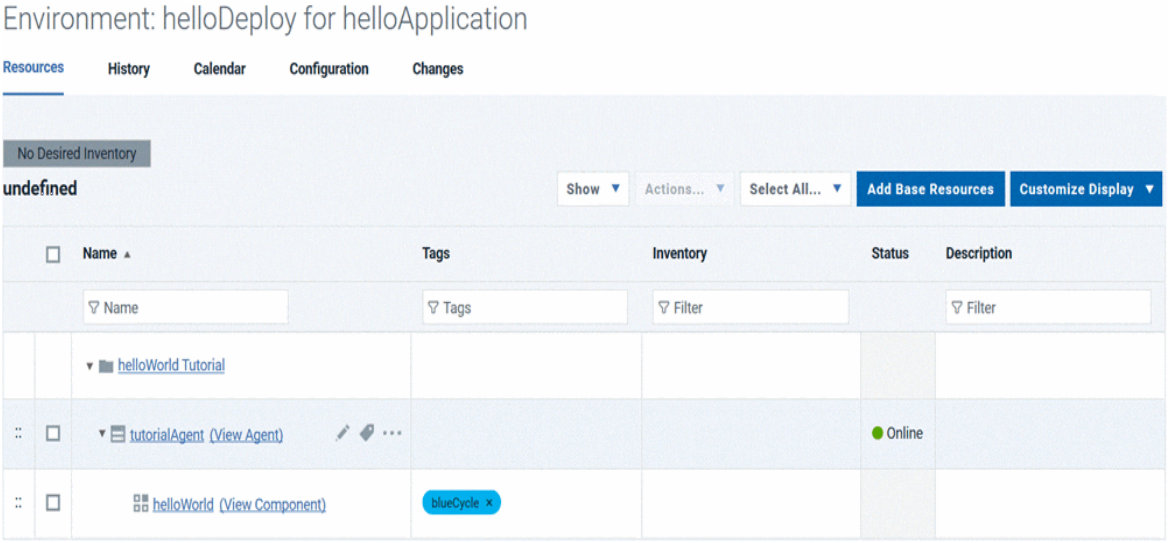


c. In the **Add New Tag** window, type something like `blueCycle` in the **Name** field, select a color for the tag, and then click **Save**.

While you can select any color, blue is a good choice. Applications can be configured to use resources with a specific tag. For example, a continually running environment might take one group of `blueCycle` tagged servers offline to update them, then put them back online and take another differently tagged group offline. You can also configure a process to deploy all components with a particular tag.

Result

The finished resource with the `blueCycle` tag is shown in the following figure:



Results

The new environment is displayed on the **Environments** tab. After the environment is prepared, you can create the application process.

In this lesson, you created an environment and added a resource group to it, then added a tag to the resource.

On the **Resources** tab, you have the resource group with your agent and the `helloWorld` component.

For more information about creating environments, see Application environments on page 2354.

Lesson 5 Create an application process

Application processes direct underlying component processes and orchestrate multi-component deployments.

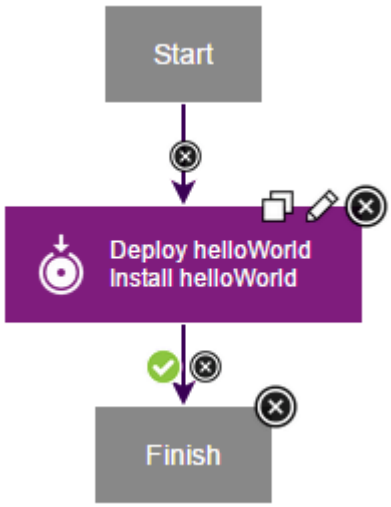
About this task

An application process, like a component process, consists of steps that are configured with the process editor. In this lesson, you create an application process that installs the helloWorld component by calling the component process that you created earlier. You must use application processes to deploy components.

1. Click the **Applications** tab, and then click **hello Application**.
2. Click **Processes**, and then click **Create Process**.
3. In the **Create an Application Process** window, name the new application process something like `hello App Process`.
4. Accept the default values for the other fields, and click **Save**.
5. To open the new process in the process editor, click the new process.
6. Add a step that deploys the helloWorld component:
    a. From the list of steps, add an **Install Component** step to the design area, and then on the process step click the **Edit** icon .
    b. In the **Edit Properties** window, name the step something like `Deploy helloWorld`.
    c. In the **Component** list, select the **helloWorld** component.
    All components that are associated with an application are available.
    d. In the **Component Process** list, select the **helloProcess** component process.
    If multiple processes were defined for the helloWorld component, they are listed.
    e. In the **Limit to Tag** list, select the **blueCycle** tag that you defined earlier.
    After you select **blueCycle**, the application deploys only components with this tag.
    f. Accept the default values for the other fields, and click **OK**.
7. Verify that the **Start** step is connected to the **Deploy helloWorld** step.
8. Verify that the **Deploy helloWorld** step is connected to the **Finish** step.
9. Save the process by clicking **Save**.

Results

The complete application process looks like the following figure:



Example

In this lesson, you created an application process that deploys the helloWorld component.

The **Processes** tab lists the application process.

What to do next

For more information about creating application processes, see Application processes on page 2428.

Lesson 6 Deploy the component

To deploy the component, run the application process on an environment.

About this task

Using the application environment and process that you created in previous steps, you can deploy the component.

1. Open the application page by clicking **Applications** and then clicking the application name.
2. In the same row as your environment, click the **Request Process** icon .
   The **Run Application Process** window opens.
3. In the **Process** list, select the **hello App Process** process.
4. Accept the default value for the **Only Changed Versions** parameter.
   If this check box is selected, no previously deployed component versions are deployed.
5. Specify component version by clicking **Select For All**, and then select **Latest Available** from the **Choose Component Versions** tab or specify a snapshot from the **Select a Snapshot** tab.
6. Set the date, time, and pattern of deployment. The **Run Now** option is enabled by default for immediate deployment. You can schedule deployments by disabling this option.
7. Review your deployment configuration and make changes, if necessary.
8. Click **Submit Deployment** when ready.
   Result

The **Application Process Request** page shows the progress of the request. From here, you can watch as the process runs.

If the application process execution is not successful, expand a process step and click **View Child Execution** to open the Deployment of Component pane, which can be used to review the deployment details. The **Deployment of Component** page shows the log for each step in the component process. In the Deployment of Component pane, you can review the deployment output log, error log, and input and output parameters.

Results

The application process installed the helloWorld component into the target environment.

Application processes can also uninstall or update components or run other configuration.

What to do next

For more information about running deployments, see Deploying applications on page 2526.

Summary

In this tutorial, you learned how to deploy a component with HCL DevOps Deploy (Deploy).

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How components, applications, and environments work together.
- How to create component versions.
- How to use plug-ins to create processes.
- How to configure environments for deployments.
- How to create and use properties.
- How to manage resources and agents.
- How to create tags and use them in applications.
- How to run deployments.

Additional resources

For more information about Deploy, see the help system and related resources on Deploy websites.

Intermediate tutorials

Tutorials for experienced users.

The tutorials in this section are for users who want to explore product features in more depth. The JPetStore on page 1934 tutorial shows you how to deploy a data-driven web application. In addition to providing more in-depth topics, the JPetStore tutorial is referenced by some of the advanced tutorials on page 1984.

Deploying a simple web application

In this tutorial, you deploy a simple web application with HCL DevOps Deploy (Deploy). You create components, create an application that contains those components, and then deploy the components to an environment.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Import artifacts from a build to create a component in Deploy.
- Create component processes and application processes to automate deployment tasks.
- Configure environments on which to deploy applications.
- Run application processes to deploy the application components.
- Update an application with new artifacts.

Time required

2-3 hours

Introduction

In this tutorial, you deploy a simple web application with HCL DevOps Deploy (Deploy). You create components, create an application that contains those components, and then deploy the components to an environment.

Deploy helps you to plan and automate the deployment of complex applications to development, test, and production environments. It can deploy applications as often as needed, helping you to find problems early in the release cycle and provide predictability late in the release cycle.

The web application that you deploy in this tutorial is a simple three-tiered web application with a database, web interface, and application logic. You import these three components to the Deploy server and create a single application that deploys these three parts. Then, you create automation instructions that are called *processes* that describe how to deploy each component. Finally, you use those processes to deploy the components automatically to a target system.

In later lessons, you update the components to a new version. Working with the sample application in this way demonstrates how you can manage a multipart application with Deploy.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Import artifacts from a build to create a component in Deploy.
- Create component processes and application processes to automate deployment tasks.
- Configure environments on which to deploy applications.
- Run application processes to deploy the application components.
- Update an application with new artifacts.

Time required

This tutorial takes 2 - 3 hours to finish. If you explore other concepts that are related to this tutorial, it could take longer to complete.

System requirements

To run this tutorial, you need the following resources:

- An installation of Deploy, version 8.2 or later
- Two computers, virtual images, or cloud instances to use as agents for the Deploy server

Prerequisites

- Make sure that you have access to the Deploy server. For information about installing a server, see Installing the DevOps Deploy server.
- The server must have the Apache Tomcat, DBUpgrader, and FileUtils plug-ins installed. If you do not have access permissions to install plug-ins, ask the system administrator to install these plug-ins. For instructions, see Installation of plug-ins on page 2558. You can verify that the plug-ins are installed by clicking **Settings > Automation > Installed Plugins** and finding Tomcat, DBUpgrader, and FileUtils in the list of installed plug-ins. The FileUtils plug-in is installed by default.
- You must have an account on the server with the permissions to create and edit applications, environments, and components, and to create and run processes.

Configuring the agent and target system

To deploy applications with HCL DevOps Deploy (Deploy), you need one or more *agents*. The server uses the agents to deploy the application components on target systems.

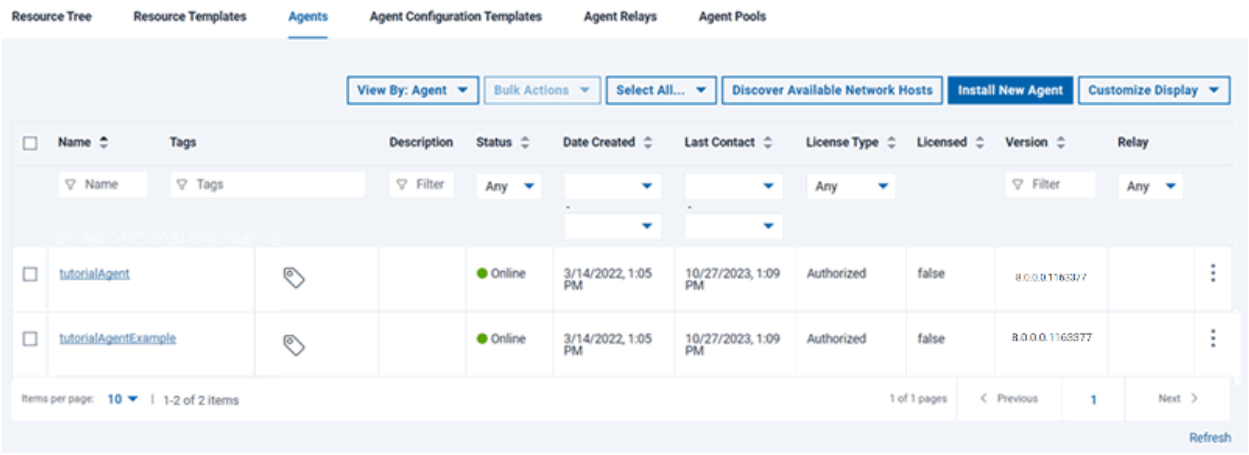
Before you begin

Before you begin the tutorial, make sure that you completed the Prerequisites on page 1935.

About this task

To work through this tutorial, you need an agent that is running on a target computer system. This target computer can be a cloud resource, a virtual image, or a physical computer. You must have access to this computer and be able to install MySQL/MariaDB, Apache Tomcat, and the Deploy agent on it. Follow these steps to set up an agent and a target system for your work with the tutorial:

1. Prepare a computer for use as the target system.
2. Install an agent on the target system.
   See Installing agents.
3. On the Deploy server, verify that the agent is installed by clicking **Resources > Agents**. Your agent must appear in the list of agents with a status of **Online**, as shown in the following figure:



4. Add the agent as a resource:

    a. Go to the **Resource Tree** tab.

    b. Click **Create Top-Level Group**, give the new group a name such as `JPetStore agents` and click **Save**.
    This group is a container for resources, such as agents.

    c. On the same row as the new resource group, click **Actions > Add Agent**, as shown in the following figure:

    d. In the **Create Resource** window, select the agent in the **Agent** field, give a name to the agent, and click **Save**.

Result

The agent is now listed as a child of the resource group. You must add agents to resource groups in this way so that applications can access the agents through the resource group.

5. Install and start the MySQL/MariaDB server on the target system.
The application uses a MySQL/MariaDB database.

Example

If you are using a Linux™ operating system, you can use the package manager to install and start MySQL/MariaDB. For example, on Red Hat Enterprise Linux™ version 7, run the following commands:

```
yum install mariadb mariadb-server
```

```
systemctl enable mariadb
```

```
systemctl start mariadb
```

Example

On Windows™, you can use a graphical installer or download a binary package for the database server. Then, start the server by going to the `bin` folder and running the mysqld command.

6. Create an empty database for the application to use:

    a. Open a command-line window and log in to the database as the root user.

    Example

    For example, run this command from the command line:

    ```
    mysql -u root
    ```

    Result

    The command line now shows a prompt that looks like this prompt:

    ```
    MariaDB>
    ```

    b. Create the database with the following command:

    ```
    create database jpetstore;
    ```

    Result

    If the command runs properly, you see the message `Query OK, 1 row affected`.

    c. Create the database user with the following command:

    ```
    create user 'jpetstore'@'localhost' identified by 'jppwd';
    ```

    Result

    If the command runs properly, you see the message `Query OK, 0 rows affected`.

    d. Give the user access rights to the database with the following command:

    ```
    grant all privileges on jpetstore.* to 'jpetstore'@'localhost';
    ```

    Result

    If the command runs properly, you see the message `Query OK, 0 rows affected`.

    e. Type `quit` to exit the MySQL command line.

7. Verify that the user can access the database:

    a. From the command-line window, log in to the database as the new user:

    ```
    mysql -u jpetstore -jppwd
    ```

    b. Run the following command to list the databases on the system:

    ```
    show databases;
    ```

    c. Verify that the `jpetstore` database appears in the list, as shown in the following figure:

    Result

```
mysql> show databases;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| jpetstore          |
| test               |
+--------------------+
3 rows in set (0.00 sec)

mysql>
```

d. Type `quit` to exit the database command line.

8. Install Apache Tomcat on the target system.
   You can use Tomcat version version 9.
   Example
   A simple way to install Tomcat on a Linux™ operating system is to download and install the binary distribution of Tomcat, as in the following steps:

   a. Download the binary distribution of Tomcat, such as `apache-tomcat-9.0.100.tar.gz` .

   b. Extract this file to a folder on the target computer, such as `/opt/apache-tomcat-9.0.100` .
      Example
      For example, on a Linux™ operating system you might run the following command:

      ```
      tar -xf apache-tomcat-9.0.100.tar.gz ; mv apache-tomcat-9.0.100/ /opt
      ```

9. Add an administrative user to the Tomcat server in the `conf/tomcat-users.xml` file.
   This user account is necessary to deploy applications to Tomcat.
   Example
   For Tomcat version 9, open the file `conf/tomcat-users.xml` and uncomment the `role` and `user` tags at the bottom of the file. Remove the text `<must-be-changed>` and replace it with passwords for the default user accounts. If you do not remove this text, the configuration file is unreadable and your sample application will not be able to access Tomcat. Then, add the following lines of code to those tags:

   ```
   <role rolename="manager-script"/>
   <role rolename="manager-gui"/>
   <user username="tomcatmanager" password="tomcatmanager" roles="manager-script,manager-gui"/>
   ```

   The end of the file might look like the following example:

   ```
   <role rolename="tomcat"/>
     <role rolename="role1"/>
     <user username="tomcat" password="tomcat" roles="tomcat"/>
     <user username="both" password="tomcat" roles="tomcat,role1"/>
     <user username="role1" password="tomcat" roles="role1"/>

     <role rolename="manager-script"/>
     <role rolename="manager-gui"/>
     <user username="tomcatmanager" password="tomcatmanager" roles="manager-script,manager-gui"/>
   ```

```
</tomcat-users>
```

10. In the `conf/server.xml` file, modify the default HTTP ports to avoid conflicts.

    a. Replace all instances of port number `8080` with port number `8081`.

    Example

    To update the port numbers from the command line, run this command:

    ```
    sed -i 's/8080/8081/g' /opt/tomcat_directory/conf/server.xml
    ```

    b. Replace all instances of port number `8443` with port number `8445`.

    Example

    To update the port numbers from the command line, run this command:

    ```
    sed -i 's/8443/8445/g' /opt/tomcat_directory/conf/server.xml
    ```

Results

Now the agent and the target system are configured for your work with the sample application. You need the passwords and locations that you specified later.

Lesson 1: Adding components

Components are groups of deployable artifacts that make up an application. Components include runnable files, images, databases, and configuration instructions.

Before you begin

- Make sure that your HCL DevOps Deploy (Deploy) server has the prerequisites that are listed in Prerequisites on page 1935.
- Make sure that you have set up the agent for the sample application as described in Configuring the agent and target system on page 1935.

About this task

These steps describe how to create the components of the sample application.

The JPetStore sample application includes three components:

- The application component includes the logic of the application. This component consists of a single web archive file that is named `JPetStore.war`.
- The web component includes the static web content for the application, including images for the web interface.
- The database component includes the database for the application and scripts that upgrade the database schema to new versions.

In most cases, you add components by connecting the Deploy server to the system that hosts the artifacts. The server can import artifacts from many build systems and source-code management systems. The server can create new versions of the components automatically as the artifacts change or as new builds run. However, for simplicity, in this lesson you copy the

files for the components to the server and access them from there. For more information about creating components from artifacts on build systems and source-code management systems, see Creating components on page 2248.

1. Download the `artifacts.zip` file by clicking the following link:
   artifacts.zip.
2. Copy the `artifacts.zip` file to the Deploy agent computer and extract it.

   This file contains a folder named `shared` which contain separate folders for each of the components; these folders are named `app`, `web`, and `db`. Each of these folders contains one or more folders with names such as `1.0` or `1.1`; these folders represent different versions of the artifacts.

   Notes:
   - For the tutorial, these folders must be on the same system that hosts the Deploy agent.
   - Note the locations of these folders as you will need the locations later.
   - Ensure that the JARs in the `db` folder are compatible with the version of MySQL/MariaDB database installed on the agent computer.

3. Log in to the Deploy server.
4. Create the application component:

   a. Click the **Components** tab, and then click **Create Component**.
   In this window, you specify where the artifacts for the component are.

   b. In the **Name** field, type `JPetStore-APP`.

   c. In the **Source Configuration Type** list, select **File System (Versioned)**.

   d. In the **Base Path** field, specify the location of the `app` folder on the server, such as `/home/user1/artifacts/shared/app`.

   e. Make sure that the **Copy to CodeStation** option is selected to copy the artifacts from the given source into the Deploy server's CodeStation repository.

   f. Under **Default Version Type**, click **Import new component versions using a single agent**, and then select your agent in the **Agent for Version Imports** list

   g. Accept the default values for the other fields on the page.

   h. Click **Save**.

5. Import the versions of the component:

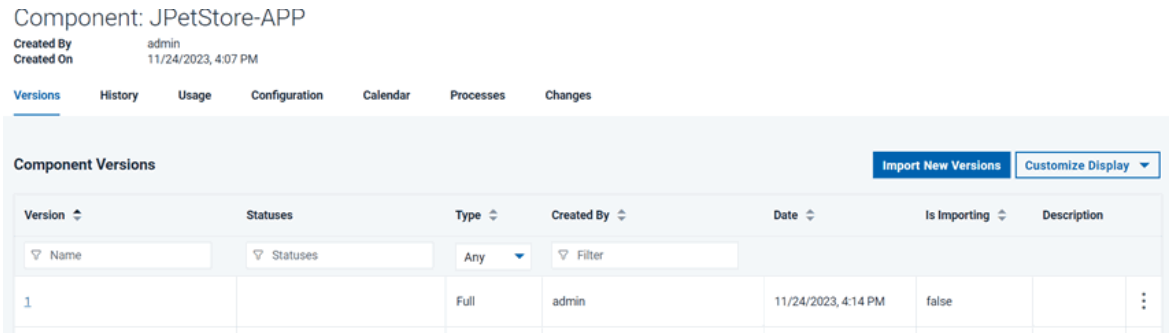
   a. Click the **Versions** tab.

   b. Click **Import New Versions**.
   Result

The import process is listed in the **Currently Running Version Imports** section. Then the process is finished, the server creates versions of the component based on the folders in the app folder. In this case, the server creates a single version of the component that is based on the `app/1.0` folder. Importing versions of small components like this one typically takes a few seconds. You might need to refresh the page or click the **Refresh** link at the bottom of the table to see the new version.

c. Verify that version 1.0 of the component is included in the list of versions, as in the following figure:

Result



If the version import failed, make sure that the files are available on the agent system and that the location of these files is correct on the component **Configuration** tab.

Result

The component is available to be used in one or more applications.

6. Create the database component:
   a. Click the **Components** tab, and then click **Create Component** again.
   b. Specify the name to be `JPetStore-DB`.
   c. In the **Source Configuration Type** list, select **File System (Versioned)**.
   d. In the **Base Path** field, specify the location of the db folder on the server, such as `/home/user1/artifacts/shared/db`.
   e. Under **Default Version Type**, click **Import new component versions using a single agent** and then select your agent in the **Agent for Version Imports** list
   f. Accept the default values for the other fields on the page.
   g. Click **Save**.
   h. Click **Versions** and then click **Import New Versions**.

Result

Now the server shows two versions of the database component.

7. Create the web component:
   a. Click the **Components** tab and then click **Create Component** again.
   b. Specify the name to be `JPetStore-WEB`.
   c. In the **Source Configuration Type** list, select **File System (Versioned)**.
   d. In the **Base Path** field, specify the location of the web folder on the server, such as `/home/user1/artifacts/shared/web`.

e. Under **Default Version Type**, click **Import new component versions using a single agent** and then select your agent in the **Agent for Version Imports** list
f. Accept the default values for the other fields on the page.
g. Click **Save**.
h. Click **Versions** and then click **Import New Versions**.

Result

Now the server shows two versions of the web component.

8. So that you can try updating the components later, delete the newest versions of the database and web components:

a. Click **Components** and then click the `JPetStore-DB` component.

b. Click **Versions**.

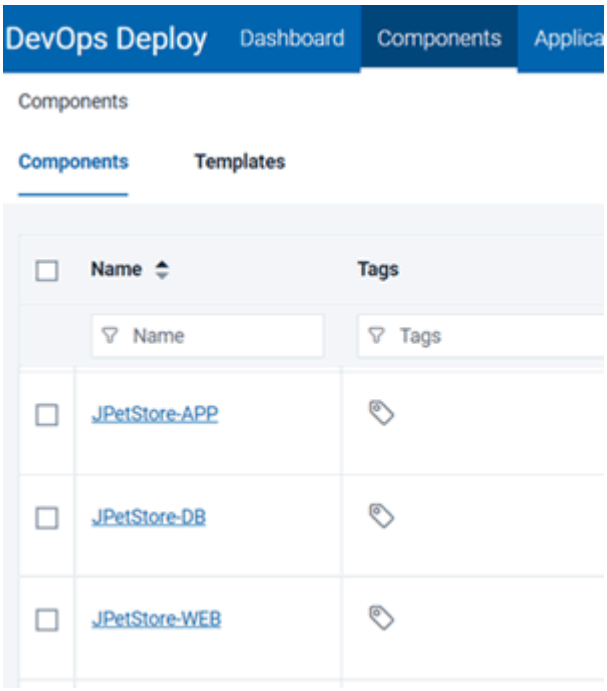
c. In the list of versions, in the same row as the version that is named `1.1`, click **Delete** and then click **OK**.
You will import this version again later.

d. Similarly, delete version `1.1` of the `JPetStore-Web` component.

Results

In this lesson, you added components that are based on files in the file system. In a production scenario, you would connect the component to a source-code management system such as Subversion or a build system such as Jenkins.

On the **Components** page, you now have three components, each with one version, as shown in the following figure:



In a later lesson, you add these components to an application.

What to do next

In addition to files and other artifacts, components also contain *component processes*, which describe how to deploy, install, uninstall, update, or run other tasks on a component. In the next lesson, you create processes that describe how to install the components.

Lesson 2: Creating component processes

Component processes describe automated tasks that run on components. Component processes can deploy, install, uninstall, update, or run other tasks on a component.

About this task

There are three types of processes:

- Generic processes run outside the context of components or applications. Generic processes are shown on the top-level **Processes** tab. You can use generic processes in these instances, for example:
  - In conjunction with a number of different component processes that do not fit well into a component template
  - When you want to run processes that directly affect HCL DevOps Deploy (Deploy) agents that are unrelated to component, such as changing the agent configuration
- Application processes run within the context of applications. In many cases, application processes call component processes. For example, an application process can call the component processes that deploy their associated components.
- Component processes run tasks on a single component, such as deploying it, uninstalling it, or running configuration tasks on it.

Processes are lists of steps and connections between those steps. Each step is an individual command that runs on a target computer. Steps can manipulate files, run system commands, download files, and run programs. Plug-ins contribute most of these steps; plug-ins are available that work with many different types of software.

Each component must have at least one component process to deploy or install the component. In this lesson, you create a deployment process for each of the three components. Later, you create an application process that calls these component processes to deploy each component.

Creating a component process for the web component

The component process for the web component downloads the most recent version of the component artifacts and puts those artifacts in the correct folder.

About this task

Follow these steps to create the component process that deploys the web component:

1. On the **Components** tab, click the **JPetStore-WEB** component.
2. Click **Processes**, and then click **Create Process**.
3. In the **Create Process** window, specify the name to be `Deploy component`.
4. In the **Process Type** list, select **Deployment**.
   This list has other options for processes that uninstall or configure components.

5. Accept the default values for the other properties, and click **Save**.
   Result
   The process opens in the process editor. This editor shows the steps in the process in a graphical form, as a flowchart. The **Start** and **Finish** boxes represent the beginning and the end of the process. From here, you add steps to the process and link them between the **Start** and **Finish** steps to show the order of the steps.
6. Add a step to clean any files out of the working directory.
   The process runs within a working directory. To ensure that you are using the most recent version of the files in the web component, run a command to clean the working directory:

   a. At the left of the process editor, in the step palette, expand **Utilities**.
      The step palette menu shows the available steps. You can explore the palette categories to find steps, or you can type in the search box at the top of the window.

   b. Under **FileUtils**, click and drag the **Delete Files and Directories** step to the process editor.
      Result
      The step is inserted between the **Start** and **Finish** steps. The inserted step is automatically connected to these steps **Edit Properties** window opens, showing the properties for the step. Some of these properties are unique to the step and others are the same for all steps.

   c. Click the **Edit** icon , and the **Edit Properties** window opens. In the **Name** field, specify the name to be `Clean working directory`.

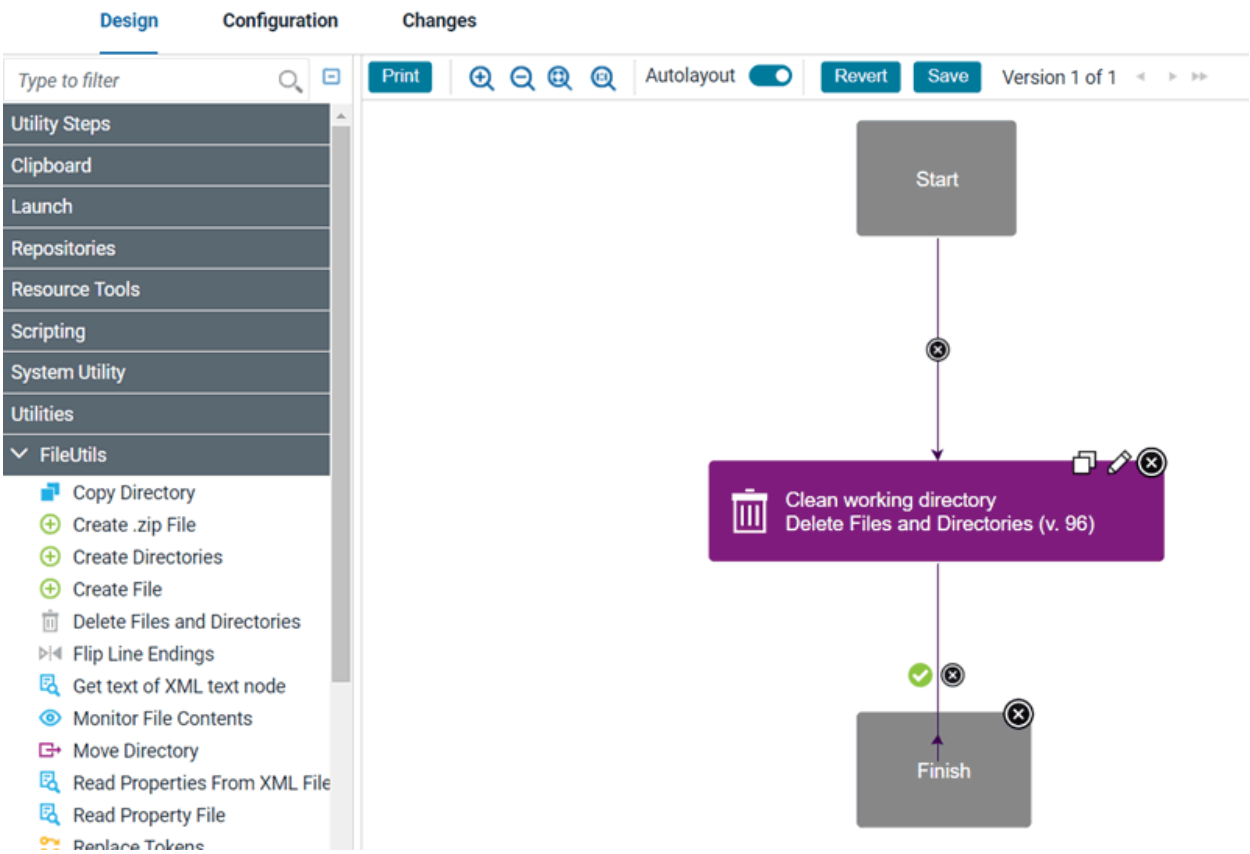
   d. In the **Base Directory** field, specify a single period (`.`).

   e. In the **Include** field, specify the following code:

      ```
      **/*
      ```

   f. Accept the defaults for the other properties and then click **OK**.

   Result
   The new step is displayed as a box in the process editor. The process editor looks like the following figure:



7. Add a step to download the latest version of the component artifacts.
   The **Download Artifacts** step is used in most deployment processes. This step downloads the specified version of the component artifacts to the target computer. When you run the process, you will specify whether to use the most recent version of the component artifacts or a specific version.

   a. **Tip:** When you drag the first step into a process editor, that step is automatically connected to the **Start** and **Finish** steps. When you drag subsequent steps into the process editor, place the cursor in the target position so that the connection arrow is highlighted, and then place the step. The new step is automatically connected. You can always change step locations and manually connect steps later.

   In the step palette, expand **Repositories**, and under Artifact/Deploy, drag the **Download Artifacts** step to the process editor.

   b. Click the **Edit** icon, and in the **Edit Properties** window, accept the default values; then, click **OK**.

8. Add a step to remove the old web content from the server:

   a. Expand **Utilities**, and under FileUtils, drag another **Delete Files and Directories** step to the process editor.

   b. In the **Edit Properties** window (click the **Edit** icon), and specify the name as `Remove old content`.

   c. In the **Base Directory** field, specify the following directory:

```
webapps/${p:environment/tomcat.contextroot}
```

The variable represents the location where Tomcat stores your deployed files. You specify a value for this variable later.

d. In the **Include** field, specify the following directory:

```
images
```

e. In the **Working Directory** field, specify the following variable:

```
${p:environment/tomcat.home}
```

This variable represents the main folder of the Tomcat web server. You will specify a value for this variable later.

f. Accept the default values in the other fields, and click **OK**.

9. Add a step to deploy the new content to the server.
This step copies the component artifacts to the application server.

a. Expand **Utilities** and under **FileUtils**, drag a **Move Directory** step to the process editor.

b. In the **Edit Properties** window, specify the name to be `Deploy new content`.

c. Click the **Edit** icon, and in the **Source Directory** field, specify a single period (`.`).

d. In the **Destination Directory** field, specify the following directory:

```
${p:environment/tomcat.home}/webapps/${p:environment/tomcat.contextroot}/
```

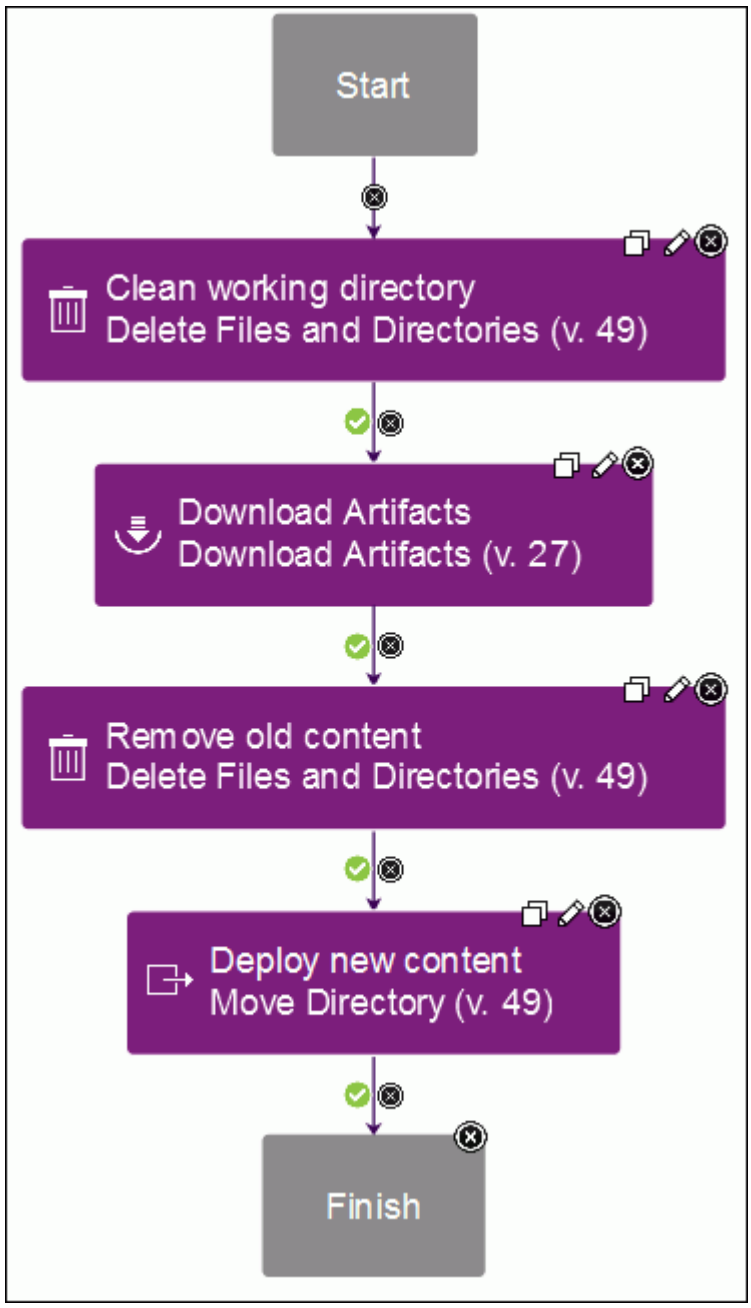
e. In the **Include Files** field, specify the following code:

```
images/*
```

f. Accept the default values in the other fields and click **OK**.

Result

Now the process has four steps, as in the following figure:



Each step has three icons at the upper right corner of the step. The **Edit** icon opens the **Edit Properties** window. The X icon deletes the step. The Copy icon copies the step to the **Clipboard** folder so you can duplicate it.

Also, if you move the mouse over a step, an arrow icon is displayed over the center of the step. This icon is used to manually create links between steps.

10. **Optional:** If your steps are not connected or are not connected in the correct order, you can connect the steps manually:

    a. If the steps are not in the correct order, remove the connection link between steps by clicking the **X** icons on any of the link arrows; then, rearrange the steps in the correct order.

    b. Move the mouse over the **Start** step, and drag the arrow icon to the `Clean working directory` step.

    Result

    The arrow between these steps represents the flow of activity from one step to another, as in the following figure:

    c. Similarly, drag an arrow from the `Clean working directory` step to the `Download Artifacts` step.

    d. Drag an arrow from the `Download Artifacts` step to the `Remove old content` step.

    e. Drag an arrow from the `Remove old content` step to the `Deploy new content` step.

    f. Drag an arrow from the `Deploy new content` step to the `Finish` step.

Result

You can connect steps in a sequence like these steps, or you can run steps in parallel with each other by creating more links. However, processes always start with the **Start** step and end with the **Finish** step. The sequence of steps in this process is as follows:

a. `Start`
b. `Clean working directory`
c. `Download Artifacts`
d. `Remove old content`

e. `Deploy new content`
f. `Finish`

11. Save the process by clicking **Save**.

Results

The complete component process for the web component looks like the following figure:

Creating a component process for the application component

The application component consists of a single WAR file. This component process downloads the most recent version of the WAR file, updates values in the file, and deploys the file on the application server.

1. From the **Components** tab, click the **JPetStore-APP** component.
2. Click **Processes**, and then click **Create Process**.
3. In the **Create Process** window, specify the name as `Deploy component`.
4. In the **Process Type** list, select **Deployment**.
5. Accept the default values for the other properties, and click **Save**.
6. In the process editor, add a step to clean the working directory.

As you did for the web component, add a **Delete Files and Directories** step named `Clean working directory`, and specify a period in the **Base Directory** field and `**/*` in the **Include** field.

7. Add a step to download the artifacts.
   As you did for the web component, add a `Download Artifacts` step, and accept the default properties.
8. Add a step to extract the WAR file.
   You must extract the WAR file so you can update a property file with the database connection information.

   a. In the list of available steps, expand **Utilities**, and under FileUtils, drag an **Unzip** step to the process editor.

   b. Specify the name as `Expand WAR`.

   c. In the **Extract directory** field, specify the following code:

   ```
   ./JPetStore_expanded
   ```

   d. In the **.zip files** field, specify the following file:

   ```
   JPetStore.war
   ```

   e. In the **Include Files** field, specify the following code:

   ```
   **/*
   ```

   f. Click **OK**.

9. Add a step to update the property file with the location of the database:

   a. In the list of available steps, expand **Utilities**, and from FileUtils add an **Update Java Properties File** step to the process editor.

   b. Specify the name as `Update property file`.

   c. In the **Directory Offset** field, specify the following folder:

   ```
   ./JPetStore_expanded/WEB-INF/classes/properties
   ```

   d. In the **File Includes** field, specify the following file:

   ```
   database.properties
   ```

   e. In the **Add/Update properties** field, specify the following code:

   ```
   url=${p:environment/db.url}
   ```

   This code updates the **url** property in the property file with the location of the database. The `${p:environment/db.url}` code is a variable that represents the location of the database component when the application is deployed.

   f. Click **OK**.

10. Add a step to update the WAR file with the new property file:

a. From the list of available steps, expand the **Utilities**, and from FileUtils, add a **Create .zip File** step to the process editor.

b. Specify the name as `Update WAR`.

c. In the **.zip File Name** field, specify the following file:

```
JPetStore.war
```

d. In the **Base Directory** field, specify the following folder:

```
./JPetStore_expanded
```

e. In the **Include** field, specify the following code:

```
**/*
```

f. Select the **Update Existing** check box.

g. Click **OK**.

11. Add a step to start Tomcat:

a. In the list of available steps, expand **Application Server**, and from Java/Tomcat, add a **Start Tomcat** step to the process editor.
If this step is not in the tree, install the Tomcat plug-in as described in the Prerequisites on page 1935 for this tutorial.

b. Accept the default name `Start Tomcat`.

c. In the **Launcher** field, specify the following code:

```
${p:environment/tomcat.start}
```

This code is another variable that represents the command to start Tomcat.

d. In the **Startup timeout (in seconds)** field, specify `60`.

e. In the **Port** field, specify the port `8081`.

f. In the **Catalina Home** field, specify the home directory where the Apache Tomcat is installed.

g. Click **OK**.

12. Add a step to remove any previous versions of the application:

a. In the list of available steps, expand **Application Server**, and from Java/Tomcat, add an **Undeploy Application** step to the process editor.

b. Accept the default name `Undeploy Application`.

c. In the **Tomcat Manager URL** field, specify the following code:

```
${p:environment/tomcat.manager.url}
```

d. In the **Tomcat Manager User Name** field, specify the user name for the Tomcat server.
You specified this user name and its password in Configuring the agent and target system on page 1935. If you used the code examples from that topic, the user name and password are `tomcatmanager`.

e. In the **Tomcat Manager Password** field, specify the password for the Tomcat server.

f. In the **Context Name** field, specify the following context name, including the preceding forward slash:

```
/${p:environment/tomcat.contextroot}
```

Ensure that you include a slash (`/`) before the variable.

g. Click **OK**.

13. Add a step to deploy the updated WAR file to the application server:

a. In the list of available steps, expand **Application Server**, and from Java/Tomcat, add a **Deploy Application** step to the process editor.

b. Accept the default name `Deploy Application`.

c. In the **Tomcat Manager URL** field, specify the following code:

```
${p:environment/tomcat.manager.url}
```

d. In the **Tomcat Manager User Name** field, specify the user name for the Tomcat server.

e. In the **Tomcat Manager Password** field, specify the password for the Tomcat server.

f. In the **Context Name** field, specify the following context name:

```
/${p:environment/tomcat.contextroot}
```

Ensure that you include a slash (`/`) before the variable.

g. In the **War File Path** field, specify the following path:

```
./JPetStore.war
```

h. Click **OK**.

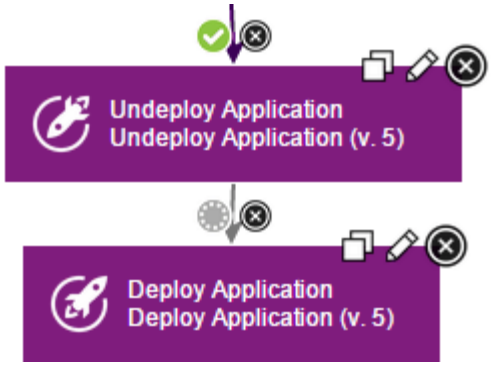
14. **Optional:** If required, arrange and connect the steps in the following order:

a. `Start`
b. `Clean working directory`
c. `Download Artifacts`
d. `Expand WAR`
e. `Update Property File`
f. `Update WAR`
g. `Start Tomcat`
h. `Undeploy Application`

i. `Deploy Application`

j. `Finish`

15. Change the conditional flag on the link between the `Undeploy Application` and `Deploy Application` steps to `both` by clicking the green check mark on the connection until it turns to a gray circle, as shown in the following figure:



Each connection from one step to another has a *conditional flag*. The conditional flag specifies a condition for the connection. Three conditional flags are available:

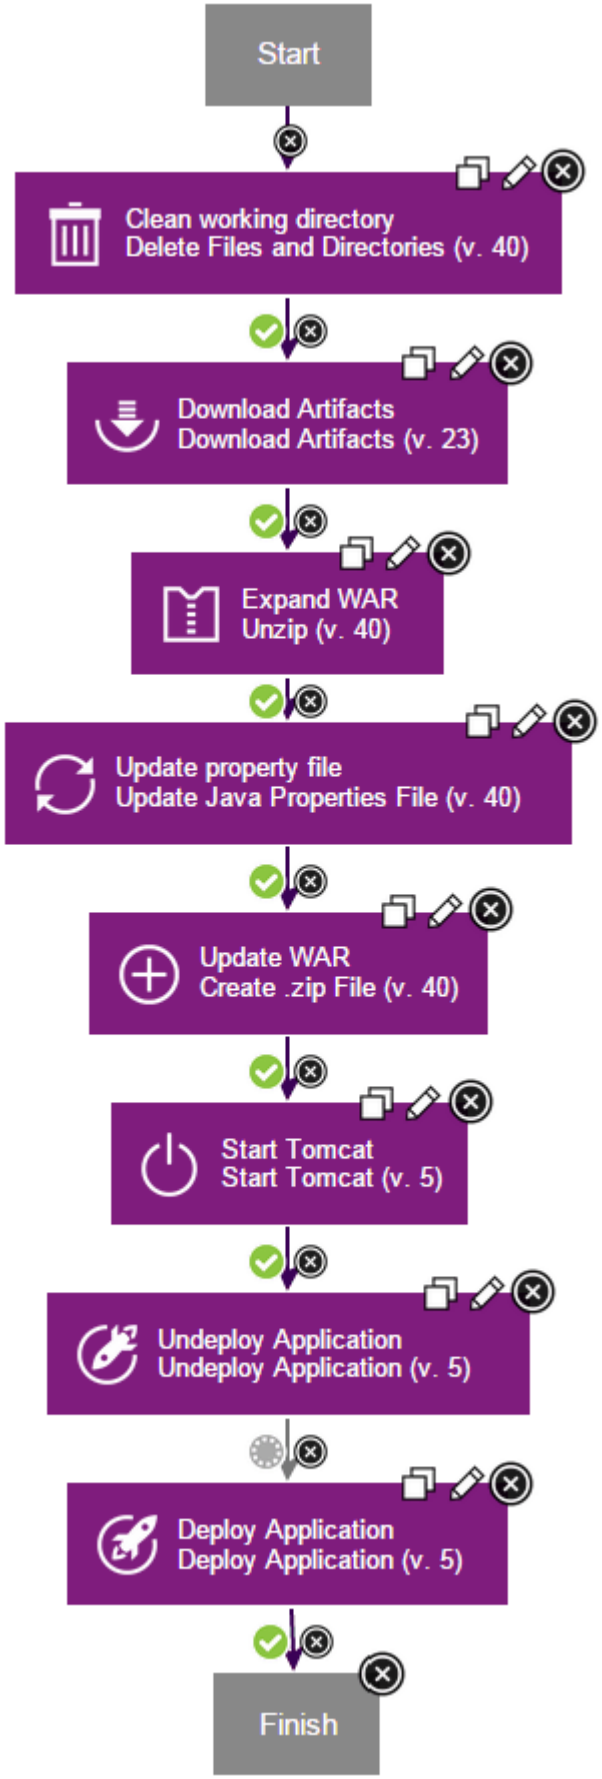
- By default, the conditional flag on each connection is set to `success`, which is represented by a green check mark. The process follows these connections when the step succeeds.
- The conditional flag `fail` is represented by an exclamation point (!) in a red field. The process follows these connections when steps fail.
- The conditional flag `both` is represented by a gray circle. The process follows these connections regardless of whether a step succeeds or fails.

The `Undeploy Application` step fails if no previous versions of the application are installed. In this case, setting the conditional flag on the connection to `both` specifies that the process keeps running regardless of whether the step fails or succeeds.

16. Save the process.

Results

The complete component process for the application component looks like the following figure:



Start
Clean working directory
Delete Files and Directories (v. 40)
Download Artifacts
Download Artifacts (v. 23)
Expand WAR
Unzip (v. 40)
Update property file
Update Java Properties File (v. 40)
Update WAR
Create .zip File (v. 40)
Start Tomcat
Start Tomcat (v. 5)
Undeploy Application
Undeploy Application (v. 5)
Deploy Application
Deploy Application (v. 5)
Finish

Creating a component process for the database component

The deployment process for the database component updates the database with sample values.

1. From the **Components** tab, click the `JPetStore-DB` component.
2. Click **Processes**, and then click **Create Process**.
3. In the **Create Process** window, specify the name as `Deploy component`.
4. In the **Process Type** list, select **Deployment**.
5. Accept the default values for the other properties, and click **Save**.
6. In the process editor, add a step to download the artifacts.
   As you did for the web component, add a `Download Artifacts` step, and accept the default properties.
7. Add a step to update the database:
   You must create a database version table on every target database either manually before you run the DBUpgrader plug-in steps for the first time or as part of the first change.

   a. In the list of available steps, expand **Database**, and under DBUpgrader, add an **Upgrade DB** step to the process editor.
      If this step is not in the tree, install the database upgrade plug-in as described in the Prerequisites on page 1935 for this tutorial.

   b. In the **Edit Properties** window, in the **Name** field, accept the default value of `Upgrade DB`.

   c. In the **Driver Classname** field, specify the following class:

   ```
   com.mysql.cj.jdbc.Driver
   ```

   d. In the **DB Driver Jar** field, specify the following path:

   ```
   lib/mysql-connector-j-8.0.33.jar
   ```

   This file is provided in the source code for the component.

   e. In the **URL** field, specify the following variable:

   ```
   ${p:environment/db.url}
   ```

   f. In the **User** field, specify the user ID of the database user.
      If you used the examples in Configuring the agent and target system on page 1935, the user ID is `jpetstore`.

   g. In the **Password** field, specify the password of the database user.
      If you used the examples in Configuring the agent and target system on page 1935, the password is `jppwd`.

   h. In the **SQL File path** field, specify a single period: `.` .

   i. In the **SQL File Include** field, specify the extension `*.xml` .

   j. In the **Current Version SQL** field, specify the following SQL code:

   ```
   SELECT VER FROM DB_VERSION WHERE RELEASE_NAME = ?
   ```

   k. In the **Delete Version SQL** field, specify the following SQL code:

```
DELETE FROM DB_VERSION WHERE RELEASE_NAME = ?
```

l. In the **Update Version SQL** field, specify the following SQL code:

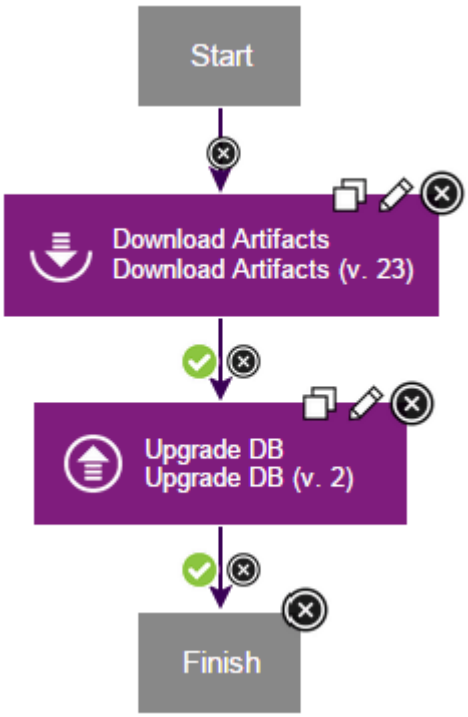
```
INSERT INTO DB_VERSION (RELEASE_NAME,VER) VALUES(?,?)
```

m. Click **OK**.

8. **Optional:** If required, arrange and connect the steps in the following order:
   a. `Start`
   b. `Download Artifacts`
   c. `Upgrade DB`
   d. `Finish`
9. Save the process.

Results

The complete component process for the database component looks like the following figure:



In this lesson, you created component processes to deploy the components.

You can use component processes to automate many different tasks on components. However, you generally do not run component processes directly; in most cases, you add them to application processes. Later in this tutorial, you will create an application process for these three component processes.

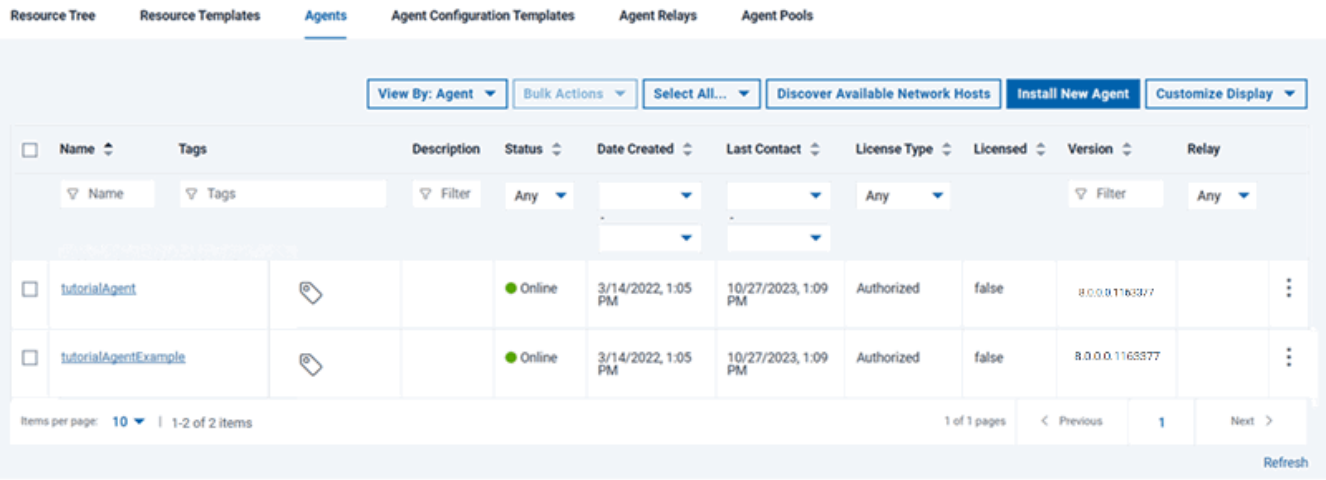
Processes consist of steps, which are provided by plug-ins. To see a list of plug-ins that are available, and for documentation on those plug-ins and steps, see HCL Plug-ins.

Lesson 3: Creating an application and an environment

Applications are collections of components. Environments represent systems on which you deploy the application components.

Before you begin

Before you start this lesson, ensure that your agent is running. Click **Resources > Agents** and make sure that your agent is listed as `Online`, as in the following figure:



About this task

In this lesson, you add the three components to an application and then create an environment on which to deploy the application. You also add your agent to the environment.

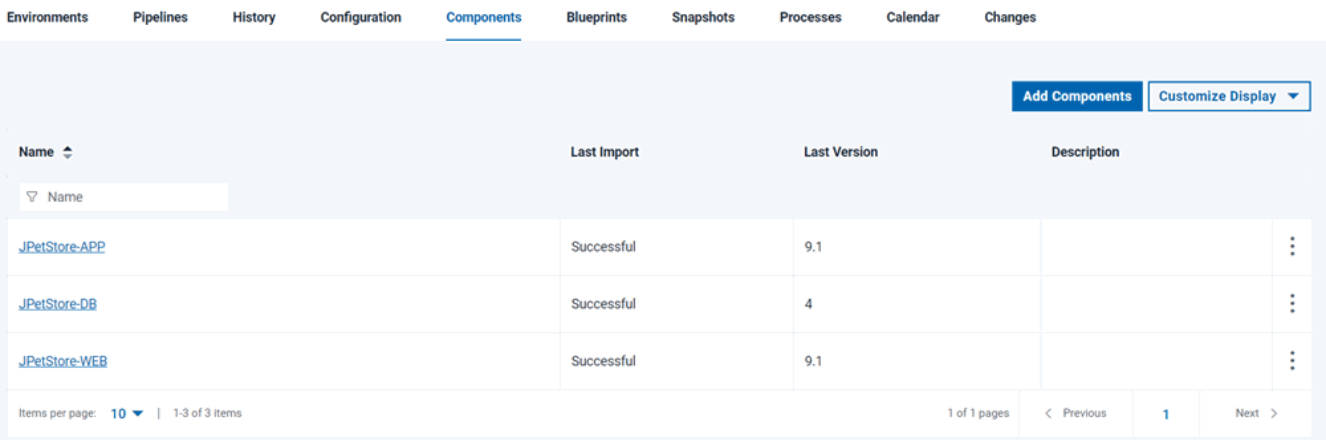
Creating an application

Creating an application involves selecting the components that are in the application.

1. Click the **Applications** tab, and then click **Create Application**.
2. Name the new application `JPetStore`, and then click **Save**.
3. Add the components to the application:
    a. Click the **Applications** tab, and then click the new application, `JPetStore`.
    b. Click the **Components** tab for the application (not the **Components** tab at the top of the page), and then click **Add Component**.
    c. In the **Add a Component** window, in the **Select a Component** list, select the three components: `JPetStore-APP`, `JPetStore-WEB`, and `JPetStore-DB`.
    d. Click **Save**.

Results

The application includes the three components, as shown in the following figure. Components can be included in any number of applications.



Creating an environment

Creating an environment involves selecting one or more agent resources and specifying which components are deployed to each agent resource.

1. Define an environment for the application:
    a. Go to the **Environments** tab for the application.
    b. Click **Create Environment**.
    c. Specify the name to be `Tutorial environment 1`.
    d. Accept the defaults in the other fields in this window and click **Save**.
2. Specify the properties for the environment.
    When you created the component processes, you included parameters that specify the location of artifacts on the target system, such as the location of the application server. Because these properties can vary on different target systems, you specify these properties as environment properties.

    a. Open the environment by clicking the environment name.

    b. Open the environment properties by clicking **Configuration** and then clicking **Environment Properties**.

    c. Add the following properties one at a time by clicking **Add Property** and specifying the name and value of the property as shown in the following table:

    Table 676. Properties for the environment

Property	Description	Example
`tomcat.home`	The Tomcat home folder on the target computer	`/opt/apache-tomcat-9.0.100` on Linux™ or `C:\apache-tomcat-9.0.100` on Windows™
`tomcat.con`	The Tomcat webapp folder on the target computer, which is an identifier in the application URL	For all versions of Tomcat, specify `JPetStoreDev`

Property	Description	Example
`textroot`		
`db.url`	The URL to the MySQL database, relative to the target system	If you installed MySQL on the same system as the agent and used the database name `jpetstore`, the URL looks like the following example: `jdbc:mysql://host-or-ip:3306/jpetstore`
`tomcat.manager.url`	The location of the Tomcat manager application	For Tomcat version 9, specify `http://host-or-ip:8081/manager/text`
`tomcat.start`	The location of the startup script for Tomcat	`/opt/apache-tomcat-9.0.100/bin/startup.sh` on Linux™ or `C:\apache-tomcat-9.0.100\bin\startup.bat` on Windows™

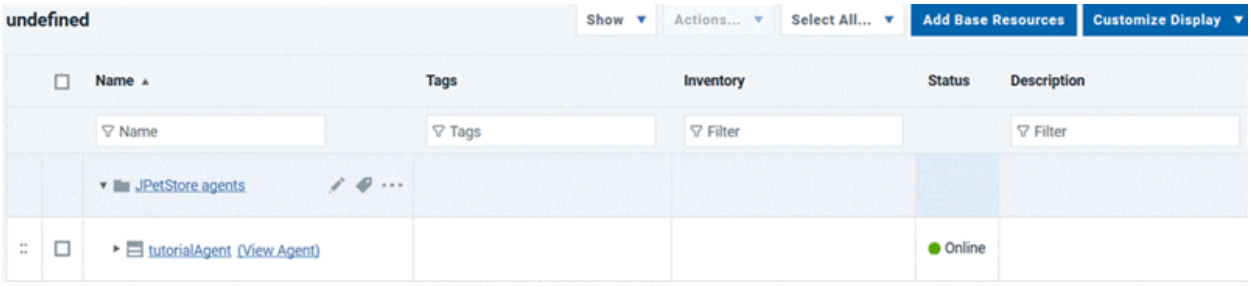
3. Add the agent to the environment.
   When you set up the agent, you added the agent as a resource to a resource group. Now you can use that resource as part of the environment, as described in the following steps:

   a. Click the **Resources** tab for the environment.
      Make sure that you are on the **Resources** tab for the environment and not the **Resources** tab at the top of the page.

   b. Click **Add Base Resources**.
      Result
      The **Add Resource to Environment window shows all of the resources that are available on the server.**

   c. Select the check box next to your agent and then click **OK**.

   Result
   The resource is shown on the **Resources** tab for the environment, as shown in the following figure:



4. Map the components to this agent resource.
   If you had many agents on a system with multiple nodes, you would specify which components run on each agent resource. In this case, you have only one agent resource, so all of the components run on this agent.

a. On the same row as the agent resource, click **Actions > Add Component**.
   The **Actions** button does not appear until you hover the mouse over the resource.

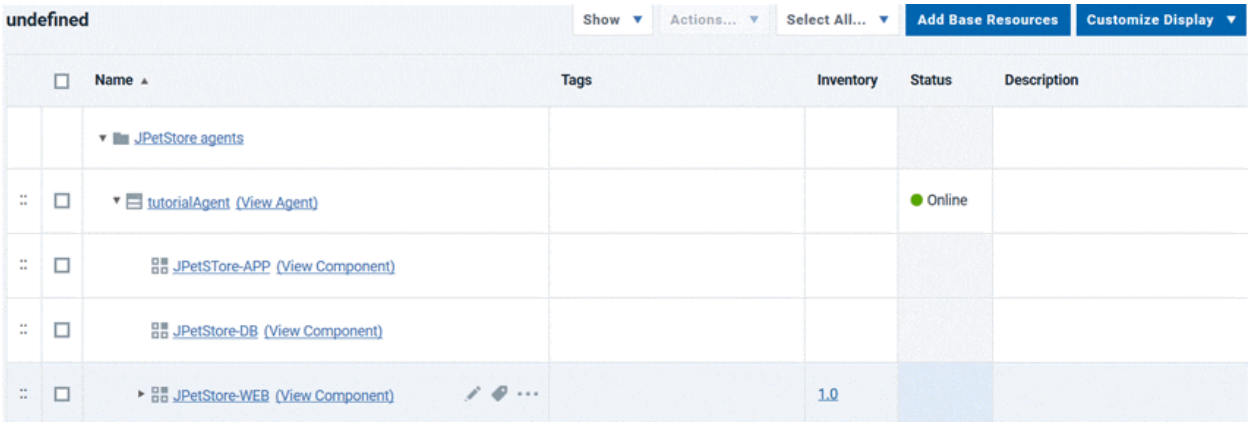
b. Select the application component and then click **Save**.

c. Repeat the process to add the other components to the resource.

Note: Be sure to add each component to the agent resource and not to another component. The components must be at the same hierarchy level, and not as child items of each other.

Result

Now the components are mapped to the target system, as shown in the following figure:



Results

The new environment appears on the **Environments** tab. Now that the environment is prepared and the agent is running, you can run application processes on the environment to deploy the components.

Lesson 4: Creating an application process

Application processes tie together component processes.

About this task

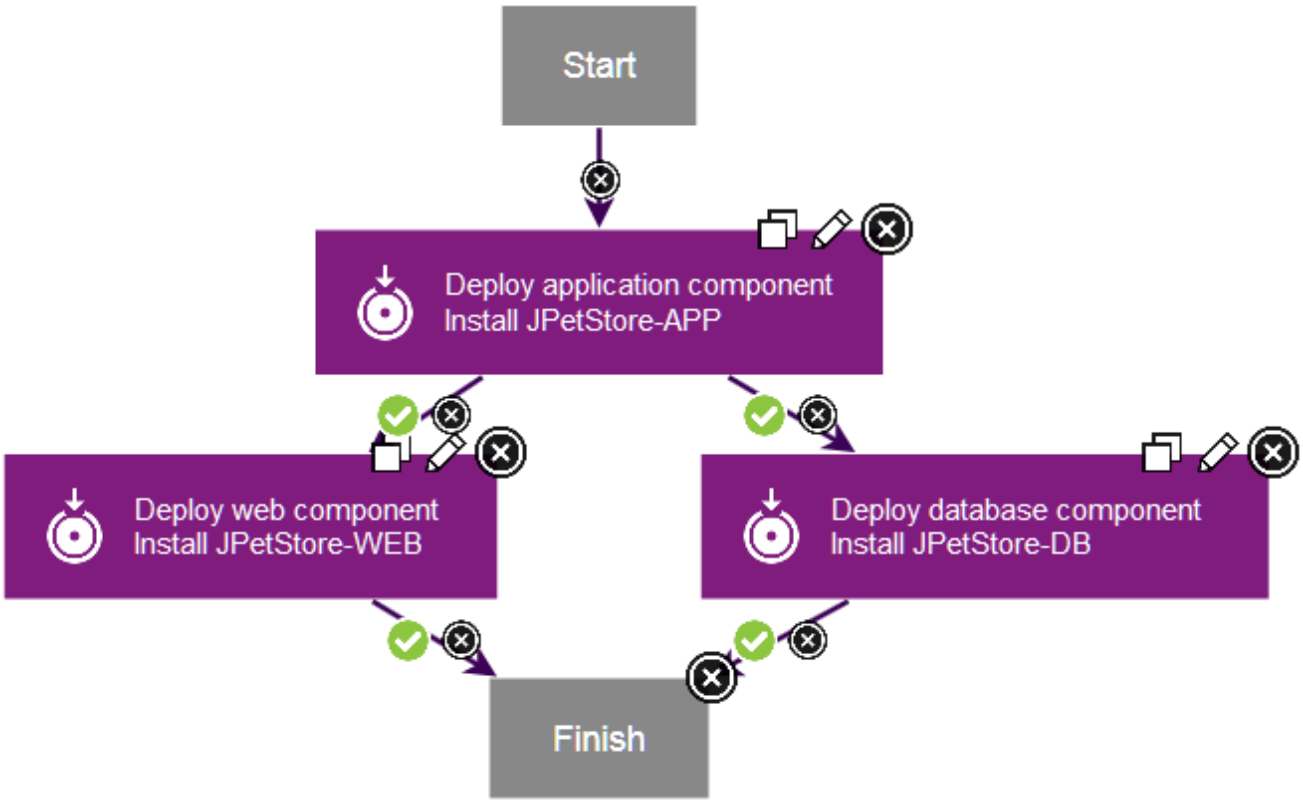
In this lesson, you create an application process to install the components by calling each component process.

1. Click the **Applications** tab, and then click the **JPetStore** application.
2. Click **Processes**, and then click **Create Process**.
   Be sure to click the **Processes** tab within the application and not the **Processes** tab at the top of the page, which leads to generic processes.
3. In the **Create an Application Process** window, name the new application process `Deploy JPetStore`.
4. Accept the default values for the other fields, and click **Save**.
5. Click the new process to open it in the process editor.
   The process editor for application processes is similar to the process editor for component processes. However, for application processes, the steps are limited to calling component processes and a few utility steps.

6. Add a step to deploy the application component:
    a. From the list of steps, add an **Install Component** step to the process editor.
    This step calls component processes that have a process type of `Deployment`.
    b. In the **Edit Properties** window, name the step `Deploy application component`.
    c. In the **Component** list, select the `JPetStore-APP` component.
    d. In the **Component Process** list, select the `Deploy Component` component process.
    e. Click **OK**.
7. Similarly, add a step that is named `Deploy component` to deploy the web and database components.
8. Verify that the `Start` step is connected to the `Deploy application component` step.
9. Instead of connecting the remaining steps in a straight line, follow these steps to connect the steps so that they run at the same time.
    Use the figure at the end of this step as a reference point.
    a. Connect the `Deploy application component` step to the `Deploy web component` step.
    b. Connect the `Deploy application component` step to the `Deploy database component` step.
    Result
    Now these two steps will run at the same time, after the application step.
    c. Connect both the `Deploy web component` step and the `Deploy database component` step to the `Finish` step.
10. Save the process.

Results

The complete application process deploys the application component first and then deploys the web component and database components at the same time. The application process looks like the following figure:



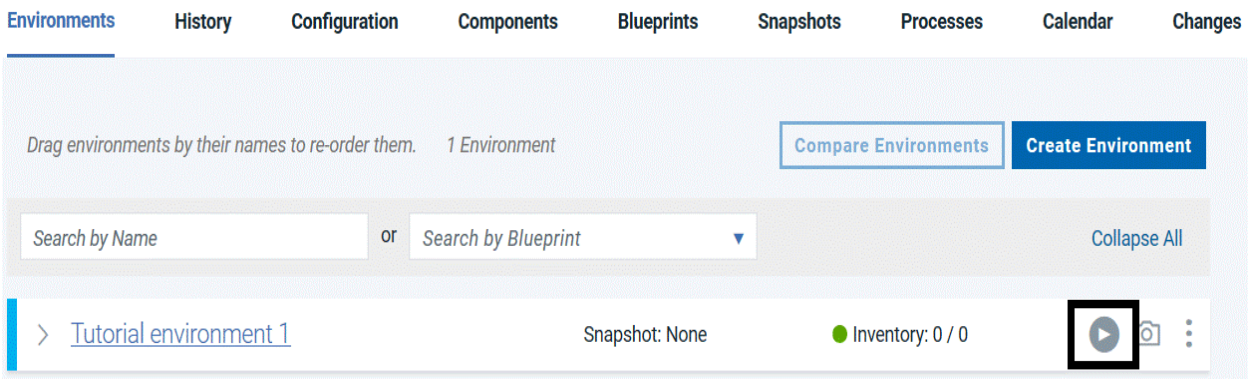
Lesson 5: Deploying the application components

To deploy the components in the application, run the application process on the new environment.

About this task

Now that you have an environment and all the necessary processes, you can deploy the components by running the application process.

1. Open the application page by clicking **Applications** and then clicking the application name.
2. In the same row as your environment, click the **Request Process** icon, as shown in the following figure.

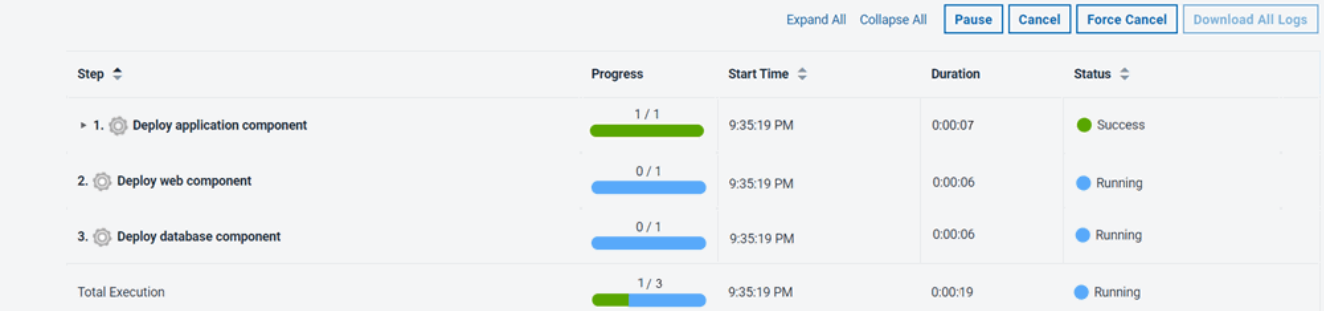


3. In the **Process** field, select the `Deploy JPetStore` process.
4. Go to **Choose Component Versions** and click **Select For All > Latest Available**.
   Make sure that version 1.0 is selected for each component, as shown in the following figure:

   You must select a version for each component; if you do not select a version, that component is not deployed.
5. Review the deployment settings and click **Submit**.

Results

The web page shows you the progress of the application process request. From this page, you can watch as the processes run. The following figure the application process partially completed. The application component process is finished and the other two component processes are running.



If the process runs successfully, the request shows that each component process is finished, as in the following figure:

Step	Progress	Start Time	Duration	Status
1. Deploy application component	1 / 1	12:28:47 PM	0:01:00	Success
1. Deploy web component	1 / 1	12:28:48 PM	0:00:15	Success
1. Deploy database component	1 / 1	12:28:49 PM	0:00:15	Success
Total Execution	3 / 3	12:28:47 PM	0:01:30	Success

In this case, you can view the running application at the following URL, by substituting the host name of your target system for *hostname*. This is the host name of the agent that you configured in Configuring the agent and target system on page 1935. In the URL, specify the *tomcat.contextroot* value that you entered for this environment after the port number.

```
http://hostname:8081/JPetStoreDev
```

The application shows a simple online shopping site in the form of a pet store. The following figure shows the home page:

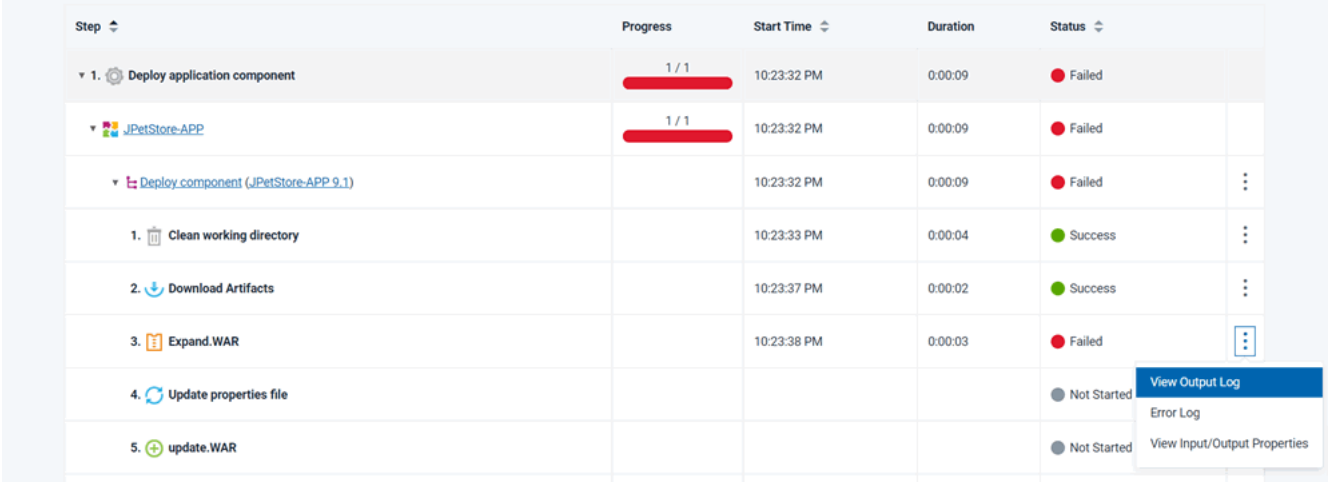
Welcome to JPetStore 4

Enter the Store

Powered By
iBATIS
© Clinton Begin

From the home page, click **Enter the Store** and then browse the items that are available, as shown in the following figure:

If the application process did not run successfully, one of the component processes might have failed. In this case, the process is listed with a status of `Failed`. To troubleshoot this failed process, expand the log section for the component, and find the step that failed:



Click **View Output Log** to look at the command-line output log for each step in the process..

If one of your component processes did not complete, identify the step that did not complete. Verify that the properties for that step are correct and that the steps are in the correct order in the process. Then, run the application process again.

Note: If you run the application process again, be sure to clear the **Only Changed Versions** check box and select the versions of each component. If you leave this check box selected, the server runs the component processes only for components that have new versions.

This application process installed each of the components in the application by running their component processes.

Application processes can also uninstall or update components or run other configuration tasks for the application and its components.

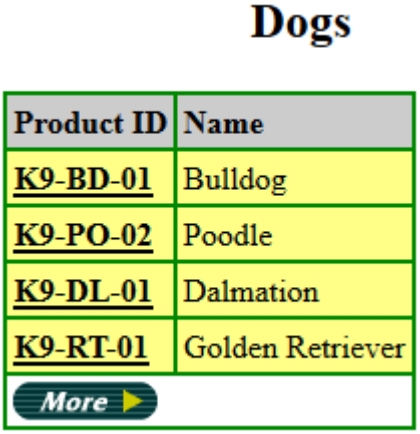
Lesson 6: Updating the application

In the first lesson, you deleted certain versions of the components. In this lesson, you add those versions again to simulate deploying a new version of the components.

About this task

The web application that you deployed in the previous lesson included version 1 of the web component and database component. Version 1.1 of these components includes a new item for the online store: a Bichon in the Dogs category.

1. Verify that `Bichon` is not available in the Dogs category:
    a. Open the application by opening a web browser to the following URL:
    ```
    http://hostname:8081/JPetStoreDev
    ```
    b. Click **Enter the Store**.
    c. Browse the Dogs category and verify that `Bichon` is not available.
    The following figure shows some of the dogs in this category:



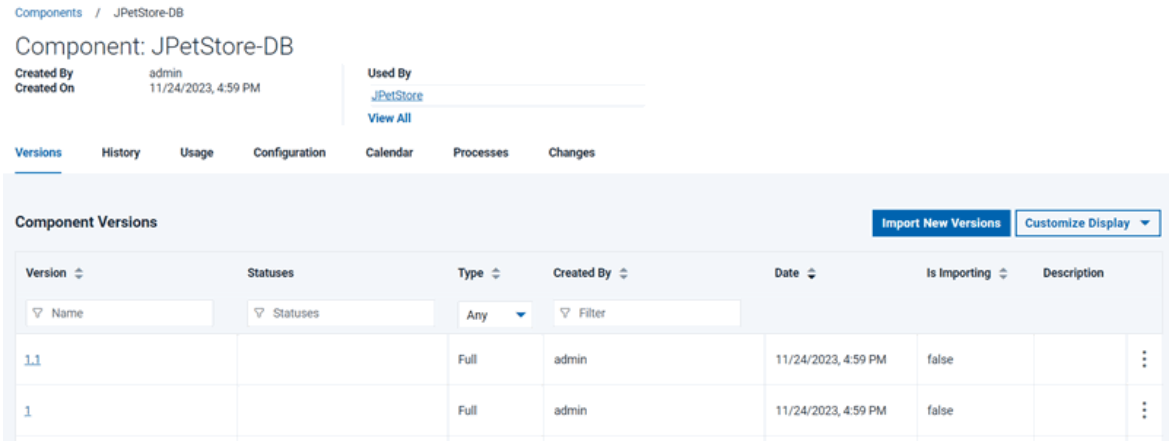
2. Import the new version of the database component:

a. On the Deploy server, click the **Components** tab and then click the JPetStore-DB component.

b. Click the **Versions** tab and then click **Import New Versions**.

Result

Now, version 1.1 is shown in the list of versions, as shown in the following figure:



c. Click the new version of the database component to open its information page.

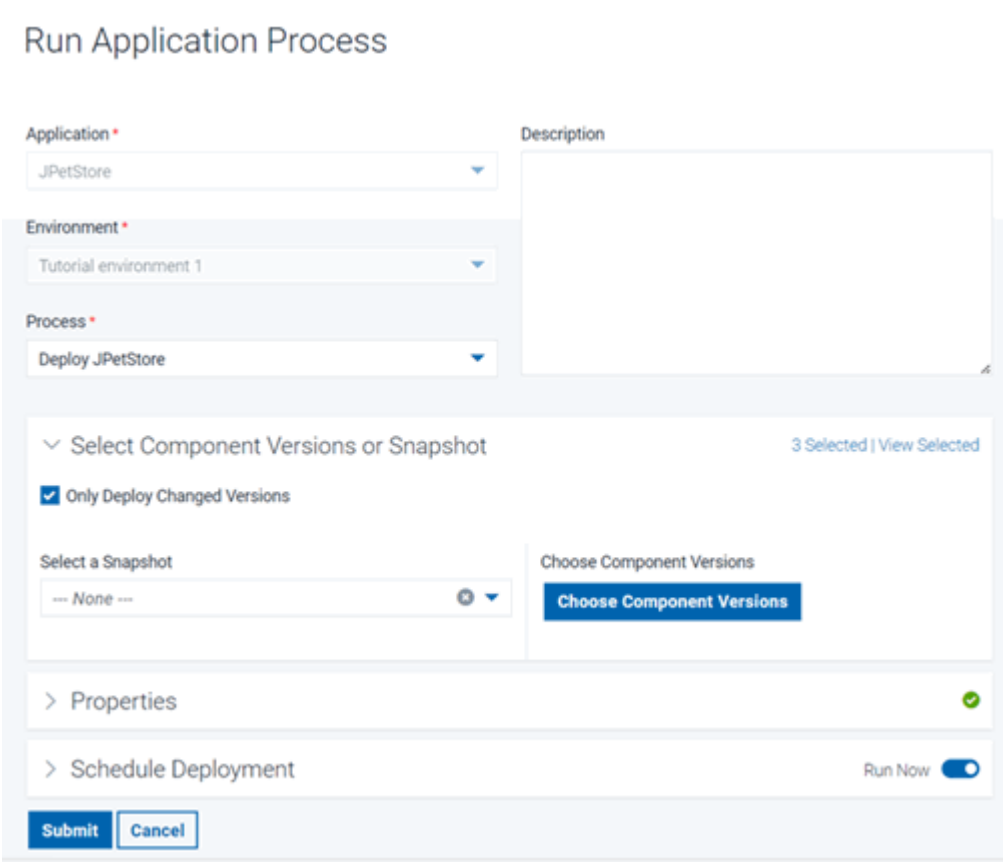
d. Click the **Configuration** tab.

e. Under **Basic Settings**, in the **Type** list, select **Incremental** and then click **Save**.

Result

This version is set to be an incremental upgrade rather than a new version. Full versions are installed directly, without installing prior versions first. Incremental upgrades start with prior versions, and then the new version is installed over the prior versions. The new database version is only an addition to the database, so it requires the prior version of the component.

3. In the same way, import version 1.1 of the web component without changing the **Type** setting.
   The application component does not have any additional versions.
4. Click **Applications** and then click the JPetStore application to get back to the list of environments.
5. On the environment, run the application process again.
   In the **Run Process** window, be sure to select the latest version for each of the components by clicking **Choose Versions** and then clicking **Select For All > Latest Available**. Optionally, you can select the **Only Changed Versions** check box so that the server deploys only the components with new versions. In this case, the server runs the component processes only for the web and database components.



6. In your web browser, reload the web application and explore the Dogs category to see the new `Bichon`, as shown in the following figure:

   This new item demonstrates that the database component is updated to version 1.1
7. Click the Product ID for `Bichon` and then the Item ID to see the product page for `Bichon`.

The new graphic for this item demonstrates that the web component is updated to version 1.1.

Results

Now the application includes the new versions of the components.

In a production scenario, new versions of components might become available frequently. You can run the application process as often as necessary to update the deployed components. You can also configure the application process to run automatically when new versions of the components are available.

Now that you have completed this tutorial, you can continue learning about how to deploy components by using snapshots. See the tutorial Creating and deploying snapshots on page 1970.

Summary

In this tutorial, you learned to deploy and update an application with HCL DevOps Deploy (Deploy).

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How Deploy structures applications and manages automated deployment instructions
- How to import the components of an application
- How to create processes that specify automated tasks for components and applications
- How to configure environments for deployments
- How to manage the component versions on an environment by running processes

Creating and deploying snapshots

In this tutorial, you deploy a simple web application to a new environment with HCL DevOps Deploy (Deploy). You create a snapshot of the components in an application, and then deploy the snapshot to an environment.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a snapshot of an environment's components to quickly deploy its application to another environment.
- Configure environments on which to deploy applications.
- Select a snapshot while you run an application process to promote the snapshots to a new environment.

Time required

Approximately 1 hour

Note: You must complete Deploying a simple web application on page 1934 before you begin this tutorial.

Introduction

In this tutorial, you deploy a simple web application to a new environment with HCL DevOps Deploy (Deploy). You create a snapshot of the components in an application, and then deploy the snapshot to an environment.

You can use Deploy to facilitate a continuous deployment pipeline in your release cycle. You can plan and automate the deployment of complex applications to development, test, and production environments. You can use this tool to deploy applications as often as needed and to as many different environments as you require. By using snapshots, you combine the planning and automation capabilities of Deploy with the ability to quickly and precisely control the contents of your delivery pipeline's environments.

When you develop a complex application, you use many tests to validate that all the application components work together. After your application passes the tests, you must ensure that you promote the correct collection of application components to the next step in your continuous delivery pipeline. However, you must ensure that you promote the set of components that passed the tests. In Deploy, you use snapshots. A snapshot specifies all the versions of an application’s components that are used in an environment. The snapshot also specifies versions of configuration, such as deployment processes, that are used to deploy those components. If you use snapshots to deploy to different environments in your continuous delivery pipeline, you no longer must track and promote individual components through the environments in your pipeline. Instead, you promote configurations of components that were tested together. This ability to promote tested snapshots of components to environments is essential in maintaining a continuous delivery pipeline.

In this tutorial, you use snapshots to deploy the components, application, and processes that you created for a three-tiered web application to a new environment. In most cases, you use snapshots to manage complex deployment environments in Deploy. You typically use snapshots to control deployments to different environments on different servers. However, for simplicity, in this lesson you use snapshots to deploy an application to two different environments on a single server.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a snapshot of an environment's components to quickly deploy its application to another environment.
- Configure environments on which to deploy applications.
- Select a snapshot while you run an application process to promote the snapshots to a new environment.

Time required

This tutorial takes approximately 1 hour to finish. If you explore other concepts that are related to this tutorial, it might take longer to complete.

System requirements

To run this tutorial, you must have an installation of Deploy, version 6.0 or later

Prerequisites

- Make sure that you completed the Deploying a simple web application on page 1934 tutorial and have access to its Deploy server and computers, virtual images, or cloud instances.
- You must have an account on the server with the permissions to create and edit environments and to run processes.
- You must know the user names and passwords for the MySQL database and Apache Tomcat manager role that you configured in the Deploying a simple web application on page 1934 tutorial.

Configuring the server and target system

Modify the HCL DevOps Deploy (Deploy) server that you used in the previous tutorial. Create another agent resource and incorporate a new environment property to allow for easy reuse.

Before you begin

Before you begin the tutorial, make sure that you completed the Prerequisites on page 1971.

About this task

To work through this tutorial, you must use the target system that you configured in the Deploying a simple web application on page 1934 tutorial.

This system hosts the following items that are associated with your Deploy JPetStore application:

- A Deploy agent
- A MySQL database
- An instance of Apache Tomcat

You must have MySQL and Apache Tomcat installed on the system. Follow these steps to set up an agent resource, create a new MySQL database, and redeploy your application to your environment:

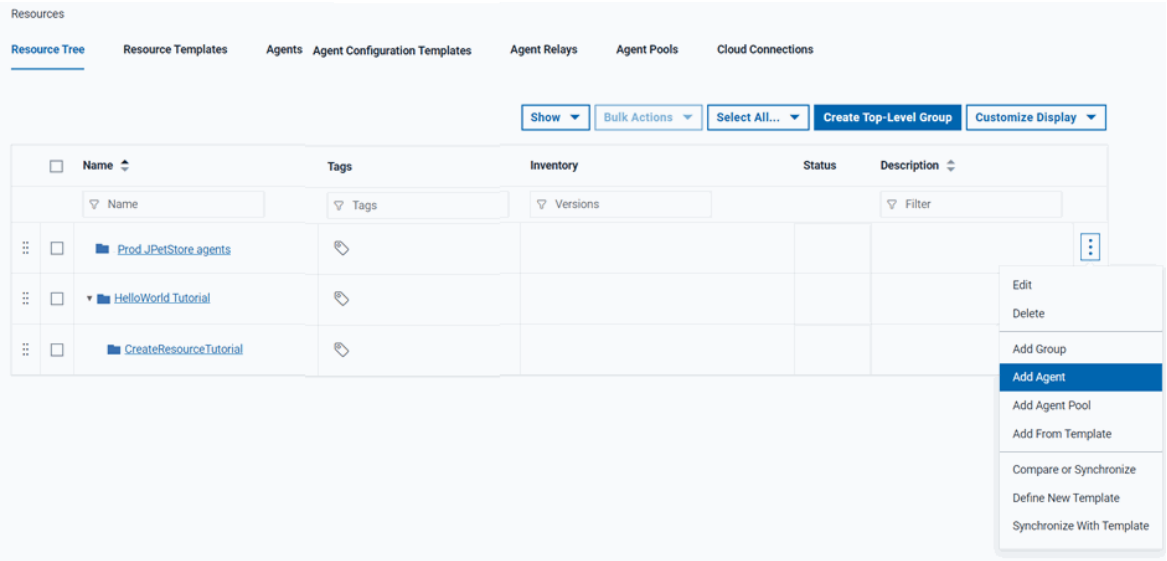
1. Create another resource and add the existing agent to it.
   To reuse the agent with another environment on the same Deploy server, you must associate the agent with another resource.

   a. On the Deploy server, click the **Resources** tab.
      Be sure to click the **Resources** tab at the top of the page.

b. From the **Resource Tree** tab that is displayed, click **Create Top-Level Group**.

c. In the **Create Resource** window, provide the new group with a name such as `Prod JPetStore agents` and click **Save**.

d. On the same row as the new resource group, click **Actions > Add Agent**, as shown in the following figure:



e. In the **Create Resource** window, select the agent in the **Agent** field and click **Save**.

Result

The agent is listed as a child of both resource groups. By associating the agent with both resource groups, you can use the same agent with your existing environment and the one that you create in a later lesson.

2. Create an empty database for the application to use in another environment:

a. Log in to the MySQL command line as the MySQL root user.

Example

For example, if you installed MySQL as the root user, run this command from the command line:

```
mysql -u root
```

Result

The command line shows a prompt that looks like this prompt:

```
mysql>
```

b. Create the database with the following command:

```
create database jpetstoreprod;
```

Result

If the command runs correctly, you see this message: `Query OK, 1 row affected`.

c. Give the existing database user access rights to the database.

The database user that has access to the `jpetstoredev` database must have access to the new database too. If you used the default user name in the Deploying a simple web application on page 1934 tutorial, create another database by using the following command:

```
grant all privileges on jpetstoreprod.* to 'jpetstore'@'host-or-ip';
```

Note: If you used the default settings when you configured the original database, the password for user `jpetstore` is `jppwd`.

Result

If the command runs correctly, you see this message: `Query OK, 0 rows affected`.

d. Type `quit` to exit the MySQL command line.

3. Verify that the user can access the database:

a. From the command line, log in to MySQL as the existing user:

```
mysql -u jpetstore -pjppwd
```

b. Run the following command to list the databases on the system:

```
show databases;
```

c. Verify that both the `jpetstoreprod` and `jpetstoredev` databases appear in the list, as shown in the following figure:

Result

```
mysql> show databases;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| jpetstoredev       |
| jpetstoreprod      |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

d. Type `quit` to exit the MySQL command line.

4. Before you deploy your application, confirm that all environment properties contain the correct values:

a. From the **Applications** tab of your Deploy server, click the `JPetStore` application.

b. Open the environment by clicking the environment name.

c. Open the environment properties by clicking **Configuration** and then clicking **Environment Properties**. Be sure to click the **Configuration** tab for your application, not the **Configuration** tab at the top of the page.

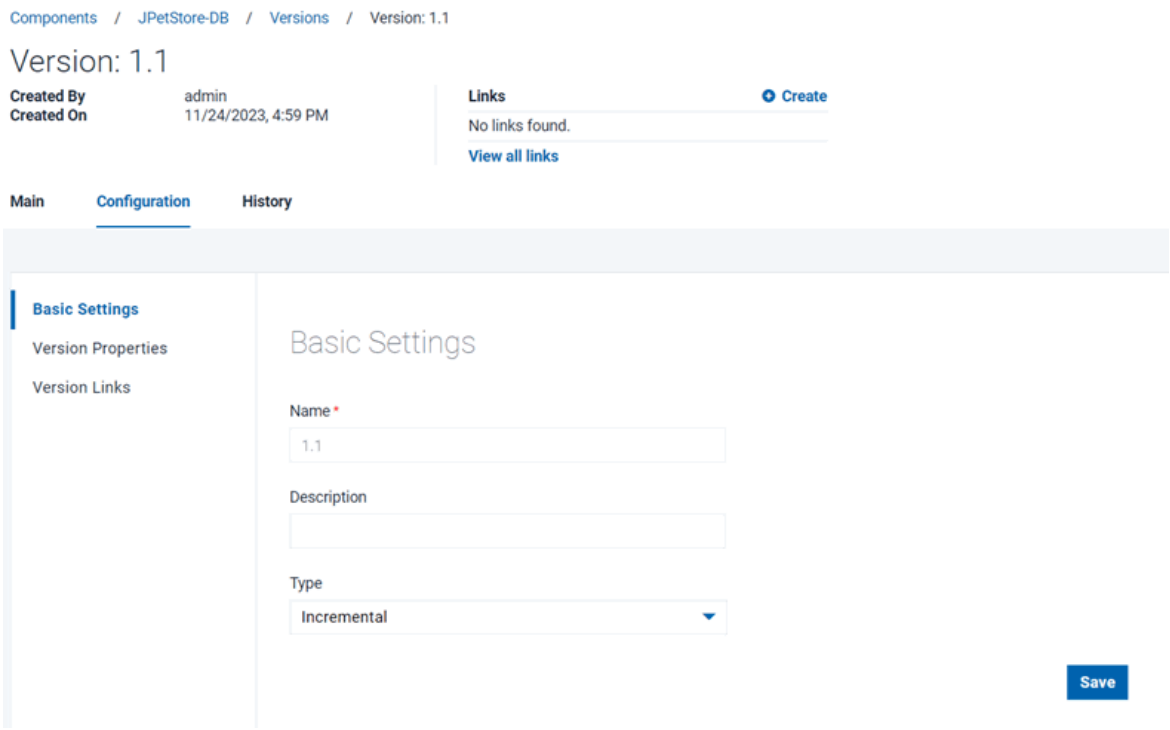
Result

The environment properties are displayed as shown in the following table:

Table 677. Properties for the environment

Property	Description	Example Value
`tomcat.home`	The Tomcat home folder on the target computer	`/opt/apache-tomcat-9.0.100` on Linux™ or `C:\apache-tomcat-9.0.100` on Windows™
`tomcat.contextroot`	The Tomcat webapp folder on the target computer, which is an identifier in the application URL	For Tomcat version 9, specify `JPetStoreDev`
`db.url`	The URL to the MySQL database, relative to the target system	If you installed MySQL on the same system as the agent and used the database name `jpetstore`, the URL looks like the following example: `jdbc:mysql://host-or-ip:3306/jpetstore`
`tomcat.manager.url`	The location of the Tomcat manager application	For Tomcat version 9, specify `http://host-or-ip:8081/manager/text`
`tomcat.start`	The location of the startup script for Tomcat	`/opt/apache-tomcat-9.0.100/bin/startup.sh` on Linux™ or `C:\apache-tomcat-9.0.100\bin\startup.bat` on Windows™

5. To ensure that the `JPetStore-DB` component is deployed correctly, confirm that component version `1.1` is an incremental version.
   An incremental component version contains only the changes that are associated with that version. For the component to be complete, you must deploy the previous versions of the component as well.
   a. From the **Components** tab, click the `JPetStore-DB` component.
   b. Click the **Versions** tab to display the available component versions, and then click `1.1` to display its attributes.
   c. Click the **Configuration** tab. Make sure to click the **Configuration** tab that is within the component, not the **Configuration** tab at the top of the page.
   d. On the **Basic Settings** panel, confirm that `Incremental` is selected from the **Type** list, as shown in the figure:



e. If `JPetStore-DB` version `1.1` is not set to **Incremental**, from the **Type** list, select **Incremental**, and then click **Save**.

6. To confirm that you configured your environment and component correctly, redeploy the application to your environment:

   a. Click the **Applications** tab, and then click the `JPetStore` application.

   b. In the same row as your environment, click the **Request Process** icon.
   Result
   The **Run Process** window opens.

   c. Clear the **Only Changed Versions** check box.

   d. In the **Process** list, select `Deploy JPetStore`.

   e. Click **Choose Versions**.
   The **Component Versions** window opens.

   f. In the **Select For All** list, click **Latest Available**.

   g. In the same row as `JPetStore-DB`, click **Add**.

   h. From the displayed list, select `1.0`.
   Result
   Your list of **Versions to Deploy** is displayed.

i. To record your version selections, click **OK**.

j. To deploy your application, click **Submit**.

Result

Deploy runs the application process, and your application is deployed.

Results

The agent and the target system are configured for your work with the sample application. You need the password that you used and locations that you specified in this lesson later.

Lesson 1: Adding snapshots

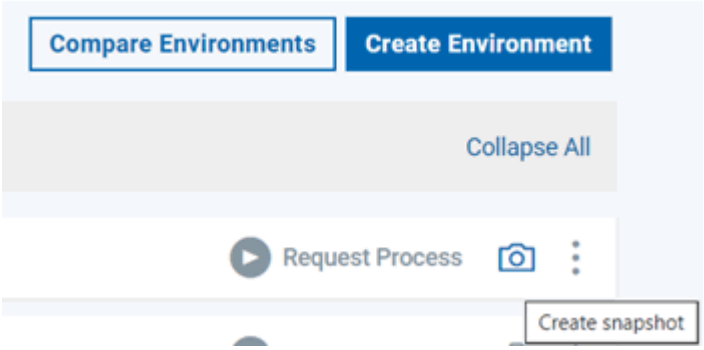
Creating a snapshot involves saving a collection of component versions that are part of an application.

About this task

These steps describe how to create a snapshot that uses components of the sample application. In the Deploying a simple web application on page 1934 tutorial, you deployed the JPetStore application twice to the same environment. In the second deployment, you used two components that contain new information. In this lesson, you create a snapshot that uses the same components as the deployed environment. You create a snapshot from a functioning development environment in preparation for deployment to the next phase of your continuous delivery pipeline. In a later lesson, you deploy this snapshot to a new environment. By deploying with snapshots in Deploy, you can quickly bring a new environment to a specific state.

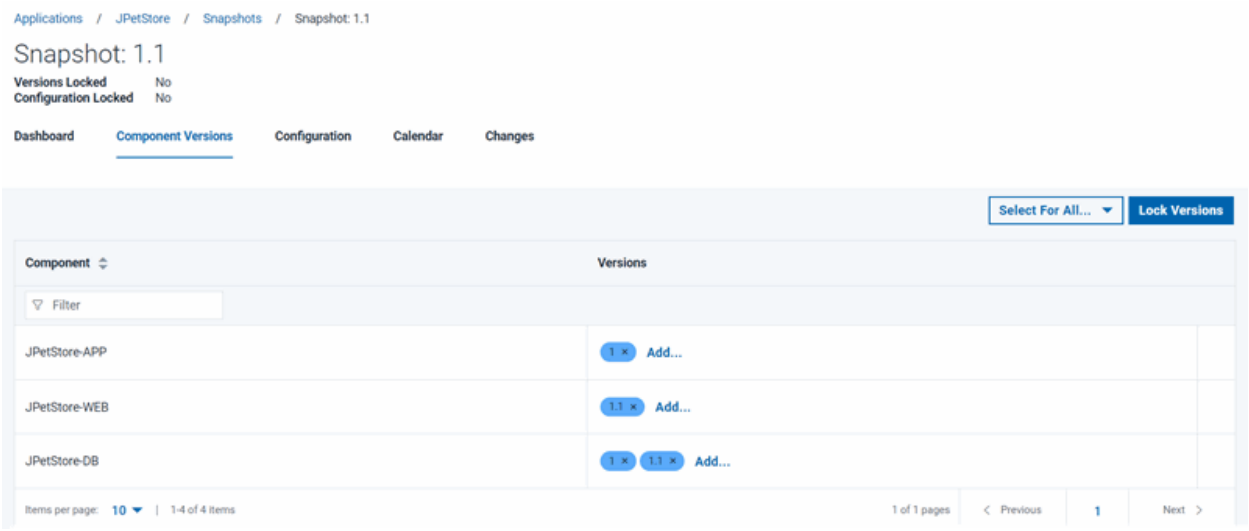
Before you begin: Make sure that your Deploy server has the prerequisites that are listed in Prerequisites on page 1971 and that you completed the steps in Configuring the server and target system on page 1971.

1. Click the **Applications** tab, and then click `JPetStore`.
2. In the same row as your environment, click the **Create Snapshot** icon, as shown in the following figure:



3. In the **Create Snapshot** window, specify the name to be `Version 1.1`.
4. Accept the default values in the other field, and then click **Save**.
5. Click the **Component Versions** tab.

   The snapshot is shown as in the following image.



The `JPetStore-DB` component uses incremental versions and must contain both the `1.0` and `1.1` versions to deploy. If the `JPetStore-DB` component does not contain both versions, you must update the component version. See Configuring the server and target system on page 1971.

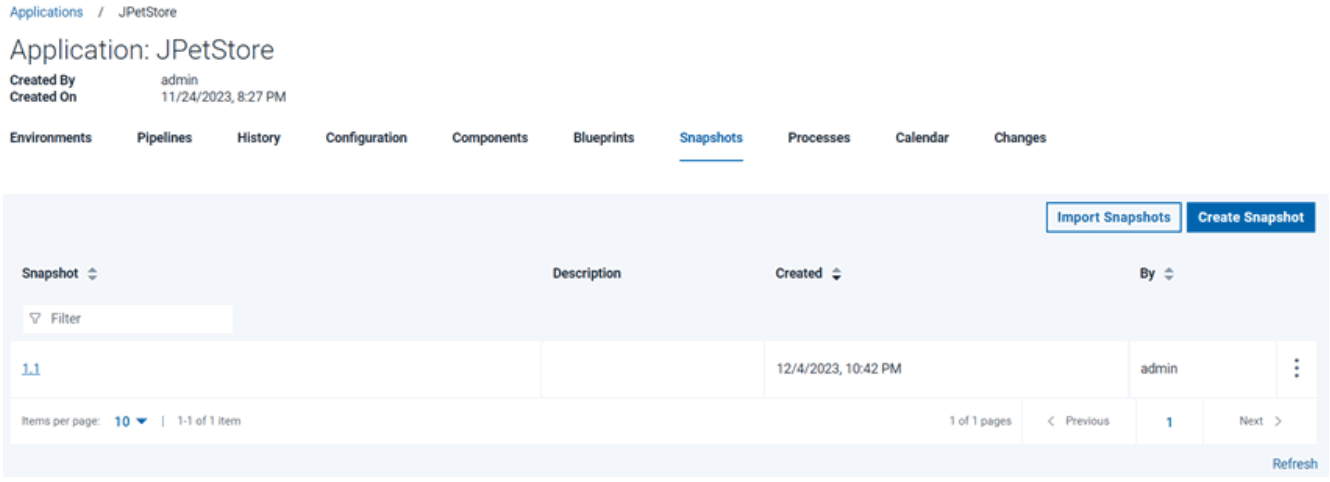
Result

The `JPetStore-DB` component uses incremental versions and must contain both the `1.0` and `1.1` versions to deploy. If the `JPetStore-DB` component does not contain both versions, you must update the component version. See Configuring the server and target system on page 1974.

Results

In this lesson, you added a snapshot to the application. The snapshot is based on the components in the application that are currently deployed to an environment.

On the application's **Snapshots** page, you have a snapshot, as shown in the following figure:



In the next lesson, you create an environment to for the next step in the JPetStore application's delivery pipeline.

What to do next

After you create a snapshot that describes a collection of components, you can deploy the snapshots to an environment. In the next lesson, you create another environment.

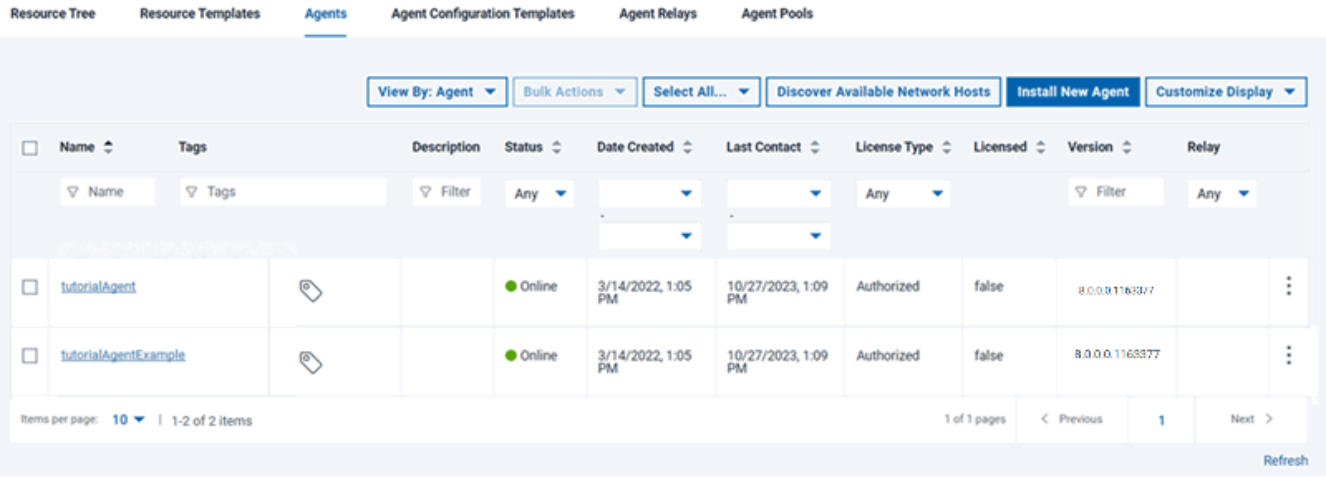
For more information about creating snapshots, see Creating snapshots on page 2383.

Lesson 2: Creating an environment

Environments are deployment targets for the application components that you specify. You create another environment in the application's delivery pipeline to facilitate multiple active applications. You apply an agent resource and specify which components the agent resource deploys.

Before you begin

Before you start this lesson, ensure that the agent is running. Click **Resources > Agents** and make sure that your agent is listed as `Online`, as in the following figure:



About this task

In this lesson, you create an environment to deploy the snapshots that you created. You also add your agent to the environment. By adding a second environment, you can mimic a simple delivery pipeline that has two environments.

1. Define an environment for the application:
    a. Click the **Applications** tab, and then click `JPetStore`.
    b. From the **Environments** tab for the application, click **Create Environment**.
    c. Specify the name to be `Tutorial environment 2`.
    d. Accept the default values in the other fields in this window, and click **Save**.
2. Specify the properties for the environment.
    When you created the component processes, you included parameters that specify the location of artifacts on the target computer system, such as the location of the application server. Because these properties can vary on different target systems, you specify these properties as environment properties.

    a. Open the environment by clicking the environment name.

    b. Open the environment properties by clicking **Configuration** and then clicking **Environment Properties**.

c. Add the following properties one at a time by clicking **Add Property** and specifying the name and value of the property as shown in the following table:

Table 678. Properties for the environment

Property	Description	Example Values
`tomcat.home`	The Tomcat home folder on the target computer	`/opt/apache-tomcat-9.0.100` on Linux™ or `C:\apache-tomcat-9.0.100` on Windows™
`tomcat.contextroot`	The Tomcat webapp folder on the target computer, which is an identifier in the application URL	For Tomcat version 9, specify `JPetStoreProd`
`db.url`	The URL to the MySQL database, relative to the target system	If you installed MySQL on the same system as the agent and used the database name `jpetstoreprod`, the URL looks like the following example: `jdbc:mysql://host-or-ip:3306/jpetstoreprod`
`tomcat.manager.url`	The location of the Tomcat manager application	For Tomcat version 9, specify `http://host-or-ip:8081/manager/text`
`tomcat.start`	The location of the start script for Tomcat	`/opt/apache-tomcat-9.0.100/bin/startup.sh` on Linux™ or `C:\apache-tomcat-9.0.100\bin\startup.bat` on Windows™

3. Add the agent to the environment.
   You added the agent as a resource to another resource group. Next, you add that resource to the environment, as described in the following steps:

   a. Click the **Resources** tab for the environment.
      Make sure that you are on the **Resources** tab for the environment and not the **Resources** tab at the top of the page.

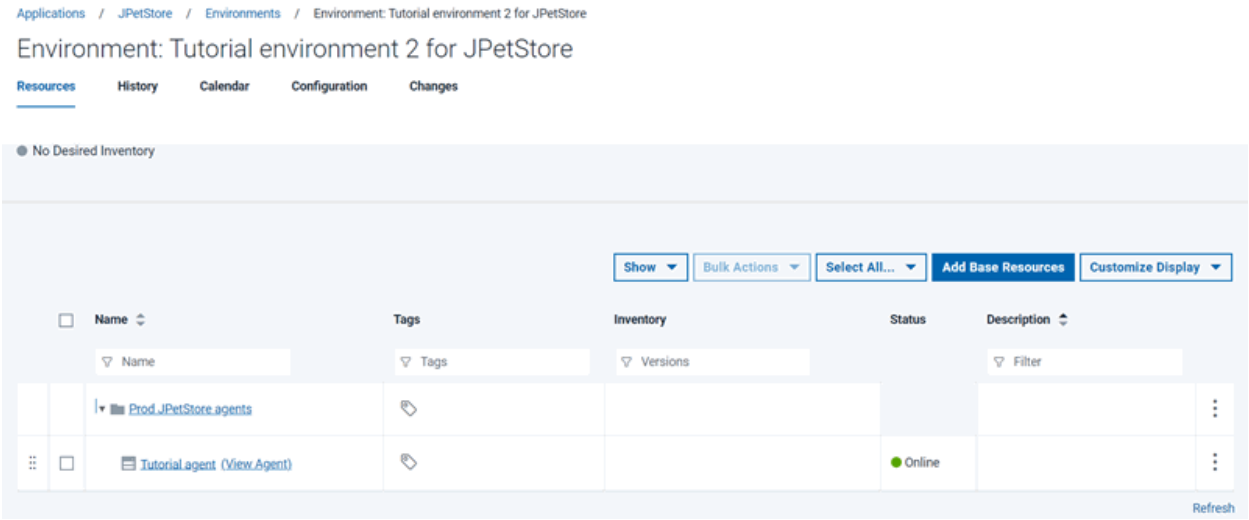
   b. Click **Add Base Resources**.
      Result
      The **Add Resource to Environment** window shows all the resources that are available on the server.

c. Select the check box next to your agent in the `Prod JPetStore agents` resource, and then click **OK**.

Note: Since one agent deploys the components for in both application environments, ensure that the agent you select is in the agent resource that you created for your new environment. You must not select the agent in the agent resource that is associated with the application's other environment.

Result

The resource is shown on the **Resources** tab for the environment, as shown in the following figure:



4. Map the components to this agent resource.
   If you had many agents on a system with multiple nodes, you would specify which components run on each agent resource. In this case, you have only one agent resource, so all the components run on this agent.

   a. On the same row as the `Prod JPetStore agents` resource, click **Actions > Add Component**.
      The **Actions** button is not displayed until you hover the mouse over the resource.

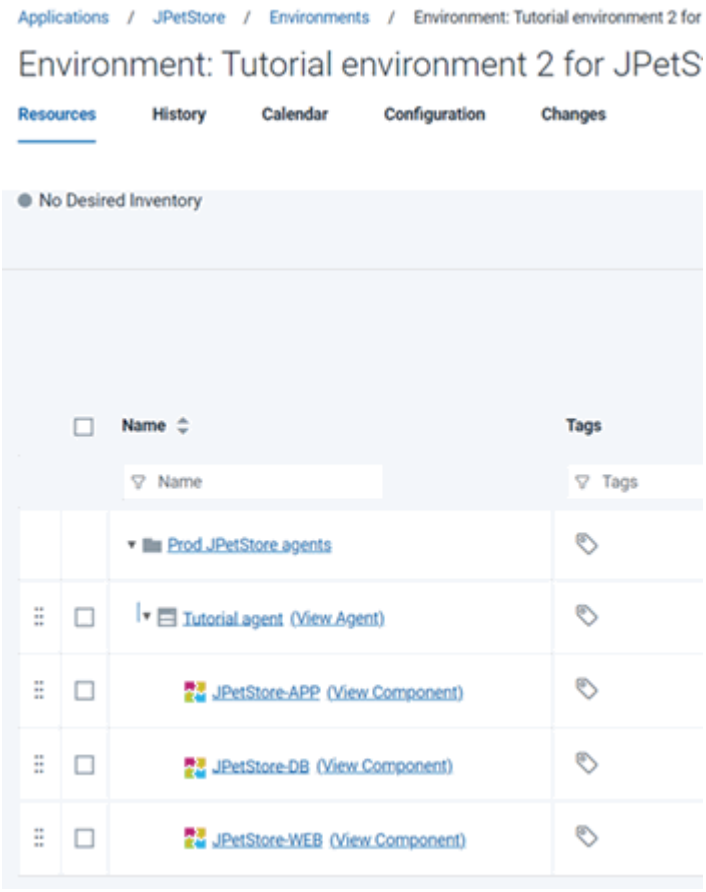
   b. Select the application component and then click **Save**.

   c. Repeat the process to add the other components to the resource.

   Note: Be sure to add each component to the agent resource and not to another component. The components must be at the same hierarchy level, and not child items of each other.

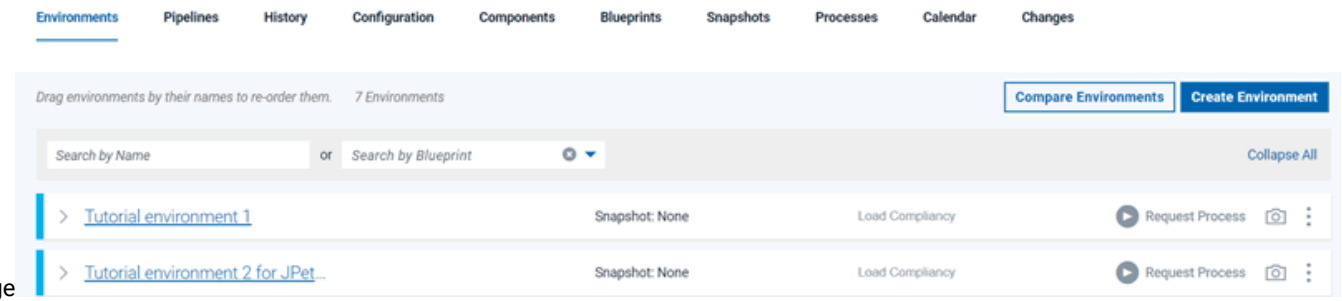
   Result

The components are mapped to the target system, as shown in the following figure:



Results

The **Environments** tab includes the new environment, as shown in the following image



With the environment prepared and the agent running, you can run the application process on the environment to deploy the components that you specified in the snapshot.

What to do next

In this lesson, you added an environment to the application

In the previous tutorial, you proved that the components in the first environment are compatible and complete. You can use the snapshot that you created to quickly promote all the components to the new environment. Your delivery pipeline might include deploying an application to testing and quality assurance servers before you deploy it to a production server. By using a snapshot, you can ensure that you quickly and correctly select all the right component versions as you move an application through the delivery pipeline.

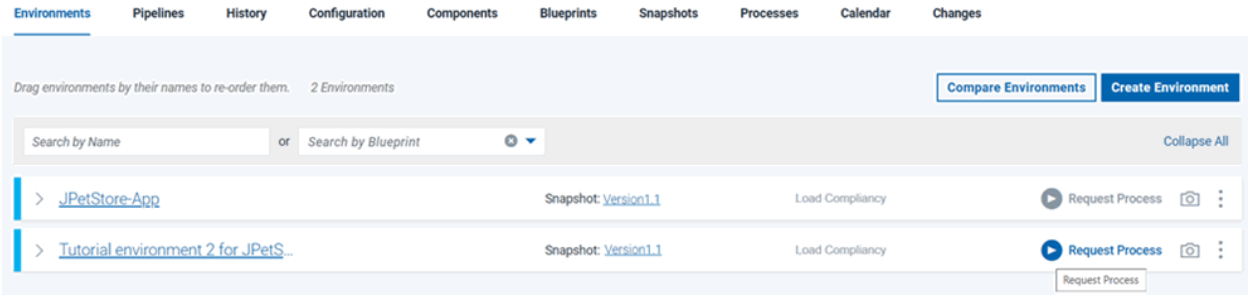
Lesson 3: Deploying the snapshots

To promote the snapshot to an environment, apply the snapshot when you run the application process.

About this task

In this lesson, you apply a snapshot to your new environment to quickly promote the components to a new environment. When you request the application process, you select the snapshot to deploy a selected set of components to an environment.

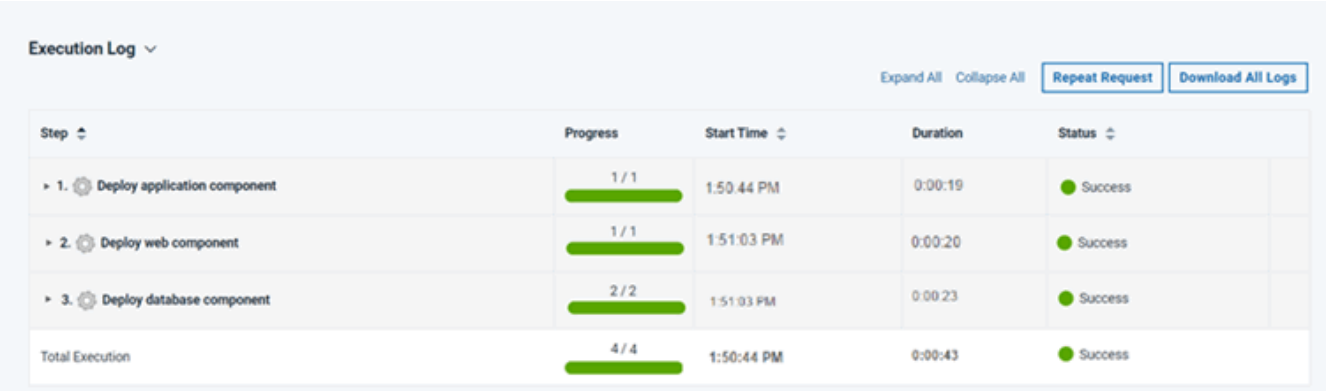
1. Open the application page by clicking **Applications** and then clicking `JPetStore`.
2. In the same row as your new environment, click the **Request Process** icon, as shown in the following figure.



3. In the **Run Process** window, in the **Process** list, select the `Deploy JPetStore` process.
4. In the **Snapshot** list, select the `Version 1.1` snapshot.
5. Click **Submit**.

Results

The web page shows you the progress of the application process request, and you can watch as the processes run. If the process finishes, the request shows that each component process is finished, as in the following figure:



You can view the running application at the following URL by substituting the host name of your target system for *hostname*. This is the host name of the agent that you configured in Configuring the agent and target system on page 1935. In the URL, specify the *tomcat.contextroot* value that you entered for this environment after the port number.

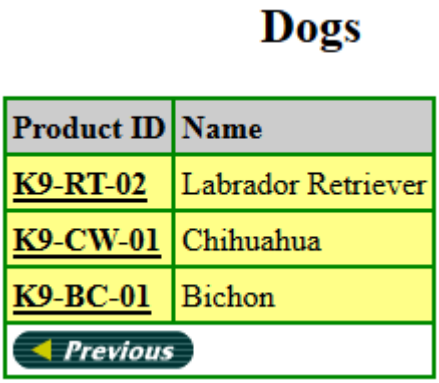
```
http://hostname:8081/JPetStoreProd
```

The application shows a simple online shopping site in the form of a pet store. The following figure shows the home page:

Welcome to JPetStore 4

Enter the Store

If you browse to the Dogs category, you see that the Bichon section is present. As you saw in the previous tutorial, this entry indicates that the JPetStore-DB component deployed both the 1.0 and 1.1 versions.



What to do next

This application process installed all components in the application by running their component processes. You defined the versions of the component processes in the snapshot.

You used a snapshot to quickly apply a compatible set of component processes to an application environment and viewed the deployed web page.

Summary

In this tutorial, you created and deployed a snapshot to an environment in HCL DevOps Deploy (Deploy).

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How to create a snapshot of the components of an application
- How to configure environments for deployments
- How to manage an application pipeline by moving specific application configurations from one environment to another

Advanced tutorials

Advanced tutorials for experienced users.

You can find tutorials in this section that cover particular use cases, such as the Blue-Green Deployment tutorial on page 1984.

Some tutorials in this section provide strategies for enterprise-scale scenarios with extensive resource requirements. Consequently, some tutorials abstractly simulate large-scale topologies. This approach means that you should be able to work through the tutorials by using a single system. Additionally, some tutorials provide a head-start by including resources that you can download or that build on other tutorials. The intermediate tutorial JPetStore tutorial on page 1934, for example, is referenced by several tutorials in this section.

Blue-green deployments

In this tutorial, you setup a deployment with two identical production environments, referred to arbitrarily as Blue and Green. One environment is always live, and the other environment is inactive and available to host an upgraded version.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Use tags to design resources for multiple-node environments Deploy.
- Configure environments for no-downtime deployments.
- Create application processes to deploy multiple components to multiple nodes.
- Configure user approvals for production deployments .

Time required

2-3 hours

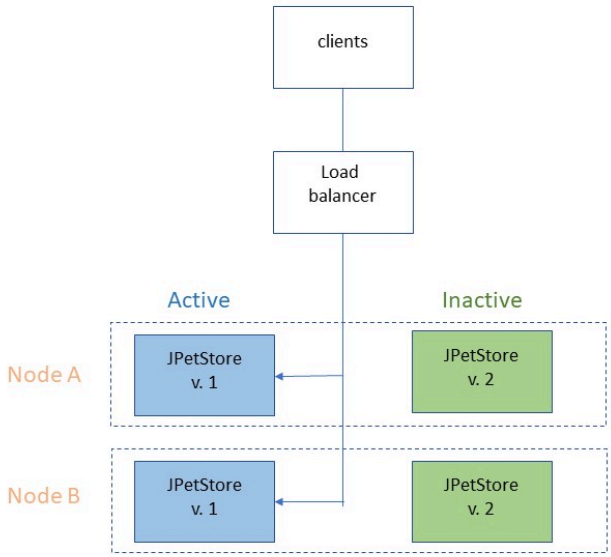
Introduction

In this tutorial, you setup a deployment with two identical production environments, referred to arbitrarily as Blue and Green. One environment is always live, and the other environment is inactive and available to host an upgraded version.

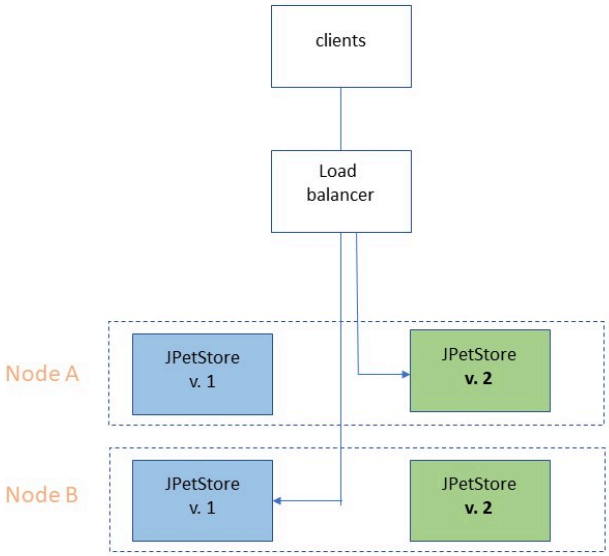
Business-critical multinode installations that must always remain in production require advanced updating strategies. *Blue-green deployments* fit this requirement because they provide smooth transitions between versions, zero-downtime deployments, and quick rollbacks.

A blue-green deployment uses two identical production environments. After verifying that an update in the inactive environment is working with a new version, you switch traffic to the new version. If anything goes wrong, you can quickly switch back to the old version.

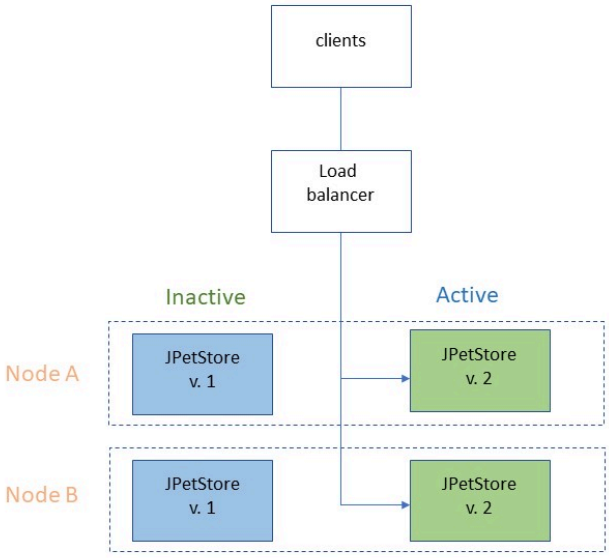
This graphic illustrates a two-node production topology. While customers use the nodes in the active blue environment, you update the inactive green environment with the new version. You can perform as many tests as required in the inactive green environment. When everything is ready, you only need to update the load balancer to switch production environments.



One approach is to switch traffic to a single updated node and validate it before switching the other nodes. Testing one node in this way is called a canary deployment. If the canary node fails, traffic remains uninterrupted because the non-updated nodes continue to serve customers.



If the update is successful, you direct the load balancer to switch all the remaining traffic to the other updated nodes.



When you are ready for the next release, you start the cycle over using the now-interactive blue environment.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Use tags to design resources for multiple-node environments Deploy.
- Configure environments for no-downtime deployments.
- Create application processes to deploy multiple components to multiple nodes.
- Configure user approvals for production deployments .

Time required

This tutorial takes 2 - 3 hours to finish. If you explore other concepts that are related to this tutorial, it could take longer to complete.

System requirements

To run this tutorial, you need the following resources:

- An installation of Deploy, version 8.2.0 or later.
- A Deploy agent installed in your environment.
- While not required, you can use multiple computers, virtual images, or cloud instances to use for agents in the tutorial.

Prerequisites

- This tutorial assumes familiarity with Deploy. If you new to the product, you might benefit from completing the Basic on page 1914 or Intermediate on page 1933 tutorials.
- You must have a Deploy account with the permissions to create and edit applications, environments, and components, and to create and run processes.
- This tutorial uses the application created in the JPetStore tutorial on page 1934. You can also download some of the resources created in the JPetStore tutorial. If you did not complete the JPetStore tutorial, you can use any multi-component application that you have sufficient permissions to update and modify.

Configuring the tutorial system

Configure the resources to define the blue and green systems.

Before you begin

Before you begin the tutorial, make sure that you complete the Prerequisites on page 1987.

About this task

Like all Deploy tutorials, to work through this one you need an agent that is running on a target computer system or systems. The target can be a cloud resource, a virtual image, or a physical computer.

1. The tutorial references the application created in the JPetStore tutorial on page 1992.
   If you did not complete that tutorial, you can use any multi-component Deploy application that you have sufficient permissions to modify.

2. While the examples in the tutorial show information for a Linux™ operating system, you can use any operating system.
3. Ensure that you have an agent installed in your environment.
   The way these logical environments are implemented relies on the way that Deploy represents target environments as resources. In the tutorial, you create a single production environment consisting of several nodes, and then duplicate the resources to represent the second system. These resources behave like separate systems, even though the resources point to the same physical system. For simplicity, you can use a single agent for the logical environments that you create in the tutorial.
4. Add component tags to the JPetStore components.

   You can tag components while you work on the **Components** tab, or you can tag components while you work in the **Resources** tab. Make sure that you use the **Components** tab because the tags that you associate with components in these two contexts behave differently.

   To add tags to components, complete the following steps:

   a. On the **Components** page, click the **Add tag** action for the JPet-Store-APP component, and then select the `JPetStore` tag.
      If you do not have the tag, in the **Add Tag** window, click **Create Tag**, and then define the new tag.

   b. Add the `JPetStore` tag to the JPet-Store-WEB, and JPet-Store-DB components.
      Later in the tutorial, you use the tag in an Install Multiple Components application process step on page 1992. For the step to work, the tagged component processes must all have the same name.

      Note: If you are using another multi-node application instead of JPetStore, add the same tag to each component used by the application.

   Result
   By using component tags, your resources and application can access all the components in an application with a single tag reference.

Creating the load balancer component

Create a component to abstractly represent the load balancer.

About this task
Multinode installations routinely use load balancers to rout incoming traffic to the next eligible node. There are many load balancers and just as many ways to configure them. For the tutorial, the load balancer is represented as a component within the JPetStore application.

The tutorial load balancer component has an operational process called `Change node port` that abstractly changes the active port on a node. You pass the port name that should be active during processing. You use the environment property `environment.LBPort` to define the logical environment's port.

1. Create a component and name it `Load balancer` or something similar.
2. Create an **Operational (No Version Needed)** process for the `Load balancer` component and name it `Change node port`, or something similar.
   You do not need versioning for the simple process that you create for the component.
3. Add the `Load balancer` component to the JPetSore application.

Results

The

Lesson 1 Define resources

Create agent resources for a multi-node deployment.

Before you begin

Before you begin the lesson, complete the Configuring the tutorial system on page 1987 topic.

About this task

In this tutorial you create two systems that are logically separate, but, for ease of use, run on the same hardware. The two environments behave in the same way and have the same dependencies.

To simulate separate physical environments, you can run the Blue and Green environments on the same server. If you have multiple servers available, of course you can use those. The Green resources run on one port, and the Blue resources run on another. This way, you can simply change the port to direct traffic to a different environment.

Deploy provides several loop-type steps that you can use to deploy multiple components. The For Each Agent loop, for instance, lets you control which agents run automated tasks. This way, even if you have a large number of agents, you can run tasks on specific agent groups by tagging agents and running tasks only on agents with those tags. The For Each Tag loop, which is similar, runs once for each of the resource tags that you specify. So you can organize the resources in your environment by tag, and then control which tags to use. For example, you can deploy to canary nodes first and all remaining nodes second, all in the same process.

Follow these steps to create the resource groups that represent the blue-green systems:

1. Create a top-level resource for the blue system.
   a. On the **Resources** page, click the **Resource Tree** tab, and then click **Create Top-Level Group**, and name the group `Blue System`.
   b. Add an agent resource to `Blue System` and name it `blue-A`
   c. Add the **JPetStore** component tag to `blue-A` agent resource.
      The single component tag references all three components in the JPetStore application.

Note: If you use you own application, make sure to tag the components and then use that tag.

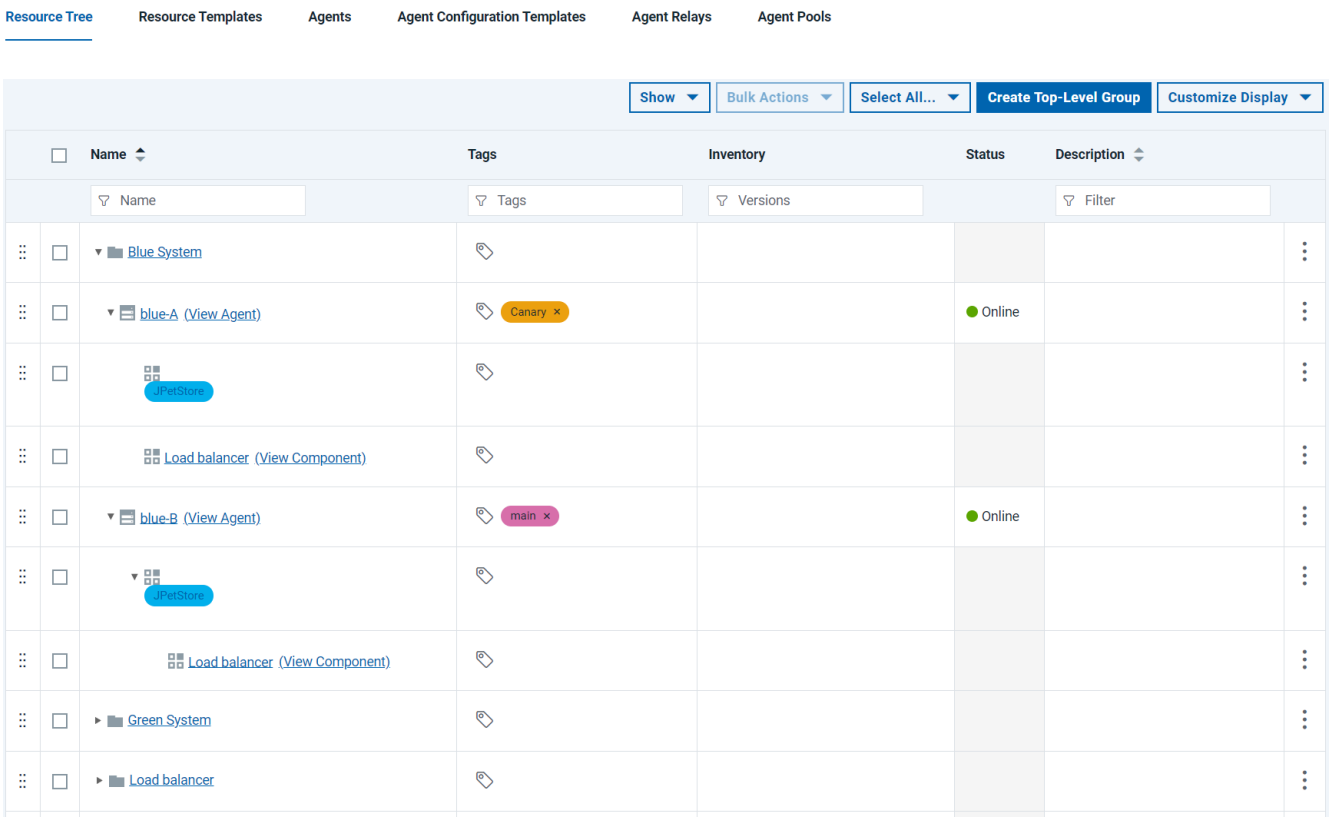
d. Create agent the `blue-B` agent resource and add to it the **JPetStore** component tag.

e. Add the `Load balancer` component to the `blue-A` and `blue-B` resources.

2. Click **Add tag** for the `blue-A` agent resource, and select the `Canary` tag, creating a new tag if necessary.
   The canary node always gets updated first. You update the other node when you're satisfied that the canary node is working properly.
3. Click **Add tag** for the `blue-B` agent resource, and select the `Main` tag, creating a new tag if necessary.
   All agent resources that are not Canary nodes use the `Main` tag.
4. Create a top-level resource for the green system by duplicating the actions in the previous steps.
5. Create a top-level resource for the load balancer, and add the `Load balancer` component to it.

Results

The complete resource trees look like the following figure:



In this lesson, you created agent resources required by the blue-green topology.

Lesson 2: Preparing the application

Prepare the application environments for the blue-green deployment.

Before you begin

Before you begin the lesson, make sure that you completed the Prerequisites on page 1987.

About this task

In this lesson, you modify the JPetStore application by adding the resources that you created in the previous lesson. To complete the lesson, you define environments and create properties that are used by the process that you create in the next lesson.

If you use another application other than JPetStore, you can still apply the steps described in this lesson.

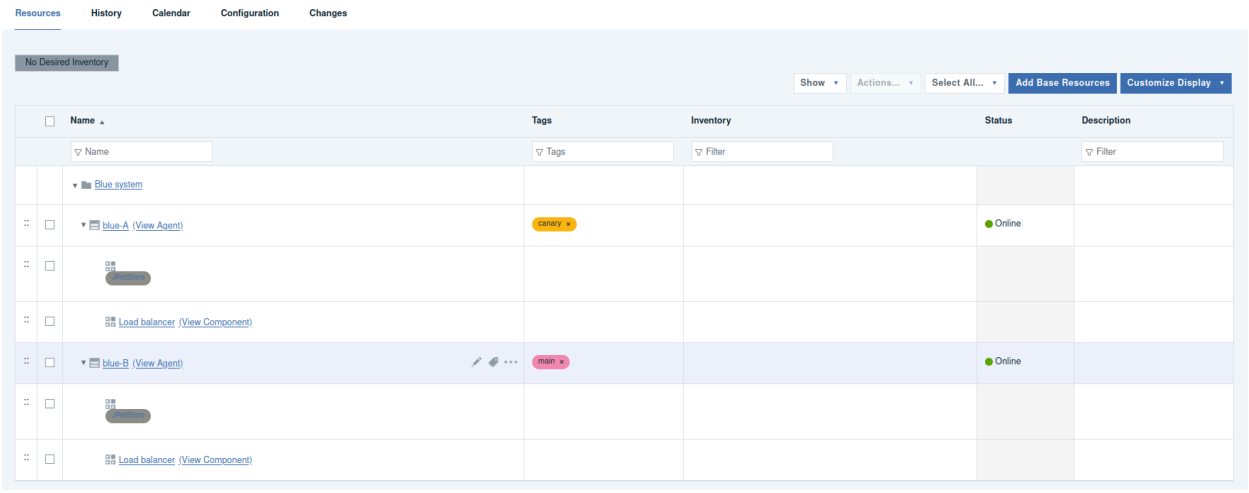
Creating the environments

Prepare the blue-green environments.

1. For the JPetStore application, create an application property and name it `activeEnvironment`, and assign it a value of `Blue environment`.
   The application process checks the value of this property to ensure that the active environment is not updated. At the start of the tutorial, the Blue environment is the active environment.
2. Create an environment, named Blue environment, to use for the Blue system.
3. Create an environment property for the Blue environment and name it `LBPort`. Assign a value of `8081` to the property.
   When you create component processes, you often define parameters that specify the location of artifacts on the target system, such as the location of the application server. Because these properties can vary on different target systems, you specify these properties as environment properties. Because you're using ports to distinguish the Blue and Green environments, you add a property to each environment named `LBPort`. This property stores the port that the application is running on in each environment; in this case, 8081 for Blue and 8082 for Green.

   Note: For the tutorial, you can use any environment property. The tutorial abstractly references ports because, as an exercise, you might use a proxy server to simulate a load balancer. Switching ports with a proxy server, such as HAProxy, is an easy way to test blue-green deployments without using an actual load balancer and separate nodes.

4. Add the JPetStore environment properties to the environment. on page 1958
   The JPetStore application uses several environment property to deploy its web application. If you are using your own application, you can skip this step.
5. Add the`Blue system` agent resource to the Blue environment.
   Because you put the `JPetStore` component tag on the resource, you don't have to map the individual components. The component tag grabs all of the components at once.
   Result
   The resource is shown on the **Resources** tab for the environment, as shown in the following figure:



6. Add the load balancer agent resource to the environment.
   Later, you call processes to update the load balancer as part of the regular deployment processes.
7. Create the Green environment similar to the Blue environment, and assign the Green system agent resource to it.
   Create the`LBPort` environment property for the Green environment, and assign the value `8082` to it.

Results

The new environments appear on the **Environments** tab.

Lesson 3: Create the application process

Create the application process used by the blue-green deployment.

Before you begin

Before you begin the tutorial, complete the Prerequisites on page 1987. Make sure to add the component tags to the JPetStore application's three components on page 1988.

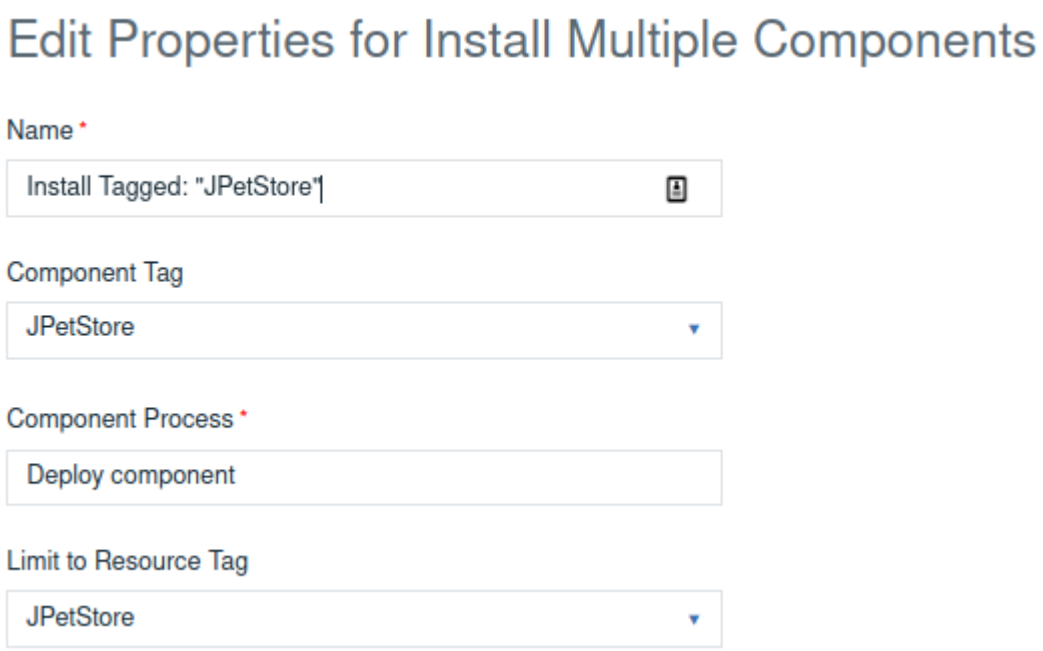
About this task

Now that you have the application, components, and environments set up, you design the automation for the Blue-Green deployment. The blue-green application deploys new version of the components, updates the load balancer, and verifies that everything is running properly.

1. Create a process for the JPetStore application, and name it `Blue-green`, or something similar.
2. On the process designer, add a **Switch** step that tests the `activeEnvironment` property.
   There are several ways to ensure that the process is running on the correct environment, but this method easy to implement. The Switch step compares on page 2400 the `activeEnvironment` property to the name of the environment on which the process is running. If those names match, that means the process is running on the active environment, which is not what you want and the process ends.

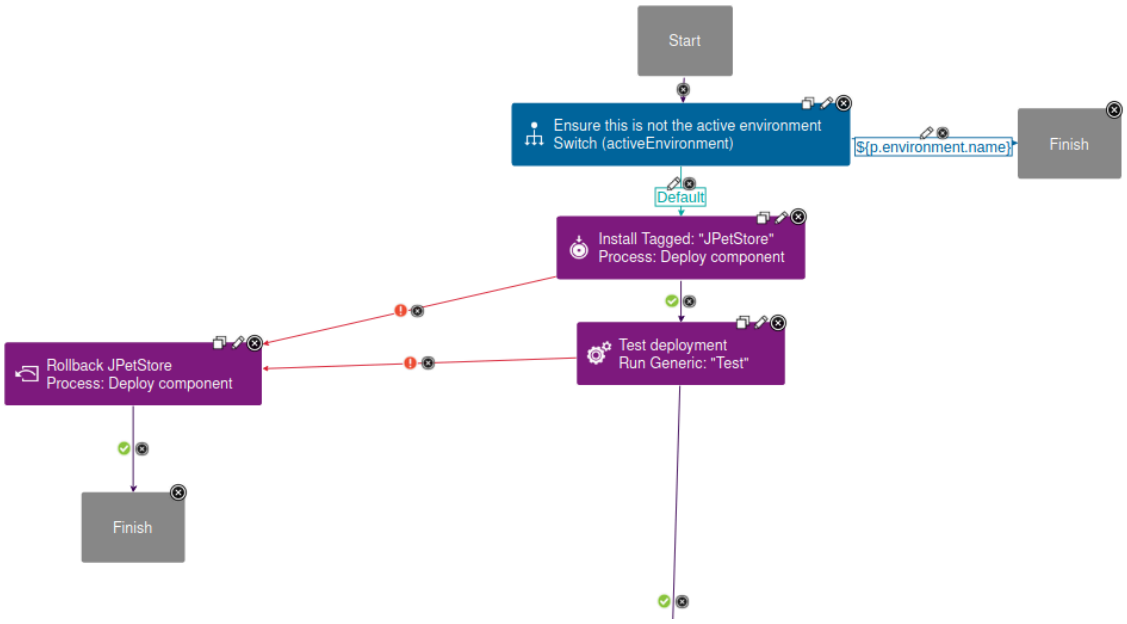
Note: If the `activeEnvironment` property is not on the **Property Name** list, review the previous lesson in Creating the environments on page 1991.

3. Add an **Install Multiple Components** step.
   This step uses the `JPetStore` tag to deploy the JPetStore components. This step iterates over each component with the specified tag. If you use your own application, ensure that the component processes all have the same name. The components are deployed to the `green-a` and `green-b` resources in the currently inactive Green system.



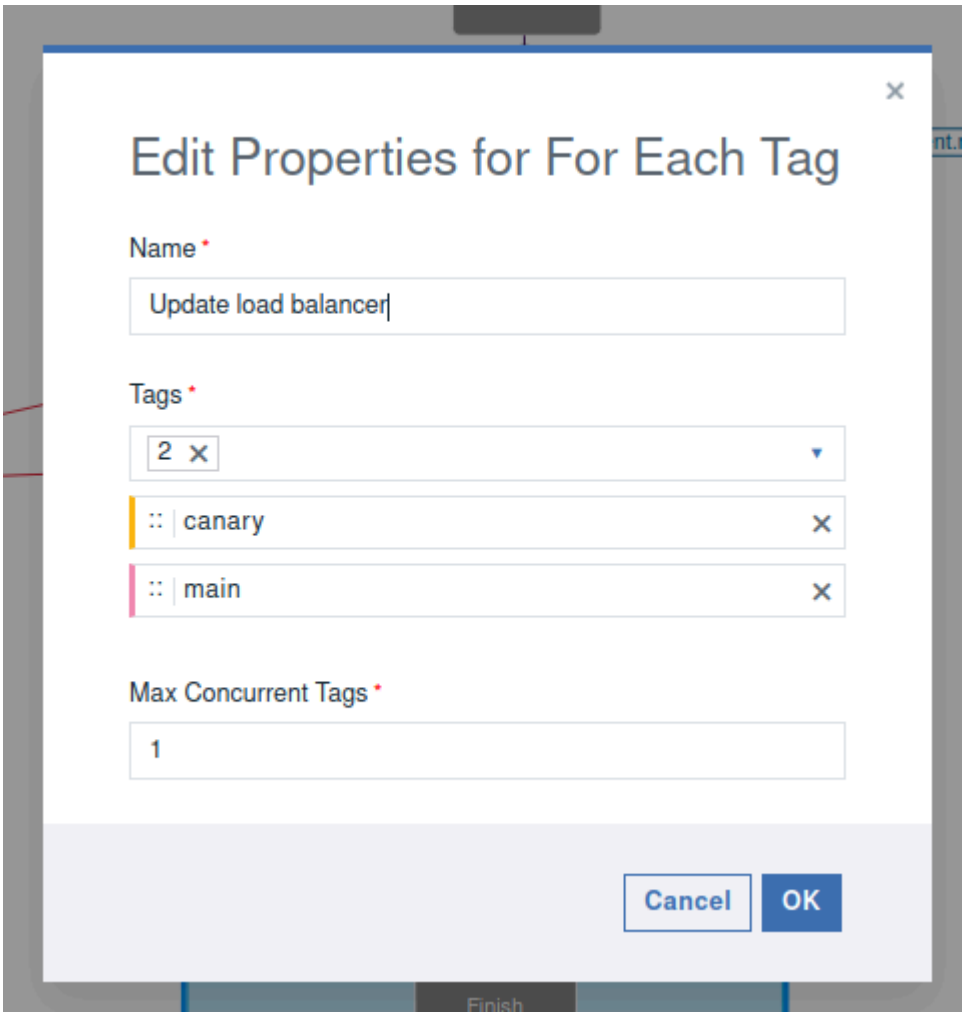
4. **Optional:** Add the optional automated testing step.
   If you typically run tests on your deployments, this is a good place to add them. For simplicity, you might use a Shell step or a generic process to as a placeholder for processing flow.
5. Add a **Rollback Multiple Components** step.
   If either the deployment step or the automated test fails, the process rolls back the newly deployed components to the version that was deployed at the beginning of this application process. As with the previous step, you might use a manual step or run a generic process step to represent the rollback feature.

   So far, the deployment is a typical multi-component deployment, and customers are unaware that an upgrade is in progress in the inactive system. In the next step, you define the **For Each Tag** loop that contains the primary blue-green processing.



6. Add a **For Each Tag** utility step to the For Each Tag loop.

   By the time processing gets to this loop, the new version of the application is already deployed to the inactive environment. The purpose of this loop is to update the load balancer in stages. In the loop, the `Canary` tag runs first, followed by the `Main` tag. This works because the For Each Tag step lets you restrict processing to specific tags and control the order in which they are processed. When the `Max Concurrent Tags` property is set to 1, only one node is processed at a time. In this case, the `Canary`-tagged node is processed before the other nodes.



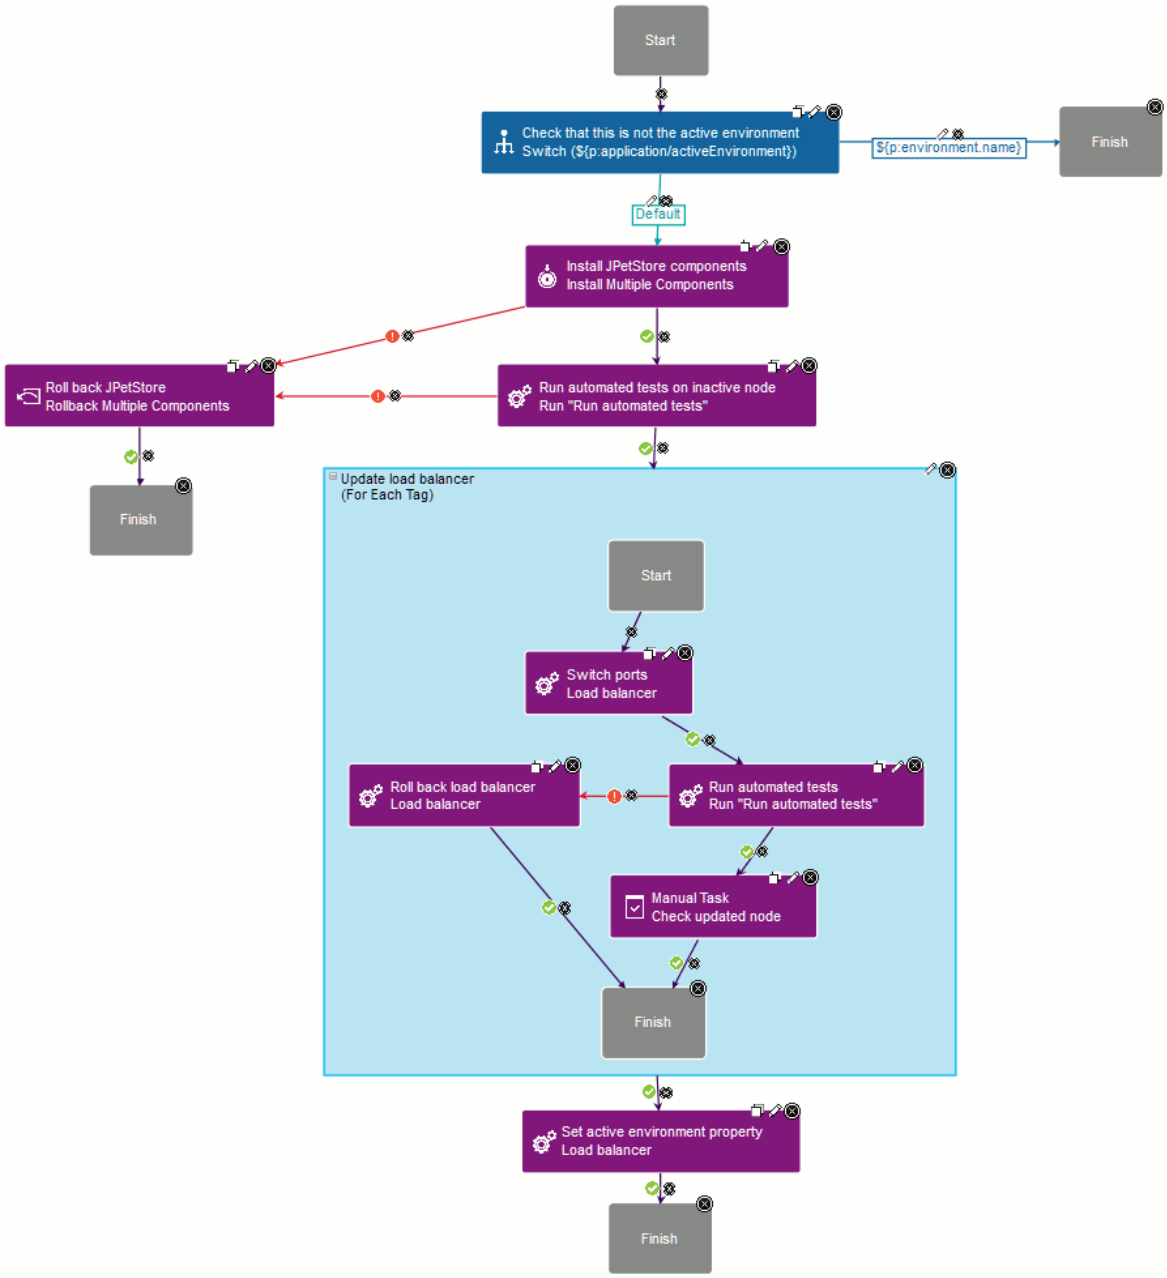
7. Within the loop, add the Load balancer component step.
   This step changes a property on the load balancer component that represents the active port on page 1988. The component process can access the properties it needs directly, without accepting any passed values.

   Now customers are using the new version of the software for the first time on the canary node. However, on the first time through the loop, the process updates the port for only the canary node.

8. In the loop, add a test step.
   The process runs automated tests on the node that is affected by the tag. If those tests fail, another step reverts the load balancer.
9. In the loop, add a rollback step.
   If the tests fail, this step reverts the load balancer to the last version.
10. Add a manual task step that you can use to verify the updated.

    The manual approval lets you verify that the canary node is working properly before the loop runs again and updates the other nodes. Your approval process is probably different, but the manual approval lets you verify that the deployment is running the way you expect for this example tutorial.

11. Click the new process to open it in the process editor.
    At the end of the process, the process updates the active environment property with the name of the newly active environment. I'm using a component process on the load balancer component for this, but there are other ways to change the application property.



Lesson 4: Deploying the application

Deploy the blue-green application.

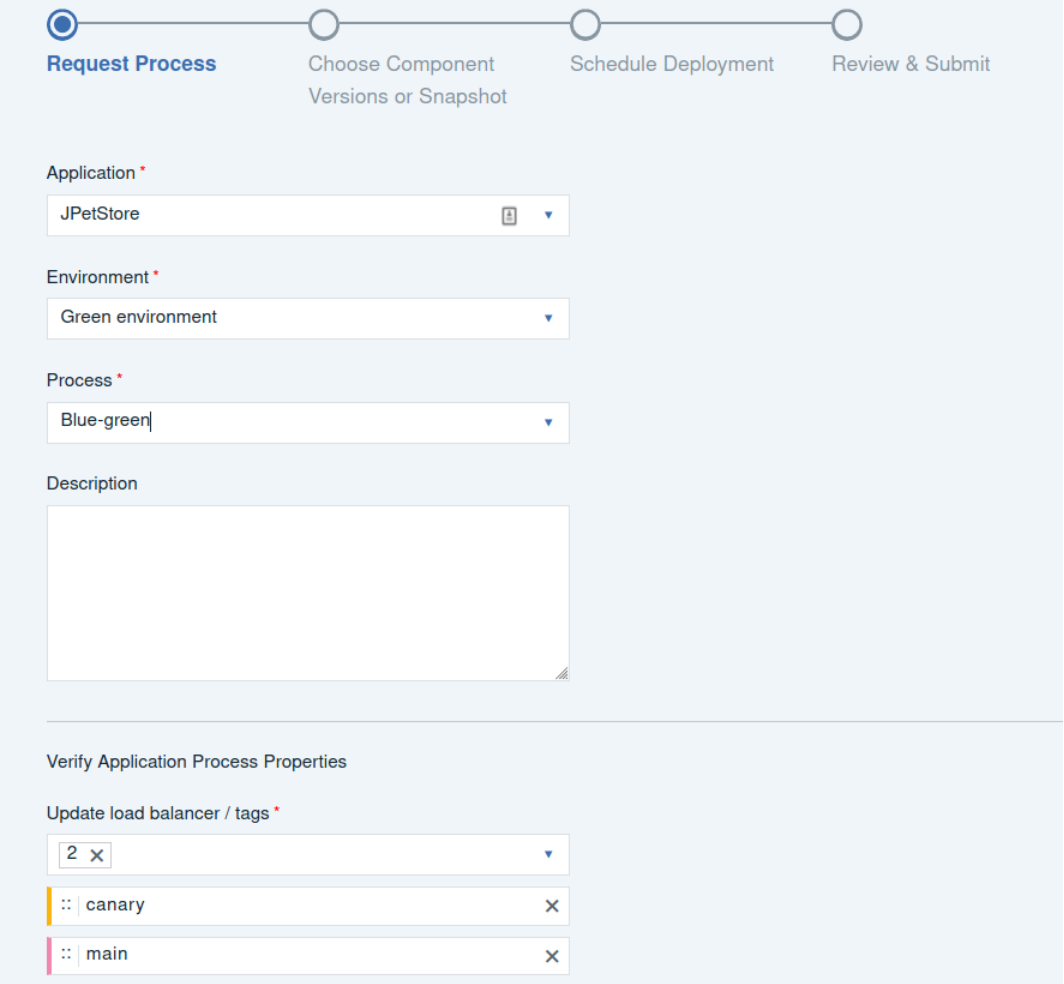
Before you begin

Before you begin the tutorial, complete the previous lesson on page 1992.

About this task

To deploy the blue-green application, run the application in the inactive environment. If you mistakenly run the application in the active environment, the process ends before any components are deployed. When the deployment finishes, the property that maintains the currently active environment is updated.

1. Run the deployment in the Green environment.
   The tutorial initially sets the active environment to the Blue environment.
2. On the **Request Process** page, select the process that you created for the tutorial, `Blue-green`.

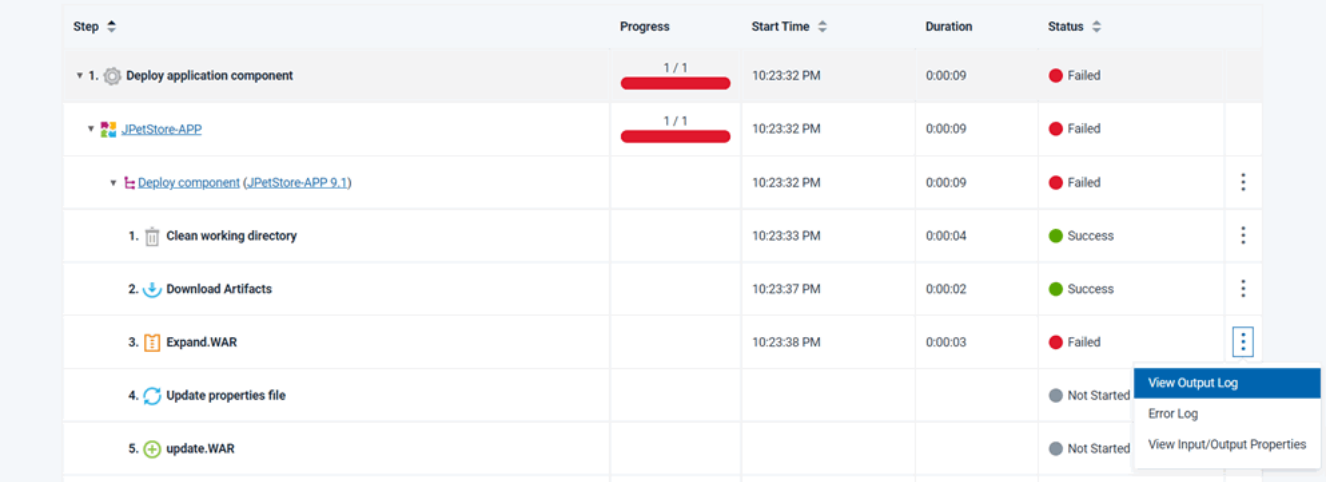


3. Go to **Choose Component Versions** and click **Select For All > Latest Available**.

Results

The web page shows you the progress of the application process request. From this page, you can watch as the processes run.

If the application process did not run successfully, one of the component processes might have failed. To troubleshoot this failed process, expand the log section for the component, and find the step that failed:



From here, you can look at the command-line output log for each step in the process by clicking the **Output Log** icon.

If one of your component processes did not complete, identify the step that did not complete. Verify that the properties for that step are correct and that the steps are in the correct order in the process. Then, run the application process again.

Summary

In this tutorial, you learned a strategy to manage blue-green deployments.

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How to model logical environments for *n* multi-node topologies
- How to incorporate a load balancer in a multi-node topology
- How to use component and resource tags in deployments
- How to use Switch steps
- How to use For All Tags loop to deploy multi-component applications

How-tos

Instructions for specific features.

This section provides instructions for specific product features, such as configuring webhooks.

How-to: Deploy applications by using REST commands

The following example describes how to use the REST commands to deploy an application.

Before you begin

This example follows the steps in the tutorial Create a simple helloWorld deployment on page 1915. Review the tutorial before you attempt to follow this example. Configure your system as described in Configure the helloWorld tutorial system on page 1916. Substitute values for your server name, user name, and password where appropriate.

About this task

This example shows the use of the Linux™ curl program to run REST commands. You can use many different programs or programming languages to run REST commands. The code authenticates with the server by specifying the user name and password on the command line. To learn more about running REST commands and authentication, see Running REST commands and Authenticating for REST commands.

The server that is used in this example is `server.example.com`. The user is `nsmith` and the password is `passwd`.

1. Create and import a component.

    a. Use the createComponent PUT command to create the component.

    Example

    ```
    curl -k -u nsmith:passwd
      https://server.example.com:8443/cli/component/create
      -X PUT -d @newComponent.json
    ```

    Note: You must enter commands on a single line. Commands are split onto different lines here for clarity.

    The following JSON file represents the component:

    ```
    {
      "name": "helloWorld",
      "description": "",
      "importAutomatically": false,
      "useVfs": true,
      "sourceConfigPlugin": "File System (Versioned)",
      "defaultVersionType": "FULL",
      "properties": {

      "FileSystemVersionedComponentProperties/basePath": "/home/user1/artifacts/shared/hell
    oWorld"
      }
    }
    ```

    Result

    The command returns a result that is similar to the following JSON information:

    ```
    {
      "id":"cf355787-a772-4533-be45-3e169e9da6eb",
      "securityResourceId":"23504603-ab8c-4740-bc2d-d18c08f790e9",
      "name":"helloWorld",
      "description":"",
      "created":1396878409753,
      "importAutomatically":false,
      "useVfs":true,
    ```

```
  "active":true,
  "integrationFailed":false,
  "deleted":false,
  "defaultVersionType":"FULL",
  "cleanupDaysToKeep":0,
  "cleanupCountToKeep":0,
  "tags":[],
  "user":"nsmith"
}
```

b. Use the setComponentProperty PUT command to set a component property.

Example

```
curl -k -u nsmith:passwd
  "https://server.example.com:8443/cli/
  component/propValue?component=helloWorld&name=helloHome&value=c%3A%5ChelloWorld" -X PUT
```

Result

The command returns a result similar to the following JSON information:

```
{
  "id":"194b6e0c-3f30-4d9a-b3cf-dd61dd1a7328",
  "name":"helloHome",
  "value":"c:\\helloWorld",
  "secure":false
}
```

c. Use the importVersions PUT command to import the component version.

Example

```
curl -k -u nsmith:passwd
  https://server.example.com:8443/cli/component/integrate
  -X PUT -d {"component":"helloWorld"}
```

Result

The command returns the following result:

```
{}
```

2. Use the createComponentProcess PUT command to create a component process.

Example

```
curl -k -u nsmith:passwd
  https://server.example.com:8443/cli/componentProcess/create
  -X PUT -d @componentProcess.json
```

The following JSON file represents this component process:

```
{
  "active": "true",
  "component": "helloWorld",
  "configActionType": "ADD",
  "defaultWorkingDir": "${p:resource/work.dir}/${p:component.name}",
  "description": "",
  "inventoryActionType": "ADD",
  "name": "helloProcess",
```

```
  "propDefs": [],
  "rootActivity": {
    "children": [
      {
        "allowFailure": false,
        "children": [],
        "commandName": "Delete Files and Directories",
        "impersonationUseSudo": false,
        "name": "Clean work space",
        "pluginName": "File Utils",
        "pluginVersion": 31,
        "properties":{
            "baseDir":".",
            "includes":"*",
            "excludes":"",
            "followSymlinks":"false",
            "caseSensitive":"true"
         },
        "showHidden": false,
        "type": "plugin",
        "useImpersonation": false
      },
      {
        "allowFailure": false,
        "children": [],
        "commandName": "Download Artifacts",
        "impersonationUseSudo": false,
        "name": "Download Artifacts",

           "label":"${p:version.name}",
           "serverUrl":"${p:server.url}",
           "compId":"${p:component.id}",
           "resId":"${p:resource.id}",
           "charset":""
        },
        "showHidden": false,
        "type": "plugin",
        "useImpersonation": false
      },
      {
```

```
        "allowFailure":false,
        "children": [],
        "commandName":"Create .zip File",
        "impersonationUseSudo":false,
        "name":"Compress artifacts",
        "pluginName":"File Utils",
        "pluginVersion":31,
        "properties":{
           "zipName":"helloWorld.zip",
           "baseDir":".",
           "includes":"*",
           "excludes":"",
           "update":"false",
           "followSymlinks":"false",
           "caseSensitive":"true"
        },
       "showHidden": false,
       "type": "plugin",
       "useImpersonation": false
     },
     {
        "allowFailure":false,
        "children": [],

      "from": "Compress artifacts",
      "to": "Deploy artifacts",
      "type": "ALWAYS",
      "value": ""
    },
    {
      "from": "Deploy artifacts",
      "to": "FINISH",
      "type": "ALWAYS",
      "value": ""
    }
  ],
  "name": "GRAPH",
  "offsets": [
    {
      "name": "Clean work space",
      "x": "-65",
      "y": "90"
    },
    {
      "name": "Download Artifacts",
      "x": "-70",
      "y": "210"
    },
    {
      "name": "Compress artifacts",
      "x": "-70",
      "y": "290"
    },
    {
      "name": "Deploy artifacts",
      "x": "-65",
      "y": "370"
    },
    {
      "name": "FINISH",
      "x": "-60",
      "y": "450"
    }
  ],
```

```
    "type": "graph"
  },
  "status": "Active",
  "takesVersion": "true"
}
```

Result

The command returns a result that is similar to the following JSON information:

```
{
  "id":"12f65517-5fc1-44ff-a58b-2401cfba8f2f",
  "name":"helloProcess",
  "description":"",
  "defaultWorkingDir":"${p:resource\/work.dir}\/${p:component.name}",
  "takesVersion":true,
  "inventoryActionType":"ADD",
  "status":"Active",
  "active":true,
  "versionCount":1,
  "version":1,
  "commit":0,
  "path":"components\/cf355787-a772-4533-be45-3e169e9da6eb\/processes\/12f65517-5fc1-44ff-a58
b-2401cfba8f2f"
}
```

3. Create an application, and then associate the component with the application.

    a. Use the createApplication PUT command to create an application.

    Example

    ```
    curl -k -u nsmith:passwd
      https://server.example.com:8443/cli/application/create
      -X PUT -d @newApplication.json
    ```

    The following JSON file represents the application:

    ```
    {
      "name": "hello Application",
      "description": "",
      "notificationScheme": "None",
      "enforceCompleteSnapshots": "false"
    }
    ```

    Result

    The command returns a result that is similar to the following JSON information:

    ```
    {
      "id":"932452cc-3562-4545-8de5-c57aa7efbcc4",
      "securityResourceId":"2bc72218-dbfe-4c11-b16f-752b7ca63d06",
      "name":"hello Application",
      "description":"",
      "created":1396882026943,
      "enforceCompleteSnapshots":false,
      "active":true,
      "tags":[],
    ```

```
  "user":"nsmith"
}
```

b. Use the addComponentToApp PUT command to associate the component with the application.

Example

```
curl -k -u nsmith:passwd
  "https://server.example.com:8443/cli/
  application/addComponentToApp?component=helloWorld&application=hello%20Application"
  -X PUT
```

Result

The command returns the following result:

```
{}
```

4. Create an environment, and associate it with a resource.

a. Use the createEnvironment PUT command to create an environment.

Example

```
curl -k -u nsmith:passwd

 "https://server.example.com:8443/cli/environment/createEnvironment?application=hello%20Applicati
on&name=helloDeploy"
  -X PUT
```

Result

The command returns the ID of the environment, which is similar to the following string:

```
2142c0e3-7ebe-4a2f-9e0d-14ccacc70a79
```

b. Use the addEnvironmentBaseResources PUT command to associate the resource that you configured earlier with the environment.

Example

```
curl -k -u nsmith:passwd

 "https://server.example.com:8443/cli/environment/addBaseResource?application=hello%20Application
&environment=helloDeploy&resource=%2FhelloWorld%20Tutorial"
  -X PUT
```

Result

This command does not return a result if the resource is correctly associated with the environment.

c. Use the createResource PUT command to map the helloWorld component to the agent resource.

Example

```
curl -k -u nsmith:passwd
  https://server.example.com:8443/cli/resource/create
  -X PUT -d @componentResource.json
```

The following JSON file represents the component resource:

```
{
  "roleId":"09456abd-65e3-469e-94c6-a6a873b971a8",
  "name":"helloWorld",
```

```
  "description":"",
  "inheritTeam":"true",
  "useImpersonation":"false",
  "roleProperties":{},
  "parentId":"b2ff919e-b4c0-4d13-8973-eff44e4835e2",
  "teamMappings":[]
}
```

Result

The command returns a result that is similar to the following JSON information:

```
{
  "id":"ba958487-fb86-4290-9240-da766af37963",
  "securityResourceId":"66685b67-21ab-411d-99bb-f577a74d88b3",
  "name":"helloWorld",
  "path":"\/helloWorld Tutorial\/fit-vm11-157\/helloWorld",
  "active":true,
  "description":"",
  "inheritTeam":true,
  "impersonationPassword":"****",
  "impersonationUseSudo":false,
  "impersonationForce":false,
  "type":"subresource",
  "status":"ONLINE",
  "hasAgent":true,
  "tags":[]
}
```

d. Use the addTagToResource PUT command to add a tag to the component resource.

Example

```
curl -k -u nsmith:passwd
  "https://server.example.com:8443/cli/
  resource/tag?resource=ba958487-fb86-4290-9240-da766af37963&tag=blueCycle&color=0000FF"
  -X PUT
```

Result

This command does not return a result if the component is correctly tagged.

5. Use the createApplicationProcess PUT command to create an application process.

Example

```
curl -k -u nsmith:passwd
  https://server.example.com:8443/cli/applicationProcess/create
  -X PUT -d @applicationProcess.json
```

The following JSON file represents the application process. The application ID is the same as the ID that is returned in step 3.

```
{
  "application": "932452cc-3562-4545-8de5-c57aa7efbcc4",
  "description": "",
  "inventoryManagementType": "AUTOMATIC",
  "name": "hello App Process",
  "offlineAgentHandling": "PRE_EXECUTION_CHECK",
```

```
"rootActivity": {
  "children": [
    {
      "children": [{
        "children": [{
          "allowFailure": false,
          "children": [],
          "componentName": "helloWorld",
          "componentProcessName": "helloProcess",
          "name": "Deploy helloWorld",
          "properties": {},
          "type": "componentProcess"
        }],
        "componentName": "helloWorld",
        "name": "inventoryVersionCheck",
        "status": "Active",
        "type": "inventoryVersionDiff"
      }],
      "componentName": "helloWorld",
      "failFast": "false",
      "maxIteration": "-1",
      "name": "Deploy helloWorld",
      "runOnlyOnFirst": "false",
      "type": "componentEnvironmentIterator"
    },
    {
      "children": [],
      "name": "FINISH",
      "type": "finish"
    }
  ],
  "edges": [
    {
      "to": "Deploy helloWorld",
      "type": "ALWAYS",
      "value": ""
    },
    {
      "from": "Deploy helloWorld",
      "to": "FINISH",
      "type": "ALWAYS",
      "value": ""
    }
  ],
  "name": "GRAPH",
  "offsets": [
    {
      "name": "Deploy helloWorld",
      "x": "-35",
      "y": "210"
    },
    {
```

```
        "name": "FINISH",
        "x": "0",
        "y": "420"
      }
    ],
    "propDefs": [],
    "type": "graph"
  }
}
```

Result

The command returns a result that is similar to the following JSON information:

```
{
  "id":"37d563ce-7885-48f1-b8c0-f79046c0f024",
  "name":"hello App Process",
  "description":"",
  "active":true,
  "inventoryManagementType":"AUTOMATIC",
  "offlineAgentHandling":"PRE_EXECUTION_CHECK",
  "versionCount":1,
  "version":1,
  "commit":0,
  "path":"applications\/932452cc-3562-4545-8de5-c57aa7efbcc4\/processes\/37d563ce-7885-48f1-b
8c0-f79046c0f024"
}
```

6. Use the requestApplicationProcess PUT command to deploy the application.

   Example

   ```
   curl -k -u nsmith:passwd
     https://server.example.com:8443/cli/applicationProcessRequest/request
     -X PUT -d @applicationDeploy.json
   ```

   The following JSON file represents the deployment request:

   ```
   {
     "application": "hello Application",
     "applicationProcess": "hello App Process",
     "environment": "helloDeploy",
     "versions": [{
       "version": "1.0",
       "component": "helloWorld"
     }]
   }
   ```

   Result

   The command returns a result that is similar to the following JSON information:

   ```
   {"requestId":"bffff82f-ff69-4c07-b010-26ca3f21be39"}
   ```

How-to: Export and import elements with YAML configuration

The following example task describes how to export and import elements with YAML configuration.

Before you begin

This example follows the steps in the Create a simple helloWorld deployment on page 1915 tutorial. Review the tutorial before you attempt to follow this example. Configure your system as described in Configure the helloWorld tutorial system on page 1916.

About this task

In this example, you export components in YAML format, configure, and import them to other HCL DevOps Deploy (Deploy)systems. However, you can export other elements such as applications, application templates, components, component templates, processes, and so on.

Exporting or importing of elements in YAML format is the same as in JSON format. The difference is that you need to specify appropriate headers in the REST calls. For APIs that take input, like import or save actions, you must add the following header: `Accept: application/yaml`. For APIs that produce output, like export and get actions, you must add the following header: `Content-Type: application/yaml`.

Note:

- If you don't use the headers, the elements are exported or imported in JSON format by default.
- Exporting and importing snapshots with YAML is not supported.

1. Export the helloWorld component you created in Lesson 1 Create the helloWorld component on page 1918 by using the REST command. See Export a component to a json file. for command reference.
   While entering the REST command, ensure that you use the following header with your request:

   ```
   Content-Type: application/yaml
   ```

   Result

   The command returns a result similar to the following YAML definition:

   ```yaml
   ---
   name: "helloWorld"
   description: ""
   created: 1700804083300
   componentType: "STANDARD"

```

```
                        \ restriction"
                    restrictions:
                        - verb: "ALL"
                          url: "/*"
                type: "plugin"
                name: "Deploy artifacts"
                children: []
configTemplates: []
genericProcesses: []
teamMappings: []
tags: []
```

2. Copy the content into a text editor and save it.
3. Edit the YAML configuration to include the changes you require.
4. Import the component in YAML format by using REST command to the destination Deploy server.
   See Import component from json file. for command reference. You must use the following header with the REST call.

   ```
   Accept: application/yaml
   ```

Results

The file is imported and the record is displayed in the Components list.

How-to: Integrate MS Teams

Integrate Microsoft Teams with HCL DevOps Deploy (Deploy) to post notifications automatically to your Teams channel whenever a specific deployment event happens.

Before you begin

- A process such as a generic process is created. See Processes on page 2398.
- Create a Webhook URL from your Teams channel. Refer to the Microsoft Teams documentation.

About this task

By using the Incoming Webhook connector in Teams, you can integrate Deploy services so that you get notified of an event through the Teams channels.

In this example, you will learn about the requirements and procedures to integrate Teams with Deploy. To integrate Teams with Deploy, follow the steps provided in this section.

Step 1: Format the message card

A message card is defined in a JSON format that includes the message in text, links, and image, if required. For HCL DevOps Deploy (Deploy), you can create a message card that refers to the process name, status, and a link to the process deployment page. The message card format is used as body in the webhook template.

About this task

The message cards can be created using the following available templates:

- Application Deployment Failure JSON body on page 2016
- Application Deployment Success JSON body on page 2019
- Application Process Request Started JSON body on page 2022
- Approval Completed JSON body on page 2022
- Approval Failed JSON body on page 2023
- External Approval Completed JSON body on page 2024
- External Approval Failed JSON body on page 2025
- Generic Process Completed JSON body on page 2026
- Generic Process Request Started JSON body on page 2026
- Scheduled Process Not Started JSON body on page 2027

Step 2: Create a webhook template

Create a webhook template for an event so that when the event happens a notification is triggered on Teams.

1. Select **Settings > Webhook Templates > Create Webhook Template**.
2. Provide a name and description for the template. For this example, give the name as `Process failure notification`.
3. Click on **Body** area and paste the example code from the step 1.
4. Choose the event type **Process Failure** from the **Type** field.
5. Submit your changes.

Results

The webhook template is created and ready to be added to an application.

Step 3: Add webhook template to an application

You can add a webhook template to applications, generic processes, and external approval processes. For this example, you add the template to an application.

Before you begin

Make sure that you created an environment for the application and have resources added to it.

1. Select **Applications > *application name* > Configuration > Webhooks > Add Webhook**.
   The **Add Webhook** window is displayed.
2. Copy the webhook URL and paste into the **URL** field.
3. If you are using a proxy server for Teams, you must specify the following details: **Proxy Host**, **Proxy Port**, **Proxy Username**, and **Proxy Password**.
   These fields can also be automatically populated by setting the corresponding system properties: `proxyHost`, `proxyPort`, `proxyUsername`, and `proxyPassword`.
4. Specify the event type as **Process Failure**.
5. Select the template name that you created in step 3 from the **Webhook Template** field.
6. Specify the environment name in the **Environments** field.
7. Submit your changes.

Results

The webhook template is added to the application. When an application process run on the environment and fails, the Teams channel shows the following example notification.

Webhook-Integration-Test 6/13 6:53 PM
An approval failed for the App application on the Env environment
An application process was rejected during its approval process
Application: App Environment: Env Requested by: admin Scheduled for: Sun Jun 13 18:52:31 IST 2021 Description: ${request.Description}
Click **View Details** for more information.

Teams message card templates

Example templates are provided that helps you to create message cards to use with MS Teams integration.

About this task

Message layouts are available for the following events:

- Application Deployment Failure JSON body on page 2016
- Application Deployment Success JSON body on page 2019
- Application Process Request Started JSON body on page 2022
- Approval Completed JSON body on page 2022
- Approval Failed JSON body on page 2023
- External Approval Completed JSON body on page 2024
- External Approval Failed JSON body on page 2025
- Generic Process Completed JSON body on page 2026
- Generic Process Request Started JSON body on page 2026
- Scheduled Process Not Started JSON body on page 2027

You can customize these available message card as per your team requirement. See MS Teams documentation for more information.

Application Deployment Failure JSON body

```
## PROPERTY Content-Type: application/json

#set ( $Q = '\\"' )

#set ( $themeColor = "#E88686" )
#set ( $warningCount = $workflowTrace.WarningCount)

#macro (showSummary $analysis $level )
  #set ($indentPixels = $level * 20)
  #set ($trace = $analysis.Trace)

How-to: Integrate Slack

Integrate Slack with HCL DevOps Deploy (Deploy) to post notifications automatically to your Slack app whenever a specific deployment event happens.

About this task

Walk through a scenario and learn how to push messages to Slack when an application process fails to deploy in Deploy.

In this example, you'll learn about the requirements and procedure to integrate Slack with Deploy. To integrate Slack with Deploy, follow the steps provided in this section:

Step 1: Create an incoming webhook app in Slack

1. Go to api.slack.com and click **Create an App**.
2. Provide an App Name and choose an appropriate workspace.
3. After you create the app, go to **Incoming Webhooks**.
4. Turn on **Activate Incoming Webhooks**, and click **Add New Webhook to Workspace**.
5. Choose a Slack channel that you want the post the messages to.
6. Click **Allow**.
7. Copy and save the generated webhook URL.

Results

The webhook is added to the Slack app and posts a confirmation message in the app.

Note: For additional information about incoming webhooks for Slack, refer to the Slack documentation.

Step 2: Define the message layout

A message layout is defined in a JSON format that includes the message in text, links, and image, if required. For HCL DevOps Deploy (Deploy), you can create message layout that refers to the process name, status, and a link to the process deployment page. This message layout is used in the webhook template. Message layout is defined differently for each event type.

About this task

The message layout is available for the following events:

- Application Deployment Failure JSON body on page 2030
- Application Deployment Success JSON body on page 2034
- Approval Completed JSON body on page 2037
- Approval Created JSON body on page 2039

- Approval Failed JSON body on page 2042
- External Approval Completed JSON body on page 2044
- External Approval Failed JSON body on page 2045
- Generic Process Failure JSON body on page 2046
- Generic Process Request Started JSON body on page 2047
- Generic Process Success JSON body on page 2047
- Process Not Started JSON body on page 2048
- Process Request Started JSON body on page 2049
- Task Created JSON body on page 2052

Step 3: Create a webhook template

Create a webhook template for an application process failure so that when the event happens a notification is triggered in your Slack app.

1. Select **Settings > Webhook Templates > Create Webhook Template**.
2. Provide a name and description for the template. For this example, give the name as `Application process failed notification`.
3. Click on **Body** and paste the example Application Deployment Failure JSON body from the step 2.
4. Choose the event type **Process Failure** from the **Type** field.
5. Submit your changes.

Results

The webhook template is created and ready to be added to an application.

Step 4: Add the webhook template to an application

You can add a webhook template to applications, generic processes, and external approval processes. For this example, you add the template to an application.

Before you begin

Make sure that you have created an environment for the application and have resources added to it.

1. Select **Applications > *application name* > Configuration > Webhooks > Add Webhook**.
   The **Add Webhook** window is displayed.
2. Copy the URL that you generated from step 1 and paste it in the **URL** field.
3. Specify the event type as **Process Failure**.
4. Select the template name created in step 3 from the **Webhook Template** field.
5. Specify the environment name from the **Environments** field.
6. Submit your changes.

Results

The webhook template is added to the application. When the application process runs on the environment and fails, the Slack app shows the following example notification.

Webhook-Integration-Test 6/13 6:53 PM

An approval failed for the App application on the Env environment

An application process was rejected during its approval process

Application: App Environment: Env Requested by: admin Scheduled for: Sun Jun 13 18:52:31 IST 2021 Description: ${request.Description}

Click **View Details** for more information.

Slack message layout templates

Example templates are provided that helps you to create message layout to use with Slack integration.

About this task

The message layout is available for the following events:

- Application Deployment Failure JSON body on page 2030
- Application Deployment Success JSON body on page 2034
- Approval Completed JSON body on page 2037
- Approval Created JSON body on page 2039
- Approval Failed JSON body on page 2042
- External Approval Completed JSON body on page 2044
- External Approval Failed JSON body on page 2045
- Generic Process Failure JSON body on page 2046
- Generic Process Request Started JSON body on page 2047
- Generic Process Success JSON body on page 2047
- Process Not Started JSON body on page 2048
- Process Request Started JSON body on page 2049
- Task Created JSON body on page 2052

Note: You can customize these available message layout as per your team requirement. Refer to Slack documentation for more information.

Video and learning resources

Many resources about effectively using HCL DevOps Deploy (Deploy) are available. You can choose which learning resources to use depending on your role, skill level, interests, and the time you have.

The following types of learning resources are available. To learn more about them, including where to find them and what you gain by using them, see the detailed descriptions.

- Videos and multimedia on page 2054
- Tours and tutorials on page 2055
- Learning circles on page 2055
- Additional resources on page 2055

Videos and multimedia

Many videos and multimedia are available to help you learn about a wide range of Deploy capabilities.

- For videos that are related to Deploy, see the following external web links:
  - Deploy video gallery
  - Deploy YouTube playlist
- For videos that are related to HCLSoftware DevOps, see YouTube playlist.

Tours and tutorials

Tutorials provide instructions for common tasks. Some tutorials also explain the concepts that you need to understand before you start a task. Complete a tutorial to learn to do a task, or revisit a tutorial for a reminder of how to do a task that you do not often do. You can access tutorials from Tutorials on page 1914.

Learning circles

A learning circle is a community space where people come to learn about a subject. Learning circles offer targeted resources and guided learning activities that are selected by subject matter experts. Use learning circles for these purposes:

- Building personal learning roadmaps that are based on learning roadmaps that were created by experts
- Discussing learning activities with other learning circle members so that you can deepen your understanding or help others
- Asking questions or joining a conversation in the community forum, where you can find answers to your getting-started questions
- Blogging about your ideas and experiences, and learning from others' blog posts
- Finding experts and more resources

Additional resources

- Much more information is available on the Deploy community.

Installing an external agent for Deploy in DevOps Loop

You can install and connect an external Deploy agent to a DevOps Loop instance running on Kubernetes (K8s), and IBM Kubernetes Service (IKS).

Before you begin

Ensure that the following prerequisites are met:

- Installed DevOps Loop on Kubernetes (K8s), or IKS.
- You have access to the Kubernetes cluster where DevOps Loop is running.

1. Obtain the Deploy web agent communication URL for the Deploy server running in the DevOps Loop instance.
   In a Kubernetes cluster, the URL is indicated as: `wss://service-{{.Values.global.domain}}:7919`

   Here, the value for the `Values.global.domain` is the same URL used to access the DevOps Loop UI.
2. Install the Deploy agent using the Deploy web agent communication URL obtained in step 1.
   During the agent installation, you must specify any teams you want the Deploy agent to be included in. Refer to Installing agents for more information on Deploy agent installation.
3. Start the external Deploy agent.
   Result
   The agent is displayed under the **Agents** section in the Deploy UI.

Troubleshooting

If you encounter issues connecting the Deploy agent to the Deploy server running in DevOps Loop, verify that the Emissary Ingress service is configured to route traffic on port 7919 to the Deploy server WSS service:

a. Run the following command to inspect the service:

```
$ kubectl get svc -n emissary
```

A correct output lists 7919 in PORT(S) column, like the following:

```
NAME                    TYPE         CLUSTER-IP     EXTERNAL-IP PORT(S)
                        AGE
emissary-ingress        LoadBalancer 172.21.20.31   xx.xx.xx.xx
 443:31734/TCP,80:32086/TCP,7919:31941/TCP,9022:31708/TCP 112d
emissary-ingress-admin  ClusterIP    172.21.9.14    <none>      8877/TCP,8005/TCP
                        112d
```

b. If the port 7919 is not listed for the emissary-ingress service, edit the service configuration:

```
$ kubectl edit svc emissary-ingress -n emissary
```

c. Under the `spec.ports` section, add the following lines:

```
- name: deploy-wss
 port: 7919
 protocol: TCP
 targetPort: 7919
```

After port 7919 is configured in the emissary-ingress service, your Deploy agent should successfully connect to the Deploy server running in DevOps Loop.

4. Perform the following steps to manually assign a license type:
   a. Navigate to **Deploy**
   b. Go to **Resources → Agents**
   c. Locate the connected agent
   d. Click the **Actions** menu for the agent
   e. Select **Set License Type**
   f. Choose the appropriate license type:
      - **Authorized (Assigned)** or
      - **Floating**
   g. Click **Save**
5. For IKS, configure the cluster service domain, if it is not configured.
   Follow steps in the **Installing DevOps Loop on IBM Cloud Kubernetes Service (IKS)** topic for setting up the service domain.

Results

You have installed and connected the external Deploy agent to DevOps Loop.

What to do next

You can now use this agent to run deployments.

Overview of integrations

HCL DevOps Deploy (Deploy) supports integrations with other IBM® and HCL products, products from others, and certain cloud systems.

Most integrations with Deploy are accomplished by using plug-ins. Plug-ins provide tools for creating component processes and integrations.

See the following page on HCL Plug-ins site for information about plug-ins that support other products: HCL Plug-ins.

Integrating with DevOps Test Performance

When you use HCL DevOps Test Performance (Test Performance), you can create tests and run those tests in HCL DevOps Deploy (Deploy) by using the Test Performance Deploy plug-in.

To learn more about integrating with Test Performance, see documentation.

Administering

Learn how to administer settings in HCL DevOps Deploy (Deploy) elements and communication between the elements.

Backup and recover

You can back up and recover the contents of your HCL DevOps Deploy (Deploy) installation.

Backing up the server

To back up the server, make a backup copy of the database and application data directory. Both frequent online backups and occasional offline backups are required.

About this task

Note the following points before performing the online or offline backup procedure.

Important:

Make sure that you take backups of the filesystem and the database at the same time, or as close as possible. The bigger the gap between backups, the bigger the data skew is likely to be. Using a backup of the server directory and the database taken from different times may cause the following problems when you restore the backups:

- If you back up the file system before the database, then the database may know of the versions or step logs that were created after the file system was backed up. This may lead to problems attempting to deploy those versions or to view those step logs.
- If you back up the database before the file system, then the file system may contain versions and step logs that the database is not aware of. Due to this, you may not get the correct available file system size.

Offline backups

Offline backups happen when the server is stopped, for example during a monthly maintenance window when you install operating system updates and other updates on the server and agent systems.

About this task

Offline backups must include both the database and the server file system, including the application data directory. Follow these steps to take an offline backup of the server:

1. Stop the server.
   See Starting and stopping the server.
2. Create a full backup of the database.
   For instructions on backing up the database, see the documentation for your database.
3. Back up the application data folder to a secure backup location.
4. Back up the `conf` folder.
   On high-availability systems, back up this folder for each server.
5. Start the server.

Online backups

Online backups happen frequently, and without stopping the server. For online backups, you need to back up only the database.

About this task

Online backups, typically include only the database and not the server file system and application data directory. Use the backup options for your database system.

Note: To make the online backups easier to restore, configure your database to create full regular restore points and to enable transaction logging. For example, the database might make full backups once a month and log transactions all the time. That way, you can restore the database at any time.

What to do next

To restore HCL DevOps Deploy (Deploy) from a backup, see Restoring a backup on page 2058.

Restoring a backup

To restore a backup of the server, stop the server and replace the existing files and databases with the backup files and databases.

About this task

You can restore the server, and the app data all at once.

1. Stop the server.
2. Copy the server files from the backup to the application data directory, overwriting the current files.
   You must restore the backup files to the same location as the existing files because configuration files include system paths.
3. Restore the database from the backup.

   Important: You must restore the database from a backup that was taken at the same time as the backup of the application data directory.

4. Restart the server.

High availability and failover

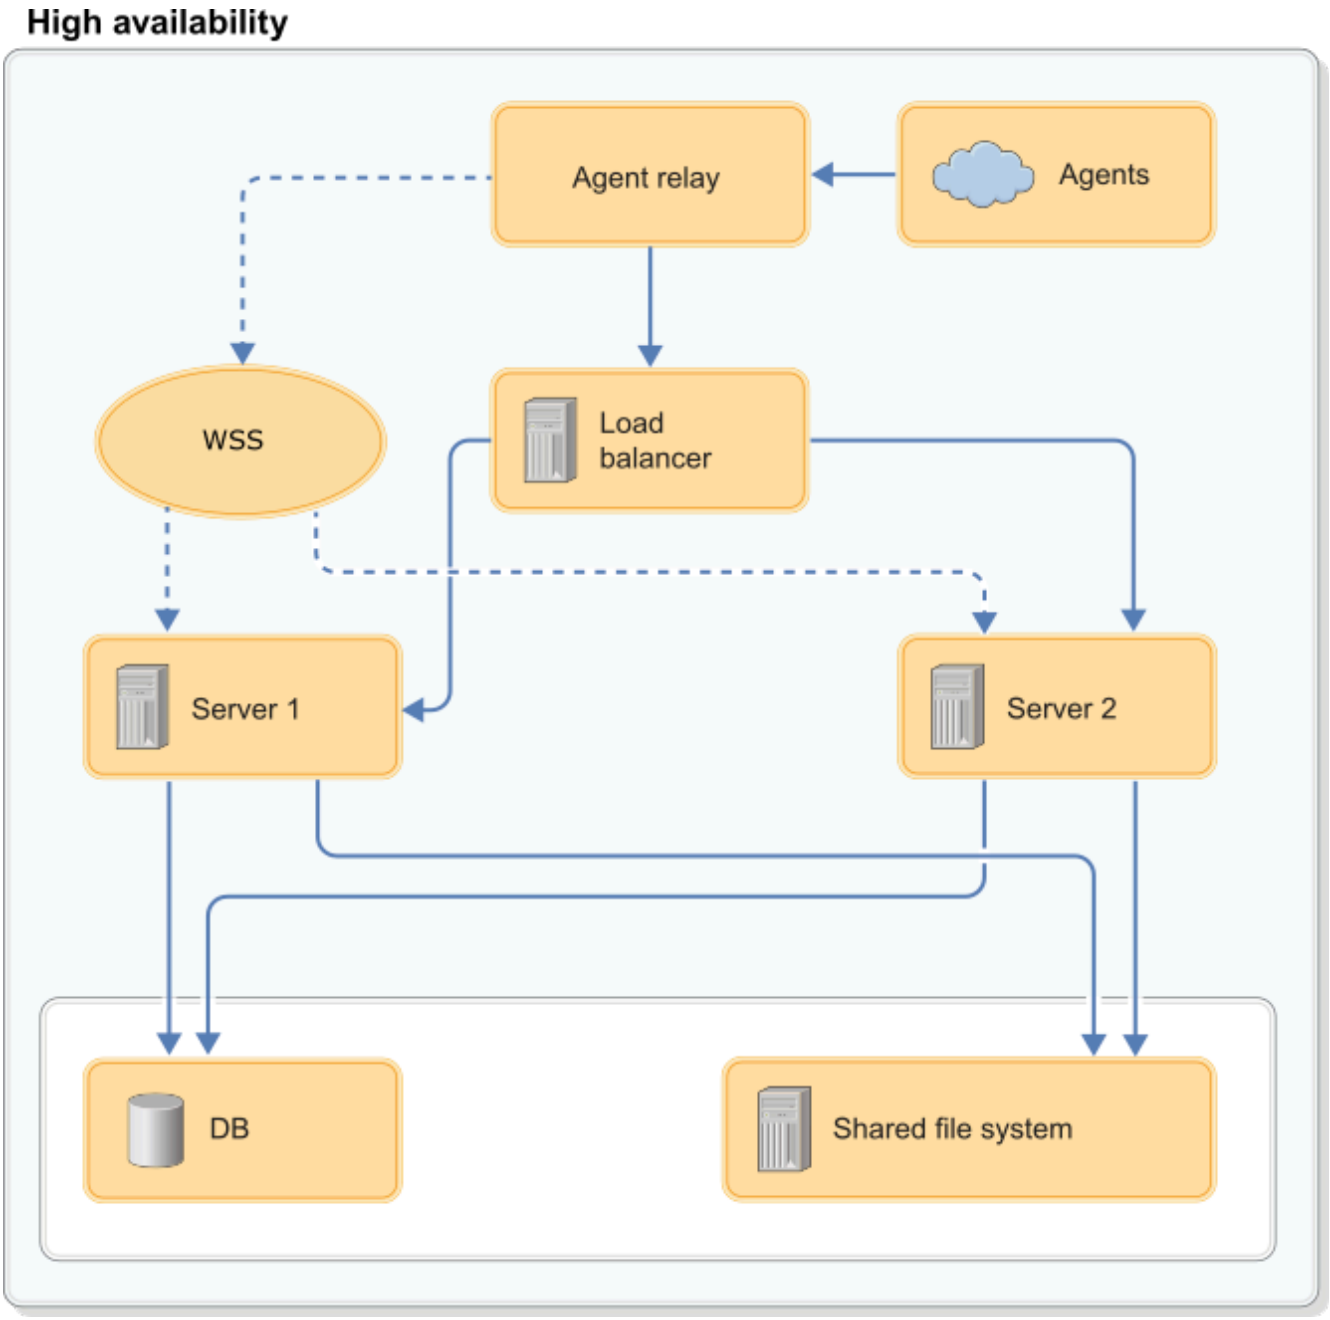
You can configure clustered HCL DevOps Deploy (Deploy) servers, and agents for high availability. You can also configure agents and agent relays for failover.

In most cases, you configure servers to be part of a high-availability cluster when you install them, but you can also convert existing servers to a cluster. To configure a high-availability cluster of Deploy servers, see Setting up high-availability clusters on page 2062.

High availability overview

To configure clustered high availability for HCL DevOps Deploy (Deploy), you must use a load balancer. You can configure a cold standby server by using a load balancer or configuring the servers' DNS.

The architecture of all high-availability scenarios can resemble the following figure:



The load balancer communicates with all Deploy servers. All servers access the same database, shared file system, and agents.

Two common high-availability scenarios are clustered and cold-standby (disaster recovery), and you can apply both scenarios to configurations that use the Deploy server.

Cold Standby

The cold standby option is simple to implement and reduces downtime. In this setup, the load balancer manages two servers, or two servers are connected through DNS settings. Both the primary and secondary servers are connected to

a database and a remote file system. The secondary server is not running. If the active node fails, you must start the secondary server so network traffic can be routed to it. This event is called *failover*. During failover, the secondary server reestablishes connections with all agents, runs recovery, and proceeds with any queued processes. Deploy has no automatic process for failover, but it can be managed by using your load balancer or DNS.

You can convert a cold-standby system to a clustered system by putting shared files on network storage and connecting the servers with cluster connections. See Setting up high-availability clusters on page 2062.

Note: The cold standby server or servers must not be running until they are started by the failover process. Even if no traffic is routed to the cold standby server, it runs internal processes that can corrupt the database. For this reason, servers must be either part of the cluster or shut down.

Clustered

The high availability (HA) feature increases server reliability by distributing processing across a cluster of servers. Each server is an independent node that cooperates in common processing. The goal is to create a fault-tolerant system that requires little or no manual intervention. All servers are running, and the load balancer routes processes to all servers, based on their availability.

All servers recognize each other, and all services are active on each server.

For installation instructions, see Setting up high-availability clusters on page 2062.

High-availability server processes

While high-availability servers complete the same processes as standalone servers, they run slightly differently and access files in run slightly different locations than individual servers do.

In a high-availability topology, all servers use the same database and a common network storage. The server log and CodeStation repository are stored in the common network storage. Most configuration information and runtime data is stored in the shared database. Each server maintains some independent configuration information, such as the connection information for the database.

Because the servers share the database, all servers run on the same interval.

Many activities run the same on high-availability servers as on a standalone server. Some activities run slightly differently:

Importing component versions (CodeStation)

In a clustered high-availability configuration, any server can start the process that imports a component version. If components are configured for automatic imports, all servers poll for component version changes, but they are limited to the polling duration in the system settings. To prevent more than one server from importing a component version or checking for new versions, the database handles server synchronization and a server acquires a database lock before importing or polling.

Notifications

Notifications are handled by the server that runs the process or starts the related event. For more information, see Creating Notifications in a Notification Scheme on page 2081.

Running processes and handling failures

While processes are running, step failures are shown in the process log as usual. Error handling is the responsibility of the process author; for example, processes can include steps that run when other steps fail, including automatic rollback steps.

When a process is requested, a request is created in the database. Servers poll the database regularly for new process requests. The first server that finds the process request runs the requested process. Due to a limitation on the server, the process can not be transferred to another server in the cluster. Therefore, if the server fails in the middle of running a process, the process fails. The other servers in the high-availability cluster run future processes, but they can not take over processes that the failed server was running.

If an agent relay stops while a connected agent is running a process, the agent uses its failover settings to connect to other servers or agent relays. If the agent exhausts its failover options, it continues trying to reconnect. If an agent relay or server comes back online, the agent continues to run the process.

Step failures do not cause agents themselves to fail. If an agent stops while it is running a process, the server assumes that the agent is still running the process and does not mark the process as failed.

High-availability agent communication

Agents communicate with the server over HTTP or HTTPS. These modes of communication are handled differently in a high availability scenario.

HTTP or HTTPS communication

A standard load balancer handles HTTP or HTTPS server-agent communications. Authentication is run on every request; any server can run validation for any request. You configure HTTP or HTTPS server-agent communication when you configure your cluster of servers. See Setting up clusters of servers on page 2063.

In case of server failure, user-server authentication must be redone unless the ‘remember me’ cookie is used.

Setting up high-availability clusters

To configure a high-availability cluster, you store shared files on network storage. Then, you configure multiple servers, set each server to access the same files and database, and configure a load balancer to distribute the traffic between the servers.

About this task

The specific steps depend when you are clustering servers. To set up a cluster of servers, see Setting up clusters of servers on page 2063.

To upgrade a high-availability installation, see Upgrading high-availability installations on page 2229.

Setting up clusters of servers

To configure a cluster of servers, set up a shared database and file system for the servers to use.

Before you begin

- Each server in the cluster must run the same version of Deploy.

About this task

To set up servers in a clustered configuration, you install servers on separate systems and connect the servers to the same database and network storage. Several log and configuration files are stored in the shared network storage, but each server also independently maintains some configuration information, such as database and connection information. The database stores other configuration information and runtime data, as well as other information. Because the servers share the database, all servers run on the same interval.

Note: To create a second server in an high-availability setup use the Deploy installer. An install which copies server install files to create a second server is not supported.

Then, you configure a load balancer to distribute the traffic between the servers. Instead of accessing the servers directly, users access the load balancer URL. To the users, that URL appears to host a single instance of the server with high capacity; users are unaware of the multiple servers.

Note: Servers, agents, and agent relays communicate in several ways: via HTTP/HTTPS on the default ports 8080 and 8443, and via WebSocket connects on the default port 7919. To set up the cluster, you must configure the load balancer to distribute the HTTP/HTTPS traffic. In general, load balancers work well with HTTP/HTTPS traffic because this traffic is stateless and works on a request and response cycle.

1. Set up a shared database for the servers to use.
   See Installing the server database.
2. Set up network storage for the server configuration files.
   Because each cluster server must access the same configuration files, each server must have access to this network storage.
3. Configure online and offline backups for the servers.
   See Backing up the server on page 2057.
4. Install a load balancer to send requests to the servers.
   The load balancer must be able to forward requests to the HTTP and HTTPS ports for the servers. For more information, see the documentation for your load balancer.

   Important: You must configure the load balancer for session persistence, also known as session affinity.

5. If you have one or more servers already installed, populate the network storage with configuration files for the servers:

a. Stop one of the existing servers.

b. On the server, mount the network storage.

c. From the server installation directory, move the following files and folders to the network storage and update the existing server to access those files and folders.

   Which folders you move depends on how the files are structured on the server and which version the server is running on:

   In this case, follow these steps:

   i. Move the application data folder to the network storage.
   ii. On the server, in the `installed.properties` file, update the **server.appdata.dir** property to the new location of the application data folder.

   If the server was upgraded from a version prior to 6.1.1.5 to version 6.1.1.5 or later, the server does not have an application data folder. In this case, you must move the folders into an application data folder on the network storage by running these steps:

   i. On the network storage, create a folder to be the application data folder, such as `/media/share/appdata`.
   ii. Copy the following folders to the application data folder:
      - *`install_folder`*`/var/plugins`
      - *`install_folder`*`/var/repository`
      - *`install_folder`*`/var/sa`
      - *`install_folder`*`/logs`
      - *`install_folder`*`/conf/server/notification-templates`
      - *`install_folder`*`/conf/encryption.keystore`
      - *`install_folder`*`/conf/server.keystore`
      - *`install_folder`*`/conf/collectors`
      - *`install_folder`*`/patches`
      - *`install_folder`*`/conf/server/log4j.properties`

      For *`install_folder`*, use the installation directory for the server.
   iii. Copy (not move) the `<server install>/conf/installed.version` file to the newly created `<appdata>/conf` directory.
   iv. Verify that the application data folder has the correct folder layout. For example, if you use the `/media/share/appdata` folder for the application data folder, make sure that you have the following folders and files:
      - `/media/share/appdata/var/plugins`
      - `/media/share/appdata/var/repository`
      - `/media/share/appdata/var/sa`
      - `/media/share/appdata/logs`
      - `/media/share/appdata/conf/server/notification-templates`
      - `/media/share/appdata/conf/encryption.keystore`

- `/media/share/appdata/conf/server.keystore`
- `/media/share/appdata/conf/collectors`
- `/media/share/appdata/patches`
- `/media/share/appdata/conf/server/log4j.properties`

Some of these files and folders might not exist yet.

v. On the server, in the `installed.properties` file, set the **server.appdata.dir** property to the new location of the application data folder.

d. Delete the original copies of the files and folders that you moved to network storage. (In other words, delete the files on the local server and keep the files on the network storage.)

6. If you terminate SSL at the server level, set the servers to use the same security certificate.

   Example

   For example, you can copy the certificate in the `/opt/tomcat/conf/tomcat.keystore` file to the other servers. Edit the *tomcat.key.alias* property in `installed.properties` file to specify the alias in the keystore that contains the certificate to use.

   ```
   tomcat.key.alias=alias_of_your_certificate_in_tomcat_keystore
   ```

7. **Optional:** Configure the license server for high availability.

   For information, see the Common Licensing documentation. Also, see High availability options for Rational License Key Server.

Results

After you configure the load balancer to distribute connections to the systems, users can connect to a single URL and use the entire cluster. The servers also ensure that the correct number of licenses are used, even if a user accesses multiple servers.

Several server processes behave differently than with individual servers. See High-availability server processes on page 2061.

What to do next

- Add servers to the cluster. See Adding servers to clusters on page 2065.
- Set up cold standby servers to use for disaster recovery. See Adding cold standby servers on page 2068.

Adding servers to clusters

You can add new servers to a cluster at installation time, or you can move existing servers to be part of a cluster.

Installing new cluster servers

The easiest way to add servers to a cluster is to install new servers. The installation program sets them up to be part of the cluster.

Before you begin

- Set up a cluster of servers, including setting up a load balancer, shared database, and network storage. See Setting up clusters of servers on page 2063.
- Each server must run the same version of HCL DevOps Deploy (Deploy).

1. On the system on which you are installing the new server, set up a connection to the network storage.
   Example
   For example, on Linux™ systems, you might mount a remote drive to the local file system.
2. Install the server as described in Installing the server in interactive mode with the following details:
   - When the installation program asks for database information, specify the shared database for the cluster.
   - When the installation program asks for the host name for users to access, specify the host name of the load balancer.
   - When the installation program asks whether the server is part of a high-availability cluster, specify `yes`.
   - When the installation program asks for the location of the application data, specify the same folder on the network storage that the other cluster servers are using. If this is the first server in the cluster, you can specify any folder on the network storage. In this case, other servers that you add to the cluster must also use this folder.
3. Set the new server to use the same security certificate as the existing servers.
   Example
   For example, you can copy the certificate in the `/opt/tomcat/conf/tomcat.keystore` file to the other servers. Edit the *tomcat.key.alias* property in `installed.properties` file to specify the alias in the keystore that contains the certificate to use.
   ```
   tomcat.key.alias=alias_of_your_certificate_in_tomcat_keystore
   ```
4. Configure the load balancer to send HTTP/HTTPS traffic to the new cluster server.

Moving existing servers to a cluster

Before you begin

- Set up a cluster of servers, including setting up a load balancer, shared database, and network storage. See Setting up clusters of servers on page 2063.
- Each server must run the same version of HCL DevOps Deploy (Deploy).

1. On the system that hosts the server, set up a connection to the network storage.
   Example
   For example, on Linux™ systems, you might mount a remote drive to the local file system.
2. If the sever contains elements that you want to keep, such as components, applications, or processes, export those elements and import them into an existing cluster server.
3. Stop the server.
4. Edit the `installed.properties` file on the server, located in the *`install_folder`*`/conf/server` directory.

a. Set the **server.appdata.dir** property to the location of the application data folder that the cluster servers are using.

b. Copy the value of the **encryption.keystore.alias** property to the equivalent file on the new cluster server from a server that is already in the cluster.

c. Add the following line of code to the file:

```
com.urbancode.ds.UDeployServer.multiserver=true
```

d. Update the database settings to use the same database as the other servers in the cluster.

5. Set the new server to use the same security certificate as the existing servers.
   Example
   For example, you can copy the certificate in the `/opt/tomcat/conf/tomcat.keystore` file to the other servers. Edit the *tomcat.key.alias* property in `installed.properties` file to specify the alias in the keystore that contains the certificate to use.

```
tomcat.key.alias=alias_of_your_certificate_in_tomcat_keystore
```

6. Start the server.
7. On the new cluster server, click **Settings > System Settings**, and set the **External Agent URL** and the **External User URL** to the URL for the load balancer.
8. Click **Save**.

Converting a stand-alone server to high availability

You can convert an HCL DevOps Deploy (Deploy) server into the first node of a high-availability cluster.

Before you begin

- Each server in the cluster must run the same version of Deploy.

About this task

To convert a stand-alone server to the first node in a clustered configuration, you first move CodeStation to shared network storage, and then modify the server settings for multi-server operation.

1. Move CodeStation to a shared storage location with a fast network connection.
   Because each cluster server must access the same configuration files, each server must have access to this network storage. See Relocating CodeStation on page 2124.
2. Install a load balancer to send requests to the servers.
   The load balancer must be able to forward requests to the HTTP and HTTPS ports for the servers. For more information, see the documentation for your load balancer.

Important: You must configure the load balancer for session persistence, also known as session affinity.

3. Stop of the server.
4. Add the following line of code to the *install_folder*/conf/server/installed.properties file:

```
com.urbancode.ds.UDeployServer.multiserver=true
```

5. Start the server.
6. On the new cluster server, click **Settings > System Settings**, and set the **External Agent URL** and the **External User URL** to the URL for the load balancer.

Results

After you configure the server and the load balancer, you can add nodes to the cluster.

What to do next

- Add new servers to the cluster. See Adding servers to clusters on page 2065.

Adding cold standby servers

You can add cold standby servers to serve as a backup server or for disaster recovery. You must start the secondary server or servers when the active server fails, and network traffic is routed to the secondary servers.

Before you begin

- Make sure that the server is connected to a license server with available licenses.
- Set up a cluster as described in Setting up clusters of servers on page 2063. Your cluster must contain at least one running server.

About this task

To set up a cold standby system, you install two or more servers on separate systems and connect the servers to the same database and network storage. Then, you configure a method to distribute the traffic to secondary servers if the primary servers fail. In most cases, you must manually start the secondary servers after the primary servers fail.

During failover, the secondary server reestablishes connections with all agents, runs recovery, and proceeds with any queued processes. Deploy has no automatic process for failover, but it can be managed by using your load balancer or DNS.

You can use cold standby servers with or without a load balancer. If you use a load balancer, instead of accessing the servers directly, users access the load balancer URL. To the users, that URL appears to host a single instance of the server with high capacity; the users are not aware of the multiple servers.

1. Install the cold standby server:
   Install the server as described in Installing the server in interactive mode with the following details:

- When the installation program asks for database information, specify the database that the cluster servers are using.
- If you are using a load balancer, when the installation program asks for the host name that users will access, specify the host name of the load balancer.
- When the installation program asks if the server is part of a high-availability cluster, say yes.
- When the installation program asks for the location of the application data, specify the same folder on the network storage that the other cluster servers are using.

Note: Do not start the server.

2. Set the new server to use the same security certificate as the existing servers.
   Example
   For example, you can copy the certificate in the `/opt/tomcat/conf/tomcat.keystore` file to the other servers. Edit the *tomcat.key.alias* property in `installed.properties` file to specify the alias in the keystore that contains the certificate to use.

   ```
   tomcat.key.alias=alias_of_your_certificate_in_tomcat_keystore
   ```

3. Set a method to route traffic to the cold standby server after failover.
   Depending on your network configuration, you might configure a DNS server routing path, Virtual IP, cluster connection, or load balancer to swap traffic.

Server settings and configuration

After you install HCL DevOps Deploy (Deploy), you can modify the server configuration and configure more options.

Other server settings control locks, notifications, and general system settings.

Increasing the amount of memory that is available to the server

If you see "Out of memory" errors or are using the server at high capacity, increase the amount of system memory that is available to the server.

About this task

For servers that are running as a service on Windows™, see the following technote: Out of memory errors while running IBM UrbanCode Deploy.

To increase the memory for the server on Windows™ for a non-service installation, or on Linux™ or UNIX™ systems, follow these steps:

1. Stop the server.
2. In the `bin/set_env.cmd` file (Windows) or `bin/set_env` file (Linux and UNIX), increase the memory in the `JAVA_OPTS` parameter.
   Example
   For example, the current file might have a line that begins with the following code:

```
JAVA_OPTS="-Xmx2048m
```

To increase the memory, change the parameter that begins with the code `-Xmx`. For example, to increase the memory to 4 GB, use the following value: `-Xmx4096m`. Be sure to include the "`m`" at the end of the parameter.

3. Save the file and restart the server.

Modifying the context root of the server

After you install the server, you can modify the context root, if your server configuration requires it.

1. Stop the server.
2. From the server installation directory, rename the directory *`server_install`*`/opt/tomcat/webapps/ROOT` to a new name, such as *`server_install`*`/opt/tomcat/webapps/deploy`
   Use the server installation directory for *`server_install`*.
3. Make a backup copy of the file `opt/tomcat/conf/server.xml`.
4. Open the file `opt/tomcat/conf/server.xml` in a text editor
5. In the `server.xml` file, find the following line of code:

```
<Context path=""
  docBase="ROOT"
  debug="0"
  reloadable="false"
  useHttpOnly="true"
  sessionCookieName="JSESSIONID_8080">
```

6. In this code, change both the **docBase** attribute and the **path** attribute to the name of the new folder.

   Example

   For example, if you renamed the `ROOT` folder to `deploy`, the code looks like the following example:

```
<Context path="deploy"
  docBase="deploy"
  debug="0"
  reloadable="false"
  useHttpOnly="true"
  sessionCookieName="JSESSIONID_8080">
```

7. Save the file.
8. Restart the server.

Results

Now you can access the server at the following URL:

```
https://hostname:port/foldername
```

Use the new name of the folder as *`foldername`*.

Management of maintenance blackouts

You can manage important updates to ensure that tasks run smoothly without interfering with ongoing deployments by using maintenance blackouts. You can manage maintenance blackouts by creating a recurrence blackout, rescheduling an existing blackout, creating a specific environment blackout, and canceling an existing blackout.

You can schedule a maintenance blackout in the daily, weekly, or monthly recurrence pattern. When a recurring scheduled deployment is created, its events are now linked together into a series.

You can update a maintenance blackout by modifying the name and description and rescheduling an upcoming maintenance blackout of a recurrent deployment series.

Rescheduling an upcoming recurring maintenance blackout changes the timing of subsequent events in the same series. For example, if the daily blackout series is moved from 7 pm to 8 pm, all future blackouts are also moved to 8 pm. Similarly, if the blackout is extended from 1 hour to 2 hours, the duration of all subsequent blackouts is extended to 2 hours.

Note: Suppose a maintenance blackout is rescheduled to a later date, any events that were scheduled before that date are removed. Recurrences that were canceled on a specific date remain canceled. For example, if the blackout event for next Monday is canceled due to a holiday, and later the Tuesday blackout is rescheduled to Wednesday, then the blackout on Monday remains canceled.

If a recurring deployment is rescheduled, the dates and cancellations of future deployments are adjusted in the same way as recurring maintenance blackouts. However, if the recurrence pattern is changed, then the cancellations are reset.

Entire recurrence series or individual events can be canceled without affecting the rest of the events in the series.

Related information

Updating maintenance blackouts on page 2072

Canceling maintenance blackouts on page 2074

Creating recurrence maintenance blackouts

You can schedule a maintenance in a daily, hourly, weekly, or monthly recurrence pattern.

Before you begin

You must ensure the following requirements are met:

- Obtained permission to manage maintenance mode.
- Enabled the maintenance mode.

About this task

You cannot alter the recurrence pattern of maintenance blackouts after you created a pattern.

1. Log in to Deploy.
2. Go to **Settings**.
3. Click **Manage Maintenance Blackouts** in the **System** panel.
   The settings **System** page is displayed.
4. Click **Create Maintenance Blackout**.
   The **Create Maintenance Blackout** window is displayed.

5. Enter the name or description in the **Name/Description** field.
6. Select the **Start Date** for the blackout.
7. Select the **Start Time** from the drop-down.
8. Select the **Estimated End Date** from the drop-down.
9. Select the **Recurrence Pattern** from the drop-down.
10. You can choose the **Hourly**, **Daily**, **Weekly**, **Monthly**, and **Weekdays** recurrence pattern.

    Note: Select **Never** for a one-time blackout event.

11. Click **Submit**.

Results

You have created a recurrence maintenance blackout. The new recurrence blackout is displayed in the maintenance blackout list.

What to do next

You can view the recurring maintenance blackout in on the **Calendar** page.

Related information

Enabling maintenance mode on page 2073

Management of maintenance blackouts on page 2070

Updating maintenance blackouts

You can change the name and description of the past and upcoming recurring blackouts in a series.

Before you begin

You must ensure the following requirements are met:

- Obtained permission to manage maintenance mode.
- Enabled the maintenance mode.

About this task

You can update a maintenance blackout by modifying the name and description and rescheduling an upcoming maintenance blackout of a recurrent deployment series.

Note: You cannot change the name and description of deployments beyond the upcoming maintenance blackout.

1. Log in to Deploy.
2. Go to **Settings**.
3. Click **Manage Maintenance Blackouts** in the **System** panel.

The settings **System** page is displayed.

4. Click and then click **Edit** for the maintenance blackout you want to reschedule.
   The **Update Maintenance Blackout** window is displayed.
5. To modify the name and description, enter a name and description in the **Name/description** field.
6. To reschedule an upcoming maintenance event, select the **Start Date** for the blackout.
7. Select the **Start Time** from the drop-down.
8. Select the **Estimated End Date** from the drop-down.
9. Select the **Recurrence Pattern** from the drop-down.
   You can choose the **Daily**, **Weekly**, or **Monthly** recurrence pattern.

   Note: Select **Never** for a one-time blackout event.

10. Click **Submit**.

Results

You have updated a recurrence maintenance blackout by modifying the name and description and rescheduling the event. The updated maintenance blackout is displayed in the maintenance blackout list.

What to do next

You can view the updated maintenance blackout in on the **Calendar** page.

Related information

Enabling maintenance mode on page 2073

Management of maintenance blackouts on page 2070

Enabling maintenance mode

Enabling the maintenance mode stops some activities on the server for a specific duration so you can run important tasks that require the server to be idle.

Before you begin

Ensure that you have the permissions to manage maintenance mode.

About this task

When you enable maintenance mode, users can log in to the server as usual and perform some limited tasks. A message is displayed at the top indicating the start and estimated end time of the maintenance activity. While the maintenance mode is enabled, some of the tasks/actions are blocked and some are allowed. Below is a list of such tasks:

Tasks blocked during maintenance mode	Tasks not blocked during maintenance mode
Execution of new global, component, and application processes.	Processes which are started before maintenance mode are allowed to run for completion.

Tasks blocked during maintenance mode	Tasks not blocked during maintenance mode
With additional permissions, you can allow users to execute new deployments while maintenance mode is enabled.	
Execution of processes triggered by the calendar, including recurring deployments.	Sub-processes kicked off by processes that are started before maintenance mode are allowed.
Execution of processes triggered by a repeating a process request.	Manual tasks that are part of a process can be responded to, and the process are allowed to continue.
Approval or rejection of any approval tasks.	Making changes to the server, such as changing properties, creating elements such as applications and resources, and editing processes.
New version imports.	-
Automatic version imports.	-
Processes started upon completion of a version import.	-
Auto Discovery.	-
Auto Compare.	-
Auto Configure.	-

1. Click **Settings > System Settings**.
2. Activate the **Enable Maintenance Mode** option in the **General Settings** field.
3. **Save** the settings.

Results

The maintenance mode is enabled.

What to do next

- After maintenance mode is enabled, make sure that you do not restart the server until all processes have completed.
- After the maintenance schedule ends, you must disable the **Enable Maintenance Mode** option manually.

Canceling maintenance blackouts

You can cancel the entire recurrent deployment series or just a single deployment blackout event without impacting the other deployments in the recurrence series.

Before you begin

You must ensure the following requirements are met:

- Obtained permission to manage maintenance mode.
- Enabled the maintenance mode.

About this task

Note: You cannot revive the cancelation of the entire recurrent deployment blackout series or a single deployment blackout event.

1. Log in to Deploy.
2. Go to **Settings**.
3. Click **Manage Maintenance Blackouts** in the **System** panel.
   The settings **System** page is displayed.
4. Click and then click **Cancel** for the maintenance blackout you want to cancel.
   The **Cancel Series or Event** window is displayed.
5. Select the **Event** or **Series** you want to cancel.
6. Click **Submit**.

Results

You have canceled the maintenance blackout event or series.

Related information

Enabling maintenance mode on page 2073

Management of maintenance blackouts on page 2070

Changing the database password

If you change the password for your database, you must update the password on the server.

1. In a text editor, open the file `conf\server\secured-installed.properties`.
2. Specify the new database password in the following line of code:

   ```
   hibernate.connection.password=newPassword
   ```

   This password will be encrypted when you restart the server.
3. Restart the server.

Changing passwords for the server KeyStore

You can change the Java™ KeyStore password for the server.

About this task

The server Java™ KeyStore password must be identical to its certificate password. After you change both the server KeyStore password and certificate password, you must update the password in the server properties.

1. Stop the server.
2. Open a command-line window, and go to the *appdata*`/conf` directory.

3. Change the server KeyStore password by using this command:

   ```
   keytool -storepasswd -new newStorePassword -keystore server.keystore
   -storepass changeit
   ```

   The default server password is *changeit*. The keytool application is included in the Java™ developer kit and is not part of HCL DevOps Deploy (Deploy).
4. Change the certificate password by using this command:

   ```
   keytool -keypasswd -alias server -keypass changeit -new newKeyPassword -keystore server.keystore
    -storepass newStorePassword
   ```

   The default server alias is *server*.
5. In a text editor, open the *server-install*\conf\server\secured-installed.properties file.
6. Specify the new Java™ KeyStore password for the server in the following line of code:

   ```
   server.keystore.password=newStorePassword
   ```

   The `javax.net.ssl.trustStorePassword` property takes precedence over the `secured-server.keystore.password` property. If it is present in *server-install*\conf\server\secured-installed.properties file, update its password with this code: `javax.net.ssl.trustStorePassword=newpassword`. This property applies to all relevant KeyStores.
7. Specify the new Certificate password for the server in the following line of code:

   ```
   server.key.password=newKeyPassword
   ```

8. Start the server.

Results

The server KeyStore password is changed and is obfuscated in the *server-install*/conf/server/secured-installed.properties file.

Changing passwords for the encryption KeyStore

You can change passwords for the encryption KeyStore.

About this task

The `encryption.keystore` password must be identical to the certificate password.

1. Stop the server.
2. Open a command line window, and go to the *app_data*/conf directory.
3. To view the alias of the secret key, run the following command:

   ```
   keytool -keystore encryption.keystore -list -storetype pkcs12 -storepass changeit
   ```

   Make a note of the alias of secret key, it is required in step 6 on page 2077. The keytool application is included in the Java™ developer kit and is not part of HCL DevOps Deploy (Deploy).
4. Back up the `encryption.keystore` file.
5. Change the encryption KeyStore password by using the following command:

   ```
   keytool -storepasswd -new newPassword -keystore encryption.keystore -storetype pkcs12 -storepass changeit
   ```

The default password is **changeit**. Replace *newPassword* with your password of choice. The keytool application is included in the Java™ developer kit and is not part of Deploy.

6. Change the secret key password by using the following command:

```
keytool -keypasswd -alias XXX -keypass changeit -new newpassword -keystore encryption.keystore
-storetype pkcs12 -storepass newpassword
```

where `alias` is the one that you noted in step 3 on page 2076, and the encryption KeyStore password and the secret key password must be the same.

7. In a text editor, open the *server-install*`\conf\server\secured-installed.properties` file. Specify the new **encryption.keystore** password in the following line of code:

```
encryption.keystore.password=newPassword
```

Note: The password that you specify here must be the same as the password for the encryption KeyStore password that you specified in step 5 on page 2076 and the secret key password that you specified in step 6 on page 2077.

8. Start the server.

Results

Starting the server automatically encrypts the `encryption.keystore` password that you specified in the `installed.properties` file.

Changing passwords for the Tomcat keystore

You must change the default passwords for the Tomcat keystore and private keys.

About this task

The default password for Tomcat private key and keystore is *changeit*. You must change the passwords by using the `keytool` command.

Note: The keytool application is included in the Java™ developer kit and is not part of HCL DevOps Deploy (Deploy).

If you change the key password to a value other than the keystore password, you must update the password in the `secured-installed.properties` file manually. The properties for Tomcat key and keystore passwords are defined as **tomcat.key.password** and **tomcat.keystore.password** in the `secured-installed.properties` file.

The properties are referenced in the `server/opt/tomcat/conf/server.xml` file as `keyPass="${tomcat.key.password}"` and `storePass="${tomcat.keystore.password}"` in the HTTPS connector configuration.

Important: If you use a plain text password in the `server.xml` file and the passwords entered in the `secured-installed.properties` and `server.xml` files do not match, then the server fails to accept any web requests

and you cannot access the application on your browser. As a Tomcat keystore limitation, you do not get any visible error messages.

You must consider the following scenarios before changing the passwords:

- If you change the keystore password, then you must change the Tomcat private key password as well.
- If the keystore has a typical configuration where no explicit key password is set, then you can just change the keystore password to change them both.
- You can directly change the key password only in advanced scenarios where the key password is already different from the store password.
- You are responsible for managing your passwords. Deploy currently does not include the password recovery feature.

When you are upgrading from version 8.1.0 or before, the plain text passwords in the `server.xml` file are replaced with the `${tomcat.key.password}` and `${tomcat.keystore.password}` variables, and the passwords are added to the `secured-installed.properties` file automatically.

1. Stop the server.
2. Open a command-line window, and go to the `opt/tomcat/conf` directory.
3. Change the Tomcat keystore password by using the following command:

   ```
   keytool -storepasswd -new newStorePassword -keystore tomcat.keystore -storepass changeit
   ```

4. Change the Tomcat private key password by using the following command:

   ```
   keytool -keypasswd -alias server -keystore tomcat.keystore -storepass changeit -keypass changeit
   ```

   Notes:
   - The default server alias is *server*.
   - In this example, the password for keystore is assumed to be the default password.
   - The passwords for the `keypass` and `storepass` attributes must be correct.

5. You are prompted to enter a new password:

   ```
   New key password for <server>:
   Re-enter new key password for <server>:
   ```

   A warning message is displayed:

   ```
   The Java Keystore (JKS) keystore uses a proprietary format. If you are using
   JKS keystore, you must migrate to Personal Information Exchange Syntax
   Standard (PKCS12) which is an industry standard format using the following
   keytool command:
   keytool -importkeystore -srckeystore opt/tomcat/conf/tomcat.keystore
   -destkeystore opt/tomcat/conf/tomcat.keystore -deststoretype pkcs12
   ```

6. In a text editor, open the *`server-install`*`\conf\server\secured-installed.properties` file.
7. Specify the new key and keystore password for the Tomcat in the following lines of code:

```
tomcat.key.password=newKeyPassword
tomcat.keystore.password=newKeystorePassword
```

8. Start the server.

Results

The Tomcat key and keystore passwords are changed and are obfuscated in the *server-install*/conf/server/secured-installed.properties file.

Changing or updating the JRE of servers

You can change the JRE of active servers by editing their configuration files.

About this task

Procedure

Note:

- Any certificates that you imported to the old JRE cacerts file must be imported into your new JRE cacerts file as well. SeeConfiguring SSL on Apache Tomcat and LDAP servers on page 2159 for more information.
- Starting from v7.2.1, the keystore converter utility is no more needed, and Deploy handles any necessary conversions itself.

1. Install the new JRE.
2. Stop the server.
3. Update the location of the JRE in the following files:
   - In the file *server_install*/bin/set_env, set the value of the **JAVA_HOME** system variable to the location of the JRE.
   - In the file *server_install*/conf/server/installed.properties, set the value of the **install.java.home** property to the location of the JRE.

Note: As a shortcut, you can delete the old JRE and move the new JRE into the location of the old JRE. In this case, you do not need to update the **JAVA_HOME** system variable and **install.java.home** property because they now point to the new JRE.

Note: The value of the **JAVA_HOME** system variable must match the value of the **install.java.home** property.

Note: If you are upgrading to Java 9 or above and are moving off Oracle Java to AdoptOpenJDK you must manually remove the `-Djava.endorsed.dir` entry from the server_install/bin/set_env file.

4. If the server is running as a service on Windows:™

a. Open the file *server_install*\bin\service_service.cmd in a text editor.

b. Edit the line that starts with the code `set JAVA_HOME` to the path to the new JRE.

c. Open a command prompt as an administrator.

d. Go to the *server_install*\bin\service folder.

e. Remove the service by running the following command:

```
service.cmd remove service_name
```

Use the name of the service for *service_name*. To find the service name, open the services view and find the entry that starts with `Deploy`. The service name is in parentheses in this entry.

f. Reinstall the service by running the following command:

```
service.cmd install service_name
```

5. Start the server.

Working with Notifications

HCL DevOps Deploy (Deploy) can send email notifications whenever user-defined trigger events occur on the server.

Notifications can be sent to different users during deployment, as a way of providing updates to the status of the deployment. For example, notifications can be sent when a deployment finishes or if an approval was accepted or rejected.

Notifications are defined in Notification Schemes. Notification Schemes allow multiple notifications to be configured and assigned to a process. Refer to Creating Notifications in a Notification Scheme on page 2081.

Notification-Approval Relationship

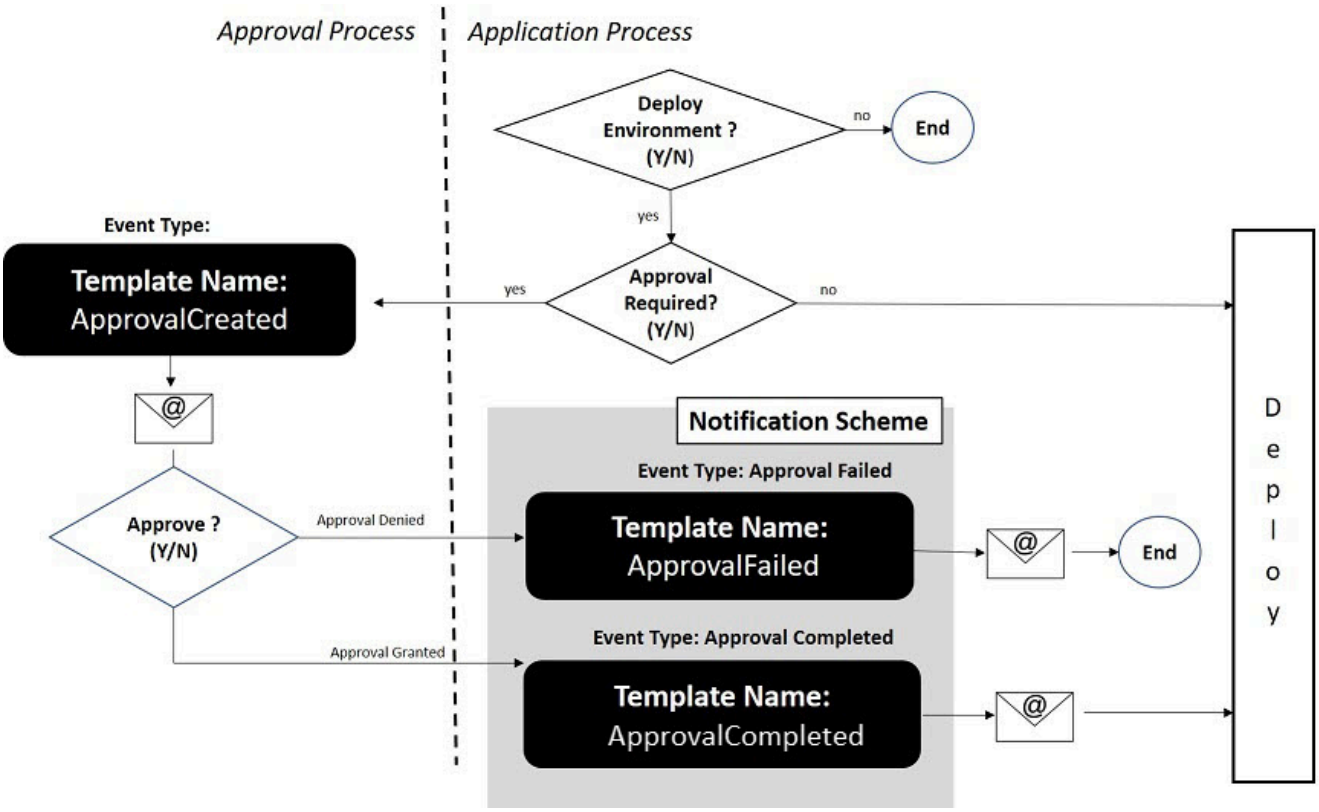
Notifications and approvals are two separate areas of functionality and are configured in two separate areas in the user interface. They are also typically configured by different types of users.

Note: Do not confuse creating the notification for an approval with actually creating the approval itself. Refer to Creating an approval process on page 2388.

Notifications are managed at a system-wide level, typically by the system administrator and can be shared across applications. Notification emails are provided for informational purposes only, and do not affect the execution of the deployment. They do not require user intervention.

Approvals are managed at an application level and require an environment developer user role. Approvals, unlike notifications, are actionable events. They are configured in an approval process and require user-intervention (acceptance or rejection of a deployment in a specific environment). If approved, the deployment executes. If rejected, the deployment remains in an on-hold status.

The only relationship between notifications and approvals is when an action defined in an approval process triggers an approval notification email.



Creating Notifications in a Notification Scheme

Notifications are defined in a notification scheme. The notification scheme is assigned to an application and the notifications are sent during the deployment of that application.

Before you begin

Each notification in a notification schemes must specify the group of users that receive the notifications. Each user in the group must have a valid email address defined on the HCL DevOps Deploy (Deploy) server. An external SMTP mail server is also required.

Prior to configuring notifications, the following prerequisites must be met.

Table 679. Notification Prerequisites

Prerequisite	Description
An external SMTP mail server is required to send notifications.	For information about configuring a mail server, see System settings on page 2086

Table 679. Notification Prerequisites (continued)

Prerequisite	Description
Notification recipients must have defined security system roles.	See Managing Security on page 2149
Notification recipients must have email addresses defined on the Deploy server.	See System settings on page 2086 Note that email addresses are not automatically imported from authentication servers such as LDAP servers. Click **Settings > Authentication**, edit a user, and ensure that the user has an e-mail address attached.

About this task

Notification schemes can be configured to hold multiple notifications related to an application. Since notification schemes are a system-resource, they and can be shared across applications for ease of use.

Each notification you configure in a notification scheme must specify the following items: a notification template, a triggering event, and a user group role to receive the notification. The user group role is inherited from the security system. For example, it is common for an administrator or environment owner to be notified when a work item is generated.

Note: Notifications are **not** sent to users assigned to any role on the System Team, regardless of whether or not that role is configured to receive notifications for the application.

1. Create the new notification scheme. Later, you can come back to add more notifications to the scheme or edit existing notifications. Display the **Notifications** pane. Click **Settings > Notification Schemes**
2. Click **Create Notification Scheme** and provide a **Name** and **Description** for the new notification scheme. (To edit an existing notification scheme, select that scheme in the list.)
3. Configure a notification for the notification scheme. Click **Add Notification Entry**, and supply parameters for the notification at the **Add Notification Entry** window. Notification parameters are listed in the following table.

Table 680. Notification Parameters

Parameter	Description	Values
Role	**Role** corresponds to the roles in the security system. The notification message goes to any user who has the specified role on a team that is associated with the **Target** element. For example, a deployment engineer would be interested in being notified about a failed deployment.	*<user group role>*
Event Type	This field lists the type of event that will trigger the notification.	Select these event types for generic and application processes: **Process Success**, **Process Failure**, or

Parameter	Description	Values
	For example, you can trigger a notification when a processes completes successfully. You can also trigger a notification when an approval is declined. Note that the **Event Type** selected should correspond to the type of process (generic, application, environment, resource, or approval) that triggers the event. Refer to Processes on page 2398 and Creating an approval process on page 2388.	**Process Started**. Select these event types for approval processes: **Approval Completed** or **Approval Failed**.
Target	The **Target** specifies the area of the deployment where the **Event Type** occurs. The target refers to the general concept of an application, environment, or resource in the deployment.	**Application**, **Environment**, or **Resource**
Type	The target can be further refined using the **Type** field. The **Type** pull-down lists the security types defined in a role's application, environment or resource permissions. Notifications will only be sent to users with roles that are configured with the selected security type indicated in the **Type** pull-down. Refer to Creating roles and assigning permissions on page 2188. For example, if the **Target** field is set to **Application**, notifications are only sent to users that are configure in that specific application permission security type when the application is deployed.	*<security type>*

Parameter	Description	Values
Template Name	Default notification templates are provided for use. The templates contain fields that are automatically populated and formatted in the email when the notification is sent to the selected role. The template you select should be based on the **Event Type**, or reason for the notification. You can select a default notification template or a notification template you have created. See Creating notification templates on page 2587. Note that the **ApprovalCreated** notification template is NOT intended for use in a notification scheme. It appears in the **Template Name** drop-down, but should only be assigned as a single template when Creating an approval process on page 2388 to notify an approver that an approval is required.	Use these default notification templates for **Process Success**, **Process Failure**, or **Process Started** event types. ◦ **ProcessRequestStarted** - indicates that a specific application, user group environment, or application resource was initiated. ◦ **ApplicationDeploymentSuccess** or **ApplicationDeploymentFailure**- indicates that a specific application deployment succeeded or failed. ◦ **TaskCreated** - reports on the state of manual tasks. ◦ **DeploymentReadied** - notifies the role that the deployment requires approval. ◦ **GenericProcessRequestStarted** - indicates that a Generic processes on page 2451 was started. ◦ **GenericProcessSuccess** or **GenericProcessFailure** - indicates that a Generic processes on page 2451 succeeded or failed. Use these notification templates for **Approval Completed** or **Approval Failed** event types. ◦ **Deployment Readied** - indicates that an approval was granted for an approval process. ◦ **ApprovalFailed** - indicates that approval was denied for an approval process.

4. Assign a notification scheme to an application or approval process. For an application process, click the application, go to the **Configuration** tab, and in the **Notification Scheme** list, select the notification scheme. For an approval process, click the application, go to the **Approval Process** tab, edit the required process step and assign the approval notification template at the **Edit Properties for Component Approval Task** window.

Managing locks

A *lock* ensures that processes do not interfere with one another. Normally, locks are released after they are no longer needed. Sometimes, a lock is not released, and its associated process is unable to complete. The lock management feature helps you to identify and resolve abnormal lock conditions.

About this task

Follow these steps to view and resolve locks.

1. A running process with a lock, like all active processes, is shown on the **Dashboard** tab with a status of `Running`. If a locked process takes longer to complete than expected, you can cancel the process from the **Dashboard**, or investigate it fully with the **Settings** tab.
2. Display the **Locks** pane by clicking the **Locks** link on the **Settings** tab (**Settings > Locks**).
   Result
   The **Locks** pane displays the following information:

   Table 681. Lock fields

Field	Description
Name	The name identifies the lock. The displayed name is a concatenation of the component or application name (depending on type) + process name + resource name.
Type	Indicates whether the process that created the lock is a component or application type. Locks can be applied only to component or application processes.
Component/Application	Displays the name of the component or application that contains the lock. Clicking an item displays (depending on the type) the **Component** pane, or **Application** pane, where you can investigate the lock.
Resource/Environment	Displays the name of the resource or environment that contains the lock. Clicking an item displays (depending on the type) the **Resource** pane, or **Environment** pane.
Process	Displays the name of the process that contains the lock. Clicking an item displays the process in the process editor.
Actions	Lists the available actions.

3. Resolve the lock by selecting an action:

   Table 682. Lock actions

Action	Description
View Request	Displays the process log for the process that contains the lock. You can use the **Actions** field on the displayed pane to see the name of the process step that is causing the lock.
Release	Releases the lock, which enables the associated process to continue processing.

If the HCL DevOps Deploy (Deploy) server and or agents go down while a locked process is running, Deploy automatically restores any interrupted processes along with any locks they might contain after service is restored.

Acquire Lock on page 2466

Release Lock on page 2483

System settings

System settings allows you to manage global settings for components, clean up, password requirement, security, mail-server, and much more.

Example

The following tables list the settings for several system-wide settings for the server.

Table 683. General settings

Field	Description
External Agent URL*	Specify the URL that the HCL DevOps Deploy (Deploy) server provides to agents as their point of contact. When an agent wants to contact the server, it retrieves this URL and opens a connection on it. This URL must point to the HTTP or HTTPS port of the server.
External User URL*	Specify the URL that users enter to connect to the Deploy server. The URL is also used when creating a notification template.
Message of the Day	A custom notification message that is displayed when users log in to the dashboard. This field supports standard Markdown syntax, which you can use to include formatted headings, bold text, numbered or bulleted lists, inline code blocks, and internal or external hyperlinks.
Validate Agent IP	When enabled, the agent IP and host name are validated against values that are used the first time that the agent is connected to the Deploy server.
Create Default Children for Plugins	When enabled, empty groups are created when plug-ins use the auto discovery feature.
Default Locale	Select a default language for the user interface.
Default Snapshot Lock Type	Determines the default lock type when users create snapshots. Lock types are the following values: **Only Component Versions**, **Only Configuration**, or **Component Versions and Configuration**. The default value is **Component Versions and Configuration**. Changes are effective after the server is restarted.
Require a Comment For Process Design Changes	When enabled, prompts users to provide a comment when a process design is updated.
Enable Maintenance Mode	When enabled. stops activities on the server so you can run important tasks that require the server to be idle.

Table 684. Component settings

Field	Description
Components copy to CodeStation by default	When enabled, newly created components copy artifacts to CodeStation by default. You can change this setting on individual components even when this option is enabled.
Enforce Deployed Version Integrity	When enabled, deployed component version artifacts cannot be changed.
Automatic Version Import Check Period (seconds)*	Specify the time-period (in seconds) between the times that Deploy polls components for new versions. If this value is changed, the server must be restarted before the change becomes effective. You can set this value to 15 seconds or higher.
Use Agent Tag For Integration	When enabled, allows agent that is identified by a specific tag to import component versions. If this setting is selected, the **Agent Tag for version imports** field is shown. Otherwise, the **Agent for Version Imports** field is displayed. For information about tagging objects, see Adding tags to objects on page 2521
Agent for Version Imports	Specify the agent that is used to import component versions. The agent must have access to component artifacts. The agent becomes the default agent for new components. This value can be overridden when a component is created. This field is displayed if the **Use Agent Tag for Integration** toggle button is set to Off. To import artifacts from the server location, install an agent in the same location and specify that agent.
Version Import Records to Retain	Specify the number of version import records to retain during cleanup. Default is 100.
Enable Safe Edit of Component Processes	When enabled, you can test component processes before making them available in normal environments. You can make updates to your component process, test those updates safely, and then promote to a new version when you are ready.
Require Approval to Promote	When enabled, any draft component process must be approved by an authorized user before it can be promoted and used in deployments.

Table 684. Component settings (continued)

Field	Description
Component Process	
Allow Process Locking	When enabled, users with 'Manage Process Lock' permission can lock component processes for editing. Users can also force unlock a process locked by another user.
Require Process Locking	When enabled, users will not be able to edit component processes without locking the process first.
Server Storage Display '100%' Size (MB)	Define the size in megabytes of '100%' storage in the dashboard server storage display. This setting only affects the dashboard display and does not enforce a limit for artifact uploads.

Table 685. Artifact cleanup settings

Field	Description
Daily Cleanup Start Time*	Enter the time when versions are cleaned. The value must be an integer from 0 (midnight) to 23 (11 pm). To preview the component versions that are scheduled for cleaning, click **Preview Version Cleanup**. See Cleaning up component versions on page 2136.
Default Application Snapshot Retention (days)*	Enter the number of days application snapshots are kept by default. A value of `-1` means that they are kept indefinitely. Component and environment settings can override this setting.
Default Version Retention for Component (days)*	Enter the number of component versions to keep by default. A value of `-1` specifies that all are kept. Component settings can override this setting.
Default Number of Versions to Retain for Component*	Enter the number of versions to retain for each component.
Default Version Retention for Environment (days)*	Enter the number of environment versions to keep by default. A value of `-1` specifies that all are kept. Environment settings can override this setting.
Default Number of Versions to Retain for Environment*	Enter the number of versions to retain for each environment.

Table 685. Artifact cleanup settings (continued)

Field	Description
Archive Path	Specify the path where the compressed file that contains the archived component versions is written. If this field is blank, the compressed file is not written, and no archive is kept.
Preview Version Cleanup	Click **Preview Version Cleanup** to see the versions that are archived using the current settings. See Cleaning up component versions on page 2136.

Table 686. Process history cleanup settings

Field	Description
Daily Cleanup Start Time	Specify the time that the daily cleanup process starts.
Daily Cleanup Duration (hours)	Specify the number of hours that the cleanup process runs daily.
Enable Deployment History Cleanup	When enabled, deployment history files are reduced. See Cleaning up deployment history files on page 2133.
Days to Retain Deployment History	Enter the number of days to retain deployment history. This setting can be overridden with the related environment setting.
Enable Generic Process History Cleanup	When enabled, the generic process history files are set to delete as per the **Days to Retain Generic Process History** setting.
Days to Retain Generic Process History	Enter the number of days to retain generic process history. This setting can be overridden with the related environment setting.
Enable Process Step Log Cleanup	When enabled, the process step log cleanup starts. The process step logs are deleted according to the values that you set without deleting other history records.
Days to Retain Process Step Logs	Enter the default number of days to retain process step logs for generic processes not associated with deployments, and for environments if the number of days is not specified directly in the environment settings. Valid range is 0 or greater.

Table 687. Audit Log settings

Field	Description
Enable Audit Log Entries for Read Events	This option is disabled by default on new installation. When disabled, no READ events are recorded in the audit log.
Enable Audit Log Cleanup	When enabled, audit log entries older than the number of days specified in the **Days to Retain Audit Log Entries** field are removed beginning at the time specified by the **Daily Cleanup Start Time** field. See Configuring log rotation settings on page 3002. Deleting audit logs from **Settings > Audit Log > Cleanup Log** creates a log entry of event type Audit Log Cleanup that are non-deletable.
Daily Cleanup Start Time	If **Enable Audit Log Cleanup** is enabled, specify the time the audit log cleanup starts. The default value is 12:00 AM.
Days to Retain Audit Log Entries	If **Enable Audit Log Cleanup** is enabled, specify the number of days that audit log records are retained. The default value is 30.

Table 688. Password requirement settings

Field	Description
Minimum Password Length*	Define the minimum length for passwords.
Require Uppercase Characters in Passwords	When enabled, passwords must contain at least one uppercase character.
Require Lowercase Characters in Passwords	When enabled, passwords must contain at least one lowercase character.
Require Special Characters in Passwords	When enabled, passwords must contain at least one special character.
Require Number Characters in Passwords	When enabled, passwords must contain at least one numeric character.
Require Password to be Unique From User Information	When enabled, passwords must not match username, actual name, or configured email.

Table 689. Security settings

Field	Description
Discovery Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Auto Discovery Steps to expire. The value must be 300 seconds or more.

Table 689. Security settings (continued)

Field	Description
Configure Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Auto Configure Steps to expire. The value must be 300 seconds or more.
Version Import Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Version Import Steps to expire. The value must be 300 seconds or more.
Plugin Step Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for plug-in steps to expire. The value must be 300 seconds or more.
Use Default Auth Token Restriction if not specified	When enabled, the default authentication token restriction for processes that are created in Deploy is used. For these versions, the default token is applied to the most current process version but not other versions. For more information, see Restricting authentication tokens on page 2223.
Require Token Restriction	When enabled, the None option is removed from the Auth Token Restriction drop-down when creating or editing an authentication token. This makes Auth Token Restriction a required field, but the user can still set a highly permissive token restriction.
"Remember me" duration (hours)	Specify the number of hours a user can optionally be remembered and remain logged in.
Maximum Login time (hours)	Define the maximum duration (in hours) a user can stay logged in. When set, it forcibly disconnects the remote users from server when the logon hours expires. This setting overrides the **"Remember me" duration (hours)** setting. You can enter `0` or a negative value to disable the setting.
Logout should invalidate all "Remember Me" cookies	When enabled, invalidates all "Remember Me" cookies for a user when they explicitly log out.
Default Teams for New Objects	Select **All Teams Available to User** to add all teams that are available to user by default when a new object is created. When set to None, no teams are assigned to the users when new objects are created. Users can override this setting while creating objects.

Table 689. Security settings (continued)

Field	Description
Trusted proxy list	Enter a regular expression pattern to match IP of the trusted proxy servers. This value affects all servers. You must restart the servers for the changes to reflect. If left blank, the proxy headers are not trusted from incoming connections, which further may affect auth token IP restriction validation and IP logging.
User Idle Days to Lock	Specify the number of days after the user's last login date before locking the user account. You can enter 0 to disable user account locking.
User Idle Days to Delete	Specify the number of days after the user's last login date before deleting the user account. You can enter 0 to disable user account deletion.
Preview Idle User Lock	Click **Preview Idle User Lock** to load the information about user accounts that will be locked or deleted.
Realm for Bearer Authentication	Select an authentication realm to be used for the bearer authentication.

Table 690. Mail server settings

Field	Description
Mail Server Host	Enter the host name of the mail server that is used for notifications. Deploy can send notifications to users based on user-configured trigger events (to set up notifications, see Creating Notifications in a Notification Scheme on page 2081). Deploy requires an external SMTP mail server to send messages. To disable notifications, leave the field blank.
Mail Server Port	Enter the SMTP port that is used by the notifications mail server.
Secure Mail Server Connection	When enabled, the SMTP server connection is secured.
Mail Server Sender Address	Enter the sender's email address for email notifications.
Mail Server Username	Enter the user name for sending email notifications.

Table 690. Mail server settings (continued)

Field	Description
	Some email servers and firewalls treat emails with different sender and user names suspiciously. Therefore, consider specifying the same name for both fields.
Mail Server Password	Enter the user password for sending email notifications.
Max Recipients Per Email	Specify the maximum number of recipients to include in a single email. Mutliple emails will be sent when this is exceeded.

Table 691. External Approval settings

Field	Description
Resource Type to Run External Approvals	Choose any of the following options: • None: to use no agent or agent pool to run external approval processes. • Agent: to use an agent as the default resource type to run external approvals. Specify agent in the **Agent for External Approvals** field which will be used for external approval processes. • Agent Pool: to use an agent pool to specify a group of agents to run external approvals on instead of using a specific agent. Specify agent pool in the **Agent Pool for External Approvals** field which will be used for external approval processes. For more information, see Managing external approval processes on page 2392.

Table 692. Legacy Configuration Options

Field	Description
Enable "Prompt On Use"	When enabled, the option to set Prompt On Use for properties in workflow steps is displayed.
Fail Processes With Unresolved Properties	When enabled, any running process which comes across a property which it cannot resolve will automatically fail.
Component Environment Properties Override Environment Properties	When enabled, component environment properties overrides environment properties when using `${p:propName}` notation as opposed to `${p:environment/propName}`.
Enable Deleting Resources From Environments	When enabled, allows you to delete resources that are mapped with environment while deleting that environment.

Table 692. Legacy Configuration Options (continued)

Field	Description
	Note that the resources are deleted globally and affects the other environments that uses the same resource tree.
Show Compliancies Automatically	When enabled, environment compliancies are loaded automatically on the **Application Environment** and **Snapshot** pages rather than loading on demand.

Setting your profile

As a HCL DevOps Deploy (Deploy) user, you can manage teams and roles for your account, and preferences such as display options, language for the server, and how the server shows times and dates.

Managing the teams and users for your account

You can view and manage the teams and roles that you are assigned on the server. Your permissions determine which changes you can make.

Setting the teams for your account

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > Team Manager**.
2. Manage the teams that you are a member of.
   For more information, see Security teams on page 2213.

Setting the users for your account

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > User Manager**.
2. Manage the user that you are a member of.
   For more information, see Security teams on page 2213.

Setting the user preferences

You can set the preferences such as language for the server, and how dates and times are shown on the server.

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > Preferences**.
2. Choose a language for the user interface in the **Locale** field.
3. Select a format for dates in the user interface in the **Date Format** field.
4. Select a format for times in the **Time Format** field.
5. Specify the calendar type you want to use for the server in the **Calendar** field.
6. Specify which teams to assign for new objects in the **Default Teams for New Objects** list.
   By default, **System Default Policy** is selected and uses the **Default Teams for New Objects** settings defined in the system settings.

- **All Available Teams** to add new objects to all of the teams that you are a member of.
- **Specific Teams** to specify specific teams, and then select one or more teams.
- **None** to specify that no new objects are added to your teams.

7. Click **Save**.

Agents and agent relay configuration

After you install an agent for HCL DevOps Deploy (Deploy), you can modify its configuration or create an agent relay to facilitate communication to remote relays.

To monitor the status of the relay and the agents that are connected to it, click **Resources > Agent Relays**. This tab shows the number of active and offline agents that are connected to each relay. For more information about an agent relay, in the **Name** column, click the relay.

Agent security and communication

Agents use SSL-secured WebSocket, and HTTPS protocols to communicate with the server.

Agent overview

Agents do the actual work of deployment, which removes the task from the server. Agents are an important part of scalability in HCL DevOps Deploy (Deploy).

Although an agent is typically considered as a single process, technically an agent consists of a *worker* process and a *monitor* process. The worker process is a multithreaded process that runs the deployment work after it receives commands from the server. Work commands come from plug-in steps, which provide integration with many third-party tools. The monitor is a service that manages the worker process: starting and stopping, handling restarts, upgrades, and security, for example. After an agent is installed, it can be managed from the Deploy web application.

Agent security

All processes, including packaging, configuration, and deploying, that the Deploy server requests run on hardware that is assigned to agents. For added security, agents do not listen to ports, but open direct connections to the server instead. After an installed agent starts, the agent opens a WebSocket connection to the Deploy server based on the installation information.

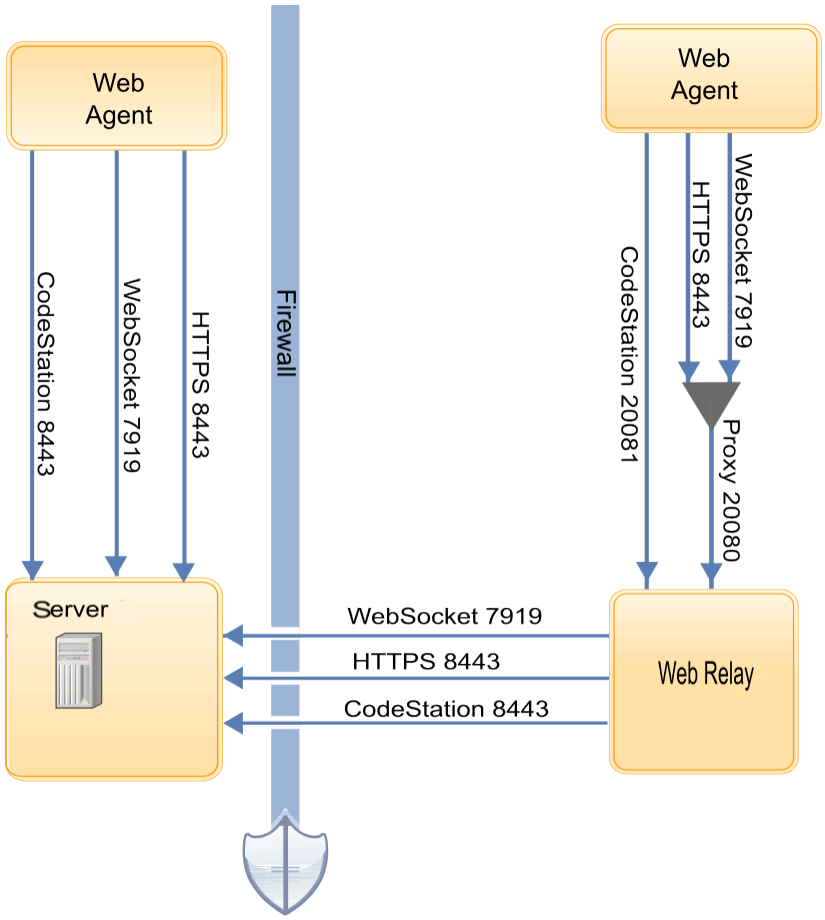
Agents on networks other than the one where the server is located might need to open a firewall to establish connection. After communication is established, the agent will be visible in the Deploy web application where it can be configured. Active agents, regardless of operating system, can be upgraded with the web application.

Agent communication

Agents are installed as Web agents on page 2096. Web agents use WebSocket connections and HTTPS for agent-server communication.

Web agents uses WebSocket connections for tracking agent status and notifications, and HTTPS for everything else.

The following diagram shows the main default ports that are involved in communication between agents, agent relays, and the server.



Stateless server-agent communication provides significant benefits to performance, security, availability, and disaster recovery. Because each agent request is self-contained, a transaction consists of an independent message, which can be synchronized to auxiliary storage as it occurs. Either endpoint, server or agent, can be stopped and restarted without repercussion, other than lost time. If communications fail midtransaction, no messages are lost. After they are reconnected, the server and agent automatically determine which messages got through and what work was completed. After an outage, the system synchronizes the endpoints and recovers affected processes. The results of work that an agent completes during the outage are communicated to the server.

Web agent configuration

Web agents use WebSocket and HTTPS connections for communication. Web agents do not use JMS.

Introduced with HCL DevOps Deploy (Deploy) V7.0.0, web agents are more scalable and secure than the previous agent type. The earlier type is called the JMS agent.

Web agents use the WebSocket protocol which is a bi-directional, point-to-point message protocol. WebSocket connections start as HTTPS requests and upgrade to the WebSocket protocol.

In the product user interface, web agents are recognized by the **Web** designation. On the **Agents** page, for example, web agents are the **Web** type.

Web agent communication

For successful server and web agent communication, you must have configurations on the server and agent sides.

In most cases, the installer configures the properties that are mentioned later. This section provides the additional information that you must consider if issues arise in server and agent communication.

Server configuration

During the server installation, you specify a secure WebSocket connection. The connection information has the following format: `agentcomm.uri=wss://physical-host:port`. The information is stored in the `server/conf/server/installed.properties` file. The default port is 7919. This port serves WebSocket endpoints that servers and web agents use and a REST API that only web agents use. While setting the `agentcomm.uri` property, make sure it meets these requirements:

- The URL is in this format: `wss://physical-host-or-ip:port`. The `wss` URL scheme is required and is the only supported scheme. The port must be explicit.
- The URL port must not conflict with ports for the UI.
- Each server must have a unique URL. URLs that refer to `localhost`, a loopback address, or a load balancer only work for a single server configuration.
- Every server in an HA cluster must be able to connect directly to this server with the URL.
- Agents and relays must be able to connect to one or more servers at the servers' URL ports. They can optionally be configured to use a common URL that all servers share, for example, one provided by a load balancer. However, servers must be configured with direct URLs.
- Relays support proxying HTTPS requests only. Any request through the relay that try to do HTTP are rejected with 501 error code. However, the relay itself listens on an HTTP protocol.

When you use web agents, each server in a cluster has a distinct URI and each server establishes a direct connection to every other server, which results in two connections between each server. The server-to-server connections advertise connected web agents to the cluster and exchange messages for them.

When a new server is added to a Web agent-enabled cluster, it connects to the previously defined servers. The other servers respond by connecting back to the new one. In normal operation, each server has two connections to each of its peers.

Web agent configuration

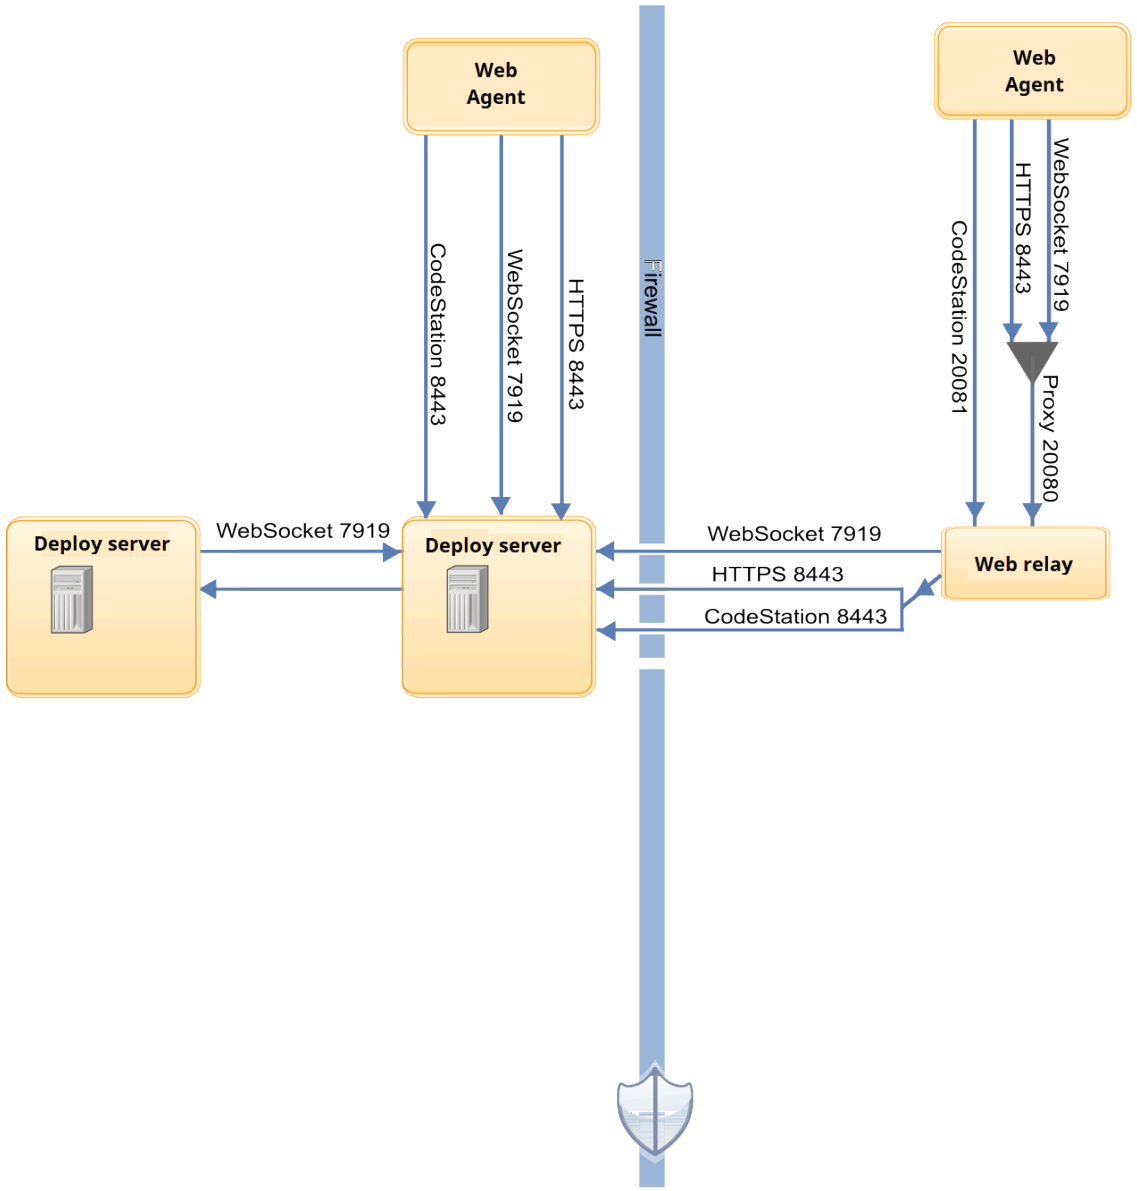
When you install a web agent, you specify the `agentcomm.server.uri` property. If there is one server or if all servers share a URL, it can be configured directly, for example, `agentcomm.server.uri=wss://examplehost.org:7919`. Configure multiple servers as a comma-separated list that is embedded in a random scheme, for example, `agentcomm.server.uri=random:(wss://examplehost1.org:7919,wss://examplehost2.org:7919)`.

Agents and relays connect to one or more servers at their respective URL ports. They can be configured to use a common URL, for example, a load balancer. However, servers must be configured with direct URLs. The `agentcomm.proxy.uri` property

can define a single HTTP proxy URL or define a list in a random scheme. The property is optional if the agent connects directly to servers.

Note:

The following diagram shows the default ports that are involved in communication between web agents, web agent relays, and servers.



Web agent relay configuration

Relays can be configured to support web agents exclusively.

You must upgrade relays for agents with web communication enabled and associate with the relay from the UI. However, a successful agent communication does not require any configuration. The following web communication parameters are defined in the *relayInstallDir*/conf/agentrelay.properties file:

```
agentcomm.enabled=true
agentcomm.server.uri=random:(wss://deploy1.example.org:7919,wss://deploy2.example.org:7919)
```

Agent relay limits

The maximum number of agents that can be assigned to a relay is limited in each of the releases. See to the following table to check the number of agents that are allowed for a relay for your installedHCL DevOps Deploy (Deploy) version.

Version	Relay mode	Agent type	Limit with default proxy
7.0.4.0 to 7.0.5.0	Web mode	Web Agents	1K
7.0.5.0 or later	Web mode	Web Agents	10K

In Linux, use the following utilities to reach the design limit of 10K concurrent agents:

- sysctl:

  ```
  fs.file-max >= 40000
  ```

- ulimit:

  ```
  nofile >= 40000
  ```

- sysctl:

  ```
  net.ipv4.ip_local_port_range >= "10000 65000"
  ```

Managing agents remotely

After an agent is installed, you can manage (with the monitor process) many of its features from the HCL DevOps Deploy (Deploy) web application.

About this task

We characterize an agent as a single process, but technically an agent consists of two processes: a *worker* process and a *monitor* process. Worker processes do the actual work of deployment, such as handling plug-in steps. Monitor processes manage the worker process, such as handling restarts, upgrades, and tests. Agent properties can be changed directly by editing the agent's conf/agent/installed.properties file and restarting the agent.

Note: Agents can access Windows shared drives. Drives are mapped on a per-user basis, you can check if the agent has the drive mapped with *fsutil fsinfo* drives.

1. Display the **Agents** pane (**Resources > Agents**).
2. Click **Actions** button on the desired agent.
   Actions are described in the following table.

Table 693. Agent management

Action	Description
Edit	Edits the agent name, description, and team configuration.
Delete	Deletes the agent permanently from the system.
Mark as Unavailable	Makes the online agent unavailable for running jobs or being used by agent pools. The `Unavailable` status acts like `Offline` status without having the agent or agent service shut down. You can make the unavailable agents online by using the **Mark as Available** option from the actions menu.
Restart	Shuts down and restarts the agent. While the agent is shut down, its status is `Offline`.
Test Connection	Runs the agent settings and connection test. Test results are displayed in the **Connection Test** dialog.
License	Sets the license from `unlicensed` to `authorized`.
Set License Type	Changes the license type.
Set Configuration Template	Applies an agent configuration template to the agent.
Upgrade	This option shuts down the agent and applies the upgrade. While the agent is shut down, its status is `Offline`. After the upgrade is applied, the agent is restarted.
Set Java Home	Updates JAVA_HOME for the agent. The Java Home lists the packages that are installed on the agent. Select an appropriate package or enter the absolute path of a valid JAVA_HOME directory.
Install Java Package	Installs the Java package on the agent. The Java Package list displays the packages that are added to the system and matches the agent architecture and OS.
Uninstall Java Package	Removes the Java package from the agent. The Java Package list displays the packages that are installed on the agent.

Note:

- The Java packages are added or managed in the **System Settings**. Ask your administrator, if you want a specific Java package added to the system.
- Agent properties and Java home information is available from the agent's **Metadata** tab.

Result

3. **Optional:** Perform the following actions on multiple selected agents using the **Bulk Actions** option:

Bulk action	Description
Restart	Shuts down and restarts the selected agents. While the agents shut down, their status is shown `Offline`. When the agents start, the status is changed to `online`.
Upgrade	Shuts down the selected agents and applies the upgrade. While the agents shut down, their status is shown `Offline`. After the upgrade is applied, the agents are restarted.
Add Tag	Allows you to apply tag to selected agents.
Remove Tag	Removes the applied tag from the selected agents.
Set License Type	Changes the license type for the selected agents.
Mark as Unavailable	Makes the online agents unavailable for running jobs or being used by agent pools.
Mark as Available	Makes the unavailable agents online for running jobs or being used by agent pools.
Apply Configuration Template	Applies the agent configuration template to the selected agents. The configuration templates must already be set the agents. See Migrating agents to Web on page 2107 for more information.
Set Configuration Template	Adds the selected agents to an agent configuration template.
Delete	Deletes the selected agents permanently from the system.
Install Preferred Java Package	Installs the Java package that are set as preferred in the Systems Settings. See Managing Java packages on agents in bulk on page 2103 for more information.
Set Java Home to Preferred Java Package	Updates the Java home of the selected agents as configured for their preferred Java package.
Remove Unused Java Packages	Removes Java packages for the selected agents that are neither active nor configured for the agent.

What to do next

Verify all actions and their details from the agent's **Maintenance** tab.

Set the configured JAVA_HOME of an agent

Restart an agent

Managing Java packages on an agent

You can upload, install, and manage Java packages on compact agent using the web UI.

Before you begin

Ensure that a supported Java package is downloaded to the system.

Important:

- See Operating systems for a list of supported versions.
- You can upload and manage Java only on the operating systems that have compact agents. Agents on operating systems like z/OS cannot manage Java.
- Deploy does not support native operating package formats or package installation tools.
- The compatible file extensions are `.zip`, `.tar`, `.tar.gz`, `.tgz`, `.tar.bz2`, and `.tbz2`.
- Newer IBM Java packages might have operating system prerequisites, such as installing updated system C++ runtime libraries. Deploy does not support installing such prerequisites.

About this task

You must upgrade Java when you have unsupported Java versions on your agents.

HCL DevOps Deploy (Deploy) identifies which agents must have an updated Java version or patches applied, and determines that status by using the real-time status of the connected agents. Java packages can be uploaded and then applied on different devices and architectures in your environment.

1. Upload the required Java package.
    a. Click **Settings > System > Manage Java Packages**.
    b. Upload a Java package by clicking **Add Package**.
    c. Provide a name for the Java package to upload.
    d. Click **Choose File**, select the Java package to upload and click **Submit**.
    The Java package is uploaded into the system.
2. Install the uploaded Java package on an agent.
    a. Click **Resources > Agents > *agent_name***.
    b. Click the menu option on the right of the agent for which you want to install the uploaded Java package.
    c. Select **Install Java Package** and specify the Java package name.
    d. Click **Install**.
    Result
    A message indicates that the Java package is being installed on the agent. When the installation finishes, the agent's Maintenance page displays the installed Java package information.
3. Go to the **Agents** page and set JAVA_HOME on the agent by selecting the **Set Java Home** menu option.

This location must be an absolute path, which is accessible to the agent.

Result

The agent restarts and runs with your new Java version.

Results

You have managed the Java packages on your agent.

What to do next

- See all Java versions installed for that agent from the agent's Metadata page.
- Remove unsupported Java package versions from the **Uninstall Java Package** menu option.
- If required, you can download this Java package at any point of time from the **Settings > System > Manage Java Packages** page.

Managing Java packages on agents in bulk

You can manage the Java distribution on your numerous agents by using **Bulk Actions**.

Before you begin

Ensure that a supported Java package is downloaded to the system.

Important:

- See Operating systems for a list of supported versions.
- You can upload and manage Java only on the operating systems that have compact agents. Agents on operating systems like z/OS cannot manage Java.
- Deploy does not support native operating package formats or package installation tools.
- The compatible file extensions are `.zip`, `.tar`, `.tar.gz`, `.tgz`, `.tar.bz2`, and `.tbz2`.
- Newer IBM Java packages might have operating system prerequisites, such as installing updated system C++ runtime libraries. Deploy does not support installing such prerequisites.

About this task

When you have multiple agents running in your production environment, it can become difficult to apply Java patches regularly. Using **Bulk Actions**, you can manage Java packages on your agents with just a few clicks.

You must consider the following scenarios before you manage Java on your agents:

- Deploy does not support native operating package formats or package installation tools.
- The compatible file extensions are `.zip`, `.tar`, `.tar.gz`, `.tgz`, `.tar.bz2`, and `.tbz2`.
- Newer IBM Java packages might have operating system prerequisites, such as installing updated system C++ runtime libraries. Deploy does not support installing such prerequisites.

1. Upload the required Java package.
    a. Click **Settings > System > Manage Java Packages**.
    b. Upload a Java package by clicking **Add Package**.
    c. Provide a name for the Java package to upload.
    d. Click **Choose File**, select the Java package to upload and click **Submit**.
    The Java package is uploaded into the system.
2. Set the Java package as preferred for the OS and CPU type from the menu option.
    Typically, you must set at least one Java package as preferred for each OS and CPU type.
3. Go to the **Agents** page and select the agents for which you want to update the Java.
4. Install the preferred Java package by clicking **Bulk Actions > Install Preferred Java Package** and confirming the action.
    A message window opens, indicating that the Java installation has started. The installation might take some time. You can close the message window while the installation runs in the background.
5. Verify that the Java is installed for the agents by checking the **Version** column.
6. Set the JAVA_HOME on the agents by clicking **Bulk Actions > Set Java Home to Preferred Java Package** and confirming the action.
    A message window opens, indicating that the Java update request was sent. This step might take some time. You can close the message window while the JAVA_HOME is updated in the background.
7. Verify that the Java home is updated for the agents.
8. Restart the agents by clicking **Bulk Actions > Restart**.
    Agents restart and run with the new Java version. You can refresh the **Agents** page to check if the agents are online.

Results

You have managed to upload, install, and update Java packages on your agents in bulk.

What to do next

You can remove unused Java package versions by clicking **Bulk Actions > Remove Unused Java Packages**.

Set the configured JAVA_HOME of agents in bulk

Updating the JRE location for agents

If you upgrade the JRE and change the JRE location on agents, you must also update the JRE location in the agent Java configuration file.

Before you begin

- Verify the supported Java version for agents. See Prerequisite software.
- You have installed the new JRE on the target agent and set the JAVA_HOME environment variable of the system.

Important: Do not use the server UI to restart the agent.

1. On the agent system, stop the agent.
   See Agent executable command-line commands on page 2339.
2. Edit the location of the JRE in the Java home configuration file.
   - On Linux™ or AIX, edit the *<DEPLOY_AGENT_HOME>*`/conf/agent/javahome` file.
   - On Windows™, edit the *<DEPLOY_AGENT_HOME>*`\conf\agent\javahome.conf` file.

     Note: For example, add the new location of the JRE on Windows™ as:

     ```
     C:\Program Files\Java\jdk-17.0.0
     ```

   - If the agent is running as a service on Windows™, remove and reinstall the service. See Removing and reinstalling agents as Windows services on page 2109.

     Note: For the Windows service of agents, you must update the **JAVA_HOME** property in *`installation_directory`*`\conf\agent\javahome.conf` file with the new location of Java, and then recreate the Windows service.
3. On the agent system, start the agent.
   See Agent executable command-line commands on page 2339.

Results

You have updated the JRE of the active agents.

Creating and managing agent pools

Similar to resource groups, *agent pools* help you organize and manage agents that are installed in different environments.

You can use an agent pool to spread the deployment processing work among participating agents and provide relief to otherwise overburdened agents. Users assign agents to pools and pools are assigned to resources, just like lone agents. When an agent pool is assigned to a resource, work items are sent to eligible agents. If you don't use a pool, then the agent that is assigned to the resource is assigned all the processing work regardless of its current workload. Such a workload might lead to bottlenecks.

Note: The agent pool algorithm will assign the workload to the most available agents in the pool. Most available agents are determined by which agents have the minimum running plugin steps in the agent pool. If there are multiple agents in the pool with the same plugin step count, the agents the database returns first will be assigned the workload.

Creating an agent pool

To create an agent pool, specify the agents that are the members of the pool.

1. From the **Resources** tab, click **Agent Pools.**
2. From the **Agent Pools** pane, click **Create Agent Pool**.
   Result
   The **Create Agent Pool** window opens.
3. Specify the pool name.
4. **Optional:** Enter a description in the **Description** field.
5. **Optional:** To manage the teams that can access the agent pool, click the plus icon by **Teams**.
6. To add agents to the pool, click the **Add Agents** field.
   Result
   A list of the available agents appears.
7. Select the agent or agents to add to the pool.
   You can filter the listed agents by entering search text into the field.
8. When you are finished, click **Save**.

Managing agent pools

You can manage agent pools from the web interface.

1. To display the **Agent Pools** pane, click **Resources > Agent Pools**.
2. Click an action link for the pool.
   Actions are described in the following table.

Action	Description
Edit	With this option, you can add or remove agents and edit the pool's name and description.

Action	Description
Copy	Creates a pool with the same agents as the selected pool.
Delete	Removes the agent pool.

To deploy a resource to an agent pool, the resource must be a child of the agent pool.

Agent pools for containers

Agent pools can be used to provide efficiency with your use of Deploy licenses. You can take advantage of running your agents in a Kubernetes-based environment where you can spin agent instances up and down quickly.

Follow these steps in order to achieve this efficiency:

1. Build the application resource tree using an Agent Pool instead of using the Agent directly. .
2. Deploy an instance of the Deploy Agent to your Kubernetes cluster. See Deploying Agent in Kubernetes Cluster.
3. The agent will be automatically get a license per the system setting on licensing agent.
4. Use the REST API to add the agent into the specified Agent Pool. See Add an agent to an agent pool.
5. Run your deployment.
6. Use the REST API to remove the agent from the specified Agent Pool. See Remove an agent from an agent pool.
7. The license will be removed if you are using server-agent license model; license will be released 15 minutes later if you are using Simultaneous Session license model.
8. Delete the instance of the Deploy Agent from the Kubernetes cluster.

Migrating agents to Web

Agent Configuration Templates allow you to migrate JMS agents on a server to Web agents with the ability to revert back to the original JMS configuration. This allows you to specify connection details for groups of agents.

Prerequisites

You must upgrade agents and server to HCL DevOps Deploy (Deploy) 7.0.1. For more information see Upgrading agents and Upgrading the server.

About this task

Deploy 7.0 introduced a new server/agent communication protocol which offers many performance improvements, and increased scalability. See Web agent configuration on page 2096. Deploy 7.0.1 is extending this capability by adding Agent Configuration Templates which will allow you to define a reusable set of configuration that can be used to easily migrate existing JMS agents to WEB agents. After you migrate JMS agents to WEB agents you have the ability revert them back to the original JMS configuration.

Note: You can only revert back an agent to JMS if that agent was previously a JMS agent.

Agent Configuration Templates

Before you can migrate an agent from JMS to Web an Agent Configuration Template will need to be assigned to the agent or agents.

1. Click **Resources** >**Agent Configuration Templates**.
2. Click on **Create Agent Configuration Template** on the right side of the page.
3. Give the template a name and description in the designated boxes.
4. Add teams that you want to give access.
5. Enter the URLs of the servers or relays where you would like agents to connect.
6. Click **Save**.
7. Click on the template name and click **Add Agents** to apply agents to the specific template.

After agents are added to templates they can be migrated to the new Web type.

Agent Migration

An Agent Configuration Template will need to be assigned to an agent before its type can be changed from JMS to Web.

1. Click **Resources** >**Agents**.
2. Select the agents that you want to convert.
3. Click bulk **Actions** menu.
4. From the **Actions** drop down dialog you can select **Migrate to Web** or **Revert to JMS**.

   Note: Agents can only be reverted to JMS if they were originally JMS.

If an agent is currently on a template there will be an icon next to **Type** on the **Agents** page. Clicking that icon will also prompt for agent migration.

A confirmation message will appear when the migration was successfully started on all agents.

The connection setting on newly migrated agents will be taken from the Agent Configuration Template that the agents belong to.

When migrating to web mode, the agents will perform a connection test that must pass for the migration to succeed. You can configure the threshold for the test to pass by providing an integer greater than one that specifies how many of the possible connection paths that have been configured.

Note: If migration fails you can view the logs by clicking on the agent name and then clicking on the **Logs** section of specified agent.

Removing and reinstalling agents as Windows™ services

If you installed an agent as a Windows™ service, you can remove and reinstall the service.

Old or non-compact agents

Before you begin, make sure that the agent is installed as a Windows service. See Installing agents from the command line for detailed instructions.

1. Open a command prompt as an administrator.
2. Go to the `C:\agent_install\bin\service` folder, where *agent_install* is the installed agent location.
3. Remove the service by running the following command:

   ```
   _agent.cmd remove service_name
   ```

   Use the name of the service for *service_name*. The default service name is `DevOps Deploy Agent`.
4. Reinstall the service by running the following command:

   ```
   _agent.cmd install service_name
   ```

   Note: While re-installing an agent, the latest PATH variable values are used.

Compact agents

Before you begin, make sure that the agent is installed as a Windows service. See Installing agents from the command line for detailed instructions.

1. Open a command prompt as an administrator.
2. Go to the `C:\agent_install\bin\` folder, where *agent_install* is the installed agent location.
3. Remove the service by running the following command:

   ```
   agent.exe uninstall-service
   ```
4. Reinstall the service by running the following command:

   ```
   agent.exe install-service
   ```

   For additional commands, see Agent executable command-line commands on page 2339.

Setting agent properties

Agent properties store information that are relevant to a specific agent.

About this task

Agents have many properties. These properties are categorized into:

- **Agent properties** - Agent properties are uploaded by the agent during installation and are stored in the database property sheet. These properties are only updated when the agent connects with the server and by using the agent property collection APIs.
- **User-defined properties** - User-defined properties are stored in VC and versioned when the properties are configured.

To view or set agent properties:

1. Navigate to **Resources > Agents >** ***agent name*** **> Configuration**.
2. View the non-versioned properties from the **Agent Properties** table.
3. View or update the versioned properties from the **User Defined Properties** table.
   You can click **Add Property** to add a property to the table. Each property can be deleted and edited.

Updating the JRE location for agent relays

If you upgrade the JRE and change the JRE location, you must also update the agent relays. If you do not change the location of the JRE, you do not have to update these files.

1. Stop the agent relay.
2. In the installation folder, locate and open this file for editing: *`install dir`*`/bin/agentrelay.cmd` (Windows) or *`install dir`*`/bin/agentrelay` (Linux).
3. In the file, edit the line that begins `set JAVA_HOME=` to point to your JRE.
   Example
   For example, `set JAVA_HOME=C:\Program Files\Java\jre8` (Windows) or `set JAVA_HOME=/opt/java/jre17` (Linux).
4. If you are running agent relays as a Windows™ service, follow these steps:
   a. Locate and open this file for editing: *`install dir`*`/services/agentrelay.cmd`.
   b. In the `agentrelay.cmd` file, edit the line that begins `set JAVA_HOME=` to point to your JRE.
      Example
      For example, `set JAVA_HOME=C:\Program Files\Java\jre8`.
   c. Open a command prompt as an administrator.
   d. Go to the *`agentrelay_install`*`\bin\service` folder.
   e. Remove the service.
      ```
      agentrelay.cmd remove service_name
      ```
      To find the service name, open the services view, and find the service with the following format: *`service_name`* `Agent Relay`.
5. Start the agent relay.

Changing passwords for the agent relay keystores

You can change the Java™ keystore passwords for the agent relay.

About this task

Each agent relay contains two keystores. The **agentrelay** keystore controls the JMS connection between the agent relay and the server and agents. The **codestation** keystore controls HTTPS connections to the agent relay and is used with server identity verification. See Enabling server identity verification on page 2152.

The password for each agent relay Java™ keystore must be identical to its certificate password. After you change both the keystore password and the corresponding certificate password, you must update the password in the agent relay properties.

Changing the passwords requires the keytool application, which is included in the Java™ developer kit and is not part of HCL DevOps Deploy (Deploy).

1. Stop the agent relay.
2. Change the **agentrelay** keystore password for the agent relay.

    a. Open a command-line window, and go to the `/agent-relay-install/conf/jms-relay` directory.
    By default, the *agent-relay-install* location is `/opt/devops-deploy/agentrelay` on Linux™ and `C:\Program Files\devops-deploy\agentrelay` on Windows™.

    b. Change the **agentrelay** keystore password by using this command:

    ```
    keytool -storepasswd -new newpassword -keystore agentrelay.keystore
    -storepass changeit
    ```

    The default password for this keystore is *changeit*.

    c. Change the **agentrelay** certificate by using this command:

    ```
    keytool -keypasswd -alias ucd-agentrelay-id -keypass changeit -new newpassword -keystore
     agentrelay.keystore -storepass newpassword
    ```

    The default keystore alias is *ucd-agentrelay-id*.

    d. In a text editor, open the `agent-relay-install/conf/agentrelay.properties` file.

    e. Specify the new Java™ keystore password for the agent relay in the following line of code:

    ```
    agentrelay.keystore.password=newPassword
    ```

3. Change the **codestation** keystore password for the agent relay.

    a. Open a command-line window, and go to the `/agent-relay-install/conf` directory.
    By default, the *agent-relay-install* location is `/opt/devops-deploy/agentrelay` on Linux™ and `C:\Program Files\devops-deploy\agentrelay` on Windows™.

    b. Change the **codestation** keystore password by using this command:

    ```
    keytool -storepasswd -new newpassword -keystore codestation.keystore
    -storepass changeit
    ```

    The default password for this keystore is *changeit*.

    c. Change the **codestation** certificate password by using this command:

```
keytool -keypasswd -alias agentrelay -keypass changeit -new newpassword -keystore
 codestation.keystore -storepass newpassword
```

The default keystore alias is *agentrelay*, and its value is shown in the `codestation.cert.alias` property in the *`agent-relay-install`*`/conf/agentrelay.properties` file.

d. In a text editor, open the *`agent-relay-install`*`/conf/agentrelay.properties` file.

e. Specify the new Java™ keystore password for the agent relay in the following line of code:

```
codestation.keystore.password=newPassword
```

4. Start the agent relay.

Results

The agent relay keystore passwords are changed and are obfuscated in the *`agent-relay-install`*`conf\server\agentrelay.properties` file.

Managing agent relays remotely

After an agent relay is installed, you can manage many of its features from the HCL DevOps Deploy (Deploy) web application.

About this task

Starting with Deploy version 7.0.4, you can test, restart, and delete **Agent Relays** directly through the user interface.

1. Display the **Agents Relays** pane (**Resources > Agents Relays**).
2. Click the **...** next to the relay.
   Actions are described in the following table.

Table 694. Agent relay management

Action	Description
Restart	This option shuts down and restarts the agent relay. While the agent relay is shut down, its status is `Offline`.
Test	This option runs a connection test. Test results are displayed in the **Connection Test** dialog window.
Delete	Removes the agent relay.

Migrating agents relays to Web

JMS agent relays on a server can be migrated to Web with the ability to revert back to the original JMS configuration. This allows you to specify connection details for groups of agent relays.

Prerequisites

Agents, agents relay, and server must be upgraded to the HCL DevOps Deploy (Deploy) 7.0.4 or later. For more information, see Upgrading agents and Upgrading the server.

JMS agents are NOT supported on Web relays. Make sure that the connected agents are migrated to Web.

About this task

Up to version 7.1.0.0, migration of agent relays can be done manually by modifying the `agentcomm` properties in the agentrelay.properties file. Relays can be automatically migrated to Web while upgrading the agent relays. For more information, see Upgrade Agent Relays. This task explains the procedure to migrate the agent relays manually.

Note: You can only revert back an agent to JMS if that agent relay was previously a JMS relay.

Manual Migration

1. Stop the relay you want to migrate.
2. Open the *relayInstallation*`/conf/agentrelay.properties` file.
3. Edit the file as follows:

```
agentcomm.enabled=true
agentcomm.server.uri=random\:(wss\://host-or-ip\:7919)
```

   Note: Change `host-or-ip` to your Deploy server name.

4. Restart the relay.
5. Verify that the Web agents are connected to the Web relay.

Note: If migration fails, you can view the logs in the *relayInstallation*`/var/log` directory.

Licensing

HCL DevOps Deploy (Deploy) provides a 60-day license-free evaluation period. You must have a license to use all product features after the evaluation period.

Unless you provide the location of a license server when you install Deploy, a 60-day evaluation period begins when you install the product. During the evaluation period, you can use all product features. A message on the web-based UI displays the number of days that remain in this period.

After the evaluation period, you can access Deploy to view and edit items but you cannot run deployments. You need a license for the agents in which you want to run the deployments. You can apply for a license at any point in time.

Note: Relays do not require any additional licenses.

HCL licensing

HCLSoftware offers My HCLSoftware (MHS) as a software license manager. The MHS portal has utilities to acquire and return licenses for `Authorized` and `Authorized zOS` agents. The licensing capabilities of MHS also provide the two important details:

- Maximum number of authorized licenses
- Maximum number of authorized z/OS licenses

An organization identifies one of its resources as a License Manager (also called Tech or Portal Admin) who is familiar with the language of licenses. The license manager is responsible for following the instructions in the document to activate entitlement, create deployments, and download the software from the portal.

Note: For information about HCL licensing, refer to the HCL Licensing documentation.

Grace period

A grace period is a duration of time that starts when Deploy server is not able to connect with the license server. You have a 24-hour grace period to restore the lost connection. During the grace period:

- You can see the following message on the banner:

  License Server Connection Issue Detected
  The connection to the license server has been lost. Deployments will work for the next 24 hours. Please contact support.

- You cannot license or unlicense agents.
- You can run the deployments for the duration mentioned in the banner.
- Deploy server continues to poll the license server and tries to establish a connection with the license server.

After the grace period ends, the licensing system proceeds to unlicense the agents. To debug licensing issues, you can add the following logger to the Deploy server:

```
com.urbancode.ds.subsys.deploy.license.hcl.HclLicenseUtil
```

See Managing loggers on page 3000 for information about how to add loggers.

License types

Depending on your agents operating system and intended use case, you can decide the license type you might need for your HCL DevOps Deploy (Deploy) agents.

There are four types of licenses available for Deploy agents:

- Authorized license for typical (non-z/OS) agents
- Authorized license for z/OS agents
- Floating license for typical (non-z/OS) agents
- Floating license for z/OS agents

Note: The Deploy server does not require any licenses in order to connect to and interact with the Web UI.

Licenses are applied to agents via the Web UI. You can configure the server to automatically apply licenses to new agents as they connect. For information about how to apply licenses, see Applying HCL licenses to agents on page 2115.

Authorized license for typical agents

The authorized license type allows you to allocate license to specific agents until they are deleted or unlicensed.

The authorized type license for typical agents is shown as `Authorized (HCL_Agent)` in Deploy.

Authorized license for z/OS® agents

Agents on z/OS® use different licensing than the typical agents. However, the z/Linux™ agents use the same licensing as the typical agents. Each z/OS agent requires a license, even if multiple agents are running on a single logical partition (LPAR). One agent is required on each environment, even if the environments are on a single z/OS sysplex.

The authorized type license for z/OS agents is shown as `Authorized (HCL_Agent_Z)` in Deploy.

Floating license type for agents and z/OS® agents

Floating licenses are required when you want multiple agents to share a limited number of licenses. In floating license type, the licenses are not tied to agents. When an agent which is not licensed performs a deployment, the server looks for an available license from the license pool. If a license is available, it reserves the license for that agent until the work is done. When the agent completes its work, the license is returned to the license pool for other agents to work.

If there are insufficient licenses for the number of floating agents, then the server records that but it still allows deployment to continue.

The floating type license for typical agents is shown as `Floating (HCL_Floating_Agent)` and for z/OS agents is shown as `Floating (HCL_Floating_Agent_Z)` in Deploy.

Applying HCL licenses to agents

You can apply licenses to HCL DevOps Deploy (Deploy) agents to run deployments in your production environment.

Before you begin

- You must have an entitled agent license and must have acquired the HCL Local License Server (LLS) or HCL Cloud License Server (CLS) URL.
- Check if the license server is reachable by opening the license server URL in your browser or by using the following curl command:

  ```
  curl --cacert /path/to/your/certificate.crt https://FQDNhostname:LLSport/v1/licensepools/deploymentID
  ```

  You can check the number of allocated licenses and used licenses on a successful connection. Refer to the HCL Licensing documentation for more information.

About this task

As an administrator or a license manager, you can configure Deploy to use the entitled license.

1. Click **Settings > System > License Management** on the dashboard.
2. Set the **Automatic Agent License Type** field to automatically apply licenses to newly created agents.

   Note: The available license types are stated by the current server license mode. For example, set the **Automatic Agent License Type** as HCL_Agent for standard agents or HCL_Agent_Z for z/OS agents.

3. Enter the license server URL in the **License Server Path** field.
   The example URLs for your license type are as follows:
   - HCL Local License Server:

     ```
     https://lls-host:lls-port/v1/licensepools/deploymentID
     ```

   - HCL Cloud License Server:

     ```
     https://cloud_server/v1/licensepools/deploymentID
     ```

4. Click **Save Connection**.

Results

Deploy is configured with the HCL license server and displays the license status in the **License Management** page.

What to do next

After applying the license, you confirm that the license is active by clicking **Resources > Agents**. The licensed agents are listed and flagged as `true` in the **License** column. In case of floating licenses, the **License** column shows `true` only when the agent is in use for deployment.

You can also enable logging for licensing. See Managing the logs on page 3002. The enabled licensing log is displayed as `True` in the log table. You can find the licensing log information in the `var\log\licensing.out` file.

Tracking agent usage

You can track daily agent usage. Agent usage can provide a rough estimate of agent license use.

HCL DevOps Deploy (Deploy) records the number of agents online and the maximum number of agents deploying at a time. Both measurements are referred to as the agent high-water mark. The records are updated every 10 minutes and are aggregated at the end of the day.

Although the agent usage records do not correspond precisely to agent license use, they can provide useful estimates of agent license use. These estimates can be especially useful for installations of Deploy on z/Linux™. If you are using z/Linux, review your agent high-water mark totals quarterly. If you discover that you significantly or routinely exceed your licenses, contact your sales representative to ensure that your installation remains compliant.

The agent usage records can be accessed at the following REST API endpoint:

```
https://{hostname}:{port}/cli/agentCLI/usage
```

The REST endpoint returns a JSON object with both the highest number of agents online for the day, and the maximum number of agents deploying at a time. A typical JSON object returned by the command is shown in the following example: `{"onlineAgents":5,"agentsrunningDeployments":4}`.

Both measurements are referred to as the agent high-water mark. For information about the CLI command, see getHighWatermarks on page 2777. For information about the REST API method, see Return high watermarks for agent usage.

Configuring the AI settings

You can configure the AI settings to integrate an AI service, such as OpenAI, Azure OpenAI, WatsonX, and Ollama. The AI service is used by the Deploy users to troubleshoot deployment failures.

Before you begin

You must have ensured that the AI provider details, such as endpoint and API key are ready.

1. Go to **Settings > System > AI Settings** from the Web UI.
2. Provide the following AI provider details:

Field	Description
AI Provider	Select the AI provider name. The OpenAI, WatsonX, and Ollama providers are supported. The AI settings are different based on your selection.
OpenAI settings	
AI Provider Endpoint	Enter the OpenAI service endpoint. If you change the endpoint, you must update the API key as well.
AI Provider API Key	Enter the API key that is used to make the OpenAI API requests.
AI Provider Project ID	Enter the OpenAI project ID, if created.
AI Provider Organization	Specify the unique organization ID.
Model Name	Choose a model name. The values in the **Model Name** field are automatically pulled based on the AI endpoint, API key, and organization details that you provided.
Azure OpenAI settings	
AI Provider Endpoint	Enter the OpenAI service endpoint. If you change the endpoint, you must update the API key as well.
AI Provider API Key	Enter the API key that is used to make the OpenAI API requests.

Field	Description
Deployment Name	Enter the name of the Azure OpenAI deployment to use for chat requests.
WatsonX settings	
AI Provider Endpoint	Enter the WatsonX service endpoint. If you change the endpoint, you must update the API key as well.
AI Provider API Key	Enter the API key that is used to make the WatsonX API requests.
AI Provider Access Token Endpoint	Enter the access token that authorizes access to WatsonX endpoint.
AI Provider Project ID	Enter the WatsonX project ID, if created.
Model Name	Choose a model name. The values in the **Model Name** field are automatically pulled based on the WatsonX endpoint and API key details that you provided.
Ollama settings	
AI Provider Endpoint	Enter the Ollama service endpoint.
Model Name	Choose a model name. The values in the **Model Name** field are automatically pulled based on the Ollama endpoint details that you provided.

3. Save your changes.

Results

You have configured the AI settings.

What to do next

You can configure a user role to allow them to use AI, and let them perform the AI analysis on the failed deployments.

Roles and permissions on page 2187

Performing AI analysis on failed deployments on page 3014

Setting up the wizard for new users

HCL DevOps Deploy (Deploy) includes a wizard to help users become familiar with the procedures and steps in creating a deployment. Some configuration is required before the wizard can be used.

Before you begin

At least one agent must be installed and accessible to users to start and complete the introductory wizard.

About this task

The wizard is enabled with new installations of Deploy. If you are working with an upgrade, the **Welcome** tab that includes the push button to open the wizard must be enabled. To enable the **Welcome** tab, open the `installed.properties` file, and add this entry: `server.enable.welcome.tab=true`. By default, this file is in this folder: `/opt/install-dir/server/conf/server`.

Tip: You don't have to create a role to assign so that they can follow the wizard. You can assign users to the Automation Engineer role, which is included on the server during installation. This Automation Engineer role has all the permissions that are required to complete the introductory wizard. If you want to create a separate role for wizard users, complete this procedure.

1. Create a role with these permissions:
    - Create Application
    - Create Component
    - Create Environment
    - Create Resource
    - View Agent
2. Give this role access to at least one agent.
3. Assign this role to users so that they can start and follow the wizard.

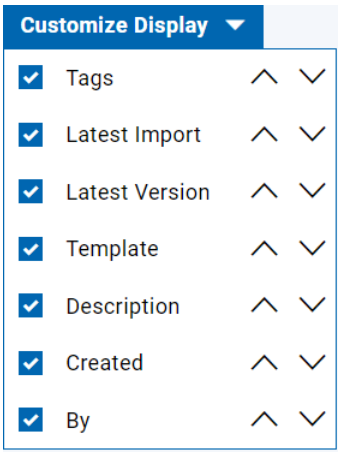
Customizing the table views

Customize a table view in the HCL DevOps Deploy (Deploy) application by hiding or showing, and reordering of the table columns.

About this task

You can customize table views available from the **Dashboard**, **Components**, **Applications**, **Processes**, **Resources**, and **Work Items** tabs using the **Customize Display** option.

1. Open the tab for which you want to customize the table view.
2. Click **Customize Display**.
   A list of table columns is displayed. The following screenshot displays an example of table columns:



By default, all columns are enabled.

3. Hide a column by deselecting the column name.
4. Reorder a column using the up and down arrow icons.

Results

The table view is updated as and when you make change.

Note:

- The changes are saved in a cookie and persist when you reopen the tab.
- At least one column is non-customizable. Generally, it is the **Name** column.

Managing data

This section gives details about how you can manage your data in HCL DevOps Deploy (Deploy)

Migrating Codestation from filesystem repositories to S3 repositories

Migrate your Codestation artifacts from filesystem to S3 using the S3 migrator tool.

About this task

You can migrate Codestation from filesystem into S3 repositories.

Table 695. Command line argument descriptions

Parameters	Description
bucketName	The name of the bucket in S3.
s3url	The URL of the S3 provider. Not required if using Amazon Web Services (AWS).

Table 695. Command line argument descriptions (continued)

Parameters	Description
s3region	The region of the S3 provider. You must specify either **s3url** or **s3region**, but not both.
s3user	The S3 username. Optional, depending on the S3 provider and system configuration. AWS uses APIKEY.
password	The S3 password. Optional. The value depends on the S3 provider and system configuration. AWS uses secret key.
signer	Optional. Consult S3 provider documentation for value. Not necessary for AWS.
enablePathStyleAccess	Optional. Consult S3 provider for documentation if this is necessary. Not necessary for AWS.
repositoryLocation	The location of Codestation repository. The default location in server is `appdata/var/repository`.
verify	Use this parameter to specify whether or not to enable verify mode. If you specify `true`, files are not uploaded to S3. Instead, the tool verifies that all expected files currently in Codestation on the filesystem are in S3.

Migrate Codestation from filesystem repositories to S3 repositories as follows:

1. Download **S3 Migrator Jar** file from the **Tools** page on machine that can access both current Codestation and S3 URLs.
2. Run the S3 Migrator tool.

```
java -jar s3migrator.jar -repo repositoryLocation -bucket bucketName [-url s3url] [-user s3user]
 [-password password] [-s3signerOverride signer] [-enablePathStyleAccess true|false(default false)]
 [-verify true|false(default false)]
```

Example usage:

```
java -jar s3migrator.jar -repo /opt/devops-deploy/server/appdata/var/repository -bucket
 deployCodestation
```

Note: The migrate tool will upload the files which are in Codestation into S3. This can be ran on a server other than the HCL DevOps Deploy (Deploy) server. It can also be ran while the Deploy server is up and handling requests. You can run the tool multiple times. Depending on the size of the Codestation repo, the process may take awhile. The tool will only upload files not currently in S3. This will allow the tool to be ran over

and over until the time to run it takes is short enough that the server can be shutdown for the last upload to ensure all artifacts are uploaded successfully.

3. Configure server to use S3 by setting the below properties based on the values you specified when you set up your S3 bucket.

```
  #installed.properties
  #required
codestation.provider=s3
codestation.s3.bucket=yourS3bucketname
codestation.s3.region=S3regionName or codestation.s3.url=S3customUrl

  #optional / setup dependent
codestation.s3.user=api_key
codestation.s3.signerOverride=signer
codestation.s3.enablePathStyleAccess=trueORfalse

  #secured-installed.properties
codestation.s3.password=api_secret
```

Note: Replace all user-provided values like *yourS3bucketname* with values as per your S3 configuration.

4. Restart the server.
5. **Optional:** If you need to roll back S3 migration to Codestation, run the migrator tool with updated properties. To recover artifacts from S3 repository, follow the external links below or contact support for assistance.
    - https://docs.aws.amazon.com/AmazonS3/latest/dev/replication.html
    - https://aws.amazon.com/backup-restore/
    - https://docs.aws.amazon.com/AmazonS3/latest/user-guide/undelete-objects.html
    - https://stackoverflow.com/questions/2426493/disaster-recovery-for-files-on-amazon-s3

Archiving version artifacts to Amazon S3

You can archive version artifacts to Amazon S3 to manage and prevent the accumulation of unwanted versions.

About this task

Configuring archiving to Amazon S3 involves adding S3 properties to the `devops-deploy\server\conf\server\installed.properties` file. After archiving is configured, the archived versions are stored in an Amazon S3 bucket in the specified region.

Note: Codestation artifacts and archived versions must use a different S3 bucket. If you configure them to use the same bucket name, the archiving does not work.

You can restore archived artifacts by navigating to **Components > *selected component* > Versions > *selected version*** and clicking **Restore from Backup** in the **Artifacts** table.

1. Configure the server to use Amazon S3 by adding or modifying the properties below:

```
# Example config
versionArchive.s3.bucket=yourS3bucketname
versionArchive.s3.url=S3Url
versionArchive.s3.accessKey=api_key
versionArchive.s3.secretKey=api_secret

# Alternative options
versionArchive.s3.region=S3regionName
versionArchive.s3.enablePathStyleAccess=trueORfalse
versionArchive.s3.signerOverride=SigV2

# Force on/off
versionArchive.s3.enabled=trueORfalse
```

Note:

- Replace all user-provided values such as *yourS3bucketname* with values according to your S3 configuration.
- Set `versionArchive.s3.enabled` to **true** to allow the server to check for the required configurations. If any configurations are missing, the server generates an error message. If set to **false**, missing configurations are ignored and S3 archiving is disabled.

If you have pre-configured Codestation S3 properties, you can reuse them by mapping them to the new version archive properties as follows:

```
# Codestation S3 config that can be reused
# Codestation Property (Source)       => Version Archive Property (Target)
codestation.s3.url                    => versionArchive.s3.url
codestation.s3.region                 => versionArchive.s3.region
codestation.s3.user                   => versionArchive.s3.accessKey
codestation.s3.password               => versionArchive.s3.secretKey
codestation.s3.enablePathStyleAccess  => versionArchive.s3.enablePathStyleAccess
codestation.s3.signerOverride         => versionArchive.s3.signerOverride
```

Optional: If you are using a RustFS container, you must configure the properties by specifying the following parameters:

```
# RustFS container config
# - enablePathStyleAccess=true is critical
# - do not put bucket name in url
versionArchive.s3.bucket=yourS3bucketname
versionArchive.s3.url=S3Url
versionArchive.s3.enablePathStyleAccess=true
versionArchive.s3.accessKey=api_key
versionArchive.s3.secretKey=api_secret
```

Note: You must enable the Path-Style Access, and the URL must not include the bucket name.

2. Save and restart the server.

Results

The archived artifacts are now zipped and moved to the specified S3 bucket.

Relocating CodeStation

You can move the CodeStation artifacts to a different location on the server.

About this task

By default, the server's log files and CodeStation artifacts are stored in the application data directory. You specified this directory when you installed the server. In the case of high-availability clusters, this directory is in a shared location where each server in the cluster can access it.

Ideally, this data is stored on robust network storage that is regularly synchronized with an off-site disaster recovery facility. In addition, the HCL DevOps Deploy (Deploy) server requires a fast network connection to this storage.

Tip: The following formula shows a good rule-of-thumb for determining CodeStation storage requirements: `average artifact size * number of versions that are imported per day * average number of days before cleanup`

Follow these steps to move the location of the CodeStation artifacts:

1. Stop the server.
   See Starting and stopping the server.
2. Move the CodeStation data to a new location.
   Which folders you move depend on whether the server uses an application data folder or not:
   - Check the `installed.properties` file on the server. If the **server.appdata.dir** property in this file has a value of two periods, (`..`) the server does not use an application data folder. If the property has a value other than two periods, the server uses an application data folder.

   When you know whether the server has an application data folder or not, you can move the correct files to a new location.

   Choose from:
   - If the server uses an application data folder, complete these steps:
     a. Move the application data folder to a new location. The default application data folder is `/opt/devops-deploy/server/appdata` on Linux™ and `C:\Program Files\devops-deploy\server\appdata` on Windows™.
     b. On the server, in the `installed.properties` file, update the **server.appdata.dir** property to the new location of the application data folder.

     If the new application data folder is on a remote system, you might have to set the **server.appdata.dir** property to a remotely mounted folder or other network storage.
   - If the server does not use an application data folder, complete these steps:
     a. Move the following individual folders to new locations:
        - *install_folder*`/var/plugins`
        - *install_folder*`/var/repository`
        - *install_folder*`/var/sa`

- *install_folder*/logs
- *install_folder*/conf/server/notification-templates
- *install_folder*/conf/encryption.keystore
- *install_folder*/conf/server.keystore
- *install_folder*/conf/collectors
- *install_folder*/patches
- *install_folder*/conf/server/log4j.properties

b. Create links from the previous folder locations to the new folder locations so that the server can continue to access the folders. For example, on Linux™ systems, you can use symbolic links, also known as *symlinks*.

3. Start the server.

Caching artifacts on agent relays

Agent relays can cache downloaded artifacts. Caching artifacts in this way improves performance because agents retrieve artifacts from agent relays instead of from the server.

When you enable artifact caching on an agent relay, the agent relay maintains a local CodeStation repository. This repository stores cached versions of artifacts that are on the server CodeStation repository. By default, the first time an agent requests an artifact, the agent relay retrieves the artifact, caches it in its CodeStation repository, and provides it to the agent. The next time an agent requests the artifact, the relay checks if the cached artifact is up to date. Then, the agent relay updates the cached artifact if necessary and provides the artifact to the agent.

By default, agent relays cache only artifacts that one or more agents request. You can also configure agent relays to pre-populate the cache with all artifacts with a specified status. In this case, the agent relays populate the cache with artifacts that have the specified status. Then, the artifacts are available immediately when agents request them.

Caching artifacts improves performance if the server is a long distance from the agents. In this case, caching artifacts on an agent relay that is close to the agents reduces the time that it takes to copy artifacts to the agents. Caching artifacts also improves performance if many agents retrieve artifacts from the server at the same time. In this case, caching the artifacts transfers server load to the agent relays.

Note: If you cache files on the relay, do not put the CodeStation cache on an NFS file system.

Before you begin

To pre-cache artifacts on agent relays, set up one or more component version statuses. Component versions with these statuses are cached on agent relays before agents request the component versions.

About this task

If you did not configure agent relay artifact caching when you installed the agent relay, you can also configure it by modifying its properties.

1. Open the */agent-relay-install*/conf/agentrelay.properties file.
2. Control caching with the `agentrelay.codestation.enable_replication` property:

Choose from:

- To enable caching, set the property to `TRUE`. An example true property resembles this code: `agentrelay.codestation.enable_replication=true`.
- To disable caching set the property to `FALSE`. An example false property resembles this code: `agentrelay.codestation.enable_replication=false`.

Note: If caching is enabled on an agent relay and disabled later, the cached artifacts are not deleted. To delete the artifacts manually, stop the agent relay and then delete the folders */agent-relay-install*/var/repository/ptr and */agent-relay-install*/var/repository/blob.

3. To preload artifact versions that contain certain statuses, specify the statuses in the `agentrelay.codestation.geotags` property.
   Separate statuses with commas. If you edit a status that contains a comma, the comma must be escaped.
   Example
   A modified `agentrelay.codestation.geotags` property might resemble the following code:
   `agentrelay.codestation.geotags=Hello%2c World,Production`

   Then, ensure that the component versions that you want to cache have one of these statuses.
4. Modify the cache size with the `agentrelay.codestation.max_cache_size` property.

Releasing VC LOB space

You can compress the amount of large object (LOB) storage space that Deploy uses in the `vc_persistent_record` database table.

Before you begin

Releasing the LOB storage space is optional. If you don't release the space, it is reused when new records are added. You can decide whether you want to release the LOB storage space for the following reasons:

- You can reduce storage space by 75%.

  Reduce the size of one of the largest tables in Deploy where the text data decreases by 50-75%.
  - A 2-byte character to an average of 1-byte per UTF-8 character which is up to 50% reduction.
  - XML might compress by 87% or more because XML data contains many repeated keywords.

- You can achieve up to a 50% reduction in read time.

Releasing LOB space in Oracle databases

You can release the large object (LOB) storage in the Oracle databases.

Before you begin

Plan downtime for upgrading HCL DevOps Deploy (Deploy) and releasing LOB space.

About this task

Run the following database commands to release LOB storage in Oracle databases. Releasing LOB storage in Oracle database requires different commands for **basicfile** and **securefile** file type.

You can also refer to the Oracle instructions for reclaiming unused space here: https://oracle-base.com/articles/misc/reclaiming-unused-space.

1. Set the **versioned_config.upgrade.enabled=true** parameter in the `conf/server/installed.properties` file.
2. Restart the Deploy server.
3. Check on the progress of the conversion:

   ```
   select count(*) from vc_persistent_record where persistent_data is not null
   ```

   The compression process is complete when the row count reported by the query is 0.
4. Check the database size:

   ```
   select sum(bytes)/1024/1024 size_in_mb from dba_segments;
   ```
5. Release LOB storage by running the following commands for the appropriate Oracle file type.
   - For **securefile** LOBs use these commands:

     ```
     select sum(bytes)/1024/1024 size_in_mb from dba_segments;
     ALTER TABLE vc_persistent_record MOVE TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_REC_PATH_VER REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_RECORD_DIRECTORY REBUILD TABLESPACE users;
     ALTER INDEX SYS_XXXXXXX* REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSIST_REC_COMMIT_PATH REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_RECORD_VERSION REBUILD TABLESPACE users;
     ALTER TABLE vc_persistent_record MOVE LOB(persistent_data) STORE AS (TABLESPACE users);
     select sum(bytes)/1024/1024 size_in_mb from dba_segments;
     ```
   - For **basicfile** LOBs use these commands:

     ```
     select sum(bytes)/1024/1024 size_in_mb from dba_segments;
     ALTER TABLE vc_persistent_record MOVE TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_REC_PATH_VER REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_RECORD_DIRECTORY REBUILD TABLESPACE users;
     ALTER INDEX SYS_XXXXXXX* REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSIST_REC_COMMIT_PATH REBUILD TABLESPACE users;
     ALTER INDEX VC_PERSISTENT_RECORD_VERSION REBUILD TABLESPACE users;
     ALTER TABLE VC_PERSISTENT_RECORD MODIFY LOB (persistent_data) (SHRINK SPACE);
     select sum(bytes)/1024/1024 size_in_mb from dba_segments;
     ```

   Note: The database generates a SYS_XXXXXXX index file. Check the indexes in the `vc_persistent_record` table for the index name.
6. **Optional:** Free the unused space so that it can be reused. Note that the process might not reduce the size of the underlying data files. To start the process of reclaiming disc storage space (if wanted), a database administrator must complete database maintenance tasks.

```
ALTER TABLE vc_persistent_record ENABLE ROW MOVEMENT;
ALTER TABLE vc_persistent_record SHRINK SPACE;
ALTER TABLE vc_persistent_record DISABLE ROW MOVEMENT;
```

What to do next

1. Verify that the space is reduced:

   ```
   select sum(bytes)/1024/1024 size_in_mb from dba_segments;
   ```

2. Set the **versioned_config.upgrade.enabled** parameter back to false in the `conf/server/installed.properties` file.

Releasing LOB space in MySQL or Maria databases

You can release the large object (LOB) storage in the MySQL or Maria databases.

Before you begin

Consider the following points when you plan an upgrade:

- You might be able to avoid the downtime by running the alter table statement before you upgrade:

  ```
  alter table vc_persistent_record modify persistent_data longtext null, add compessed_data longblob null,
   lock=none
  ```

  If this command fails, an online change of the table before upgrade isn't possible with your version of MySQL. Downtime is required during the upgrade.
- Based on the MySQL version you are using, the upgrade or pre-upgrade table change temporarily uses additional space to rebuild the table.
- For bext results, run the statement on a table clone to estimate the upgrade time.
- Use the alter table command only if the table does not include a compressed_data column.

About this task

Release LOB storage for MySQL and Maria databases using the following steps:

1. Set the **versioned_config.upgrade.enabled=true** property in the `conf/server/installed.properties` file.
2. Restart the HCL DevOps Deploy (Deploy) server.
3. Check on the progress of the conversion:

   ```
   select count(*) from vc_persistent_record where persistent_data is not null
   ```

   The compression process is complete when the row count reported by the query is 0.

4. Check the database size:

   ```
   select table_schema, sum((data_length+index_length)/1024/1024) AS MB from information_schema.tables
    group by 1
   ```

5. Compress the database table.
    - Use the optimize statement for MySQL v5.6 and later, and MariaDB v10.0 and later:

      ```
      optimize table vc_persistent_record
      ```

      See the MySQL documentation about using the optimizing statement: https://dev.mysql.com/doc/refman/5.7/en/optimize-table.html.

    - For all other versions of MySQL, complete these steps:
        a. Backup your database:

           ```
           mysqldump -h hostname -u username -p password --databases dbname > ~/mysql-backup.sql
           ```

        b. Create a new database and restore the old database:

           ```
           mysql -h hostname -u username -p password < mysql-backup.sql
           ```

      Note: The backup and restore must be done when the system is offline to prevent loss of new data while restoring.

What to do next

1. Verify that the space is reduced:

   ```
   select table_schema, sum((data_length+index_length)/1024/1024) AS MB from information_schema.tables
    group by 1
   ```

2. Set the **versioned_config.upgrade.enabled** parameter back to false in the `conf/server/installed.properties` file.

Releasing LOB space in Microsoft SQL Server databases

You can release the large object (LOB) storage in the Microsoft SQL Server database.

Before you begin

Plan downtime for upgrading HCL DevOps Deploy (Deploy) and releasing LOB space.

About this task

Release LOB storage for Microsoft SQL Server database using the following steps:

1. Set the **versioned_config.upgrade.enabled=true** parameter in the `conf/server/installed.properties` file.
2. Restart the Deploy server.
3. Check on the progress of the conversion:

   ```
   select count(*) from vc_persistent_record where persistent_data is not null
   ```

   The compression process is complete when the row count reported by the query is 0.

4. Check the database size:

```
EXEC sp_spaceused @updateusage = N'TRUE';
```

5. Compress the database table:

```
DBCC SHRINKDATABASE (dbname, 0);
DBCC SHRINKDATABASE (dbname);
```

What to do next

1. Verify that the space is reduced:

```
EXEC sp_spaceused @updateusage = N'TRUE';
```

2. Set the **versioned_config.upgrade.enabled** parameter back to false in the `conf/server/installed.properties` file.

Releasing LOB space in DB2 databases

You can release the large object (LOB) storage in the DB2 database.

Before you begin

Plan downtime for upgrading HCL DevOps Deploy (Deploy) and releasing LOB space.

About this task

Release LOB storage for DB2 database using the following steps:

1. Set the **versioned_config.upgrade.enabled=true** parameter in the `conf/server/installed.properties` file.
2. Restart the Deploy server.
3. Check on the progress of the conversion:

```
select count(*) from vc_persistent_record where persistent_data is not null
```

   The compression process is complete when the row count reported by the query is 0.

4. Catalog the Deploy DB2 database:

```
db2 catalog tcpip node dbname remote ipAddress server port
db2 catalog database dbname at node dbname
```

   For example, enter the following command:

```
db2 catalog tcpip node mydb remote 10.134.119.178 server 48408
```

   You must catalog the database only once on the client system. If you have to catalog a different database, either use a different node and database name (mydb in this example) or uncatalog the cataloged database:

```
db2 uncatalog database mydb
db2 uncatalog node mydb
```

5. Connect to the cataloged database:

   ```
   db2 connect to mydb user db2inst1 using db2inst1
   ```

   Catalog the database every time you start up the DB2 command window.
6. Check the database size:

   ```
   db2 -v "CALL GET_DBSIZE_INFO(?, ?, ?, -2)"
   ```

7. Check how much space each tablespace is using:

   ```
   db2 -v "SELECT varchar(tbsp_name, 30) as tbsp_name, decimal(tbsp_free_pages * tbsp_page_size)/1024/1024
    as free_space_mb, decimal(tbsp_total_pages * tbsp_page_size)/1024/1024 as total_space_mb FROM
    TABLE(MON_GET_TABLESPACE('',-2))"
   ```

8. Compress the database table:

   ```
   db2 -v "REORG TABLE VC_PERSISTENT_RECORD LONGLOBDATA"
   db2 -v "ALTER TABLESPACE USERSPACE1 LOWER HIGH WATER MARK"
   db2 -v "ALTER TABLESPACE USERSPACE1 REDUCE MAX"
   ```

   The preceding example includes the assumption that the vc_persistent_record table is in a tablespace called USERSPACE1. Replace USERSPACE1 with the tablespace name that contains the vc_persistent_record table.

   Note: The ALTER TABLESPACE commands must only be performed if the Deploy is offline.

What to do next

1. Verify that the space is reduced:

   ```
   db2 -v "CALL GET_DBSIZE_INFO(?, ?, ?, -2)"
   ```

2. Set the **versioned_config.upgrade.enabled** parameter back to false in the `conf/server/installed.properties` file.

Scanning and removing orphaned Codestation blob files

The csorphanscan tool in the `/bin` directory scans for orphaned Codestation blob files and relocates them to an orphan's directory.

About this task

An orphaned Codestation blob file is a file that contains data for a component version that is no longer referred to by any component version currently recorded in the database. Such files use disk space but can never be accessed by a deployment process.

By default, the tool runs in a dry-run mode such that the file system is not modified and the tool only reports statistics. The tool requires some time to execute.

The csorphanscan tool supports only disk-based blob storage. S3 storage is unsupported.

The csorphanscan tool can run while the server is online. In an HA cluster, it must be run on only one cluster member.

To scan and remove orphaned Codestation blob files:

1. Run the csorphanscan command without the --move-orphans argument to report statistics.

   This run takes some time. In an HA cluster, all members share the same database and Codestation storage, so run the csorphanscan tool on only one cluster member.

2. Run the csorphanscan command with the --move-orphans argument to relocate orphans.
   This process takes some time. The orphan files are relocated to the `<appdata>/var/repository/blob/orphans` folder. In an HA cluster, all members share the same database and Codestation storage, so run the csorphanscan tool on only one cluster member.

   You can also use the following flags with the csorphanscan tool:

Option	Description
`--orphan-list-file <path>`	Write a list of orphaned files to a file in the specified path.
`--workers N`	Set the number of concurrent workers. The default number is 4, and the minimum number is 1. Values greater than 4 might not reduce tool run time.
`--memory N[k|m|g]`	Set the amount of heap memory. The default size is 2 GB. Instances with very large numbers of component versions stored in Codestation might require additional memory. The default value is sufficient for at least 400K component versions.

3. Back up the `<appdata>/var/repository/blob/orphans` file and delete it to free the disk space. You must use the file deletion tools of your operating system. In an HA cluster, all members share the same Codestation storage, so perform this procedure on only one cluster member.

   Note: You must never manually delete any other `<appdata>` content outside the orphan's directory.

Cleaning up targets

If you have storage issues and feel that you need to cleanup some unnecessary stored data, you can use cleanup settings to cleanup your database and file system storage.

You can define the cleanup settings for the deployment history, generic process history, snapshots, and component versions from the **System Settings** page. Before you define the cleanup settings, know how these cleanup settings affect your database and file system storage:

- **Deployment History Cleanup:** This setting primarily deletes database files or entries. However, it also removes log files from the file system.
- **Component Version Cleanup:** This setting mainly cleans up the file system, but it also deletes some associated database files.
- **Generic Process History Cleanup** and **Snapshot Cleanup**: Both of these settings exclusively delete database files.
- **Process Step Log Cleanup**: This setting cleans up the file system exclusively.

Creating a rotating audit log file

You can create rotating audit log file at a regular interval, such as every day.

About this task

You can create a rotating audit log file by adding the `audit-log-to-file` appenders to the log4j.properties. Starting with 7.0.1.1, you can find the appenders in the log4j.properties file. Go to **Settings > Logging**, and uncomment the respective appenders.

The following code fragment shows the `audit-log-to-file` appenders to be used to create a rotating audit log file:

```
log4j.appender.audit-log-to-file=org.apache.log4j.DailyRollingFileAppender
log4j.appender.audit-log-to-file.File=../var/log/audit.log
log4j.appender.audit-log-to-file.MaxFileSize=100MB
log4j.appender.audit-log-to-file.DatePattern='.'yyyy-MM-dd
log4j.appender.audit-log-to-file.layout=org.apache.log4j.PatternLayout
log4j.appender.audit-log-to-file.layout.ConversionPattern=%m%n
log4j.logger.AuditLog=DEBUG, audit-log-to-file
log4j.additivity.AuditLog=false
```

1. Edit the `log4j.properties` file.
   Use a text editor to edit the file. You can also access the file by clicking **Settings > Logging**.
2. Modify the appenders.
3. Restart the server.
4. Verify the logs generating in the `/var/log/audit.log` file.

What to do next

This feature works especially well with audit log cleanup enabled. Go to **Settings > System > Audit Log > Audit Log settings > Enable Audit Log Cleanup** to enable audit log cleanup. Additionally, configure your audit log settings from the System settings on page 2086 as required.

Cleaning up deployment history files

You can clean up the deployment history files to reduce the database storage that HCL DevOps Deploy (Deploy) uses.

About this task

You can enable the deployment history cleanup and specify when the cleanup process begins, the duration of the cleanup, and the number of days to retain the deployment history. You can clean up the deployment history files in the following three ways:

- By configuring the cleanup settings from the system settings. See Configuring the system settings on page 2135.
- By configuring the cleanup settings for specific environments. See Configuring individual environment settings on page 2135
- By configuring the cleanup setting for multiple environments.Configuring bulk cleanup settings on page 2147

Important: The deployment history cleanup process deletes all records in the database and the file system that are related to the deployments that you're deleting. The cleanup cannot be undone. It is important that you carefully choose the items that you delete.

For the cleanup process to start and run according to specifications, the cleanup process must be turned ON in by your administrator in **System Settings** and **Use Deployment History Cleanup** must be selected in environment settings. By default, the deployment history cleanup settings in both the administrator and environment settings are turned off.

The following table shows how the cleanup configuration works based on your selection:

Table 696. Enabling deployment history cleanup

Enable Deployment History Cleanup option in System Settings (administrator's setting)	Use Deployment History Cleanup check box in environment settings	Result
On	Selected	Cleanup starts as specified for deployments that are associated with this environment.
On	Cleared	Cleanup does not start for deployments that are associated for this environment.
Off	Selected	Cleanup does not start for deployments that are associated with this environment.

For example, you have two environments; environment A and environment B and your administrator has enabled deployment history cleanup settings in **System Settings**. In the environment B settings, the **Use Deployment History Cleanup** check box is cleared. The **Use Deployment History Cleanup** check box is selected for environment A. When the cleanup process starts, the deployments history associated with environment A will only be deleted per your configuration.

While the administrator has the **Enable Deployment History Cleanup** option turned off, even when a user selects **Use Deployment History Cleanup** for an environment, the deployment history cleanup process remains turned off.

An example usage of the cleanup configuration fields are explained in Example usage on page 2136.

Note: Despite these settings, deployment history cleanup will not work when:

- The deployments are associated with an active inventory of any type, such as deployed component version, resource, resource configuration, and environment properties.
- The server is in an HA cluster and one of the instances is actively running a deployment history clean up job.

Configuring the system settings

Before you begin

Ensure that you have the following permissions to edit the system settings:

- **Web UI > Settings Tab**
- **Server Configuration > Edit Basic System Settings**

1. In Deploy, click the **Settings** tab, and then in the **System** column, click **System Settings**.
2. Scroll to the **Process History Cleanup** area.
3. Set **Enable Deployment History Cleanup** option to **On**.
4. In **Daily Cleanup Start Time**, select the hour to start the daily cleanup process.
5. In **Daily Cleanup Duration (hours)**, specify the number of hours for the cleanup process to run.
6. In **Days to Retain Deployment History**, specify the default number of days to keep the deployment history before the cleanup process removes the history.

Results

When cleanup begins, a progress indicator shows details about the cleanup process.

Configuring individual environment settings

Before you begin

Ensure that you have the following permissions to edit the deployment history files for individual environments:

- **Environment > Edit > Manage Environment Cleanup**
- **Web UI > Applications Tab**

1. Click **Applications**, click an application, click an environment, click **Configuration**, and then click **Basic Settings**.
2. Select **Use Deployment History Cleanup**.
3. Perform any one of the following steps:
    - Select **Use Default Deployment History Retention** to keep deployment history details for the number of days that the administrator specified.
    - Clear the **Use Default Deployment History Retention** option and specify the number of days to keep deployment history details in the **Days to Retain Deployment History** field.

Results

When cleanup begins, a progress indicator shows details about the cleanup process.

Example usage

About this task

This example helps you understand how cleanup works in Deploy.

If the date is 14 December 2016, and you have used the following settings:

- **Enable Deployment History Cleanup** in System Settings: Enabled
- **Daily Cleanup Start Time** in System Settings: `9:00 PM`
- **Daily Cleanup Duration (hours)** in System Settings: `3`
- **Days to Retain Deployment History** in System Settings: `15`
- **Use Deployment History Cleanup** in the environment settings: Enabled
- **Use Default Deployment History Retention** in the environment settings: Enabled

At 9:00 PM on 14 December 2016, the deployment history begins to run for 3 hours. During the 3 hours, all records of the deployment that are 15 days old and older are deleted. The three hours might be insufficient to delete all records that meet the cleanup criteria. In this case, cleanup resumes operations the next day as scheduled. If you need to clear more disk space, increase the cleanup duration.

Notes:

- If the cleanup settings are changed before 14 December 9:00 PM, then items that are deleted will not be the same as in this example.
- You can make changes to the settings after this date and change it multiple times.
- At any time, the administrator or users with privileges can change whether the cleanup process runs, what cleanup removes, when cleanup starts, and how long cleanup runs.

Tip: It is not recommended to cleanup all history at once. For example, if your goal is to keep certain data for 10 days before it is cleaned up, you should slowly reduce the number of days to keep, so that you do not attempt to cleanup the last 4 years all at the same time.

Cleaning up component versions

You can configure the server to reduce the number of component versions by archiving them. You can specify artifacts cleanup settings from the System Settings, or cleanup settings for individual components, and environments.

About this task

The server archives a full or incremental component version if the version does not meet any of the criteria for versions to keep. When archiving versions, the server retrieves the settings from the **Settings > System Settings > Artifact Cleanup** options first. Then it retrieves the settings for the individual components, which override the system settings. Finally, it checks the settings on the environments to which the component has been deployed. If any of these settings specify to keep the component version, it is not archived.

These settings include a number of days for which to retain versions and a number of versions to keep. The system default component settings, and the component settings refer to the creation date of the version. For example, if the system default settings or component settings keep versions for 30 days, a version is not archived until its creation date is more than 30 days in the past. Similarly, if the system default settings or component settings keep the 10 most recent versions, a version is not archived until there are 10 more recently created versions. Component settings override system default settings for that component.

By contrast, the environment settings refer to the most recent deployment date of the version. For example, if the environment settings keep versions for 30 days, a version is not archived if it has been deployed in the last 30 days. If an environment does not have settings, the server uses the system settings instead. For example, if the server settings keep versions for 30 days and the version was created more than 30 days ago but was deployed to an environment within 30 days, the version is kept.

The server uses the following criteria to determine which versions to keep and which to archive:

First, the server checks the settings on the component. If the component has settings to keep versions, the server uses those settings. Otherwise, the server uses the defaults in the server settings.

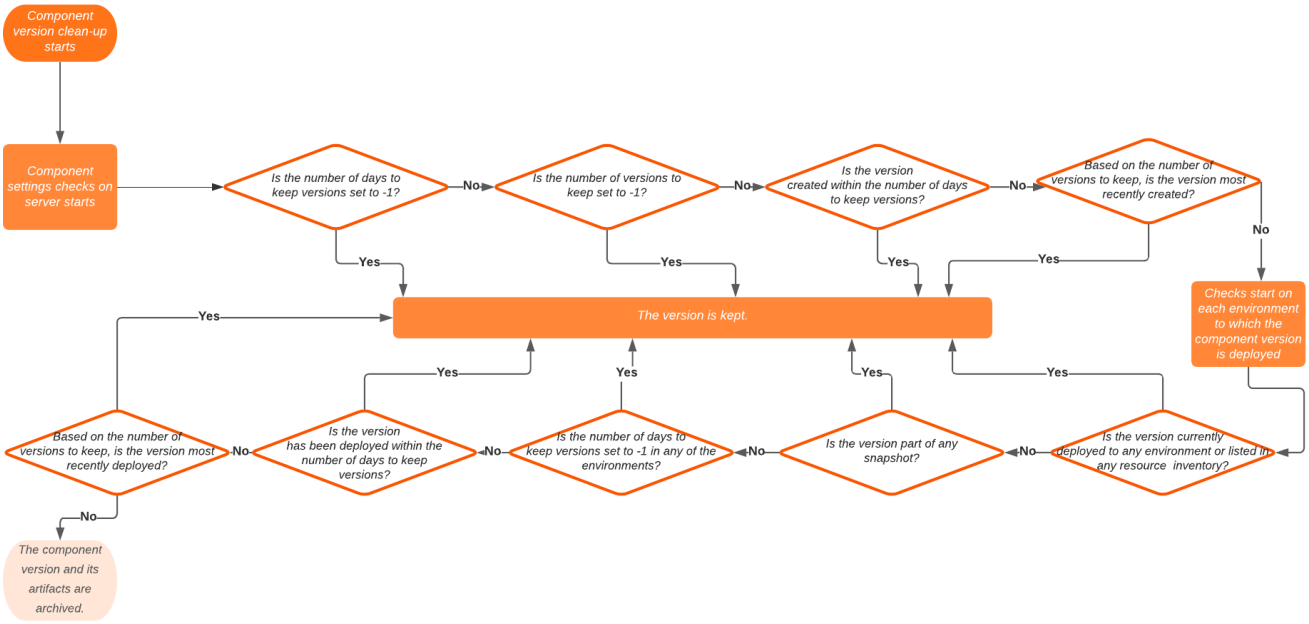
- If the number of days to keep versions is set to -1, the version is kept.
- If the number of versions to keep is set to -1, the version is kept.
- If the version was created within the number of days to keep versions, it is kept.
- Based on the number of versions to keep, if the version is in the most recently created versions, it is kept.

Then, the server checks the settings for each environment to which the component version has been deployed. If an environment does not have settings, the server uses the system settings for that environment. In the context of environments, the settings refer not to the creation date of the component but the date of the most recent deployment of that component. For example, if the system settings keep the 20 most recent versions, and the version is one of the 20 most recently deployed versions in an environment, the version is kept. Using these settings, the server uses the following criteria:

- If the version is currently deployed to any environment or is listed in the inventory of any resource, it is kept.
- If the version is part of any snapshot, it is kept.
- If the number of days to keep versions is set to -1 in any of the environments, the version is kept.
- If the number of versions to keep is set to -1 in any of the environments, the version is kept.
- If the version has been deployed within the number of days to keep versions, it is kept.
- Based on the number of versions to keep, if the version is in the most recently deployed versions, it is kept.

If none of these criteria are true, the component version and the artifacts in it are archived, even if the version was deployed to an environment in the past.

The following diagram is a graphical representation of the checks performed on the server for the clean-up of component versions.



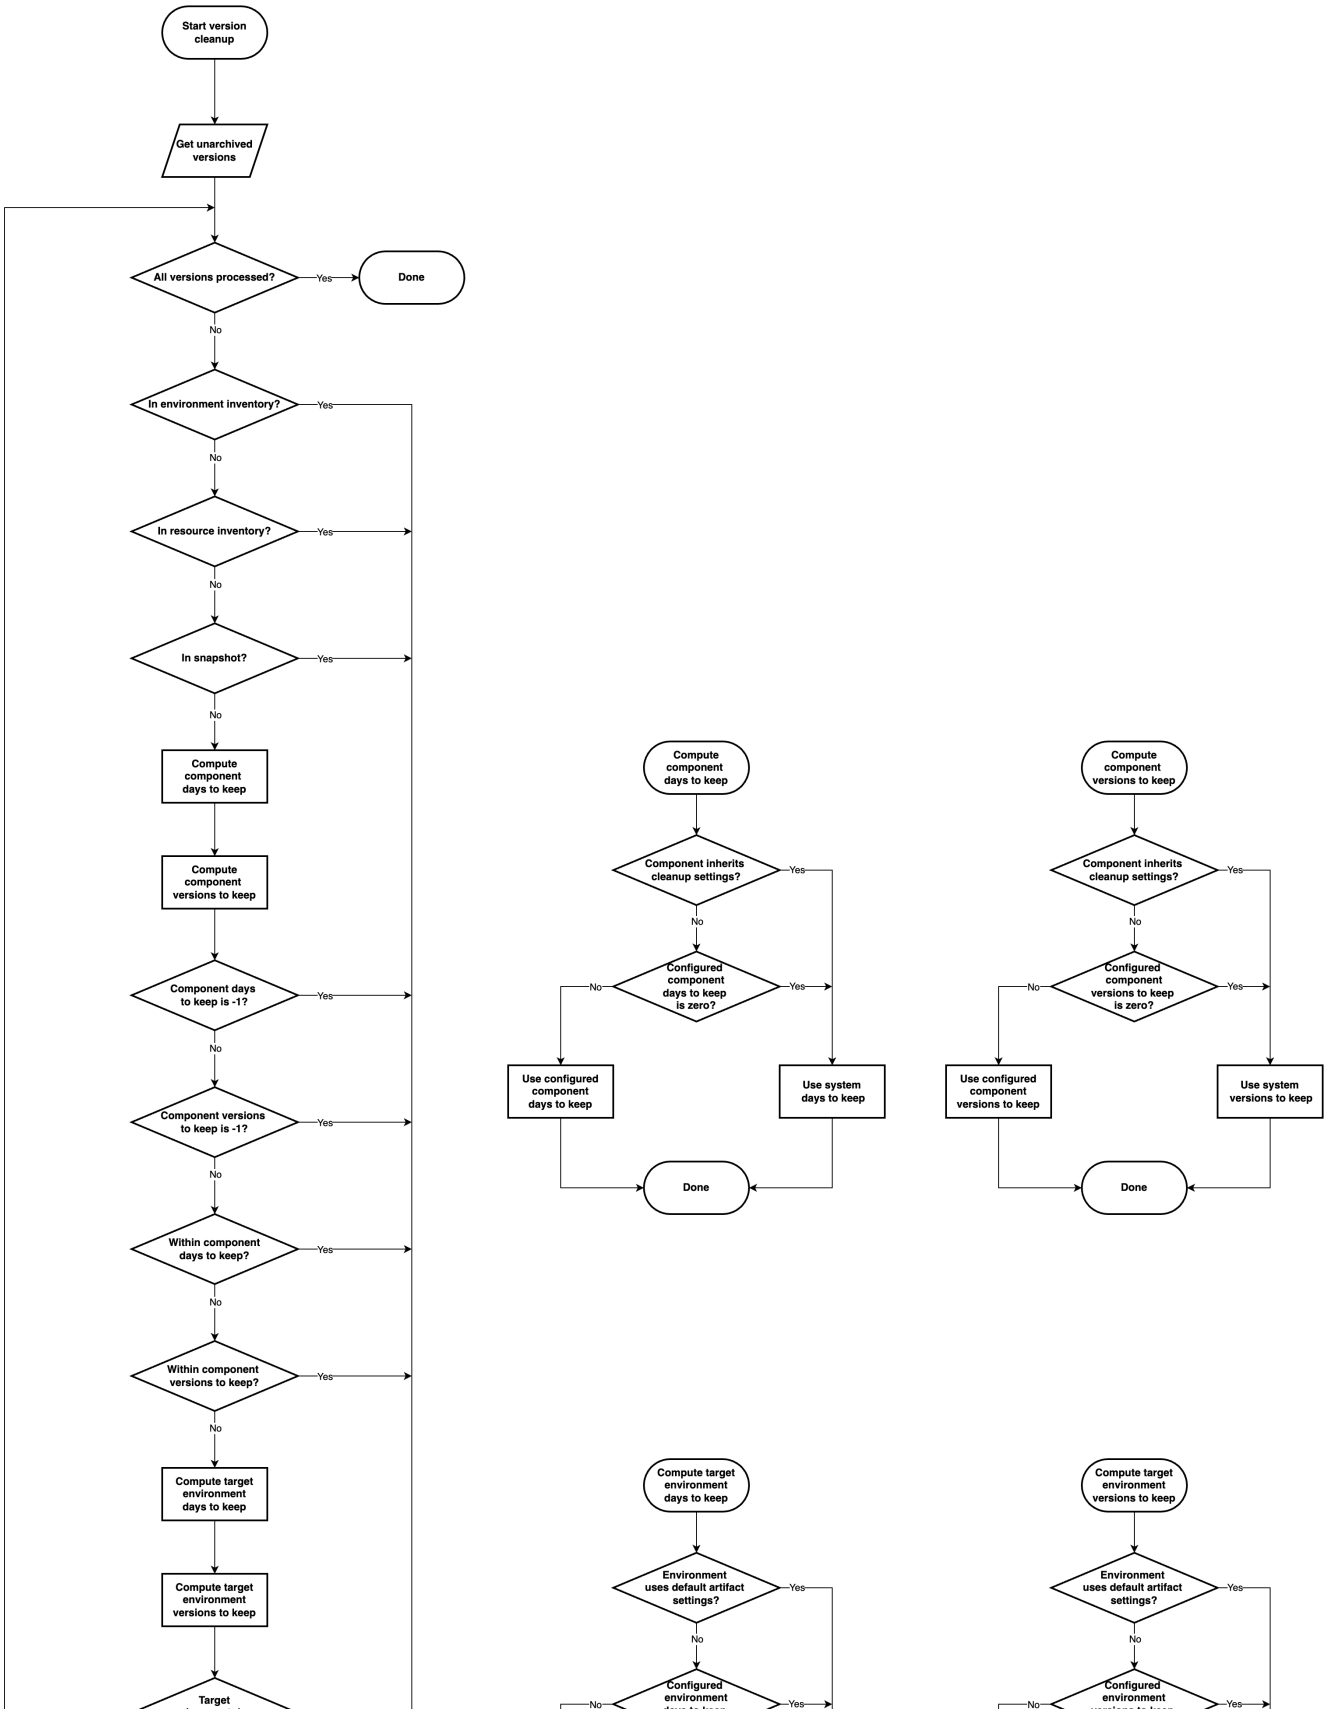
Component version clean-up starts
Component settings checks on server starts
Is the number of days to keep versions set to -1?
No
Is the number of versions to keep set to -1?
No
Is the version created within the number of days to keep versions?
No
Based on the number of versions to keep, is the version most recently created?
No
Yes
Yes
Yes
Yes
Checks start on each environment to which the component version is deployed
The version is kept.
Yes
Yes
Yes
Yes
Yes
Based on the number of versions to keep, is the version most recently deployed?
No
Is the version has been deployed within the number of days to keep versions?
No
Is the number of days to keep versions set to -1 in any of the environments?
No
Is the version part of any snapshot?
No
Is the version currently deployed to any environment or listed in any resource inventory?
No
The component version and its artifacts are archived.

Note:

- The server stores full copies of each file in each component version, even if the files are duplicates.
- When you perform an artifact cleanup, upcoming or scheduled processes are not taken into consideration. You must be aware that the artifact cleanup removes all versions according to the schedule, regardless of the

versions that might be used in upcoming scheduled deployments. Schedule artifact cleanups with upcoming deployments in the timing to avoid deployment problems.

This additional flowchart provides a more comprehensive view of the cleanup, showing the cleanup steps in detail.



1. Specify the artifacts cleanup settings:

    a. Click **Settings > System Settings**.

    b. Under **Artifact Cleanup**, in the **Daily Cleanup Start Time** field, specify the hour of the day to start the cleanup process.

    c. In the **Default Application Snapshot Retention (days)** field, specify the minimum age in days to save snapshots.
    For more information, see Cleaning up snapshots on page 2143.

    d. In the **Default Version Retention for Component (days)** field, specify the minimum age in days to save a component version.
    Example
    For example, to keep all component versions that are 5 days old or newer, specify `5`. If you specify `-1`, all versions are saved, regardless of the setting in the **Default Number of Versions to Retain for Environment** field.

    e. In the **Default Number of Versions to Retain for Component** field, specify the minimum number of versions to keep.
    Example
    For example, to save the five most recent component versions, specify `5`. If you specify `-1`, all versions are saved, regardless of the settings in the **Default Version Retention for Component (days)** field.

    When the server runs the cleanup, it deletes or archives all component versions that are older than the minimum age. However, the server retains at least the number of versions in the **Default Number of Versions to Retain for Component** field.

    f. In the **Default Version Retention for Environment (days)** field, specify the minimum age in days to save a environment version.
    Example
    For example, to keep all environment versions that have been deployed with in the last 5 days, specify `5`. If you specify `-1`, all versions are saved, regardless of the setting in the **Default Number of Versions to Retain for Environment** field.

    g. In the **Default Number of Versions to Retain for Environment** field, specify the minimum number of environment versions to keep.
    Example
    For example, to save the five most recently deployed versions, specify `5`. If you specify `-1`, all versions are saved, regardless of the settings in the **Default Version Retention for Environment (days)** field.

    When the server runs the cleanup, it deletes or archives all versions that have been deployed prior to the minimum age. However, the server retains at least the number of versions in the **Default Number of Versions to Retain for Environment** field.

h. In the **Archive Path** field, specify the path of the location on the server to write compressed versions of each version that is archived.
If you do not specify a path, then the server does not store the component versions that it removes.

i. To preview the component versions to be archived the next time that an archive file is created, on the **System Settings** tab, click the **Preview Version Cleanup** link, and select a component.

j. Click **Save**.

2. **Optional:** Specify cleanup settings for individual components.
These settings override the system settings and are editable only if you are assigned to a role that has the **Manage Component Cleanup** setting enabled.

a. Click **Components**, click a component, go to the **Configuration** tab for the component, and then click **Basic Settings**.

b. Clear the **Inherit Cleanup Settings** check box, and specify the following cleanup settings for the selected components:
   - Number of days you want to keep the versions in the **Days to Keep Versions** field.
   - Number of versions you want to keep in the **Number of Versions to Keep** field.

c. Click **Save**.

3. **Optional:** Specify cleanup settings for individual environments.
These settings override the system settings and are editable only if you are assigned to a role that has the **Manage Environment Cleanup** setting enabled.

a. Click **Applications**, click an application, click an environment, click **Configuration**, and then click **Basic Settings**.

b. Clear the **Use Default Artifact Cleanup Settings** check box and provide values for the following fields:

Field	Description
Days to Retain Application Snapshots	Specify the number of days to retain snapshots after they are not the most recently deployed snapshot in this environment. The most recently deployed snapshot is always retained. To retain application snapshots indefinitely, enter -1. To use the system default retention value, enter 0.
Days to Retain Versions	Specify the minimum age in days to save a component version. If you set both component and environment settings, the higher value is used.

Field	Description
Number of Versions to Retain	Specify the minimum number of versions to keep.

c. Click **Save**.

Results

The artifacts, components, and environments are archived as per the cleanup settings defined by you.

What to do next

You may find environment inventory entries for components that no longer have resources mapped with an environment. These environment inventory entries will cause component versions to be unavailable for cleanup. To remove inventory entries of an environment, open the environment options, and click **Sync Inventory**. A message displays the number of entries removed from the environment.

Cleaning up snapshots

You can configure the server to reduce the number of snapshots by deleting old snapshots. You can specify global cleanup settings and cleanup settings for specific environments.

About this task

Snapshot cleanup runs daily, at the same time as component version cleanup. The server deletes snapshots that do not meet any of the criteria for snapshots to keep. The effect is the same as if you delete the snapshot manually. These snapshots are not archived and are not recoverable.

When cleaning up snapshots, the server retrieves the settings from the **Settings > System Settings > Artifact Cleanup** options first. Then it retrieves the settings for individual environments, which override the system settings. If any of these settings specify to keep the snapshot, it is not deleted.

The settings for snapshot cleanup specify a number of days to keep snapshots. This time period is measured from the day that the snapshot is no longer the most recently deployed snapshot in an environment. For example, assume that the **Default Application Snapshot Retention (days)** system setting is set to 30 days. If a snapshot is deployed on day 1 and another snapshot is deployed on day 10, the first snapshot can not be cleaned up until day 40.

The system setting also refers to the number of days since the snapshot was created. If a snapshot was created fewer days ago than the **Default Application Snapshot Retention (days)** system setting, it is kept.

The criteria for keeping or deleting snapshots are as follows:

- If the snapshot is the most recently deployed snapshot in any environment, it is kept.
- In any environment, if the snapshot was the most recently deployed snapshot within the number of days in the system setting or the environment setting, it is kept.
- If the snapshot age in days is less than the system setting, it is kept.

If none of these criteria are true, the snapshot is deleted, even if it was deployed to an environment in the past.

1. Specify the system snapshot cleanup settings:
    a. Click **Settings > System Settings**.
    b. Under **Artifact Cleanup**, in the **Default Application Snapshot Retention (days)** field, specify how long to retain snapshots, in days.
    c. Click **Save**.

   For information about the other settings in this section, see Cleaning up component versions on page 2136.
2. **Optional:** Specify cleanup settings for individual environments.

   These settings override the system settings.
    a. Click **Applications**, click an application, click an environment, click **Configuration**, and then click **Basic Settings**.
    b. Clear the **Use Default Artifact Cleanup Settings** check box.
    c. In the **Days to Retain Application Snapshots** field, specify how long to keep a snapshot after it is not the most recently deployed snapshot in the environment.
    d. Click **Save**.

Cleaning up generic process history files

You can clean up generic process history files that are generated when you run the process manually.

About this task

Generic processes can be run as part of a deployment process, or independent of deployment processes. Cleaning up of these two types of generic processes is handled differently in HCL DevOps Deploy (Deploy). In the traditional cleanup process, all logs associated with the deployment process, including generic process logs, are cleaned up. See Cleaning up deployment history files on page 2133 for more information. However, logs that are generated by running a generic process manually are cleaned up by using the generic process cleanup settings.

Note: This procedure does not impact the generic process history files that are part of a deployment process.

The administrator enables the generic process history cleanup and specifies when the cleanup process begins, the duration of the cleanup, and the number of days to retain the process history. By default, the generic process history cleanup enablement settings are turned off.

Important: The cleanup cannot be undone. Carefully choose the time and duration for which you want to delete the records.

To enable, disable, or configure generic process history cleanup settings, an administrator completes these steps:

1. In Deploy, click the **Settings** tab, and then in the **System** column, click **System Settings**.
2. Scroll to the **Process History Cleanup** area.
3. Set **Enable Generic Process History Cleanup** to **On**.
4. In **Daily Cleanup Start Time**, select the hour to start the daily cleanup process.
5. In **Daily Cleanup Duration (hours)**, specify the number of hours for the cleanup process to run.
6. In **Days to Retain Generic Process History**, specify the number of days to keep the generic process history before the cleanup process removes the history.

Results

When cleanup begins, a progress indicator shows details about the cleanup process.

Cleaning up process step log files

You can clean up process log files that are generated when you run deployment process steps to free up storage space in the file system.

About this task

When you run an independent process step or process step which is part of a deployment process, the log files are generated. The process step logs are part of the deployment history files, but you can clean up the step log files independent of the deployment history cleanup. By cleaning up the step log files separately, you can retain deployment history and information such as workflow traces and inventory information.

You can clean up the process step logs in the following three ways:

- By configuring the cleanup settings from the system settings. See Configuring the system settings on page 2146.
- By configuring cleanup settings for individual environments. See Configuring individual environment settings on page 2147.
- By configuring cleanup settings for multiple environments. See Configuring bulk cleanup settings on page 2147.

Important: The process step logs cleanup process deletes all logs in the file system that are related to the deployments that you're deleting. The cleanup cannot be undone. It is important that you carefully choose the items that you delete.

For the cleanup process to start and run according to specifications, the cleanup process must be turned on by your administrator in **System Settings** and the **Use Process Step Log Cleanup** option is selected in environment settings. By default, the process step log cleanup settings in both the administrator and environment settings are turned off.

The following table shows how the cleanup configuration works based on your selection:

Table 697. Enabling step log cleanup

Enable Process Step Log Cleanup option in System Settings (administrator's setting)	Use Process Step Log Cleanup check box in environment settings	Result
On	Selected	Cleanup starts as specified for deployments that are associated with this environment.
On	Cleared	Cleanup does not start for deployments that are associated with this environment.
Off	Selected	Cleanup does not start for deployments that are associated with this environment.

An example usage of the cleanup configuration fields is as follows:

If the date is 14 November 2024, and you have used the following settings:

- **Enable Process Step Log Cleanup** in System Settings: Enabled
- **Daily Cleanup Start Time** in System Settings: `9:00 PM`
- **Daily Cleanup Duration (hours)** in System Settings: `3`
- **Days to Retain Process Step Logs** in System Settings: `15`
- **Use Process Step Log Cleanup** in the environment settings: Enabled
- **Use Default Step Log Retention** in the environment settings: Enabled

At 9:00 PM on 14 November 2024, the process step log cleanup begins to run for 3 hours. During the 3 hours, the step logs that are 15 days old and older are deleted.

Notes:

- You can make changes to the settings after this date and can change it multiple times.
- This procedure does not impact the process step log files that are part of a running deployment process.

Configuring the system settings

As a system administrator, you can enable and configure the process step clean up settings to delete the old process step log files.

Before you begin

You must have the following permissions to edit the system settings:

- **Web UI > Settings Tab**
- **Server Configuration > Edit Basic System Settings**

1. In Deploy, click the **Settings** tab, and then in the **System** column, click **System Settings**.
2. Scroll to the **Process History Cleanup** area.
3. Set the **Enable Process Step Log Cleanup** option to **On**.
4. In the **Daily Cleanup Start Time** field, select the hour to start the daily cleanup process.
5. In the **Daily Cleanup Duration (hours)** field, specify the number of hours for the cleanup process to run.
6. In the **Days to Retain Process Step Logs** field, specify the number of days to keep the process log files before the cleanup process deletes the logs.
7. Save your changes.

Results

You have configured the process step log files cleanup in the system settings. When cleanup begins, a progress indicator shows details about the cleanup process.

Configuring individual environment settings

As a user, you can configure the process step clean up settings for a specific environment.

Before you begin

- You must have the following permissions to edit the process step log cleanup for individual environments:
  - **Environment > Edit > Manage Environment Cleanup**
  - **Web UI > Applications Tab**
- The administrator has enabled the **Enable Process Step Log Cleanup** system setting.

1. Click **Applications**, click an application, click an environment, click **Configuration**, and then click **Basic Settings**.
2. Select **Use Process Step Log Cleanup**.
3. Perform any one of these steps:
   - Select **Use Default Step Log Retention** to keep step log files for the number of days that the administrator specified.
   - Clear the **Use Default Step Log Retention** check box and specify the number of days to keep step logs in the **Days to Retain Step Logs** field.
4. Save your changes.

Results

You have configured the process step log files cleanup setting for the environment. When the cleanup begins, a progress indicator shows details about the cleanup process.

Configuring bulk cleanup settings

You can delete components and environments in bulk automatically when they reach a certain number of versions or after certain days.

Before you begin

You must have the following permissions:

- **Server Configuration > Bulk Manage Cleanup**
- **Web UI > Settings Tab**

About this task

You can configure the cleanup criteria for component versions and environments in bulk.

1. On the Web UI, open the **Cleanup Configuration** page by clicking **Settings > Cleanup Configuration**.
   The list of all components is displayed.
2. Configure cleanup setting for components in bulk.

   a. Select components by using any of the following ways:
      - Filter the component list by **Name** and **Cleanup Setting**.
      - Select all displayed rows by clicking **Select All**.

   b. Click **Set Cleanup Configuration**.

   c. Clear the **Inherit Cleanup Settings** check box, and specify the following cleanup settings for the selected components:
      - Number of days you want to keep the versions in the **Days to Keep Versions** field.
      - Number of versions you want to keep in the **Number of Versions to Keep** field.

3. Configure cleanup setting for environments in bulk.

   a. Select **Environments** from the drop-down on the left.

   b. Select environments by using any of the following ways:
      - Filter the environment list by **Environment** and **Application** name.
      - Select all displayed rows by clicking **Select All**.

   c. Click **Set Cleanup Configuration**.

   d. Select **Use Default Artifact Cleanup Settings** to use the artifact cleanup settings that are defined in the system settings.
   If you do not want to use the system settings, then deselect the **Use Default Artifact Cleanup Settings** option and specify the following cleanup settings for the selected environments:

Field	Description
Days to Retain Application Snapshots	Specify the number of days to retain snapshots after they are not the most recently deployed snapshot in this environment.

Field	Description
	The most recently deployed snapshot is always retained. To retain application snapshots indefinitely, enter -1. To use the system default retention value, enter 0.
Days to Retain Versions	Specify the minimum age in days to save a component version. If you set both component and environment settings, the higher value is used.
Number of Versions to Retain	Specify the minimum number of versions to keep.

e. Select **Use Deployment History Cleanup** to delete the deployment history records of the selected environments.
You can select the **Use Default Deploy History Retention** option to use the deployment history cleanup settings that are defined in system settings.
If you do not want to use the system settings, then deselect the **Use Default Deploy History Retention** option and specify the number of days you want to keep the deploymemt history records in the **Days to Retain Deployment History** field.

f. Select **Use Process Step Log Cleanup** to delete the process step logs of the selected environments.
You can select the **Use Default Step Log Retention** option to use the process log cleanup settings that are defined in the system settings.

If you do not want to use the system settings, then deselect the **Use Default Step Log Retention** option and specify the number of days you want to keep the process step logs in the **Days to Retain Step Logs** field.

4. Save your changes.

Results

You have configured the cleanup settings for components and environments in bulk.

Managing Security

HCL DevOps Deploy (Deploy) uses a flexible team-based and role-based security model that maps to your organizational structure.

From a high level, the security system for the server consists of an authentication realm, authorization realm, roles, and teams. The authentication realm verifies the identity of the user or system that is trying to log on to the Deploy server. The authorization realm manages user groups. Roles manage permissions. Teams join users with roles and specify which objects the team can access.

Permissions

Deploy uses the term *permission* in a way that is familiar to most readers: each permission controls access to a product area or product function. Most permissions refer to typical activities such as creating, reading, updating, and deleting. Separate

permissions are available for each type of object on the server, including components, applications, and environments. Permissions define what can be done, not who can do it.

Within each security type, you specify the permissions that each role has. For example, administrator or team lead roles have many permissions, while observer roles have limited permissions.

Security types

Security types divide one type of object into categories. For example, you can set one security type for production environments and a separate security type for development environments for the same object type. Then, you can set different permissions for each type of environment. Security types are optional; you can define security types or use the default security type for all objects.

Roles

A *role* is a set of granted permissions. A developer-type role might have permissions for creating applications but not running them in production environments. Alternatively, a deployer-type role might be able to run applications but not create them. You decide the number of roles and their functions. By default, Deploy provides several roles. The administrator role, for example, is granted permissions for all security types. You must create your own roles and specify the permissions for each role.

When you create a role, that role becomes available on each team. Then, you can assign users to that role for a specific team.

Important: A role by itself does not impart its granted permissions to any actual user. Like permissions, roles define what can be done, not who can do them. Roles and their associated permissions are applied to users by teams.

Teams

A *team* is a construct that associates users or groups with roles. When a user is added to a team, that person is assigned to one or more roles. Users cannot be added to a team unless they have a role assignment. Role members are granted all permissions that are defined for the role. Groups can also be added to roles, in which case all group members are granted the permissions that are defined for the role.

Teams secure resources. To secure an environment, for example, assign a team to it. After the environment is secured, only team members who are assigned a role with an appropriate permission can affect the environment.

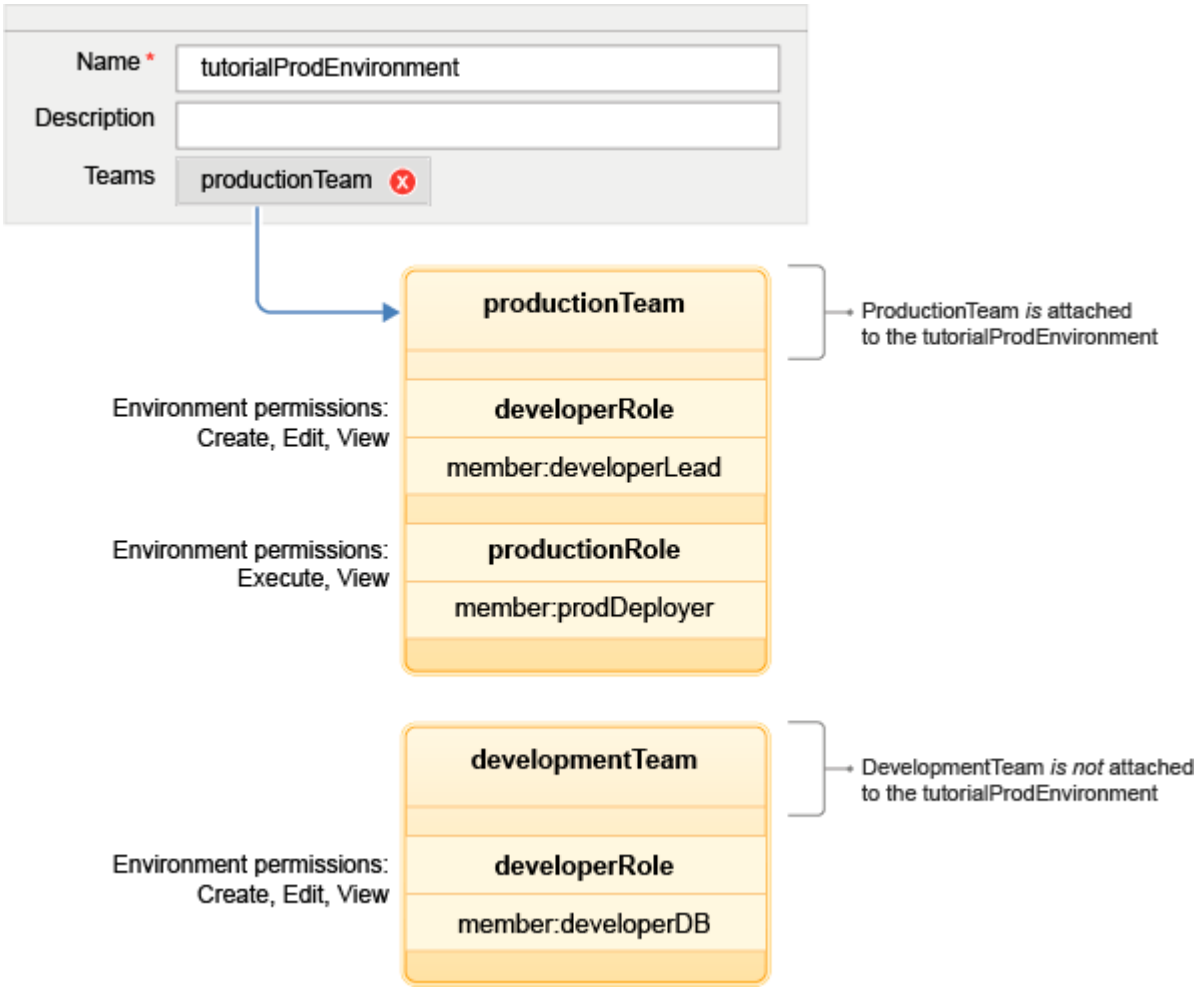
The System Team that comes with Deploy has several users, such as the admin user which is assigned to the Administrator role. The Administrator role has all permissions that are granted for all standard security types and for the server and web UI settings. The System Team cannot be deleted.

The System Team has access to everything on the server according to the permissions in the standard security type. For example, the members of the System Team have the environment permissions that are listed in the Standard Environment security type for all environments.

Resource and object security

To give team users access to a resource or object (such as a component, application, or environment), assign that resource or object to a team. In the following figure, the *productionTeam* team is attached to the *tutorialProdEnvironment* environment. The *productionRole* role has the execute permission for environments. Team members with that role, such as *prodDeployer*, can run applications in the environment. Team members without that role, such as *developerLead*, cannot run applications even though the team is attached to the environment.

Figure 5. Team security permissions



The *developerLead* user can create and modify environments. Additionally, the *developerDB* user can create environments even though the *developmentTeam* team is not attached to this or any other environment.

When a team is assigned to an object, the security type is also determined. By varying security types, you can fine-tune team permissions. For example, a team might have one set of permissions for a component and, by changing the security type, another set for a different component.

Guidelines for setting up server security

Although there is no single best way to set up security for the server, the following steps are sufficient in most cases.

About this task

If you are upgrading from an earlier version, see Migrating security settings.

1. Create an authorization realm for the server. Authorization realms are used by authentication realms to associate users with groups and to determine user access. HCL DevOps Deploy (Deploy) includes an internal database for storing security information and integration with the Lightweight Directory Access Protocol (LDAP). LDAP is a widely used protocol for accessing distributed directory information over IP networks.
2. Create an authentication realm for the server. The authentication realm is used to determine a user's identity within an authorization realm.
3. **Optional:** Create security types.
   Security types classify artifacts such as environments and components by level of security.
4. Create roles and define permissions for them.
5. Create and import users and groups.
6. Create teams, and assign users and groups to them.
7. Assign elements, such as applications and environments, to teams.
   Result
   After you complete the preceding steps, users on the associated teams have access to those elements. The access rights that each user has for those elements depend on the user's role within that team.

SSL configuration

With Secure Sockets Layer (*SSL*) technology, clients and servers can communicate securely by encrypting all communications. Data is encrypted before it is sent and decrypted by the recipient. This communication cannot be deciphered or modified by third-parties. In addition to encryption, SSL can also support authentication.

HCL DevOps Deploy (Deploy) servers and agents communicate via HTTPS. Typically, HTTPS is used for file transfers between the server and an agent. For example, HTTPS is used when an agent is downloading a new plug-in, or when an agent is uploading or downloading version artifacts.

Enabling server identity verification

You can enable extra security to configure the agents to verify the identity of the server for communication that uses the HTTPS protocol.

Before you begin

Upgrade the following plug-ins to the latest versions that are available:

- All source configuration plug-ins
- z/OS® Utility plug-in
- MobileFirst Platform Foundation (formerly Worklight) plug-in
- WebSphere® Application Server - Deployment plug-in

Versions of these plug-ins that were released before March 2016 do not support server identity verification.

Ensure that the keytool utility, which is provided with the Java™ developer kit and is not part of Deploy, is available in the system path.

About this task

When you install the Deploy server, a private key and self-signed certificate with the alias `server` are stored in the *`server_installation_directory`*`/opt/tomcat/conf/tomcat.keystore` file. This certificate is presented to agents, agent relays, and users that connect to the server via HTTPS. Because the certificate that is associated with the private key has a generic distinguished name (DN), you must replace the key so that the agent or agent relay can correctly verify the host name of the server. After you configure the server to present a certificate with a valid host name, you then configure the agents to accept that trusted certificate and to require verification of the host name of the server.

1. Stop the Deploy server.
2. Open a command-line window, and go to the *`server_installation_directory`*`/opt/tomcat/conf` directory.
3. Generate a private key that is associated with the correct host name to use for HTTPS communication. Run a command similar to the following command:

   ```
   keytool -genkeypair -alias serverNewCN -keysize 2048 -sigalg SHA256withRSA -keyalg RSA -keystore
    tomcat.keystore
   ```

   The existing key is stored in the `tomcat.keystore` file with the `server` alias.
4. Edit the `tomcat.key.alias` property in the installed.properties file to specify the alias in the keystore that contains the certificate to use.

   ```
   tomcat.key.alias="serverNewCN"
   ```
5. Edit the following properties in the `secured-installed.properties` file to specify the password for the certificate and keystore to use.

   ```
   server.key.password=<new_certificate_password>
   tomcat.keystore.password=changeit
   ```

   Enter the passwords in plain text, so that it automatically encrypts once the server runs.
6. **Optional:** Create a certificate signing request that uses the new private key, and then use an internal or external certificate authority to sign it.
7. Export the server certificate. Run a command similar to the following command:

   ```
   keytool -exportcert -alias server -keystore tomcat.keystore -file server.cert
   ```
8. Start the Deploy server.
9. If you used a certificate authority that is not already trusted by the agents, copy the server certificate to the agent computer, and then import the certificate into the keystore of the JRE that is used to run the agent process.
   By default, the path to the keystore is `$JAVA_HOME/lib/security/cacerts`. If you use agent relays, repeat this step for all agent relays.
10. If you use agent relays, complete the following steps to configure the agents to verify the identity of the agent relays.

Note: Server identity verification uses the HTTPS, or *codestation*, keystores for the agent relays.

a. Open a command-line window on the agent relay computer, and go to the `/agent_relay_install/conf/` directory.
By default, the *agent-relay-install* location is `/opt/devops-deploy/agentrelay` on Linux™ and `C:\Program Files\devops-deploy\agentrelay` on Windows™.

b. Generate a private key that is associated with the HTTPS connection for the agent relay. Run a command similar to the following command:

```
keytool -genkeypair -alias agentrelay -keysize 2048 -sigalg  SHA256withRSA
    -storepass changeit -keypass changeit -keyalg RSA -keystore codestation.keystore
```

For the `-alias` argument, specify the certificate alias of the *codestation* keystore for the agent relay. The certificate is in the `agentrelay.properties` file for the agent relay, in the property **codestation.cert.alias**. The default value is `agentrelay`.

c. Export the agent relay certificate. Run a command similar to the following command:

```
keytool -exportcert -alias agentrelay -keystore codestation.keystore -file agentrelay.cert
```

d. Copy the agent relay certificate to the agent computer, and then import the certificate into the keystore of the JRE that is used to run the agent process.
By default, the path to the keystore is `$JAVA_HOME/lib/security/cacerts`.

11. Add `verify.server.identity=true` to the *<DEPLOY_AGENT_HOME>*`/conf/agent/installed.properties` file on each agent.
If you use agent relays to cache artifacts, repeat this step for all agent relays.
12. Upgrade each agent or agent relay. If an agent is already upgraded, restart the agent.
Agents can communicate with the server during this process, so you can upgrade agents one at a time.

Supported TLS and SSL protocols and ciphers

HCL DevOps Deploy (Deploy) supports multiple SSL protocols and ciphers for communication among servers.

Deploy supports TLS v1.2, TLS v1.3, and SSL protocols. Deploy supports the SSL v3 protocol only if older agents require it.

Note:

- Limiting and disabling SSL and TLS protocols and ciphers is done at the JVM level rather than the application level.
- Support for TLS v1.0, TLS v1.1, and SSL v2Hello is deprecated.

Deploy uses SSL to communicate between the web UI and server and between the servers that use ActiveMQ. The SSL certificates that control both types of communication use the Java™ KeyStore (JKS) format. These certificates are generated by an RSA key with a 2048-bit length and are signed by a SHA256withRSA algorithm.

By default, the web UI connects on port 8443. The server certificate is in the `opt/tomcat/conf/tomcat.keystore` file. See Configuring SSL on Apache Tomcat and LDAP servers on page 2159 for more information.

The SSL ciphers you can use depend on which ciphers the Java crypto provider of the JRE supports on which you installed your Deploy server, relay and agent. For example, refer to a list of providers by Oracle/OpenJDK Java 11.

The following SSL cipher suites are enabled by default:

Table 698. Default cipher suites

AES_256_GCM_SHA384
AES_128_GCM_SHA256
AES_128_CCM_8_SHA256
AES_128_CCM_SHA256

RSA_WITH_CAMELLIA_256_CBC_SHA256

Overriding suggested cipher suites

Deploy suggests ciphers based on their availability and what the system identifies as secure. You can use system properties to add specific ciphers or prevent the system to add a cipher automatically to the default cipher list.

To add a cipher to the list of default ciphers, add the following property to the system property:

```
com.urbancode.commons.util.ssl.sslContextEnabledCiphers
```

Example

For example, you can add cipher1 and cipher2 to the default ciphers by adding the following property:

```
com.urbancode.commons.util.ssl.sslContextEnabledCiphers=cipher1,cipher2
```

To prevent the system from adding a cipher to the default cipher list, add the following property:

```
com.urbancode.commons.util.ssl.sslContextIgnoreSuggestedCiphers=true
```

Enforcing the use of a security protocol or set of ciphers

For security reasons, ensure that all SSL connections to and from the HCL DevOps Deploy (Deploy) server uses the TLSv1.2 protocol. To configure SSL globally, follow these instructions under jdk.tls.disabledAlgorithms here.

The Deploy server uses the following communication protocols that rely on SSL at the transport level:

- HTTPS for displaying the user interface
- LDAP to connect to LDAP and Active Directory servers
- JDBC to connect to the database containing the schema of the Deploy server application

Note: Support for TLSv1.0, TLSv1.1, and SSLv2Hello is deprecated.

The following sections explain how to enforce the usage of TLSv1.2.

Environment

Enforcing TLSv1.2 is possible if the Deploy server, relay, and agent are running a JVM version that supports this protocol. For more information on such JVM versions, see Oracle JRE and JDK Cryptographic Roadmap. Before you enforce TLSv1.2 as the only supported protocol in Deploy, make sure that the external tools like LDAP servers, database servers, and middleware that the plug-ins deploy to, also support TLSv1.2 or else the connections will fail.

Deploy server: HTTPS protocol

The HTTPS protocol is configured in the `devops-deploy/server/opt/tomcat/conf/server.xml` file. The `server.xml` file contains the following relevant entries:

```
    <Connector port="${install.server.web.https.port}"
               address="${install.server.web.ip}"
               server="SERVER"
               maxThreads="150"
               enableLookups="false"
               acceptCount="100"
               debug="0"
               connectionTimeout="20000"
               disableUploadTimeout="true"
               compression="1024"
               noCompressionUserAgents="gozilla, traviata"
               compressableMimeType="text/html,text/xml,text/javascript,text/css,text/plain,application/json"
               algorithm="${install.server.ssl.algorithm}"
               SSLEnabled="true"
               scheme="https"
               secure="true"
               clientAuth="false"
```

```
               URIEncoding="UTF-8"
               ciphers="${install.server.ssl.enabledCiphers}"
               sslEnabledProtocols="${install.server.ssl.enabledProtocols}"
               keystoreFile="${tomcat.keystore.file}"
               keyAlias="${tomcat.key.alias}"
               keystorePass="${tomcat.keystore.password}" />
```

To enforce TLSv1.2, add or modify the `install.server.ssl.enabledProtocols=TLSv1.2` property in the `devops-deploy/server/conf/server/installed.properties` file. Note that this property might be missing, or it might be present and have a different value, including an empty value. The property is referred to as: `${install.server.ssl.enabledProtocols}` in the `server.xml` and `installed.properties` files.

Deploy Server: LDAP integration

The Deploy server uses the LDAP client that is contained in the JRE that is running on the server. You must specify a URL for the LDAP server, which uses the `ldaps://` protocol that uses port 636 but default to connect through SSL or TLS.

Note: The `install.server.ssl.enabledProtocols` parameter changes the SSLContextParameters which might affect the LDAP connection that is opened.

Deploy Server: JDBC connection to the database server

JDBC is used to connect Deploy to the backend database.

DB2

Refer to the DB2 documentation - Configuring SSL support in a DB2 instance for detailed information. Configure the DB2 instance according to the instructions, and test after you compete the configuration.

Postgres

Connection string: `connectionString=jdbc:postgresql://dbhost/dummy?ssl=true jdbcDriver=org.postgresql.Driver jdbcJar=C:\devops-deploy\agent\postgresql-42.1.4.jar`.

Import the database certificate to the Deploy Agent Java keystore. The latest available plug-in is version 13, see SQL JDBC plug-in for Deploy.

Microsoft SQL Server

1. Ensure that your Microsoft SQL server supports TLSv1.2 and have the right FixLevel and KB 3052404 installed on it.
2. Enable TLSv1.2.
    a. Depending on the Microsoft SQL Server JDBC type 4 driver version, you can pass in the JDBC a connection string that enforces TLSv1.2, that is sslProtocol=TLSv1.2 protocol.
    b. You can enforce TLSv1.2 at the JRE level that runs the Deploy server. Enabling TLSv1.2 has the following results:
        - Outgoing connections to the LDAP database all are made with TLSv1.2.
        - Incoming connections from Deploy agents, Deploy agent relays, and WebUI require TLS v1.2.

These results can be undesirable if one of the involved components does not support TLSv1.2. You must make sure that the JDBC drivers support TLSv1.2. To ensure this support, change the `jdk.tls.disabledAlgorithms` line in the `jre/lib/security/java.security` file to `jdk.tls.disabledAlgorithms=SSLv3, TLSv1, TLSv1.1`. You can also pass the `devops-deploy/server/bin/set_env JAVA_OPTS` string through a java.security file.

Note: You cannot disable the SSLv2Hello, because it is used as the initial handshake from the Deploy agents with the Deploy server.

c. For the JDBC connection string, refer to the SQL Server 2017 documentation - Understanding SSL Support. The `encrypt=true` property uses TLS/SSL.

Do not blanket `trustServerCertificate=false`. Every SSL certificate from Microsoft SQL server uses the default JRE's trust store `jre/lib/security/cacerts`. Use `hostNameInCertificate=yes` to verify that DNS and `SubjectAltName` in the SSL certificate are the same. For `trustStore=/my/own/trustStore.jks`, do not use the default JRE's trust store `jre/lib/security/cacert`, use a separate one. The `trustStorePassword=changeit` is the password for the trust store.

Oracle

To enforce TLSv1.2 for Oracle12c:

1. Ensure that you have a JDBC driver version higher than 12.2.0.1.
2. In the file `devops-deploy/server/bin/set_env.sh` append the following -D argument `-Doracle.net.ssl_version='1.2'` in the value you currently set for JAVA_OPTS variable.
3. Restart the Deploy server.

Deploy Agent

To add TLSv1.2 protocol to Deploy agents using HTTPS communication with the Deploy server, add `-Djdk.tls.client.protocols=TLSv1.2` line to the `devops-deploy/agent/bin/worker-args.conf` file.

For a step running on Deploy agent, add `-Djdk.tls.client.protocols=TLSv1.2` line to the `devops-deploy/agent/conf/plugin-javaopts.conf` file.

Configuring SSL on Apache Tomcat and LDAP servers

The steps for configuring secure HTTPS connections with the HCL DevOps Deploy (Deploy) server are similar to the steps for any Java™ Platform, Enterprise Edition server.

Before you begin

To set up SSL security, you must have a certificate for the server. If you use certificates that are self-signed or certificates that are issued by a certificate authority that is not trusted, you must import these certificates into the trust store. A trust store contains trusted certificates from servers and certificate authorities. Import the self-signed certificates, certificate authority certificates, and intermediate certificate authority certificates to the *JRE_install*`/jre/lib/security/`

`cacerts` file. For an example of importing a certificate to a trust store, see the Importing the Certificate Reply from the CA topic in the IBM® SDK, Java™ Technology Edition help.

In the case of LDAP servers, SSL certificates must have valid chains of authority. If you use your own certificate authority, add that certificate authority to the local trust store.

About this task

Because the Deploy server runs on Apache Tomcat, you can refer to the instructions for configuring security on Tomcat on the Apache Tomcat website. You can enable SSL security for Apache Tomcat when you install Deploy. If you enable SSL security during installation, a self-signed certificate is generated and added to the `tomcat.keystore` file. The common name (CN) in the self-signed certificate is set to 0.0.0.0.

Note: The presence of a self-signed certificate is flagged as a warning by many web browsers when you connect to a Deploy server that uses a self-signed certificate in the `tomcat.keystore` file.

Setting up SSL security for the server involves these general steps:

1. Transfer the files for the certificate to the computer that hosts the Deploy server.
2. Add the certificate to the server keystore.
   The server has a default keystore in the *`server_install`*`/opt/tomcat/conf/tomcat.keystore` file. The default password for this keystore is `changeit`.
3. Edit the `tomcat.key.alias` property in the `installed.properties` file.
   ```
   tomcat.key.alias=alias_of_your_certificate_in_tomcat_keystore
   ```
4. Restart the server.
5. Similarly, add the same certificate to the keystore of each agent and agent relay.
   Example
   For example, the default location of an agent keystore is *`agent_install`*`/conf/agent.keystore`.
6. **Optional:** To configure secure communication between the Deploy server and an LDAP server, add the LDAP server certificate to the *`JRE_install`*`/jre/lib/security/cacerts` file. This file is on the Deploy server. Use the installation folder of the JRE for *`JRE_install`*.

Implementing custom trust stores

A trust store defines the roots of the certificate trust chain. Typically, these are the certificate authority root certificates that sign other certificates. It can also be end entity certificates that are directly trusted. Java® includes a default trust store that contains certificate authority root certificates for many well-known authorities. This trust store is a file called `cacerts` and is contained in the Java installation. The file has the same format as a keystore, but it never contains a private key. It is possible to modify or replace this file to alter the trust roots with the keytool program. Otherwise, a custom trust store must be used instead.

A custom trust store is simply another keystore file containing the custom trust roots. It is even possible to copy `cacerts` and modify the copy to expand the set of trust roots. Unlike with the default trust store, a configuration step is required enable use of a custom trust store.

You can turn on custom trust stores selectively. For example, you can configure agents to always verify the server without the server doing any verification, or you can have the servers verify each other only in the client role.

Note: Trust stores can be used with agents and servers, but not agent relays. The agent relay has no custom trust store support for web agent communication because it does not participate in authenticating communications.

Agent

For web agent communication, the agent permits a custom trust store for validating connections to the server. For the custom trust store to take effect, **verify.server.identity** must be set to **true**. This parameter can be configured in the installer (Agent installation properties), although it can also be set without configuring a custom trust store.

By default, setting this property will use the default trust store in the `cacerts` file. It also performs an extra hostname verification on the server certificate, which is the same as in a web browser.

A custom trust store is configured by setting **agentcomm.truststore** to the path of trust store file and setting **agentcomm.truststore.password** to the keystore file password. If unset, it will default to **changeit**.

```
installed.properties:
  verify.server.identity=true
  agentcomm.truststore=<path>
  agentcomm.truststore.password=<password>
```

Server

The server's use of a trust store is similar to the agent, but has potentially two custom trust stores, depending on the role of the server in the connection. The trust stores are independent and can be selectively enabled, or both can be configured to share the same trust store file.

Server: Server Role

When the server is in the server role, it will authenticate clients, which are both agents and other servers in the same cluster. In this scenario, **verify.client.identity** must be set to **true**.

The default cacerts trust store is used. There is no hostname verification step because client certificates do not contain a hostname. **agentcomm.serverTruststore** is set to the path of the trust store file. **agentcomm.serverTruststore.password** is set to the trust store file password (**changeit** by default). Unlike the agent, the password property is stored in **secured-installed.properties** with other passwords.

Note: Although the trust store is configured for the server role, that server verifies the identity of clients. This explains the asymmetry in the names of this group of properties. When the server is in the client role, the naming is reversed.

```
installed.properties:
  verify.client.identity=true
  agentcomm.serverTruststore=<path>

secured-installed.properties
  agentcomm.serverTruststore.password=<password>
```

Server: Client Role

When the server is the client role, it is only verifying the identity of the other server members of its cluster. In this scenario, **verify.server.identity** must be set to **true**.

The default cacerts trust store is used. As required by the client role, a hostname verification step is also performed. **agentcomm.serverTruststore** is set to the path of the trust store file. **agentcomm.serverTruststore.password** is set to the trust store file password (**changeit** by default).

```
installed.properties:
  verify.server.identity=true
  agentcomm.clientTruststore=<path>

secured-installed.properties
  agentcomm.clientTruststore.password=<password>
```

Upgrading encryption key strength

When you upgrade the server, you can upgrade the SSL encryption.

About this task

This upgrade is optional, but it strengthens server security. The `keytool` application is included in the Java™ developer kit and is not part of HCL DevOps Deploy (Deploy).

1. Upgrade the HTTPS certificate for the server:

    a. On the server, open a command-line window to the *`server_install`*`/opt/tomcat/conf` folder, where *server_install* is the server installation folder.

    b. Delete the existing certificate with the following command:

    ```
    keytool -delete
      -alias tomcat
      -keystore tomcat.keystore
      -storepass changeit
    ```

    Note: Each command in this example must be written on one line. Also, the commands in the following examples must be written on one line. The commands are written on multiple lines for clarity.

    c. Create a certificate with the following command:

    ```
    keytool -genkey
      -alias tomcat
      -storepass changeit
      -keypass changeit
      -keyalg RSA
      -sigalg SHA256withRSA
      -keysize 2048
      -validity 7305
      -dname CN=host_name
      -keystore tomcat.keystore
    ```

For *host_name*, use the host name of the server.

d. Go to the folder *app_data*/conf.

e. Delete the existing entry to the keystore with the following command:

```
keytool -delete
  -alias server
  -keystore server.keystore
  -storepass changeit
```

f. Create an entry to the keystore with the following command:

```
keytool -genkey
  -alias server
  -storepass changeit
  -keypass changeit
  -keyalg RSA
  -sigalg SHA256withRSA
  -keysize 2048
  -validity 7305
  -dname CN=host_name
-keystore server.keystore
```

For *host_name*, use the host name of the server.

2. For each of your agent relays, upgrade the encryption with the following steps:

a. In a command-line window, go to the *relay_install*/conf/jms-relay folder, where *relay_install* is the relay installation folder.

b. Delete the existing entry in the keystore for the agent relay with the following command:

```
keytool -delete
  -alias agentrelay
  -keystore agentrelay.keystore
  -storepass changeit
```

c. Add an entry with the new encryption level with the following command:

```
keytool -genkey
  -alias agentrelay
  -keystore agentrelay.keystore
  -storepass changeit
  -keypass changeit
  -keyalg RSA
  -sigalg SHA256withRSA
  -keysize 2048
  -validity 7305
  -dname CN=host_name
```

For *host_name*, use the host name of the server.

3. If you are using mutual encryption between servers and agents, upgrade the encryption on each agent:

a. In a command-line window, go to the *agent_install*`/conf/jms-relay` folder, where *agent_install* is the agent installation folder.

b. Delete the existing entry in the keystore for the agent with the following command:

```
keytool -delete
  -alias alias
  -keystore keystore_file
  -storepass changeit
```

Replace the *alias* variable with the alias of the server certificate in the agent keystore. The *keystore_file* variable represents the keystore file. The default name of the keystore file is `agent.keystore`. To find the alias, run the following command, and look for the alias name in the output:

```
keytool -list -v -keystore keystore_file
```

Note:

Although agents and relays that use the JMS communication protocol cannot establish connections with HCL DevOps Deploy (Deploy) v7.2.0 and later, the references to JMS persist in some file names, property names, folder names, and directory names.

For example, the following names that are associated with JMS are still used in **Deploy** v7.2 and later: agentrelay.jms_proxy.name, agentrelay.jms_proxy.id, jms-relay.log directory, and jms-relay folder.

Keystores configuration

Server, agents, and agent relays keystores are used for a secured web communication between servers and agents.

Web agents come with and use Public Key Pinning for strong security. Agents and servers identify each other with SSL certificates. The public keys in the certificates are pinned on the initial connection. When a public key is pinned, any certificate that asserts the same identity must be generated with the same public and private key pair that was used to create the original certificate. Connections from clients or servers that do not correctly identify themselves are closed.

Deploy supports pinning multiple server public keys on an agent. Server public key pin information and limit is available in the agent's metadata. To use a new key, generate a key, and deploy the key to the agent. See Add public key pin for a server host to an agent for more information. Atleast one key must be deployed to an agent.

Server keystores

Server keystore locations are defined in the `installed.properties` file.

Server keystore	Description
`agentcomm.keystore`	The keystore contains the certificate and public and private key pair that the server uses to identify itself as the client. Keys are stored in the *serverInstallDir*`/conf/server/s2s-client-identity.keystore` file. These keys are not shared in high-availability environments. The server uses its web

Server keystore	Description
	certificate to identify itself as the server in a connection. The subject DN must be in this format: `CN=ucd-server-`*`EndpointID`*.
`encryption.keystore`	Server property encryption secret keys are stored in the *`serverInstallDir`*`/appdata/conf/encryption.keystore` file. These keys are shared in high-availability environments.
`server.keystore`	The `server.keystore` property points to the server keystore that contains the certificate and public and private key pair that the server uses to identify itself as the server. Keys are stored in the *`serverInstallDir`*`/appdata/conf/server.keystore` file. These keys are shared in high-availability environments.
`tomcat.keystore`	The keystore points to server UI/API HTTP server certificate and key. Keys are stored in the *`serverInstallDir`*`/opt/tomcat/conf/tomcat.keystore` file. These keys are not shared in high-availability environments.
`extra-cacerts.keystore`	The keystore points to the extra TLS/SSL certificates that are separate from the Java cacerts file. By using the extra keystore, you can eliminate the risk of losing custom certificates during Java upgrades. Keys are stored in the *`serverInstallDir`*`/appdata/conf/extra-cacerts.keystore` file. These keys are shared in high-availability environments.

Important: Do not lose the server public/private key. Recovery requires manually clearing the server certificate pins for every web agent. To help prevent loss, make a secure backup of all server keystores.

To override any of the server keystore passwords, see Changing passwords for the server KeyStore on page 2075.

Web agent relay keystores

Each agent relay contains two keystores. The **agentrelay** keystore controls the web connection between the agent relay and the server and agents. The **codestation** keystore controls HTTPS connections to the agent relay and is used with server identity verification. See Enabling server identity verification on page 2152.

The **agentrelay** keystore stores web agent communication client certificate and keys (alias `ucd-agentrelay-id`). The subject DN must be in this format: `CN=ucd-agentRelay-`*`EndpointID`*.

Note: For more information about changing relay keystore password, see Changing passwords for the agent relay keystores on page 2110

Certificate Expiration Enforcement and Auto-Rotation

You can configure the server and agents to mitigate the security risks associated with vulnerable agent certificate expiration dates.

When you install an agent, a self-signed certificate and a key pair are generated with a validity of 20 years. However, you can allow agents to automatically rotate their certificates at regular intervals of time. You can also configure the Deploy server to enforce the certificate expiration of all clients and set their validity.

Automatic rotation of agents certificate

You can configure the agents to generate new certificates periodically by enabling agent certificate auto-rotation.

You can configure agents to generate a new key pair and certificate automatically by using any of the following methods:

- The bulkSetAgentKeypairPolicy on page 2625 udclient command for generating the key pair of agents in bulk.
- The setAgentKeypairPolicy on page 2877 udclient command for generating the key pair of a specific agent. Alternatively, you can add the following parameter to the agent's `installed.properties` file:

  ```
  agentcomm.keypair.maxAgeDays=90
  ```

  The `agentcomm.keypair.maxAgeDays` property defines the validity of the certificate in days. The minimum allowed value is 90 days.

  Note: You must restart the agent if you are editing the agent's `installed.properties` file.

After you define the agents' maxAgeDays property, the agents are configured to automatically rotate their certificates. The agents will attempt to rotate their certificate 30 days before they expire. For example, if you have set the agents' maxAgeDays property as 90, the agents will attempt to rotate their key pair after 60 days.

Important: The unupgraded agents and agents that are often offline intentionally do not rotate certificates or might not rotate certificates promptly. You must ensure that you upgrade and start such agents once before their expiry to rotate their certificates automatically.

Notes:

- The certificate rotation does not interfere with any running deployment process.
- You can verify that the agents have rotated the certificate as configured from the agent's **Agent Security** page.

Enforcing certificate expiration and setting certificate validity

You must enforce the expiry of certificates and set their validity so that the server fails to communicate with the agents with expired certificates and the agents auto-rotate their certificates at a regular interval of time.

Before you begin

You must have completed the following tasks:

- Enabled the automatic rotation of agent certificates. See Automatic rotation of agents certificate on page 2166.
- You must rotate the server and relays client certificates manually before you enable the certificate expiration.

  When you set the enforcement of certificate expiration, the enforcement is set for all client certificates, including the servers' client certificate and the relays' client certificates. However, server and relays cannot rotate their certificates. Therefore, before enabling enforcement you must plan to perform regular rotation of server and relay client certificates manually before they expire.

1. Force the server to reject an expired certificate by adding the following property to the server's `installed.properties` file:

   ```
   agentcomm.clientCertificate.enforceExpiration=true
   ```

   The `agentcomm.clientCertificate.enforceExpiration` property causes the server to enforce the expiration date specified in the agent certificates regardless of their duration. For example, if the agent certificate is valid for 7300 days (20 years), the server accepts it for 7300 days (20 years).

   Notes:
   - If the enforceExpiration property is set to `false` or not set, then the agent's certificate expiration is ignored.
   - If the **verify.client.identity** parameter is `true` in the server's `installed.properties` file, then your certificate authority (CA) TLS rules will be applied. For example, the certificate is signed by the CA, the expiration date is enforced, and so on. These rules are enforced by Java before the enforceExpiration setting gets a chance to run. So, the enforceExpiration setting is redundant with the TLS system. Therefore, you should use `verify.client.identity=true` or `agentcomm.clientCertificate.enforceExpiration=true` setting, but not both.

2. Force the server to limit an acceptable certificate date range for valid certificates by setting the following parameter in the server's `installed.properties` file:

   ```
   agentcomm.clientCertificate.maxAgeDays=730
   ```

   The `agentcomm.clientCertificate.maxAgeDays` property defines the validity of the certificate in days. The minimum allowed value is 90 days.

   Note: Offline agents cannot rotate a certificate. If you have agents that are offline for extended periods of time, do not set `agentcomm.keypair.maxAgeDays` or `agentcomm.clientCertificate.maxAgeDays` to a combination that results in expired or invalid certificates. When these agents are started, they cannot rotate to a valid certificate and connect with the server.

   The following scenarios are explained that describe the server behavior on how you set the agent's and server's maxAgeDays property:

Scenario 1: When you set the agent's maxAgeDays property to 7300 days (20 years) and set the server's maxAgeDays property to 730 days (2 years).

In this scenario, the agent will automatically attempt to rotate the certificate every 20 years. If the agent is offline for 731 days or more, the server will reject the agent's certificate and will fail to communicate with the agent. You must start the agent and manually rotate the agent's certificate.

Scenario 2: When you set the agent's maxAgeDays property to 90 days (3 months) and set the server's maxAgeDays property to 730 days (2 years).

In this scenario, the lower bound is set by the agent. The server accepts the agent's certificate validity of 90 days and the agent will attempt to rotate the certificate every 60 days, which is 30 days before its expiry. If the agent is offline for 91 days, the agent will not be able to rotate its certificate even if the server's maxAgeDays property is set to 730 days. You must start the agent and manually rotate the agent's certificate.

Scenario 3: When you set the agent's maxAgeDays property to 90 days (3 months), have not enabled the enforcement, and the agent is offline for 91 days.

In this scenario, the server will be able to communicate with the agent when the agent is started later. The agent will rotate its certificate when it comes back online. No manual intervention is required in this scenario.

3. Restart the server to apply the changes.
   Result
   The expired agent certificates are now rejected and any existing certificate expire in the time period defined. As in the example used, the certificates will expire in 730 days even if they are not expired according to their stated expiration date.

Results

You have enforced certificate expiration and set the validity of the certificate.

Encryption key tools

Using the encryption key tools, you can manage your encryption keys.

HCL DevOps Deploy (Deploy) includes encryption tools that you can use to create, delete, and rotate your encryption keys. The keycreate, keydelete, and keyrotate tools are available in the `/bin` directory.

Creating an encryption key

Use the **`keycreate`** tool to create a key for secure property encryption without removing previous keys or changing the primary encryption key.

About this task

If you complete the processs, the tool provides instructions to make the new key primary. A new non-primary key cannot be used for property encryption. It must be made primary first.

To create an encryption key:

1. Run the `keycreate` command to create an encryption key.
   It also prints the alias of the new key. You can run the keycreate tool while the server is online. In an HA cluster, it must be run on only one cluster member because all clusters share the same keystore. The usage is keycreate and requires no arguments.
2. Configure the server to use the new key as its primary key.

   Edit the `installed.properties` file and set the **`encryption.keystore.alias`** property to the alias that the `keycreate` command prints. In an HA cluster, each member has its own `installed.properties` file, so you must edit each cluster individually.
3. Restart the server.

   The server loads keys and the primary key setting only at startup. In an HA cluster, you must restart each member.

Results

When this process is complete, the server (or all servers in an HA cluster) uses the new primary key to encrypt new data exclusively. Previous keys can be used only to decrypt previous data.

Rotating an encryption key

The **`keyrotate`** tool uses the primary encryption key to re-encrypt database secure data that was encrypted with other keys.

About this task

You can run the keyrotate tool in dry-run mode such that the database is not modified, and the tool only demonstrates the changes. The --change-database argument is required if you want to carry out the changes in the database. You must take a backup of the database before you use the --change-database argument.

The keyrotate tool can be run while the server is online. In an HA cluster, all members share the same database, so you must run the keyrotate tool on only one cluster member.

The keytool cannot detect if all members of an HA cluster are using the same primary key. If some servers are using different keys, the tool cannot guarantee that all data has been re-encrypted with the current primary key. To resolve this, update the misconfigured cluster members and re-run the tool by using the following procedure:

1. Edit the `installed.properties` file and set the **`encryption.keystore.alias`** property to the correct alias.

   In an HA cluster, each member has its own `installed.properties` file, so each must be edited individually.
2. Restart the updated server.

   The server loads keys and the primary key setting only at startup. In an HA cluster, you must restart each updated member.

Runtime

Generally, the keyrotate tool in dry-run mode requires a significant amount of time to run. Running the tool with --change-database argument might take much longer than the dry-run mode as writes are typically slower than reads. It's important to note that the run times involved with rotating and deleting the keys depends on the resources available in the database, and the amount of data that needs to be processed.

Rotating 3DES keys

When rotating encryption keys, the keyrotate tool displays below error when a 3DES key is found:

```
Cannot upgrade the server: a 3DES property encryption key was detected. 3DES keys are no longer supported. Before you can upgrade the server, you must first upgrade to a 7.2.3 release and use the 'keyrotate' tool to replace references to 3DES keys in your database. Then remove those keys from your property encryption keystore with 'keydelete' or with your JVM 'keytool' utility.
```

To rotate a secure property encryption key:

1. Create and configure a new primary encryption key. See Creating an encryption key on page 2168 for the procedure.
2. Dry-run the keyrotate command and verify that the encryption key is rotating.
   You can use the following supported arguments with the keyrotate command:

Supported arguments	Description
`--workers N`	Sets the number of concurrent workers. The default value is `2`, and the minimum required value is `1`. The database must accept N+1 concurrent connections. Values greater than `8` might not reduce tool execution time.
`--status-interval-secs N`	Prints the status of keyrotation every `N` seconds. The default is `5` seconds. You can set the interval to `0` to disable printing. Changes are logged into the `stdout` file. To troubleshoot errors, check the `stderr` log file.
`--batch-sizes`	Reduces the memory requirements for tables with large rows , such as `wf_workflow_trace` and `vc_persistent_record` tables. For example, you can use the argument as follows: `--batch-sizes "vc_persistent_record=15,wf_workflow_trace=10"` The argument value is a comma-separated list of table names with their reduced batch size. The default batch size for all tables is 50. **Note:** You may need to quote the argument depending on your shell. The quotes used in the example command are not part of the syntax.

Result

The output demonstrates the changes without making actual changes to the database.

3. For a real-run execution, run keyrotate with the --change-database argument to rotate the encryption keys.
   Running the keyrotate tool with the `--change-database` flag enables modification of the database.

   ```
   ./keyrotate --product-home "/opt/devops-deploy/server" --change-database
   ```

   Note: Use the same arguments for both the steps to ensure that the dry-run is as close as the real run.

   Result

   The keyrotate tool lists the keys in keystore, the keynames, and their rotation status. An example output is shown below:

   ```
   key=[desedekey<key1>] refs=0 replaced=0
   key=[aes128key<key2>] refs=2 replaced=2
   key=[aes128key<key3>] refs=0 replaced=0
   key=[aes128key<key4>] refs=12953555 replaced=0
   key=[desedekey<key5>] refs=0 replaced=0
   unknown=[desedekey<key6> refs=10
   ```

   Note: For best results, do not delete previous keys. You might require them to decrypt older data that was encrypted with the previous keys. See Deleting an encryption key on page 2171 for the procedure and an explanation for why this is not recommended. However, you must delete any 3DES keys to be able to use 7.3.0 or newer versions. The keyname in output can be used to delete the 3DES keys.

Deleting an encryption key

The **`keydelete`** command removes a key for secure property encryption.

About this task

You can run the tool in dry-run mode such that the keystore is not modified and the tool only demonstrates the change. The --change-keystore argument is required to cause the tool to complete the change.

The keydelete tool can be run while the server is online. In an HA cluster, you must run the tool on only one cluster member because all members share the same keystore.

Note:

- The keydelete tool cannot remove the primary encryption key.
- The tool can only determine the primary key for the local server member in an HA cluster. It cannot detect if other members have configured a different primary key. For best results, set up the cluster so that all members use the same primary key.

Note: Do not delete keys unless you have a compelling reason to do so. Only the primary key is used for encrypting new secure data. After the previous data is re-encrypted with the new key by using the keyrotate tool, previous keys are not used in normal operation. In some scenarios, you might require previous keys, such as decrypting data

that you restore from a backup that used previous keys or when importing configurations that were created with a previous key. Retain previous keys for these kinds of scenarios.

To delete an encryption key:

1. Confirm that the server is configured to use a different key as its primary.
   The tool cannot delete the primary key. View the `installed.properties` file and check that the value of the **encryption.keystore.alias** property is not the alias of the key that you are targeting for deletion. In an HA cluster, each member has its own `installed.properties` file, so each must be checked individually.
2. Update servers that use the targeted key.

   Edit the `installed.properties` and set the **`encryption.keystore.alias`** property to the alias of another key. In an HA cluster, each member has its own `installed.properties` file, so you must edit each member individually. For best results, set up the cluster so that all members use the same primary key.
3. Restart any updated servers.

   The server loads keys and the primary key setting only at startup. In an HA cluster, each updated member must be restarted.
4. Run the keydelete command without the --change-keystore argument to verify the action.
   In an HA cluster, all members share the same keystore file, so you must run the `keydelete` command on only one cluster member. For example, run the following command:

   ```
   keydelete --target-key <key>
   ```

   Here, the --target-key <key> flag is required. The <*key*> variable is the name of the key you are targeting for deletion. The key is not deleted unless `--change-keystore` is also specified.
5. Run the keydelete command again with the --change-keystore argument to complete the action.
   In an HA cluster, all members share the same keystore file, so you must run the **`keydelete`** command on only one cluster member:

   ```
   keydelete --target-key <key> --change-keystore
   ```

   Note that the `--change-keystore` argument is optional. It enables the modification of the keystore. Unless this flag is specified, the tool only demonstrates the change without completing the action.
6. Restart the server.

   The server never unloads a key. In an HA cluster, you must restart each member.

Authorization realms

Use the **Authorization Realms** pane to create authorization realms and user groups for the server. Groups can be imported from external systems, such as LDAP.

The available authorization realms for the server are as follows:

Internal Storage

Uses internal role management. The default authorization realm (Internal Security) is of this type.

LDAP or Active Directory

Uses external LDAP role management.

SSO

Provides single sign-on authorization.

OpenID Connect

Provides integration with Microsoft Entra ID for role-based authorization and Okta for group-based authorization.

Creating an internal storage authorization realm

Internal storage realms do not retrieve users from any external source. Instead, you add users to internal storage authorization realms manually.

1. On the server, click **Settings > Authorization (Groups) > Create Authorization Realm**. The **Create Authorization Realm** dialog box opens.
2. Enter a name in the **Name** field.
3. Ensure that **Internal Storage** is selected in the **Type** list.
4. Click **Save**.

Creating an LDAP authorization realm

An LDAP authorization realm defines how to use an external LDAP server for group authorization.

Before you begin

You must have the URL of the external LDAP server that you want to use for authorization.

About this task

An LDAP authorization realm defines how to search user groups. Typically, authorization realms work in tandem with LDAP authentication realms. When unknown users attempts to log on, an external LDAP server is used to authenticate them by using the authorization and authentication realms that you define. Administrators can also use the authorization and authentication realms to import users. Before importing users, make sure that authorization realm matches with the authentication realm unless there are two different LDAP systems being used. You might want to import users and assign them to teams before their first logon attempt. When you import users, you can supply additional parameters to further refine the search. For more information, see Importing LDAP users on page 2184.

To create an LDAP authorization realm, you identify the URL of the LDAP server, and define a role-based search. If you use an LDAP authentication realm, you do not need to define a user-based search. If you use an SSO authentication realm, you must also define a user-based search.

1. On the server, click **Settings > Authorization (Groups) > Create Authorization Realm**. The **Create Authorization Realm** dialog box opens.
2. In the **Name** field, enter a realm name.
3. In the **Type** list, select **LDAP or Active Directory**.
4. In the **LDAP URL** field, enter the URL of the LDAP or LDAPS server.
   Separate multiple servers by commas.
   Example
   For example, `ldap://ldap_server.my_domain.com:389,ldap://ldap_server.my_domain2.com:389,ldaps://ldaps_server.my_domain3.com:389`.
5. Define a role-based search by completing one of these steps:

   a. If you want to reference roles by members, select **Roles in LDAP reference their members; look up group membership by searching for roles**, and then specify the following parameters:

   Table 699. LDAP roles referenced by member properties

Field	Description
Group Search Base	The directory that is used for group searches, such as `ou=employees,dc=mydomain,dc=com`.
Group Search Filter	The LDAP filter expression that is used when you search for user entries. The user name replaces the *{1}* variable in the search pattern and the full user distinguished name (DN) replaces the *{0}* variable, for example, `(&(uniqueMember={0})(cn=BSO*))`.
Group Name	The name of the entry that contains the users' group names in the directory entries that are returned by the group search. If this entry is not specified, no group search runs. For example, enter `cn`.
Search Group Subtree	Subtrees (if any) are searched. If the item is not selected, the search is limited to the group search base.
Search For Containing Groups	Perform additional lookups to find indirectly assigned groups. This option may significantly increase the amount of time required to authenticate users. Consult your LDAP administrators before enabling this option.

   The values in the **Group Search Base** and **Search Group Subtree** fields define the scope of the search. Within the scope, groups that match the group search filter are searched. The value in the **Group Name** field specifies the LDAP attribute that contains the group name.

   b. If you want to reference roles by user attributes, select **User roles are defined as an attribute on that user; look up group membership using this attribute**, and then, in the **User Group Attribute** field, specify the attribute that contains group names in the user directory entry.
   If user groups are defined in LDAP as an attribute of the user, you must use the Group Attribute configuration.

6. **Optional:** Define a user-based search by completing one of these steps:

   Note: If you plan to use an SSO authentication realm with this authorization realm, you must define a user-based search. If you plan to use an LDAP authentication realm, you can skip this step.

   a. If user records exist in multiple directories, select **LDAP users may exist in many directories; search across LDAP using a criteria.**, and then specify these parameters:

   Table 700. LDAP user properties

Field	Description
User Search Base	The starting directory for the search, such as `ou=employees,dc=mydomain,dc=com`.
User Search Filter	The LDAP filter expression that is used when searching for user entries. The user name replaces the *{0}* variable in the search pattern, for example, `uid={0}`. If the value is not part of the DN pattern, wrap the value in parenthesis, such as `(sAMAccountName={0})`.
Search Group Subtree	Subtrees (if any) are searched. If the item is not selected, the search is limited to the search base.

   b. If users exist in a single directory, select **LDAP users exist in a single directory; use a pattern to create the DN for users**, and then, in the **User DN Pattern** field, specify the name.
   The name is substituted in place of *{0}* in the search pattern, such as `cn=[0],ou=employees,dc=mydomain,dc=com`.

7. **Optional:** Secure the communication between the LDAP server and the HCL DevOps Deploy (Deploy) server as described in Configuring SSL on Apache Tomcat and LDAP servers on page 2159.
8. **Optional:** Set the length of time for the server to wait for a response from the LDAP server. On the server, in the `installed.properties` file, set the property **com.sun.jndi.ldap.read.timeout** to the timeout period in milliseconds. Then, restart the server.
9. **Optional:** Enable **Nested Groups**. This feature enables Deploy to recursively search for roles in the LDAP server. **Note:** If a user logs in who has many direct LDAP group mappings, this feature could generate many extra LDAP queries.

   if a user logs in that has a lot of direct ldap group mappings

Results

The first time an unknown user attempts to log on, LDAP authorization realms are searched in an attempt to identify the user. If the user is found, a corresponding user ID is created in Deploy. In addition, if the user is part of an LDAP group, that group is imported too.

Creating an SSO authorization realm

A single sign-on (SSO) authorization realm uses an external server for authorization.

1. On the server, click **Settings > Authorization (Groups) > Create Authorization Realm**. The **Create Authorization Realm** dialog box opens.
2. Enter a name in the **Name** field.
3. Ensure that **SSO** is selected in the **Type** list.
4. Specify these parameters:

Table 701. SSO properties

Field	Description
Groups Header	The name of the SSO server parameter that contains the list of groups to which the user belongs.
Groups Delimiter	The string that delimits values that are found in the group header. Regular expression special characters must be escaped with the backslash (\) character.
Groups Regex	The regular expression that is used to parse the values in the group header. If specified, only the first matching group is used. If left unspecified, all values in the group header are used.

The values in the group header that match the search criteria are used to create HCL DevOps Deploy (Deploy) groups into which the user is placed.

Creating an OpenID Connect authorization realm

You can create an OpenID Connect (OIDC) authorization realm to use Microsoft Entra ID or Okta server for authorization.

1. On the server, click **Settings > Authorization (Groups) > Create Authorization Realm**. The **Create Authorization Realm** dialog box opens.
2. Enter a name in the **Name** field.
3. Ensure that **OIDC** is selected in the **Type** list.
4. Select any of the following vendors:

Table 702. OIDC Vendors

Vendor name	Description
Microsoft Entra ID	Allows you to retrieve group details from Microsoft Entra ID. When selected, specify any of the following group source: ◦ App Roles – To enable Application Role validation through the `roles` claim, the Microsoft Entra ID authorization realm requires specific configuration. You must ensure that the Entra ID manifest is set to `requestedAccessTokenVersion: 2` and that the application is exposed as an API. Finally, you must map the resulting API ID as a designated scope within the Deploy authentication realm settings.

Vendor name	Description
	◦ Security Groups – Microsoft Entra ID authorization realm calls the Microsoft Graph API to fetch Security Groups. The group's Object ID (GUID) is used to map to groups in Deploy. You must ensure that the Entra ID manifest is set to `requestedAccessTokenVersion: 2`.
Okta	To enable group-based authorization, the Okta realm validates the `groups` claim within the security token. This action requires a dedicated authorization server to be defined in Okta. Additionally, configure the application's authentication realm with the specific Issuer and associated endpoints provided by that authorization server.

5. Click **Save**.

Results

You have created an OIDC authorization realm with the selected vendor.

Creating a security group

You can create a group and grant permissions simultaneously to multiple users in a group. By grouping users, you can simplify the management of access control across various applications, environments, and resources.

About this task

You can create groups to authorize realms of the internal storage type. Other types, such as Lightweight Directory Access Protocol (LDAP) and import groups, do not allow manually created groups.

Note: Adding groups to LDAP and single sign-on (SSO) realms is deprecated.

1. Log in to Deploy.
2. Click **Settings > Authorization (Groups) > Groups > Create Group**.
   The **Create Group** dialog is displayed.
3. Type a name for the group in the **Name** field.
4. Optional: Type the description for the group in the **Description** field.
5. Select an authorization realm from the drop-down.

   Note: Groups are applicable only within the selected realm.

6. Click **Save**.

Results

You have created a group.

What to do next

You can add users to groups mannually. See, Adding users to groups manually on page 2178.

Related information

Creating an internal storage authorization realm on page 2173

Creating an LDAP authorization realm on page 2173

Creating an SSO authorization realm on page 2176

Adding users to groups manually

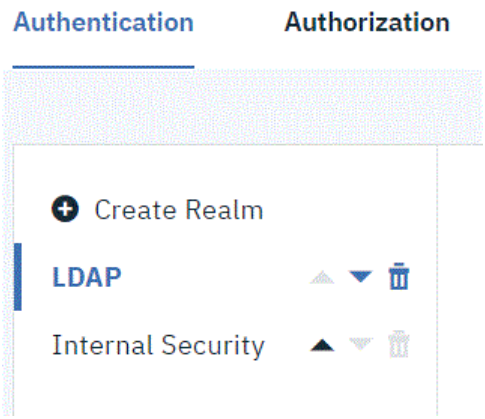
Authorization realms of the internal storage type can have manually created users. Others types, such as LDAP, import user groups cannot have manually created users.

1. On the server, click **Settings > Authorization (Groups) > Groups > Members > Add Member**. The **Add Group Member** dialog box opens.
2. Select the user from the **Group Member** list.
3. Click **Save**.

Authentication realms

Authentication realms manage users and determine user identity within authorization realms for the server.

Users can be created manually or imported from external systems, such as LDAP. Authentication is determined following the hierarchy of realms that is displayed on the **Authentication** tab. In the following figure, authentication is first determined in the Internal Security realm followed by the LDAP realm. A user who is listed in the LDAP realm can have different authorizations from those in the other realms.



If you have a number of authentication realms, you can reorder them by using the operation tools. Each realm can be moved up to a higher priority, moved down, or deleted by using the operation tools.

For information about authorization realms, see Authorization realms on page 2172.

Creating authentication realms

Use authentication realms to manage users and determine their identity within authorization realms.

About this task

To create an authentication realm on the server, specify where to store user information, such as internal storage on the server, a single sign-on service, an LDAP or Active Directory, or in OpenID Connect.

1. On the Web UI, click **Settings > Authentication (Users) > Create Realm**.
   The **Create Authentication Realm** window opens.
2. Enter a name and description for the realm.
3. Select the authentication realm type from the **Type** list.
   The available authentication realm types are: **LDAP or Active Directory** on page 2179, **Single Sign-on (SSO)** on page 2181, **Internal Storage**, and **OpenID Connect** on page 2181.
   If you select **Internal Storage**, no additional parameters are required.
   If you select **LDAP or Active Directory**, specify the following parameters:

Table 703. LDAP or Active Directory authentication realm properties

Field	Description
LDAP URL	The URL of the LDAP server that begins with `ldap://` or `ldaps://`. You can provide more than one URL, separated by provide more than one URL, the server tries the URLs one at a time until the server succeeds.
Authentication Mechanism	Indicates the authentication mechanism for use. The default mechanism is Simple. Select **DIGEST-MD5** to configu server to use DIGEST-MD5, and then specify the SASL realm.
Search Anonymously	When this checkbox is selected, LDAP accepts anonymous queries. If this check box is cleared, specify the LDAP s connection DN and associated password. This check box is selected by default.
Search Connection DN	Complete the LDAP distinguished name to search. This parameter is required if the **Search Anonymously** check bo
Search Connection Password	The password that is used for LDAP searches. This parameter is used with the value in the **Search Connection DN**
Specify how to search LDAP	Specifies how LDAP is searched. If users exist in multiple directories, select **LDAP users may exist in many directo across LDAP using a criterion**. Otherwise, select **LDAP users exist in a single directory; use a pattern to create the** Depending on the selection, more fields are displayed.
User Search Base	When you search multiple directories, specify the starting directory that is used for searches, such as `ou=employees,dc=mydomain,dc=com`.

Field		Description
	User Search Filter	The LDAP filter expression to use when you search for group entries, such as `(&(mail={0})(objectclass=ePerson)(sAMAccountName={0}))`. The user name replaces the *{1}* variable in the search p the full user DN replaces the *{0}* variable. If the value is not part of the DN pattern, enclose the value in parentheses `(accountName={0})`. For more information, see the help information for your LDAP server and look for information a user search filters.
	Search User Subtree	When you search multiple directories, select this check box to search directories that are subordinate to the base d
	User DN Pattern	When you search a single directory, the name is substituted in place of 0 in the pattern, for example, `cn={0},ou=employees,dc=yourcompany,dc=com`.
Name Attribute		Contains the user name in LDAP.
Email Attribute		Contains the user email address in LDAP.
Login Mechanism		Enables you to use OpenID Connect as an authentication mechanism with two modes: UID and alternate ID. For the properties that are common to both types, refer to the OpenID Connect authentication realm properties in th follows.
	Force Authentication through OpenID Connect	Prevents direct username and password authentication with LDAP for this realm.
	UID Claim	The OpenID Claim that contains the unique ID to use for LDAP lookup.
	Alternate ID Claim	The OpenID Claim that contains the alternate or custom ID to use for LDAP lookup.

Field		Description
	Alternate ID Search	The LDAP search filter that uses the alternate ID as `{0}`.

If you select **Single Sign-on**, specify the following parameters:

Table 704. SSO authentication realm properties

Field	Description
User Header Name	The header that contains the list of users.
Email Header Name	The header that contains the list of user email addresses.
Logout URL	The URL to which users are redirected after they log out of HCL DevOps Deploy (Deploy).

If you select **OpenID Connect**, specify the following parameters:

Table 705. OpenID Connect authentication realm properties

Field	Description
OpenID Provider Vendor	The vendor of the OpenID Provider. On selecting a vendor, the group membership is processed with Oper
OpenID Provider and Client Identity	
Client ID	The client ID that is registered with the OpenID provider.
Client Secret	The client secret that the OpenID provider issues upon registration.
Issuer	The issuer identifier for the issuer of the token response. Enter the issuer identifier, and click **Discover** to endpoint configuration automatically. The issuer identifier must not contain a query or fragment.
OpenID Endpoints	
JWKS URI	The JSON Web Key Sets (JWKS) URI endpoint.
Authorization Endpoint	The endpoint for authorization with the OpenID provider.
Token Endpoint	The endpoint for token requests with the OpenID provider.
Userinfo Endpoint	The endpoint for user information requests with the OpenID provider.
End Session Endpoint	The endpoint for RP-Initiated logout request (Deploy logout request). On logout, the Deploy user is redirected to the OpenID Provider logout page from which the user can log o Provider.
Custom OpenID Claims	
Username Claim	The claim that contains the username or account name of the user. Defaults to `sub`.

Field	Description
Name Claim	The custom claim that you want to use to display as a name in the Web UI. Defaults to `name`.
Email Claim	The custom claim that contains the user's e-mail ID and is displayed as email in the Web UI. Defaults to `e`
Additional Scopes	Any scope values that should be sent to the OpenID Provider in addition to the defaults openid, profile, ar
OpenID Options	
End session with ID token hint	Append the `id_token_hint` parameter to the end session endpoint URL. The effect of the hint is specific t provider. Some providers require the hint to successfully log out. Other providers alter their behavior with logout. Some providers may ignore it or some do not require it at all. Refer to the provider documentation

Notes:

- The Custom OpenID Claims and OpenID Options are not available in LDAP with OpenID Connect type authentication realm.
- Make sure that the external agent URL matches with the OpenID provider configuration for the redirect URI.
- The OpenID provider must be set to use RS256 as its token signature algorithm, so that Deploy communicates with it correctly.

4. Disable password-based login for the authentication realm by checking the **Disable Browser Login** option.

Notes:

- Administrators can still log in by using the login password via the admin URL, that is `https://hostname:port/admin`.
- Authentication tokens that are defined in this realm continue to work.
- Changing this setting does not disrupt active sessions.

5. Enter the number of user login attempts to accept in the **Allowed Login Attempts** field.
   A blank value means that an unlimited number of attempts is allowed. If a user exceeds the attempt limit, use the **Unlock User** action on the **Authentication** page to unlock the user.
6. Select the authorization realm from the **Authorization Realm** list.
   The internal security realm is available by default. See Authorization realms on page 2172.

Note: If you use an LDAP authentication realm with an LDAP authorization realm, the settings in this authentication realm override the settings in the LDAP authorization realm. If you use an SSO authentication realm with an LDAP authorization realm, you must specify connection settings on the LDAP authorization realm.

Results

The new user is created or imported, and listed on the **Authentication** page. When new users log on to the server and use their LDAP or SSO credentials, they are listed in the **Authentication** tab.

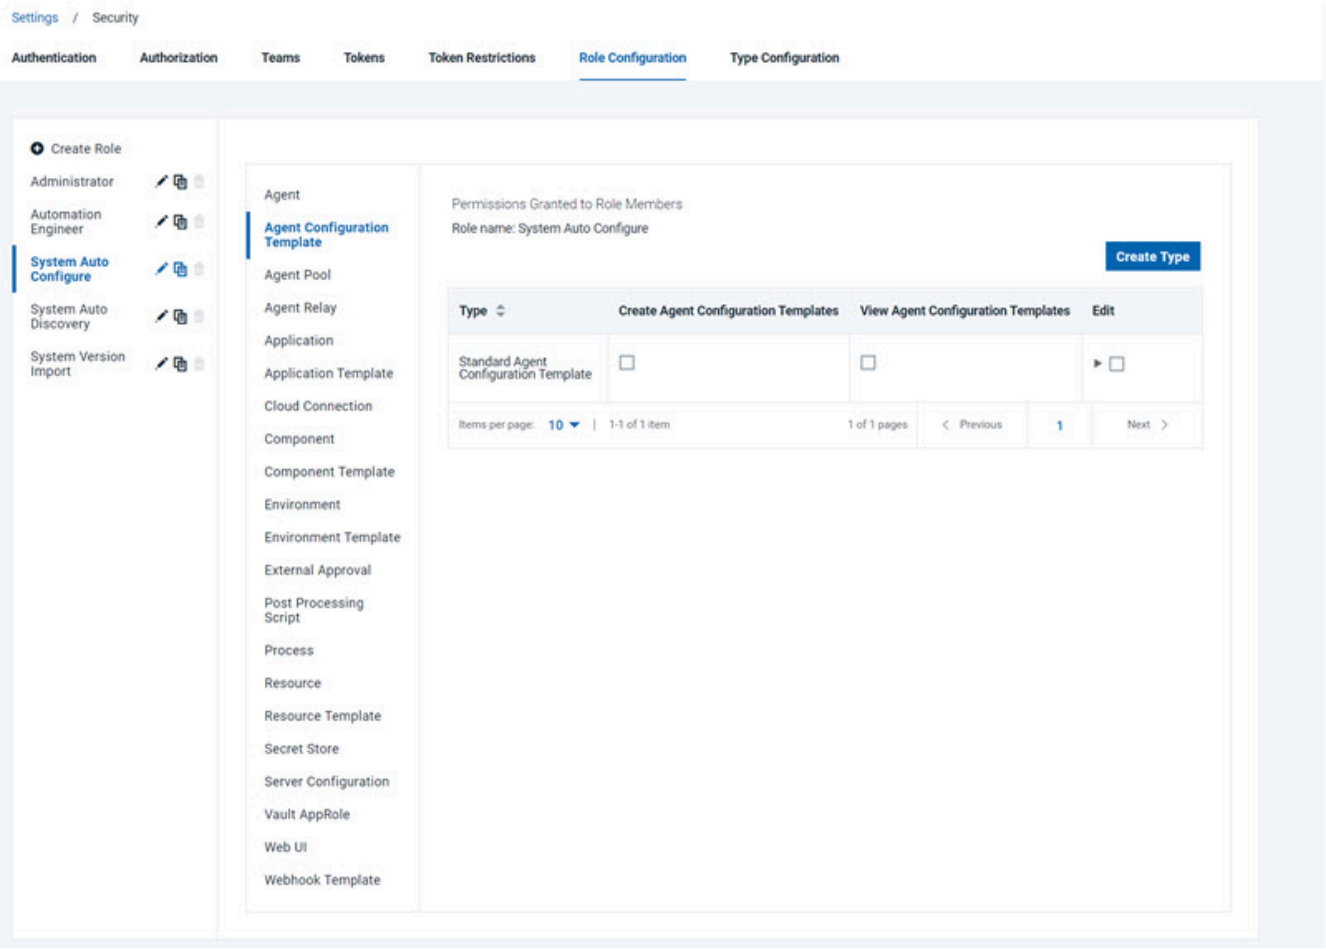
Note: In most cases, do not manage user passwords or remove users from the **Authentication** page. If an active user is removed from Deploy, the user can still log on to the server while their LDAP credentials are valid.

Creating users manually

You can manually create users on the server for internal security and SSO type authentication realms.

Before you begin

Editing user information requires permission to view the **Authentication (Users)**page. Make sure that the user's role has the **Manage Teams** and **WebUI | Settings Tab** permissions enabled.



1. On the server, click **Settings > Authentication (Users) > *target realm* > Create User**.
2. In the **Create User** dialog box, enter the user information:
    a. Enter the user name that is associated with the account in the **Username** field.
    b. Enter the password for the user in the **Password** field.
    Password complexity can be configured from the System Settings page.

c. Enter the user's name in the **Name** field.

d. Enter the email address that is associated with the account in the **Email** field.

3. Save your work when you are done.

What to do next

After you add a user to an authentication realm, you must also add the user to groups or teams.

Importing LDAP users

On the server, LDAP authentication realm users are imported from external LDAP systems.

About this task

LDAP authentication realms are searched whenever an unknown user attempts to log on to the server. If the user is found, a corresponding record is created in HCL DevOps Deploy (Deploy). Because LDAP users cannot be assigned to groups and teams until they have corresponding Deploy accounts, you can import users directly from LDAP systems.

1. On the server, click **Settings > Authentication (Users) > *selected LDAP realm* > Import User**.
2. In the **Import Users** dialog box, enter a name or pattern to search in the **Username or Pattern** field.
   The asterisk character (*) can be used as a wildcard in the pattern. If you use an asterisk by itself, you import all users for the selected LDAP realm.
3. Click **Save** to start the search.

Updating LDAP users and groups

LDAP users' name, addresses, and groups can be updated.

About this task

LDAP users and groups can be updated in following ways:

- **LDAP or Active Directory Authentication Realms** using LDAP authorization realms to update names and email addresses.
- **SSO authentication realms** using LDAP authorization realms to update groups. Names and email addresses are updated when user logs-in through SSO.

Note: You can not update users or groups if there is no LDAP Authorization realms being used.

1. On the server, click **Settings > Authentication (Users) > *select LDAP/SSO realm* > Update Users** for the LDAP authentication realm to use.
2. In the **Update All Users** dialog box, click **Submit** to update the LDAP user information for the selected LDAP or SSO realm.
   Result

The names, email addresses, and/or groups for all users in the realm are updated.

Note: User information is also synced when a user logs-in manually from the LDAP or Active Directory.

Editing user information manually

You can manually edit the stored name, email address, password, and additional settings for user accounts on the server for internal security realms. For an SSO authentication realm, name and email address are passed in via HTTP headers (for example, from an HTTP proxy that is translating Kerberos tokens into HTTP headers).

Before you begin

Editing user information requires permission to view the **Authentication (Users)** page. Make sure that you are assigned to an appropriate team and that the **Web UI | Settings Tab** permissions are granted.

Note: All of the following user configuration is optional and does not require to be performed in a particular order. You can make the changes as appropriate.

1. Go to **Settings > Authentication (Users)** and select an authentication realm.
2. In the **Actions** column, click **Edit** for the user account that requires updates.
    a. Edit the **Name** and **Email** fields as needed.
    b. Specify whether you want to disable automatic deletion of the user by using the **Exempt from Auto-Delete** option.
    c. Click **Save**.
3. Click **Delete** for the user that you want to delete.

    The user is removed from any groups and roles. This user may be re-added if this authentication realm is configured to create users automatically.
4. Click **Reset Password** to change the password for a user account.
    The **Reset User Password** window is displayed.
    a. Enter the new password in the **Password** field.
    b. Click **Save**.
5. Click **Lock User** for the user that you want to lock.
    The user is locked till the time you unlock it manually.

Results

The user information is updated.

Locking and deleting user accounts automatically

As part of your secured user account management process, you can configure the system to lock and delete idle or inactive users automatically.

Before you begin

You must have the following role permissions:

- **Web UI > Settings Tab**
- **Server Configuration > Edit Basic System Settings**
- **Server Configuration > View Users**

About this task

A user account is considered idle or inactive if the user has not logged in for a specific duration. You can configure the system to lock these accounts after a specific duration and further delete them, if neccessary.

1. On the Web UI, go to **Settings > System Settings > Security** settings.
2. Specify the number of days users must be inactive before their accounts are locked in the **User Idle Days to Lock** field.

   Note: You can leave the field empty or set the value to 0 to disable locking of the user accounts.

3. Specify the number of days users must be inactive before their accounts are deleted in the **User Idle Days to Delete** field, .
   The value must be greater than the value specified in the **User Idle Days to Lock field** or you can set the value to 0 to disable deletion of the user accounts.
4. Save the settings.

Results

You have configured automatic locking and deletion of user accounts in the system. The users are locked and deleted automatically based on your defined settings.

What to do next

At any point of time, you can click **Preview Idle User Lock** in the system settings to check the number of user accounts that are going to be locked and deleted. Additionally, you can view the Last Logon Time, Locked Time, Will Lock, and Will delete times of each user in the **Authentication (Users)** page.

Enforcing a maximum login duration

You can enforce a maximum login duration to require users to re-authenticate after a specific period, regardless of the user activity. This setting is useful for organizations whose security policies prohibit persistent login sessions.

Before you begin

You must have the following role permissions:

- **Web UI > Settings Tab**
- **Server Configuration > Edit Basic System Settings**
- **Server Configuration > View Users**

About this task

The **Maximum Login Time** setting overrides the **Remember me** configuration. After this setting is active, a countdown timer is displayed in the log-off menu. The system provides the following visual warnings:

- A black banner appears when the session time remaining reaches 30 minutes.
- The message changes to red when the time remaining drops below 5 minutes.

1. In the Web UI, navigate to **Settings > System Settings > Security** settings.
2. In the **Maximum Login time (hours)** field, specify the number of hours users may remain logged in.

   Note: If the value is set to 0 or a negative number, the maximum login time enforcement is disabled.

3. Save the settings.
4. Log out and log back into the Web UI.

   Note: Changes to this setting only apply to new sessions. Existing active sessions remain unchanged until the user logs out and back in.

Results

The maximum login time is enforced. When the timer reaches zero, the following actions occur:

- The server terminates the session immediately.
- The client triggers the logout endpoint and refreshes to the login screen.
- OIDC and single sign-on (SSO) sessions are redirected for full de-authentication.

Roles and permissions

A *role* is a list of permissions that users have on the HCL DevOps Deploy (Deploy) server. These permissions include the ability to create, edit, and delete objects, such as applications, environments, and components. The permission also includes the parts of the server interface that users can access.

When you assign users to a role, they get all permissions that are granted to the role. However, these permissions apply only to the team on which the user has the role. For example, if a user has the Developer role on team A, that user has the role permissions on the environments, applications, and components that are assigned to team A. The user does not have any permissions on the environments, applications, and components that are assigned to team B unless you assign that user a role on team B.

You can assign permissions to a user only by giving that user a role on a team. You cannot assign a user to a role without also putting that user on a team. Similarly, you cannot assign a user to a team without giving that user a role on the team.

Typically, the permissions that are granted to a role define a particular activity that a user might do, such as running deployments. Users can be assigned to more than one role, and users can have different roles on different teams. You decide the number of roles and their permissions that you assign to users. Initially, Deploy provides one role, the Administrator role, which has all possible permissions granted to it.

Note: If a role grants the Create permission for some object type, such as components, it is important that the role also grant the Edit Basic Settings and Manage Teams permissions for that type. Otherwise, the options for creating the object are limited.

The Create permission is different from other permission types. The create type is not scoped to a specific resource but is more broadly scoped. Team members with a create-type permission can create resources of the related type without team members first being attached to a specific resource. To continue the environment example, users with the create environment permission can create environments even if their team is not attached to a specific environment.

Most objects have the create, view, and edit permissions that most object types. Environments and processes have an execute permission. This permission controls the ability to run processes.

Creating roles and assigning permissions

You can create roles on the server and assign permissions to them.

About this task

By default, new roles have no permissions. Therefore, when you create a role, you must add all the permissions for that role. For example, if you do not add permission to view the pages of the server user interface in the **Web UI** section, users can log in to the server but cannot see any information.

Several default roles are available. These roles have matching default users.

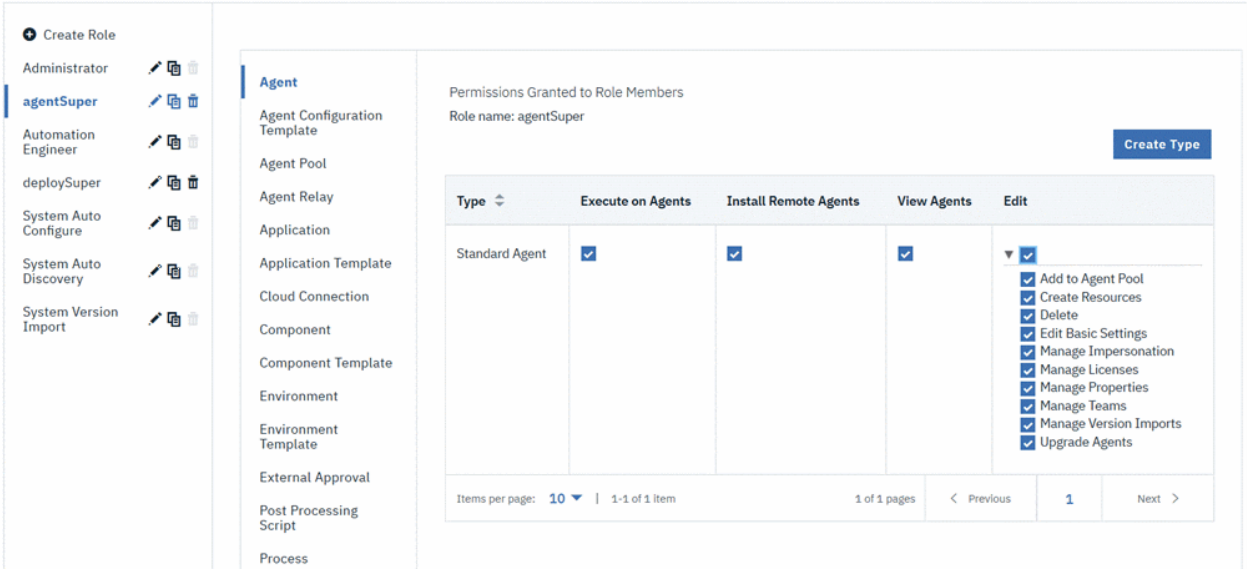
- **Administrator** role has all permissions. It is appropriate for administrators.
- **Automation Engineer** is an example of a role for a typical non-adminstrator user. It includes permissions to create and edit most things on the server, including applications, component, and processes, but not the permission to delete things, change permissions, or change system settings.
- **System Auto Configure** role has the permissions to create resources.
- **System Auto Discovery** role is used by plug-ins that discover information about systems, such as the WebSphere® Application Server - Deploy plug-in.
- **System Version Import** role has only the permission to manage versions.

Create roles and assign them permissions as follows:

1. On the server, click **Settings > Role Configuration**.
2. In the **Role Configuration** pane, click **Create Role**.
3. Enter a name for the role, and then click **Save**.
4. Click the role to select it.
5. With the role selected, select the object type to which you want to assign permissions, such as environments, applications, or components.
   All security types for the selected object type are displayed. For information about creating security types, see Creating security types on page 2221.

In the following figure, the security types for the **Agent** product area are displayed. Because the `agentSuper` role is selected, only that role is affected by permission changes to the `Standard Agent` and `agentManager` security types. That is, if you select the **Agent** object type for the `deploySuper` role, the granted permissions reflect the settings that were defined the last time that role was modified.

Tip: Some users might no be unable to see agent relays in the user interface, even though they were visible before the upgrade. You can set the permission for these users to view agent relays: Click **Agent Relay** in the permissions area list, and then select **View Agent Relays**.



6. In the **Permissions Granted to Role Members** pane of an object type, grant permissions by selecting the associated checkbox for a security type.
   You can select all edit subpermissions by selecting the **Edit** check box. To deselect all subpermissions, clear the corresponding check boxes. Select individual subpermissions by expanding the **Edit** list and clicking the corresponding check boxes. For information about editing subpermissions, see Security types on page 2219

   Note: If a role grants the Create permission for some object type, such as components, it is important that the role also grant the Edit Basic Settings and Manage Teams permissions for that type. Otherwise, the options for creating the object are limited.

7. **Required:** Click the **Web UI** category, and specify the pages in the server user interface that the role can access. Each option in this list refers to a top-level page in the user interface.
   Example
   For example, if you do not select the **Applications Tab** option in this list, users with this role do not see the top-level **Applications** tab when they log in to the server. You can select each tab separately.
8. **Optional:** If the role users need system permissions, such as the ability to change permissions, click **Server Configuration**, and specify those permissions.

For more information, see Setting server configuration security on page 2190.

9. **Optional:** Create a role from an existing role by clicking icon next to the role you want to copy.
   Copying a role helps you save time in creating a similar role. The copied role duplicates the permission set of the existing role to allow to make minor modifications.

What to do next

Assign roles to users by adding users or groups to teams. You cannot assign a role to a user directly; users must be assigned roles when they are added to teams. See Assigning users to teams on page 2214.

Setting server configuration security

Set the server configuration permissions to define what users can do with the HCL DevOps Deploy (Deploy) server security, also referred to as system security. Typically, these permissions are granted to administrative roles.

The following server configuration permissions are available:

Table 706. Server configuration permissions

Permission	Description
Add Team Members	Add users to roles that have the same or fewer permissions than those of the granting user.
Bulk Manage Cleanup	Allows users to view, and edit the cleanup settings of multiple components and environments from the **Cleanup Configuration** page.
Create with Team Assignment	Grants users the ability to add any additional team and type combination to an object if they have the Create permission on atleast one team/type mapping.
Create Tags	Grants users the permission to create tags. Users can create tags in the **Tags** page with only this permission. To create tags on an object, users must have the **Edit Basic Settings** permission on the object type. See Creating tags on page 2520.
Edit Basic System Settings	Enables users to edit the options on the **System Settings** page. See, System settings on page 2086. This activity is written to the audit log.
Edit Network Settings	Grants users the permission to access the **Network** page and manage servers in a server cluster.
Edit Tags	Grants users the permission to edit tags. Users can edit tags in the **Tags** page. Users can apply tags to an object only if they have the **Edit Basic Settings** permission enabled on the object type. See Adding tags to objects on page 2521.
Manage Audit Log	Grants users the permission to manually cleanup the audit log, and configure automatic cleanup settings. If you have this permission but not the edit basic

Table 706. Server configuration permissions (continued)

Permission	Description
	settings permission, you can edit the audit cleanup settings from the **Audit Log** page. This activity is written to the audit log.
Manage Auth Token Restrictions	Create, modify and delete token restrictions. See, Restricting authentication tokens on page 2223
Manage Diagnostics	Enable users to access the diagnostics information including the Rest Call Log, Java Thread dumps, and Metadata indexing. This activity is written to the audit log.
Manage Java Packages	Allows users to add and delete Java packages.
Manage Logging Settings	Grants users the permission to view the **Logging** page and edit the log4j configuration. This activity is written to the audit log.
Manage Maintenance Mode	Allows users to enable maintenance mode.
Manage Notifications Schemes	Enable users to manage notification schemes used for notification emails. See, Creating Notifications in a Notification Scheme on page 2081. This activity is written to the audit log.
Manage Plugins	Grants users the permission to install new plug-ins; see Installing plug-ins from the plug-in site on page 2559. Install and delete activities are written to the audit log.
Manage Resource Roles	Grants users the permission to create and delete resource roles, which are created by some plug-ins. In most cases, you do not need to add or change resource roles because they are used internally.
Manage Security	Grants users the permission to manage security configuration, including roles, authentication realms, authorization realms, and tokens. Users without this permission cannot access or change the security functions. This activity is written to the audit log.
Manage Server Keystore	Grants users the permission to add and remove server keystore entries.
Manage Statuses	Grants users the permission to create and edit version, inventory, and snapshot statuses.
Manage System	Grants users permission to view and manage options on the **System Settings** page. See System settings on page 2086. This activity is written to the audit log.
Manage System Properties	Grants users the permission to create and edit system properties. This activity is written to the audit log.
Read Artifact Set List	Enables agent relays to use component version replication by status. Assign a user with this permission to an authentication token intended for an agent relay.
Read Z Inventory	Grants users the permission to perform z/OS inventory search filter.

Table 706. Server configuration permissions (continued)

Permission	Description
Release Locks	Enables users to manually release any locks currently held. See, Managing locks on page 2084. This action is written to the audit log.
Run Deployment Triggers	Grants users permission to run the deployment from deployment triggers. The user will need to have the required permissions and roles as if they were executing the deployment manually.
Run Processes in Maintenance Mode	Allows users to execute a new deployment while the maintenance mode is enabled.
Use AI	Allows users to perform AI analysis on failed deployments.
View Audit Log	Grants users the permission to view the **Audit Log** page and download log files. This activity is written to the audit log.
View Basic System Settings	Enables users to view the options on the **System Settings** page. See, System settings on page 2086.
View Bulk Reports	Enables users to view bulk reports.
View Locks	Enables users to view any locks currently held. See, Managing locks on page 2084. This action is written to the audit log.
View Network Settings	Grants users the permission to access the **Network** page.
View Output Log	Grants users the permission to view the **Output Log** page and download log files. This activity is written to the audit log.
View Security	Grants users the permission to view the security configuration including the **Role Configuration**, **Authentication Settings**, **Authorization**, **Teams**, **Token Restrictions**, and **Type Configuration**. Users with this permission have read-only access and cannot modify the security functions. This activity is written to the audit log.
View Users	Enables users to view users activity.

To add system security permissions to roles:

1. Click **Settings > Role Configuration > *selected role* > Server Configuration** to open the **Permissions Granted to Role Members** page for the target role.
2. Use the toggle button to add appropriate permissions to the role.

Permission reference

This table lists the permissions on the server that you can assign to roles.

The following table lists the product areas with their available permissions. Because of the large number of edit sub-permissions, they are provided in a separate column.

Table 707. Permissions

Product area	Available permissions	Subpermissions
Agent	• **Execute on agents**: run processes on the agent • **Install Remote Agents** enable you to install remote agents. • **View Agents**: access agents in the UI but cannot modify them • **Edit**: modify and delete agents	Edit • **Add to Agent Pool**: assign agents to agent pools • **Create Resources**: create agent-type resources • **Delete**: delete agents • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Impersonation**: set up user impersonation for agents • **Manage Licenses**: set agent license type • **Manage Properties**: create and modify agent properties • **Manage Teams**: assign agents to teams • **Manage Version Imports**: import component versions with the agent • **Upgrade Agents**: upgrade agents
Agent Configuration Template	• **Create Agent Configuration Templates**: create agent configuration templates • **View Agent Configuration Templates**: access agent configuration template in the UI but cannot modify them • **Edit**: modify and delete agent configuration templates	Edit • **Delete**: delete agent configuration templates • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign agent configuration templates to teams
Agent pool	• **Create Agent Pools**: create agent pools • **View Agent Pools**: access agent pools in the UI but cannot modify them • **Edit**: modify and delete agent pools	Edit • **Create Resources**: create agent pool resources • **Delete**: delete agent pools • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Pool Members**: change the agents that are in a pool • **Manage Teams**: assign agent pools to teams

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
Agent relay	• **View Agent Relays**: see the agent relays that are listed on the **Resources** tab	Edit • **Delete**: delete agent relays • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign agent relays to teams
Application	• **View Applications**: access applications in the UI but cannot modify them • **Create**: create applications • **Edit**: modify and delete applications	Create • **Create Applications**: create applications without using a template • **Create Applications From Template**: create applications by using templates to define their attributes Edit • **Delete**: delete applications • **Delete Snapshot**: delete snapshot • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Blueprints**: create and modify blueprints • **Manage Components**: add and remove components • **Manage Environments**: create and modify environments • **Manage Pipelines**: create and modify pipelines • **Manage Processes**: create application processes • **Manage Properties**: create and modify application properties • **Manage Snapshots**: create and modify snapshots • **Manage Teams**: assign teams to applications

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
		• **Manage Webhooks**: create and modify webhooks • **Run Component Processes**: run processes that are defined for components that are attached to the application
Application template	• **Create Application Templates** • **View Application Templates** • **Edit**	Edit • **Delete**: delete applications • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Blueprints**: create and modify blueprints • **Manage Component Tags**: add and remove component tags • **Manage Environment Templages**: create and modify environment templates • **Manage Processes**: create application processes • **Manage Properties**: create and modify application properties • **Manage Teams**: assign teams to applications
Cloud connection	• **Create Cloud Connections**: create connections • **View Cloud Connections**: access connections in the UI but cannot modify them • **Edit**: modify and delete connections	Edit • **Delete**: delete cloud connections • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to cloud connections
Component	• **View Components**: access components in the UI but cannot modify them • **Create**: create components • **Edit**: modify and delete components	Create • **Create Components**: create components without using a template • **Create Components From Template**: create components by using templates to define their attributes

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
		Edit • **Approve Promotion**: approve component version promotion • **Delete**: delete components • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Component Cleanup**: modify component cleaup settings • **Manage Configuration Templates**: create configuration templates • **Manage Process Lock**: create process lock • **Manage Processes**: create component processes • **Manage Properties**: create component properties • **Manage Teams**: assign teams to components • **Manage Version Status**: create component version status • **Manage Versions**: import component versions
Component template	• **Create Component Templates**: create component templates • **View Component Templates**: access component templates in the UI but cannot modify them • **Edit**: modify and delete component templates	Edit • **Approve Promotion**: approve component template promotion • **Delete**: delete component templates • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Process Lock**: create component template process lock • **Manage Processes**: create and modify component template processes • **Manage Properties**: create and modify component template properties • **Manage Teams**: assign teams to component templates

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
Environment	• **Execute on Environments**: run parent applications • **View Environments**: access environments in the UI but not modify them • **Create**: create environments • **Edit**: modify and delete environments	Create • **Create Environments**: create environments without using a template • **Create Enviornments From Template**: create environments by using templates to define their attributes Edit • **Delete**: delete environments • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Approval Processes**: create and modify approvals and notifications • **Manage Base Resources**: add base resources to environments • **Manage Deployment Triggers**: create and modify deployment triggers. • **Manage Environment Cleanup**: modify environment cleaup settings • **Manage Properties**: create and modify environment properties • **Manage Teams**: assign teams to environments
Environment template	• **Create Environment Templates** • **View Environment Templates** • **Edit**	Edit • **Delete**: delete applications • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Approval Processes**: create modify approvals and notifications • **Manage Environment Template Cleanup**: modify environment template cleaup settings

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
		• **Manage Properties**: create and modify environment properties • **Manage Teams**: assign teams to environments
External Approval	• **Create External Approvals:** create external approvals • **View External Approvals:** access external approval definitions in the UI but cannot modify them • **Edit:** modify and delete external approvals	Edit • **Delete**: delete external approvals • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Properties**: create and modify external approval properties • **Manage Teams**: assign teams to external approvals
Post Processing Script	• **Create Post Processing Script:** create post processing scripts • **View Post Processing Script:** access post processing script definitions in the UI but cannot modify them • **Edit:** modify and delete post processing script	Edit • **Delete**: delete post processing script • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to post processing script
Process	• **Create Processes**: create processes • **Execute Processes**: run processes • **View Processes**: access process definitions in the UI but cannot modify them • **Edit**: modify and delete processes	Edit • **Delete**: delete generic processes • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Properties**: create and modify generic process properties • **Manage Teams**: assign teams to generic processes • **Manage Webhooks**: create and modify webhooks

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
Resource	• **Create Resources**: create resources • **Execute on Resources**: Run processes on agent resources • **View Resources**: access resources in the UI but cannot modify them • **Edit**: modify and delete resources	Edit • **Delete**: delete resources • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Children**: create, modify, and delete resource hierarchies • **Manage Impersonation**: set up user impersonation for agent and agent pool resources • **Manage Properties**: create and modify resource properties • **Manage Teams**: assign teams to resources • **Map to Environments**: assign resources to application environments
Resource template	• **Create Resource Templates**: create resource templates • **View Resource Templates**: access resource templates in the UI but cannot modify them • **Edit**: modify and delete resource templates	Edit • **Delete**: delete resource templates • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Resources**: create, modify, and delete resource hierarchies • **Manage Teams**: assign teams to resource templates
Secret Store	• **Create Secret Stores**: create secret stores • **View Secret Stores**: access Secret Stores in the UI but cannot modify them • **Edit**: modify and delete secret stores	Edit • **Delete**: delete secret stores • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to secret stores

Table 707. Permissions (continued)

Product area	Available permissions	Subpermissions
Vault AppRole	• **Create Vault AppRoles**: create Vault AppRoles • **View Vault AppRoles**: access Vault AppRoles in the UI but cannot modify them • **Edit**: modify and delete Vault AppRoles	Edit • **Delete**: delete Vault AppRoles • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to Vault AppRoles
Vault Certificate	• **Create Vault Certificates**: create Vault certificate • **View Vault Certificates**: access Vault certificates in the UI but cannot modify them • **Edit**: modify and delete Vault certificates	Edit • **Delete**: delete Vault certificates • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to Vault certificates
Vault Ldap User	• **Create Vault Ldap Users**: create Vault LDAP users • **View Vault Ldap Users**: access Vault LDAP users in the UI but cannot modify them • **Edit**: modify and delete Vault LDAP users	Edit • **Delete**: delete Vault LDAP users • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to Vault LDAP users
Webhook Template	• **Create Webhook Templates**: create webhook templates • **View Webhook Templates**: access webhook templates in the UI but cannot modify them • **Edit**: modify and delete webhook templates	Edit • **Delete**: delete webhook templates • **Edit Basic Settings**: edit configuration settings on the **Basic Settings** panel • **Manage Teams**: assign teams to webhook templates

The page of permissions also includes **Server Configuration** and **Web UI** sections. These permissions affect how users can modify security settings on the server and which pages in the server user interface they can see.

Table 708. Server configuration permissions

Permission	Description
Add Team Members	Add users to roles that have the same or fewer permissions than those of the granting user.
Bulk Manage Cleanup	Allows users to view, and edit the cleanup settings of multiple components and environments from the **Cleanup Configuration** page.
Create with Team Assignment	Grants users the ability to add any additional team and type combination to an object if they have the Create permission on atleast one team/type mapping.
Create Tags	Grants users the permission to create tags. Users can create tags in the **Tags** page with only this permission. To create tags on an object, users must have the **Edit Basic Settings** permission on the object type. See Creating tags on page 2520.
Edit Basic System Settings	Enables users to edit the options on the **System Settings** page. See, System settings on page 2086. This activity is written to the audit log.
Edit Network Settings	Grants users the permission to access the **Network** page and manage servers in a server cluster.
Edit Tags	Grants users the permission to edit tags. Users can edit tags in the **Tags** page. Users can apply tags to an object only if they have the **Edit Basic Settings** permission enabled on the object type. See Adding tags to objects on page 2521.
Manage Audit Log	Grants users the permission to manually cleanup the audit log, and configure automatic cleanup settings. If you have this permission but not the edit basic settings permission, you can edit the audit cleanup settings from the **Audit Log** page. This activity is written to the audit log.
Manage Auth Token Restrictions	Create, modify and delete token restrictions. See, Restricting authentication tokens on page 2223
Manage Diagnostics	Enable users to access the diagnostics information including the Rest Call Log, Java Thread dumps, and Metadata indexing. This activity is written to the audit log.
Manage Java Packages	Allows users to add and delete Java packages.
Manage Logging Settings	Grants users the permission to view the **Logging** page and edit the log4j configuration. This activity is written to the audit log.
Manage Maintenance Mode	Allows users to enable maintenance mode.

Table 708. Server configuration permissions (continued)

Permission	Description
Manage Notifications Schemes	Enable users to manage notification schemes used for notification emails. See, Creating Notifications in a Notification Scheme on page 2081. This activity is written to the audit log.
Manage Plugins	Grants users the permission to install new plug-ins; see Installing plug-ins from the plug-in site on page 2559. Install and delete activities are written to the audit log.
Manage Resource Roles	Grants users the permission to create and delete resource roles, which are created by some plug-ins. In most cases, you do not need to add or change resource roles because they are used internally.
Manage Security	Grants users the permission to manage security configuration, including roles, authentication realms, authorization realms, and tokens. Users without this permission cannot access or change the security functions. This activity is written to the audit log.
Manage Server Keystore	Grants users the permission to add and remove server keystore entries.
Manage Statuses	Grants users the permission to create and edit version, inventory, and snapshot statuses.
Manage System	Grants users permission to view and manage options on the **System Settings** page. See System settings on page 2086. This activity is written to the audit log.
Manage System Properties	Grants users the permission to create and edit system properties. This activity is written to the audit log.
Read Artifact Set List	Enables agent relays to use component version replication by status. Assign a user with this permission to an authentication token intended for an agent relay.
Read Z Inventory	Grants users the permission to perform z/OS inventory search filter.
Release Locks	Enables users to manually release any locks currently held. See, Managing locks on page 2084. This action is written to the audit log.
Run Deployment Triggers	Grants users permission to run the deployment from deployment triggers. The user will need to have the required permissions and roles as if they were executing the deployment manually.
Run Processes in Maintenance Mode	Allows users to execute a new deployment while the maintenance mode is enabled.
Use AI	Allows users to perform AI analysis on failed deployments.
View Audit Log	Grants users the permission to view the **Audit Log** page and download log files. This activity is written to the audit log.
View Basic System Settings	Enables users to view the options on the **System Settings** page. See, System settings on page 2086.

Table 708. Server configuration permissions (continued)

Permission	Description
View Bulk Reports	Enables users to view bulk reports.
View Locks	Enables users to view any locks currently held. See, Managing locks on page 2084. This action is written to the audit log.
View Network Settings	Grants users the permission to access the **Network** page.
View Output Log	Grants users the permission to view the **Output Log** page and download log files. This activity is written to the audit log.
View Security	Grants users the permission to view the security configuration including the **Role Configuration**, **Authentication Settings**, **Authorization**, **Teams**, **Token Restrictions**, and **Type Configuration**. Users with this permission have read-only access and cannot modify the security functions. This activity is written to the audit log.
View Users	Enables users to view users activity.

Table 709. Web UI permissions

Permission	Description
Applications Tab	Access to the **Applications** tab. See Applications on page 2344.
Components Tab	Access to the **Components** tab. See Components on page 2247.
Configuration Tab	Access to the **Configuration** tab. See Creating, setting, and editing properties on page 2504.
Dashboard Tab	Access to the **Dashboard** tab. See Dashboard on page 2245.
Deployment Calendar Tab	Access to the **Calendar** tab; see Scheduling deployments on page 2545.
Processes Tab	Access to the **Processes** tab; see Generic processes on page 2451.
Reports Tab	Access to the **Reports** tab; see Reporting on page 2547.
Resources Tab	Access to the **Resources** tab; see Resources on page 2312.
Secret Store Tab	Access to the **Secret Store** tab; see Secret stores on page 2206.
Settings Tab	Access to the **Settings** tab; see Server settings and configuration on page 2069.
Work Items Tab	Access to the **Work Items** tab; see Responding to approval requests on page 2394.

Permissions reference for using application templates

Permissions for roles that create applications from templates.

Application templates can contain information about the components and environments that are initially available to applications that are created from the templates. The composition of the application template determines which role permissions are needed to create an application from a template.

Note: The role permissions in the following tables are only the permissions that are required to create the application from a template. More permissions are necessary to add elements to an application, run processes, or complete a deployment.

To create an application from a template, the user's role must have the following minimum permissions.

Note: The user cannot select components or create environments for the application.

Table 710. Permissions for role that creates applications from an application template

Product area	Permissions	Subpermissions
Application	• **View Applications**	Edit • **Edit Basic Settings** • **Manage Properties** • **Manage Teams** Create • **Create Applications From Template**
Application Template	• **View Application Templates**	
Resource	• **Create Resources**	Edit • **Manage Teams**

To assign existing components to an application from the application template wizard, the user's role must also have the following permissions.

Note: To create an application from the application template wizard, the user's role must also have the permissions that are listed in Table 1.

Table 711. More permissions that are required to specify components

Product area	Permissions	Subpermissions
Application		Edit • **Manage Components**
Component	• **View Components**	

To create environments for an application from the application template wizard, the user's role must also have the following permissions. To map resources to the environments from the application wizard, the role must also have the permissions in Table 2.

Note: To create an application from the application template wizard, the user's role must also have the permissions that are listed in Table 1.

Table 712. Permissions to create environments and map resources to them

Product area	Permissions	Subpermissions
Agent	• **View Agents**	
Application		Edit • **Manage Approvals** • **Manage Environments**
Environment	• **View Environments**	Edit • **Edit Basic Settings** • **Manage Base Resources** • **Manage Properties** Create • **Create Environments From Template**

Table 712. Permissions to create environments and map resources to them (continued)

Product area	Permissions	Subpermissions
Environment Template	• **View Environment Templates**	
Resource	• **View Resources**	Edit • **Manage Children** • **Map to Environments** • **Manage Teams**
Resource Template	• **View Resource Templates**	

Secret stores

You can store user credentials in Hashicorp Vault and integrate with HCL DevOps Deploy (Deploy) to retrieve values from the Vault.

In Deploy, you store passwords as secured properties. For example, the database credentials. These passwords are stored in the database. Instead of storing the passwords in the database, you can store them in HashiCorp Vault. HashiCorp Vault is a third-party tool that stores and controls access to passwords and other secrets critical in modern computing.

The Deploy secret store enables you to retrieve user credentials during deployment without having stored the passwords in the database.

Deploy uses the following Vault authentication methods:

- **App Roles** - A role-based authentication mechanism where you have a defined set of access. AppRole uses RoleID and SecretID as the master authentication mechanism which allows Deploy to get the passwords that an AppRole can access. For information about the Vault AppRole, refer to the Vault AppRole auth documentation.
- **LDAP Users** - An LDAP-based authentication mechanism to call LDAP users from the Vault secret store. For information about the Vault LDAP, refer to the Vault LDAP auth documentation.
- **Certificates** - An SSL/TLS client certificate-based authentication mechanism to call certificate from the Vault secret store. For information about the Vault TLS certificate, refer to the Vault TLS certificate auth documentation.

The Deploy secret store is different from the Vault secret store. Deploy secret stores can have multiple secret stores. Each secret store in Deploy can connect to a different Vault server.

Adding Vault AppRoles to the Deploy secret store

You can add Vault AppRoles users to the HCL DevOps Deploy (Deploy) secret store to authenticate users with Vault-defined AppRole.

Before you begin

- Ensure that you have installed the Vault server and obtained the server address.
- You must have the following permissions:
  - Create, view, and edit secret store permissions to create a secret store.
  - Create, view, and edit Vault AppRole permissions to manage AppRoles of a secret store.

1. Click **Create Vault Secret Store**.
2. Create a secret store in the **Manage Vault Secret Store** window and provide the following details:

Parameter	Description
Name	Identifies the Vault secret store name. **Note:** Characters other than `a-z`, `A-Z`, `0-9`, and `-` are not allowed.
Description	Conveys more information about the Vault.
Teams	Allows access to the Vault secret store to specific teams.
URL	Indicates the Vault server address.

3. Save your changes.
   The secret store lists on the **Secret Stores** page.
4. Add AppRoles users to the secret store.
   a. Click the secret store to which you want to add the AppRole.
   b. Click **App Roles**.
   c. Click **Create Vault AppRole**.

      The **Manage Vault AppRole** window is displayed.

   d. In the **Manage Vault AppRole** window, enter the following AppRole details:

Parameter	Description
Name	Identifies the Vault AppRole name. **Note:** Characters other than `a-z`, `A-Z`, `0-9`, and `-` are not allowed.
AppRole Id	Specifies the RoleID of the Vault AppRole.
Secret Id	Specifies the SecretID of the Vault AppRole.
Teams	Allows access of the AppRole to specific teams.

e. Save your changes.

The AppRole is added to the Vault AppRoles page.

Results

You have added AppRole users to the Deploy secret store.

What to do next

You can test the integration. See Testing Vault AppRole integration on page 2211.

Adding Vault LDAP users to the Deploy secret store

You can add Vault LDAP users to the HCL DevOps Deploy (Deploy) secret store to authenticate users with Vault-defined LDAP.

Before you begin

- Ensure that you have installed the Vault server and obtained the server address.
- You must have the following permissions:
  - Create, view, and edit secret store permissions to create a secret store.
  - Create, view, and edit Vault Ldap User permissions to manage LDAP users of a secret store.

1. Click **Create Vault Secret Store**.
2. Create a secret store in the **Manage Vault Secret Store** window and provide the following details:

Parameter	Description
Name	Identifies the Vault secret store name. **Note:** Characters other than `a-z`, `A-Z`, `0-9`, and `-` are not allowed.
Description	Conveys more information about the Vault.
Teams	Allows access to the Vault secret store to specific teams.
URL	Indicates the Vault server address.

3. Save your changes.
   The secret store lists on the **Secret Stores** page.
4. Add LDAP users to the secret store.
   a. Click the secret store to which you want to add the LDAP users.
   b. Click **Ldap Users**.
   c. Click **Create Vault Ldap User**.

   The **Manage Vault Ldap User** window is displayed.

d. In the **Manage Vault Ldap User** window, enter the following LDAP user details:

Parameter	Description
Name	Identifies the Vault LDAP user name.
Password	Specifies the password of the LDAP user.
Teams	Allows access of the LDAP user to specific teams.

Note: The LDAP user name field does not allow characters other than `a-z`, `A-Z`, `0-9`, and `-`.

e. Save your changes.

The LDAP user is added to the Vault LDAP page.

Results

You have added LDAP users to the Deploy secret store.

What to do next

You can test the integration. See Testing Vault LDAP integration on page 2211.

Adding Vault certificate to the Deploy secret store

You can add the Vault certificates to the HCL DevOps Deploy (Deploy) secret store to authenticate with Vault-defined SSL/TLS client certificate.

Before you begin

- You must have completed the following tasks:
  - Installed the Vault server and obtained the server address.
  - Ensured that an SSL/TLS client certificate is available in the PEM format.
- You must have the following permissions:
  - Create, view, and edit secret store permissions to create a secret store.
  - Create, view, and edit Vault Certificate permissions to manage certificate of a secret store.

1. Click **Create Vault Secret Store**.
2. Create a secret store in the **Manage Vault Secret Store** window and provide the following details:

Parameter	Description
Name	Identifies the Vault secret store name.

Parameter	Description
	Note: Characters other than `a-z`, `A-Z`, `0-9`, and `-` are not allowed.
Description	Conveys more information about the Vault.
Teams	Allows access to the Vault secret store to specific teams.
URL	Indicates the Vault server address.

3. Save your changes.
   The secret store lists on the **Secret Stores** page.
4. Add certificate to the secret store.
   a. Click the secret store to which you want to add the certificate.
   b. Click **Certificates**.
   c. Click **Create Vault Certificate**.

      The **Manage Vault Certificate** window is displayed.

   d. In the **Manage Vault Certificate** window, provide the following details:

Parameter	Description
Name	Identifies the Vault certificate name. The certificate name must match with the name in the Vault server.
Certificate	Copy the certificate in PEM format.
Private Key	Enter the private key in PEM format.
Teams	Allows access of the certificate to specific teams.

   e. Save your changes.

      The certificate is added to the **Certificates** page.

Results

You have added certificate to the Deploy secret store.

What to do next

You can test the integration. See Testing Vault certificate integration on page 2212.

Vault integration test

You can test the Vault integration to ensure that HCL DevOps Deploy (Deploy) can retrieve values from the Vault server.

After you add Vault AppRole or LDAP users to the Deploy secret store, you can test whether the integration is successful. You can test the Vault integration before you use the Vault property in a plug-in step to ensure the step doesn't fail.

Testing Vault AppRole integration

You can test the Vault AppRole integration before you use the Vault property in a plug-in step.

Before you begin

You must have created a secret store and added an AppRole to the HCL DevOps Deploy (Deploy) secret store. See Adding Vault AppRoles to the Deploy secret store on page 2206.

1. On the web UI, click **Secret Stores > *vaultname* > App Roles**.
2. Click the menu options on the right-side of the desired AppRole.
3. Click **Test**.
   The **Test Vault AppRole** window is displayed.
4. Enter the Vault key or property you want to test in the **Property** field.
5. If the secret ID is not configured for the role, specify the secret ID of the AppRole in the **Secret Id** field.
6. Click **Test**.

   A message is displayed which indicates whether the test is successful or failed.

Results

You have tested the Vault AppRole integration.

What to do next

You can use the secret store property in a plug-in step. See Secret store property usage on page 2212.

Testing Vault LDAP integration

You can test the Vault LDAP integration before you use the Vault property in a plug-in step.

Before you begin

You must have created a secret store and added an LDAP user to the HCL DevOps Deploy (Deploy) secret store. See Adding Vault LDAP users to the Deploy secret store on page 2208.

1. On the web UI, click **Secret Stores > *vaultname* > Ldap Users**.
2. Click the menu options on the right-side of the desired LDAP user.
3. Click **Test**.
   The **Test Vault Ldap User** window is displayed.
4. Enter the Vault key or property you want to test in the **Property** field.
5. If the password is not configured for the user, then specify the password of the LDAP user in the **Password** field.
6. Click **Test**.

   A message is displayed which indicates whether the test is successful or failed.

Results

You have tested the Vault LDAP integration.

What to do next

You can use the secret store property in a plug-in step. See Secret store property usage on page 2212.

Testing Vault certificate integration

You can test the Vault certificate integration before you use the Vault property in a plug-in step.

Before you begin

You must have added a certificate to the Deploy secret store. See Adding Vault certificate to the Deploy secret store on page 2209.

1. On the Web UI, click **Secret Stores > *vaultname* > Certificates**.
2. Click the menu options on the right-side of the desired certificate.
3. Click **Test**.
   The **Test Vault Certificate** window is displayed.
4. Enter the Vault property you want to test in the **Property** field.
5. Click **Test**.

   A message is displayed which indicates whether the test is successful or failed.

Results

You have tested the Vault certificate integration.

What to do next

You can use the secret store property in a plug-in step. See Secret store property usage on page 2212.

Secret store property usage

At times, you may need to retrieve values from Vault and add them to a plug-in step. For example, `start tomcat` plug-in step from the Apache Tomcat plug-in. After you create a HCL DevOps Deploy (Deploy) secret store and add users to it, you can add an input property for Vault at any of the levels where secure passwords are allowed. For example, at application level or at resource level. You can use the Vault property in an automation or source configuration plug-in step.

You can retrieve user credentials from the Vault by using the following property in a plug-in step:

```
${p:secret:vault:<secretStoreName>:<vaultUsername>:<vaultSecretPath>:<vault-key>}
```

Here,

- *<secretStoreName>* is the name of the Deploy secret store.
- *<vaultUsername>* is the Vault AppRole name or LDAP user name whose credentials are required to run the plug-in step.
- *<vaultSecretPath>* is the path to the Vault secret.
- *<vault-key>* is the Vault key or property.

When the process runs, on reaching the step where the property is defined, the process validates and authenticates the credentials from the Vault.

Security teams

Users and groups on the server are assigned roles when they are added to teams.

Teams provide two important functions. First, a team provides the mechanism to assign roles to users. When a user is assigned a role, all permissions that are granted to the role are automatically granted to the user, but only for objects that the team has access to. Second, teams secure objects such as applications, components, and environments. When a team is attached to an object, only team members with the appropriate permissions can interact with the affected resource.

The System Team that comes with HCL DevOps Deploy (Deploy) has all permissions granted for all Standard security types for its Administrator role.

Creating a team

You can create a team by adding members to manage roles and access permissins for the HCL DevOps Deploy (Deploy).

Before you begin

You must have permissions to create and edit teams.

About this task

You can use the **Teams** tab to create a team. Additionally, you can view and manage the existing teams by adding members.

1. Log in to Deploy.
2. Click **Settings > Teams**.
   The **Teams** page is displayed.
3. Click **Create Team**.
   The **Create Team** dialog is displayed.
4. Type a name for the team in the **Name** field.
5. Optional: Type a description for the team in the **Description** field.
6. Click **Save**.

Results

You have created a team.

What to do next

You can assign users to the team. See, Assigning users to teams on page 2214.

Related information

Mapping teams to objects on page 2215

Roles and permissions on page 2187

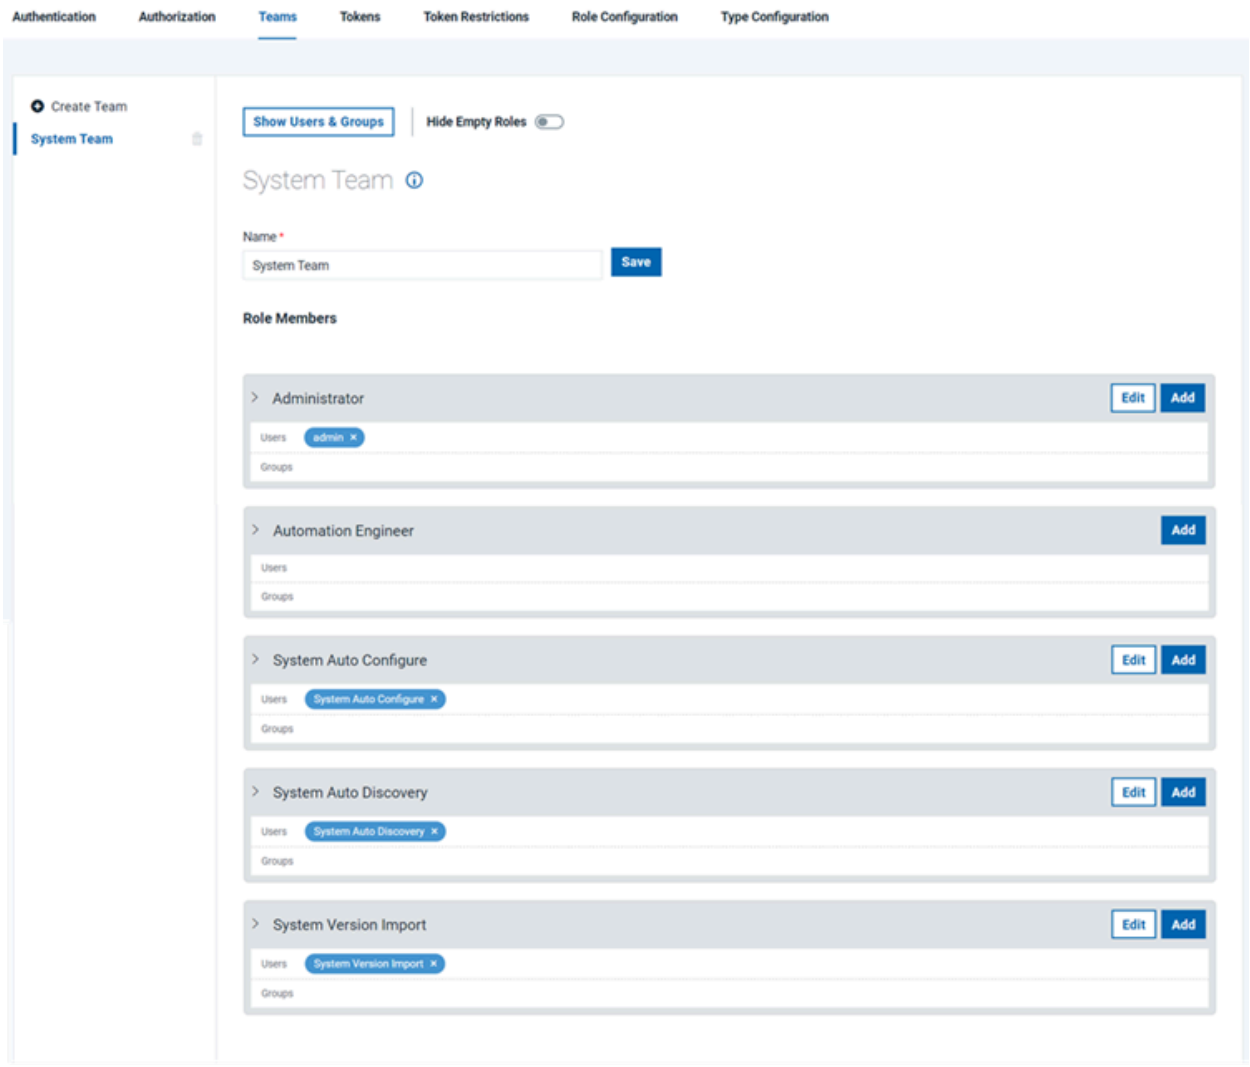
Assigning users to teams

Assign users to teams so that users can be assigned to roles and work with objects that are associated with the teams.

1. On the server, click **Settings > Teams**.
2. In the **Teams** pane, select the team to add users to.

   Example

   When a team is selected, all previously defined roles are available. In the following figure, the **System Team** is selected. All roles are displayed, and users are listed below their assigned roles. Users and groups are added to a team by assigning them to a specific role or roles.



3. To add users to roles, do one of the following actions:

   Choose from:

   - Click **Add** for the target role, and then select the appropriate check boxes from the list of users and groups.
   - Click **Add Users and Groups**, and then drag users and groups onto target roles.

What to do next

Assign teams to objects, such as applications, environments, components.

Mapping teams to objects

In addition to assigning a team to an object (such as a component or application), when you create the object, you can use the **Teams** page on the server to map teams to objects.

Before you begin

To map a team to an object, you must:

- be a member of the team
- have the create and/or manage teams subpermission enabled for that type of object

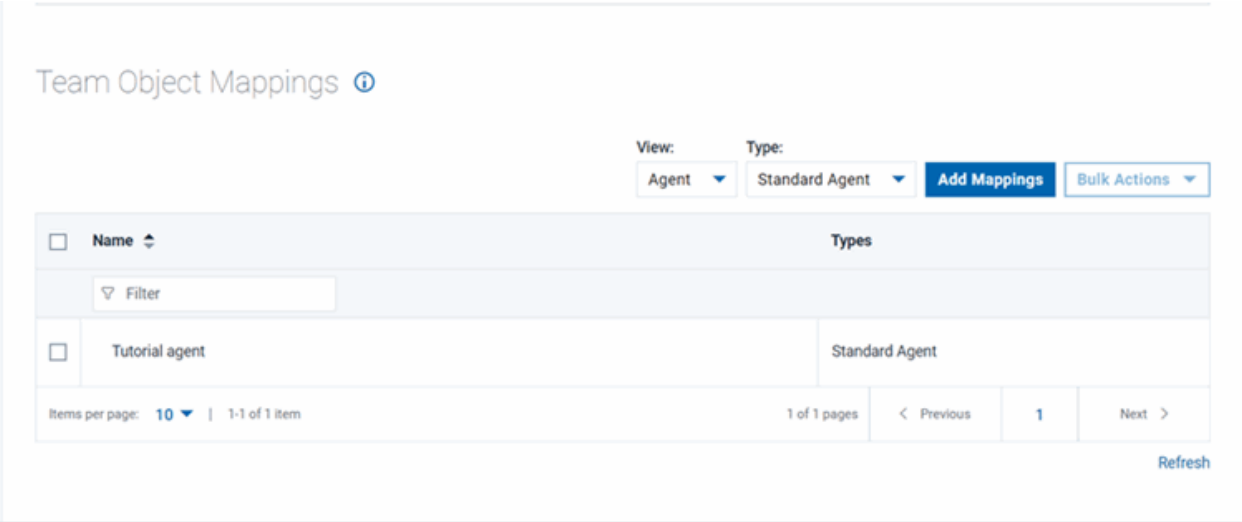
About this task

You can assign teams to many of the objects that you create. When you create an object, you can assign teams by using the associated **Create item** window. You can also assign teams by using the **Configuration** page for the object. You can also map teams to objects as described here. When you assign a team to an object, such as an environment, only team members with the appropriate permissions can interact with the affected object.

Note:

- By default, new objects are assigned to all teams that you are a member of. To specify which teams to assign new objects to, see Managing the teams and users for your account on page 2094.
- Starting with 7.3.2, if a user belongs to multiple teams, the role permissions from the most restrictive team determines the user's overall access.

1. On the server, click **Settings > Teams**.
2. From the list of teams, select the team to use.
3. Under **Team Object Mappings**, in the **View** list, select the type of object.

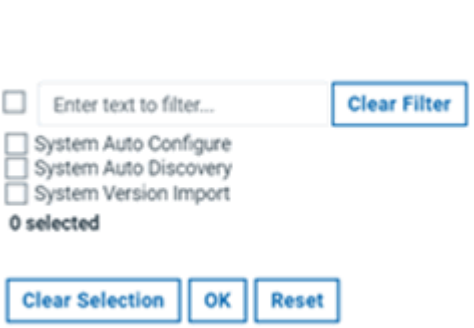


Result

The table shows the objects that are associated with the team.

4. From the **Type** list, select the security type.
5. Click **Add**.

   A list of user-created objects that are not already assigned to the current product area is displayed.



6. Select the appropriate check boxes for the objects to assign to the team, and then click **OK**.

Results

Teams that are mapped to objects are displayed on the associated object page.

Assigning teams to objects

You can assign a team to an object (such as a component or an application) when you create the object.

About this task

When a team is assigned to an object, only team members with the appropriate permissions can interact with that object. You can assign your teams to the objects that you create. To assign a team, you must be a team member and have the manage teams permission.

You can assign teams to an object when you create an object in the associated **Create item** window or by using the **Configuration** page after the object is created.

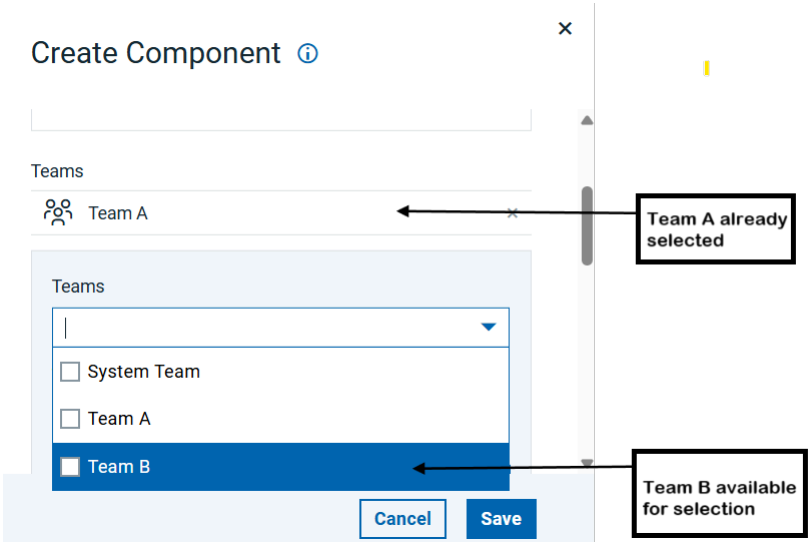
You can also assign teams by mapping teams to objects by using the mapping security feature. See Mapping teams to objects on page 2215.

Note:

- By default, new objects are assigned to all teams that you are a member of. To specify which teams to assign new objects to, see Managing the teams and users for your account on page 2094.
- Starting with 7.3.2, if a user belongs to multiple teams, the role permissions from the most restrictive team determines the user's overall access.

With the **Create with Team Assignment** permission enabled, you can add any additional team and type combinations to an object if you have the **Create** permission on at least one team-type mapping. With this permission, you can also add those team/type combinations in which you are not even a member.

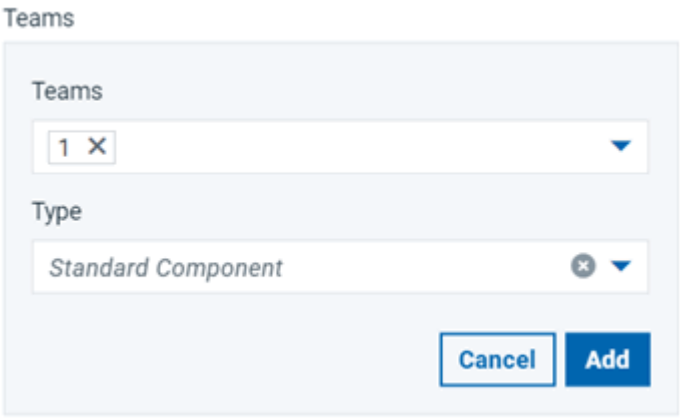
For example, there are two teams: Team A and Team B. Team A is mapped with a standard component type. Team B is mapped with a standard component and component type 2. You are a member of Team A only and have the **Create with Team Assignment** permission enabled. As a member of Team A with **Create with Team Assignment** permission, when creating a component in HCL DevOps Deploy (Deploy), Team A is automatically selected. You can add Team B in the **Add Teams** field, even if you are not a member of Team B, provided both teams are mapped with standard component type. When editing a component, you cannot unmap Team A since you are a member, but you can select Team B as both teams share a standard component type and you are a member of one.



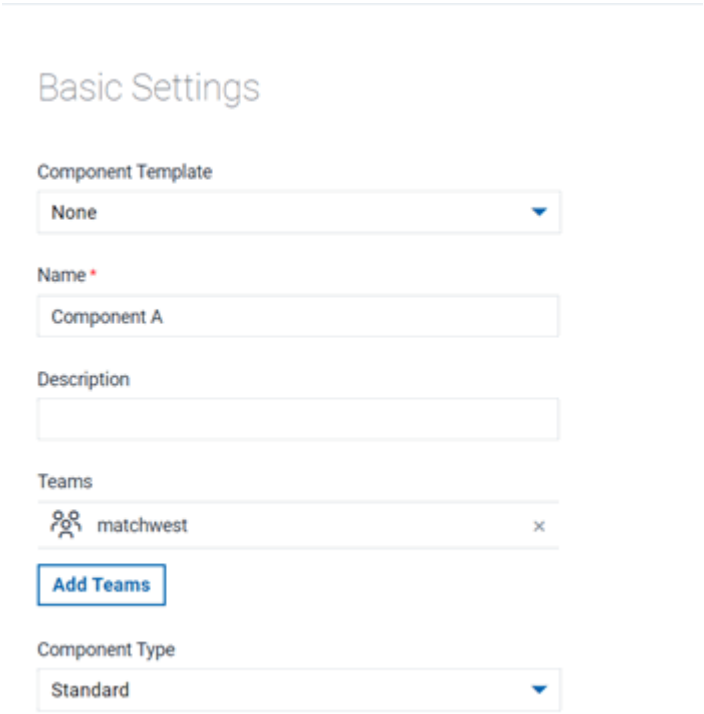
To assign teams to objects:

1. On the server, open the **Configuration** pane or the **Create** dialog box for an object, such as a component. For a list of product areas that you can assign teams to, see Security types on page 2219.
   Example

In the following figure, the **Teams** field opens in the **Create Component** window.



2. Click the checkbox to select a team from the **Team** list.
3. Select a security type for the object from the **Type** list.
   The type defines the set of object permissions that are available to the team. Security types for the current object type are available. Initially, a type of object, such as components, has a single type that is defined for it, the standard type. For information about security types, see Security types on page 2219.
4. Click **Add**.
   More than one team can be added to an item.
   Result
   The selected team or teams can interact with the object immediately. Teams and their security type are listed on the **Configuration** page that is associated with the object. In the following figure, the matchwest team with the cHolder security type is assigned to a component.



5. **Optional:** To remove a team from an object, click the cancel icon ✕ for the team.

Security types

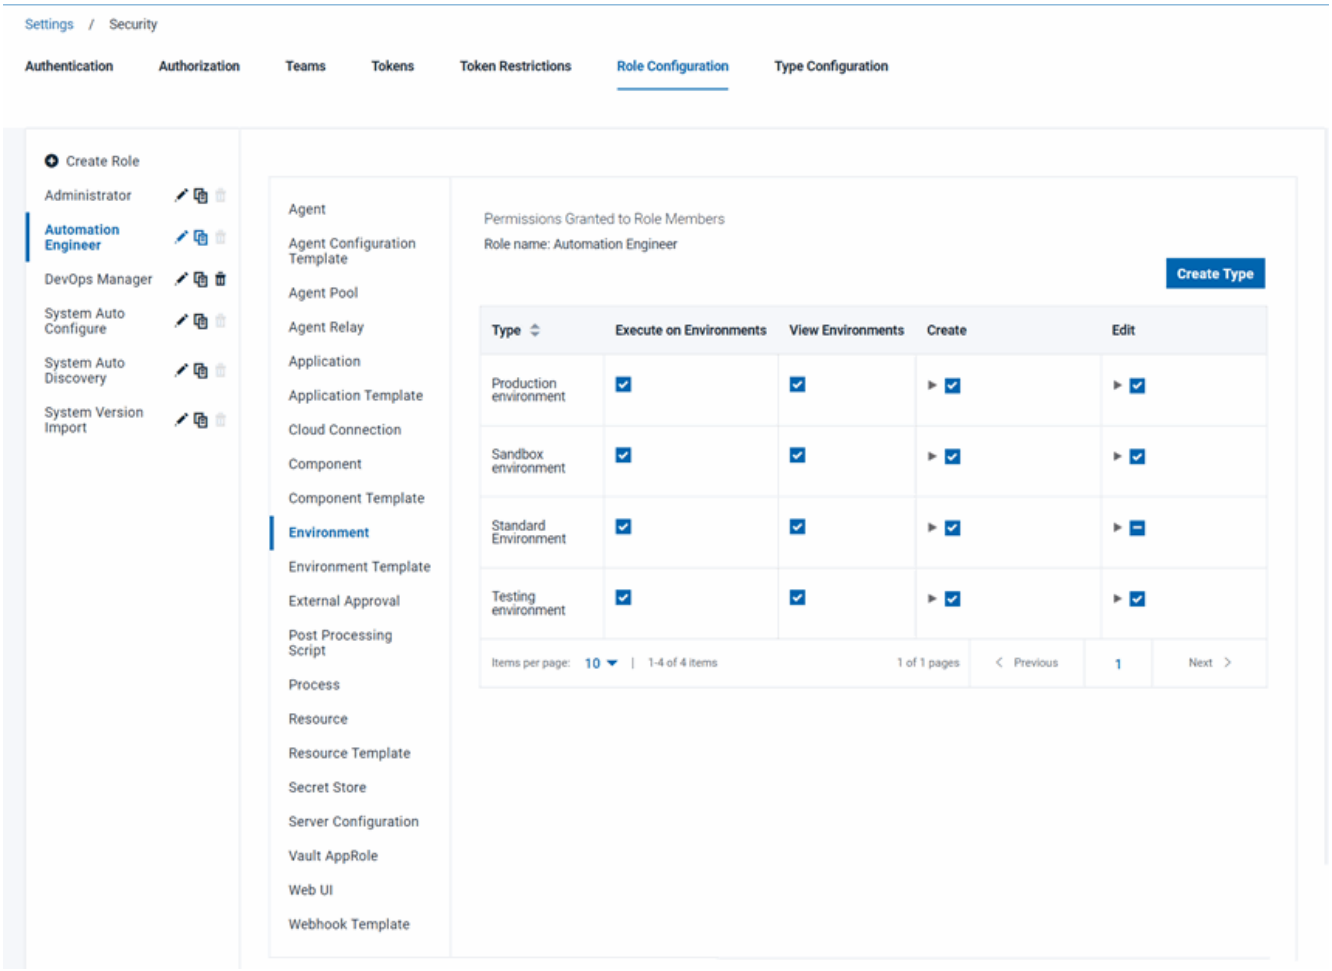
Security types define categories of objects on the server. You can put all objects into a single category, or you can put them in separate categories and give roles different access rights to different categories.

By default, all object types on the server have a standard security type. For example, applications have the Standard Application security type, and environments have the Standard Environment security type. You do not have to create more security types unless you want to give different levels of access to different roles.

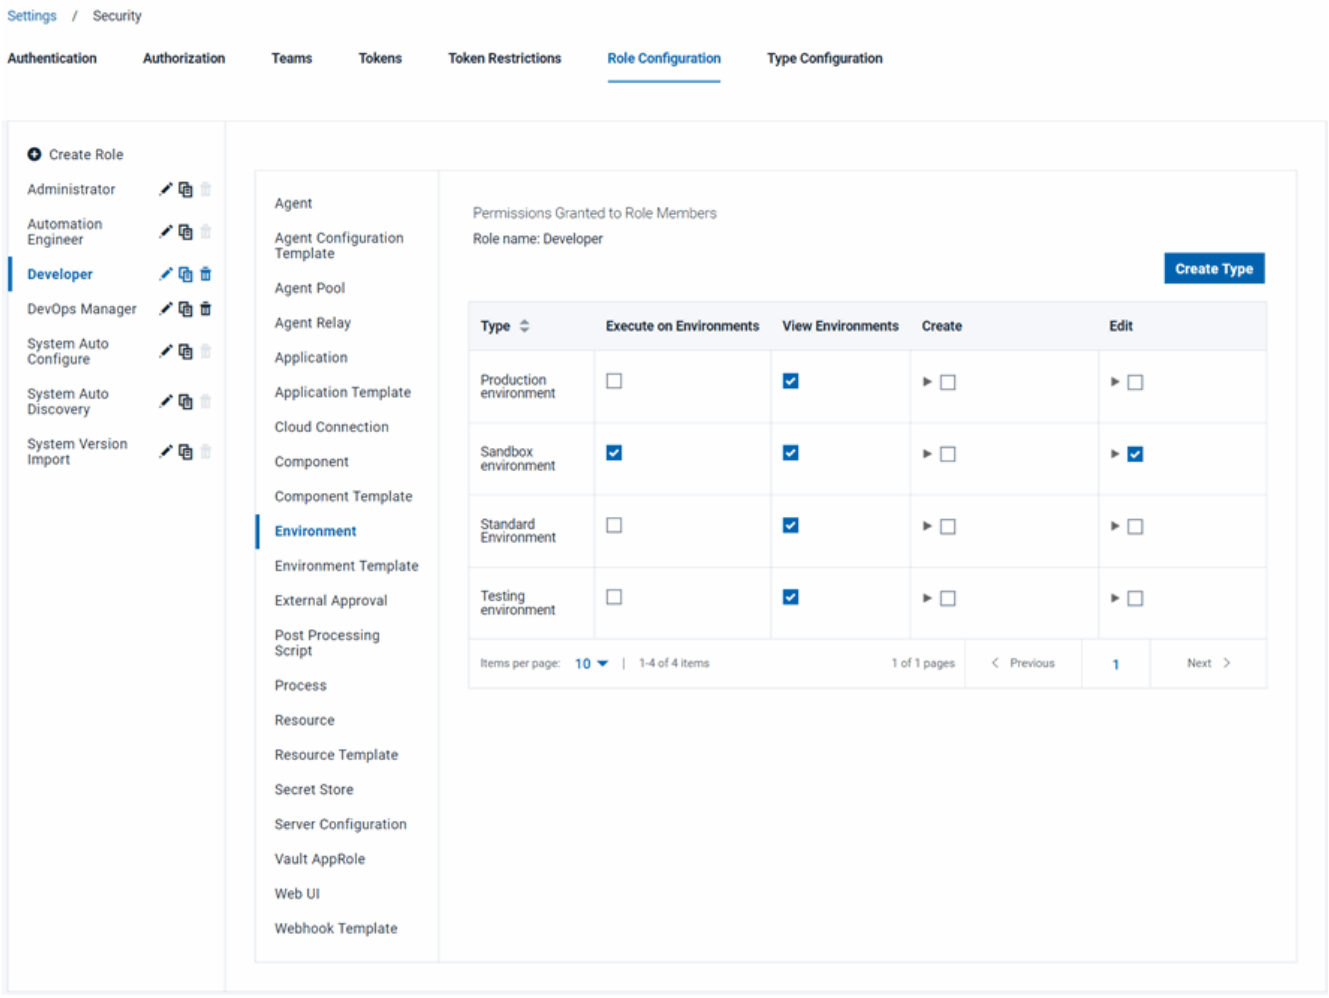
For example, suppose that you have different environment categories for different purposes, such as production environments, testing environments, and sandbox environments. You want to give different users different levels of access to these environments. You can allow only development superusers to modify production environments but allow other users to view the state of these environments. You can also allow anyone to modify sandbox environments.

In this case, you create security types for different categories of environments and assign the environments to those types. Then, you create roles for different levels of access to the environments. For example, you might create a deployment superuser role that can create and edit environments. Then, within that role, you specify the access that users have for each type of environment.

For example, the following figure shows a role that is named `Development superuser`. This role has full access to production environments, testing environments, sandbox environments, and standard environments.



A role for less-privileged users might be able to view and edit existing sandbox environments but only view production environments. The following figure shows the permissions for the `Developer` role. This role can view and edit existing sandbox environments. It can view but not edit production environments.



The System Team has access to everything on the server according to the permissions in the standard security type. For example, the members of the System Team have the environment permissions that are listed in the Standard Environment security type for all environments.

For information about assigning permissions to roles, see Creating roles and assigning permissions on page 2188.

Creating security types

Create security subtypes to help you manage access to objects through the server.

About this task

Except for the web UI and server configuration product areas, you can create security subtypes for most object types, such as applications, environments, and components.

1. On the server, click **Settings > Type Configuration**.
2. From the list of object types, select the type to add a security subtype to.
3. Click **Create Type**.

4. In the **Create Type** dialog box, enter a name for the type.
5. Click **Save**.

What to do next

Assign security subtypes to roles and grant permissions to the roles. Agent subtypes that are assigned to roles, for example, can have view and edit permissions that are granted or withheld. See Creating roles and assigning permissions on page 2188.

To delete a user-created security type, on the **Type Configuration** page, select the object type, and then click **Delete** for the type from the row options. Standard types cannot be deleted.

Tokens

Tokens provide authorization for agents, agent relays, users, and external systems or applications from the server. Agents use tokens when they run process steps and communicate with the HCL DevOps Deploy (Deploy) server and external services.

Users can use tokens with the command-line interface (CLI) client instead of supplying a user name and password in certain situations. For information, see Command-line client (CLI) reference on page 2591.

Follow these steps to create a token. You can also create a token through the CLI; see createAuthToken on page 2644.

1. Log in as a user with the **Manage Security** permission. See Setting server configuration security on page 2190.
2. On the server, click **Settings > Tokens > Create Token**. The **Create Token** dialog box appears.
3. From the **User** list, select the user for the token. You can limit the actions available to the token by applying a token restriction to it. For information about creating and applying token restrictions, see Restricting authentication tokens on page 2223.

   Note:

   If you are using the token to integrate with IBM DevOps Release, you must specify the administrator.

   If the token is for an agent relay that is intended to use component version replication, the user must have a role that has the Read Artifact Set List permission. For information about the Read Artifact Set List permission, see Setting server configuration security on page 2190.

4. Specify the expiration date and time.
5. To limit the use of the token to certain IP addresses, specify one or more IPv4 addresses in CIDR notation in the **Allowed IPs** field, such as `10.15.10.0/24`.

Note: If you are using clustered servers as described in Setting up high-availability clusters on page 2062, leave this field blank.

6. To map token restrictions to user tokens within the Deploy server during token creation, scroll through the created restrictions in the **Auth Token Restriction** field and select the desired list. Select **New** and fill out the required fields to create a new Auth Token Restriction. This feature allows you to restrict a token's usage down to specific REST API endpoints. For example, locking down an administrator user's token to only be able to call /cli/agentCLI/info.
7. Click **Save**.

Important: The token is shown only one time after you create it. Copy the token immediately, because you cannot see it again.

Tokens can be used immediately after they are created. You can revoke a token at any time by clicking **Delete** in the **Actions** column.

Note: How to generate AuthTokens

Authentication tokens (AuthTokens) are randomly generated as 128-bit values through the SHA-256 algorithm. These tokens are associated with a user ID and a set of restrictions when they are created. The value is produced by using a type 4 Universally Unique Identifier (UUID) and the Java Virtual Machine's (JVM) Secure Random generator. The generator provides 122 bits of entropy due to the inclusion of 6 bits of UUID variant information.

The UUID generation is managed by the JVM, which uses its configured secure random data source, which is typically `/dev/random` or `/dev/urandom`. However, this source can vary based on the JVM configuration.

The 128 bit entropy is generated by the *java.util.UUID.randomUUID()* variant, which calls the java.security.SecureRandom.nextBytes() bytes to produce 16 bytes (128 bits) of random data. The SecureRandom instance is created by a plain call of a new SecureRandom() object. You must consult the JVM documentation for details about entropy this process is not implemented in Deploy.

For complete information about the JVM, see the following resources:

- SecureRandom
- UUID

Restricting authentication tokens

Limit authentication token actions by applying token restrictions to process plug-in steps.

Before you begin

To create token restrictions, you must be in a role that has the Manage Auth Token Restrictions permission. See, Setting server configuration security on page 2190.

About this task

The HCL DevOps Deploy (Deploy) server generates an authentication token whenever it runs a plug-in process step. The token authenticates the user that is running the step and has the same permissions as that user. You can limit the actions available to tokens by applying token restrictions to them. A token restriction is a set of one or more REST API commands. When a token-restricted plug-in step runs, it uses the commands that are defined by the token restriction regardless of the user's permissions.

You apply token restrictions to plug-in steps in processes. You can apply a different token restriction to every plug-in step in a process. If you do not apply a restriction to a step, the default token restriction is used. The default token enables all the supported methods for all REST resources. You can modify the default token restriction but you cannot delete it.

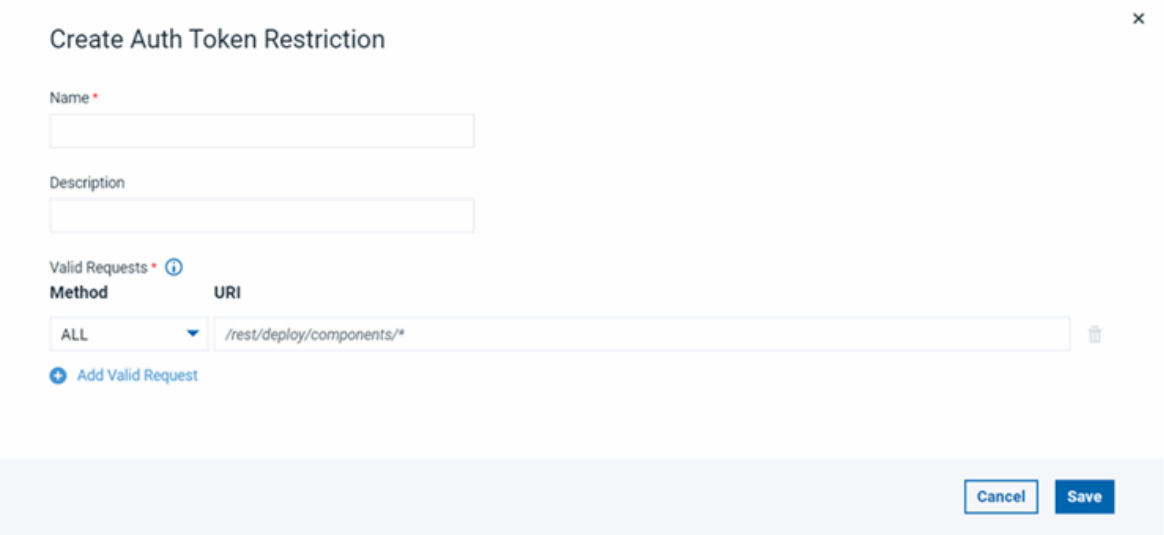
Each token restriction command consists of a verb and a URI. Verbs are methods that you can use on the REST resources. The URI represents a REST resource, such as `https://hostname:port/rest/deploy/component/`. You can define 30 commands in a single token restriction.

The methods that you can use in a command are described in the following table.

Table 713. REST API commands

Method	Description
ALL	Enable all other verbs for the associated URI.
Delete	Delete the object at the REST endpoint.
POST	Create an object of the type that is defined by the URI, or update the object at the URI.
GET	Retrieve information about the service at the URI.
PUT	Update the object at the URI.

1. On the server, click **Settings > Token Restrictions**.
2. On the **Token Restrictions** pane, click **Create Auth Token Restriction**.
3. In the **Create Auth Token Restrictions** dialog box, in the **Name** field, enter a name for the token restriction.
4. In the **Description** field, enter a description for the restriction.
5. Define one or more requests by completing the following steps:
    a. In the **Method** list, select the request verb.
    b. In the **URI** field, paste or enter the URI. The URI must start with the forward-slash character "/". You can use the asterisk (*) wildcard as the last character in the URI. For example, the following request allows information to be retrieved from all REST services:



c. If you want to define another request, click **Add**; otherwise, click **Save**.

Result

After you save the token restriction, you can copy, edit, and delete it.

Note: You cannot delete the default restriction.

What to do next

When you configure a plug-in step, you can apply a token restriction to the step. You can also create a token restriction from the plug-in process step. By default, the default token restriction is applied to each plug-in step.

Token expiration settings

Tokens provide authorization for agents, agent relays, users, and external systems or applications from the server. Agents use tokens when they run process steps and communicate with the HCL DevOps Deploy (Deploy) server and external services. In the **Security** settings area, you can set time limits for four tokens types. Two tokens types work with plug-ins that enable discovering and applying configurations. The third type is used when component versions are automatically imported. You can set the how much time elapses before the token expires and if you want to use the default auth token restrictions.

The tokens are generated automatically when the steps are run. The first three tokens use the built-in UC Auto Configure, UC Auto Discovery, and UC Version Import users and their permissions. The plug-in token has the permissions of the user who requests the process that plug-in runs from. These tokens are the same as those that you can create in the user interface and a command-line interface. See Tokens on page 2222.

Go to the HCL Plug-ins to access plug-ins that work with Deploy and provide steps that create these tokens.

The tokens are generated automatically when the steps are run. The first three tokens use the built-in UC Auto Configure, UC Auto Discovery, and UC Version Import users and their permissions. The plug-in token has the permissions of the user who requests the process that plug-in runs from. These tokens are the same as those that you can create in the user interface

and a command-line interface. See Tokens on page 2222. Go to the HCL Plug-ins website to access plug-ins that work with Deploy and provide steps that create these tokens.

To access the **Security** settings area, click **Settings**, click **System Settings**, and then scroll down.

You can specify these expiration delays for tokens:

Discovery Auth Token Expiration Delay (seconds)

Set the expiration delay in seconds for authorization tokens that are created for autodiscovery steps. You must specify at least 300 seconds. Typically, discoveries do not require more than 300 seconds (5 minutes).

Configure Auth Token Expiration Delay (seconds)

Set the expiration delay in seconds for authorization tokens that are created for auto configuration steps. You must specify at least 300 seconds. Be sure to specify sufficient time for auto configuration, because the step processes stop when the token expires.

Version Import Auth Token Expiration Delay (seconds)

Set the expiration delay in seconds for authorization tokens that are created for version import steps. You must specify at least 300 seconds. The time required to import versions depends on component size.

Plugin Step Auth Token Expiration Delay (seconds)

Set the expiration delay in seconds for authorization tokens that are created for plug-in steps. You must specify at least 300 seconds. The time required to import versions depends on component size.

Updating the agent relay authentication token password

The authentication token password for the agent relay is specified during installation of the agent relay. You can update the authentication token and provide a password for the token by updating the agent relay properties file.

Before you begin

The new authentication token for the server must be available before changing the password. For information about creating a token, see Tokens on page 2222.

1. Open the `agentrelay.properties` file located in *`agent_relay_home`*`/conf` directory.
2. Change the value for the **agentrelay.codestation.server_password** property to the new password value.
   The following is from the sample `agentrelay.properties` file. The password shown is encrypted.

   ```
   agentrelay.codestation.server_password=pbe{UlfTbYJYm2i7VIN4D0/8dYeqI6T54heliAURNECl0p4l8/3h72Fv2n3G3yylWwdCnRY57wXcLT8=}
   ```

   Specify the new password. The new password is encrypted when the agent relay is started.

   ```
   agentrelay.codestation.server_password=new_password
   ```
3. Save your changes and close the file.
4. Stop the agent relay.
5. Start agent relay .
6. Verify that the agents connected through the changed agent relay are connecting.

FIPS mode enablement

You can enable Federal Information Processing Standards (FIPS) mode on the systems that run the HCL DevOps Deploy (Deploy) server, agent, and relays to make them FIPS compliant.

While installing the server, agent, and relay with the `-fips-semeru` flag, the installer adds the FIPS properties to the system settings and the Deploy server, agent, or relay Java configuration automatically. However, you can enable the FIPS mode by adding the following FIPS properties manually:

- `-Dsemeru.fips=true` to activate the FIPS.
- `-Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced` to enable the weak enforcement policy that:
    - Limits the TLS ciphers to the approved set.
    - Uses the approved cipher implementations when provided.

      The policy does not restrict the use of non-approved algorithms for other uses, such as keystores.

Prerequisites for enabling FIPS

Ensure that you have:

- Installed a minimum supported version of IBM Semeru. See Operating systems for a list of supported versions.
- Set the JAVA_HOME on the system settings.

Enabling FIPS mode on server

You can enable the FIPS mode on your HCL DevOps Deploy (Deploy) server to make it FIPS compliant.

1. Stop the server.
2. Open the `<serverInstall>/bin/set_env.cmd` file.
3. Add the following lines to the JAVA_OPTS line:

   ```
   -Dsemeru.fips=true
   -Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced
   ```

4. Start the server.
   The following message indicates that the server has started with the FIPS mode:

   ```
   Java FIPS Support: active
   ```

Results

The FIPS mode is enabled on the server.

Enabling FIPS mode on compact agents

You can enable the FIPS mode on the HCL DevOps Deploy (Deploy) compact agent to make it FIPS compliant.

1. Stop the agent.
2. Open the `<DEPLOY_AGENT_HOME>/conf/agent/javaopts.conf` file.
3. Add the following lines to the `javaopts.conf` file:

```
-Dsemeru.fips=true
-Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced
```

4. Start the agent.

Results

The FIPS mode is enabled on the compact agent.

Enabling FIPS mode on non-compact agents

You can enable the FIPS mode on the non-compact agent to make it FIPS compliant.

1. Stop the agent.
2. Open the `<agentInstall>/bin/worker-args.conf` file.
3. Add the following lines to the `worker-args.conf` file:

```
-Dsemeru.fips=true
-Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced
```

4. Start the agent.

Results

The FIPS mode is enabled on the non-compact agent.

Enabling FIPS mode on agent relays

You can enable the FIPS mode on the HCL DevOps Deploy (Deploy) agent relay to make it FIPS compliant.

1. Stop the relay.
2. Open the `<relayInstall>/bin/worker-args.conf` file.
3. Add the following lines to the `worker-args.conf` file:

```
-Dsemeru.fips=true
-Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced
```

4. Edit the `conf/agentrelay.properties` file and add the following line:

```
fips.flag=-Dsemeru.fips=true\n-Dsemeru.customprofile=OpenJCEPlusFIPS.FIPS140-3-Weakly-Enforced
```

Note: The `\n` separating the two properties is important.

5. Start the relay.

Results

The FIPS mode is enabled on the agent relay.

toc = no

Setting your profile

As a HCL DevOps Deploy (Deploy) user, you can manage teams and roles for your account, and preferences such as display options, language for the server, and how the server shows times and dates.

Managing the teams and users for your account

You can view and manage the teams and roles that you are assigned on the server. Your permissions determine which changes you can make.

Setting the teams for your account

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > Team Manager**.
2. Manage the teams that you are a member of.
   For more information, see Security teams on page 2213.

Setting the users for your account

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > User Manager**.
2. Manage the user that you are a member of.
   For more information, see Security teams on page 2213.

Setting the user preferences

You can set the preferences such as language for the server, and how dates and times are shown on the server.

1. At the upper-right corner of the server window, click your user name, and then click **My Profile > Preferences**.
2. Choose a language for the user interface in the **Locale** field.
3. Select a format for dates in the user interface in the **Date Format** field.
4. Select a format for times in the **Time Format** field.
5. Specify the calendar type you want to use for the server in the **Calendar** field.
6. Specify which teams to assign for new objects in the **Default Teams for New Objects** list.
   By default, **System Default Policy** is selected and uses the **Default Teams for New Objects** settings defined in the system settings.
   - **All Available Teams** to add new objects to all of the teams that you are a member of.
   - **Specific Teams** to specify specific teams, and then select one or more teams.
   - **None** to specify that no new objects are added to your teams.
7. Click **Save**.

Upgrading high-availability installations

All servers that are configured for the HA feature must be on the same version. Thus, all servers must be upgraded at the same time.

Before you begin

Note: During the upgrade of HCL DevOps Deploy (Deploy), the contents of the appdata/patches directory (including all .jar files) will be appended with `.off`, preventing the existing test fixes from being loaded once the Deploy server is started post-installation. All UI test fixes applied to the Tomcat directory will be wiped by the upgrade and will not be recoverable.

If a text fix received for a reported defect is not fixed in the upgraded version, you may need to open a Support Case to request a new build.

1. Back up the database and file system.
   See Backup and recover on page 2057.
2. Ensure that no application and generic processes are running.
   Open the **Dashboard** and confirm that no processes are running. If processes are running, you can wait for them to complete or by clicking **Cancel** in the same row as each process, cancel them. You can use the Message of the Day feature (**Settings > System > General Settings**) to notify users of the planned upgrade, and request that they do not start new processes.
3. Download and extract the installation package.
   Upgrades are done with the same package used to perform new installations.
4. Shut down the servers.

   Warning: Ensure that all servers are stopped. If any servers are accessing the database when the upgrade happens, the upgrade will cause errors.

5. Ensure that each server is stopped and unable to connect to the load balancer.

   a. Check to ensure that there is no file `server.pid` in the *`server_install`*`/var` folder.

   b. Check for running system processes.

   Example

   For example, on Linux™, you can use the netstat or ps commands. For example, if the server is running on port 8443, use the command `netstat -nap | grep 8443`. You can also run `ps -ef | grep server` and look for the server system process in the results.

   c. If any server processes are still running, stop them.

   If a server process is still running, when you install the new version, you see an error that says "A previously installed version of Deploy is running. Please shutdown the running Deploy and start the installation again."
6. Run the server installation script.
7. From the command line, run the server installer program.

   Choose from:

   - On Windows™, run the `install-server.bat` file.
   - On Linux™, run `./install-server.sh`.

- To install a FIPS-compliant server, add the `-fips-semeru` parameter to the command, such as `install-server.sh -fips-semeru`.

  Note:
  - If you install a FIPS-compliant server, cloud provisioning is not available.
  - Deploy supports IBM Semeru versions 17.0.12, 21.0.4, 25.0.0 or higher.

  Depending on your system settings, you might need to run this file as an administrator.

8. When prompted for the location of the installation directory, enter the path to one of the servers.
   By specifying an existing installation, you are asked if you want to upgrade the current installation. If you answer yes, the script leads you through the upgrade steps.
9. Restart the upgraded server.
   Always use service scripts to start or stop the server. See Starting and stopping the server.
10. After the first server is back online, upgrade the other servers. After you upgrade the first node, you will not be prompted to upgrade the database when you upgrade the other nodes.

Managing locks

A *lock* ensures that processes do not interfere with one another. Normally, locks are released after they are no longer needed. Sometimes, a lock is not released, and its associated process is unable to complete. The lock management feature helps you to identify and resolve abnormal lock conditions.

About this task

Follow these steps to view and resolve locks.

1. A running process with a lock, like all active processes, is shown on the **Dashboard** tab with a status of `Running`.
   If a locked process takes longer to complete than expected, you can cancel the process from the **Dashboard**, or investigate it fully with the **Settings** tab.
2. Display the **Locks** pane by clicking the **Locks** link on the **Settings** tab (**Settings > Locks**).
   Result
   The **Locks** pane displays the following information:

   Table 714. Lock fields

Field	Description
Name	The name identifies the lock. The displayed name is a concatenation of the component or application name (depending on type) + process name + resource name.
Type	Indicates whether the process that created the lock is a component or application type. Locks can be applied only to component or application processes.
Component/Application	Displays the name of the component or application that contains the lock. Clicking an item displays (depending on the type) the **Component** pane, or **Application** pane, where you can investigate the lock.

Field	Description
Resource/Environment	Displays the name of the resource or environment that contains the lock. Clicking an item displays (depending on the type) the **Resource** pane, or **Environment** pane.
Process	Displays the name of the process that contains the lock. Clicking an item displays the process in the process editor.
Actions	Lists the available actions.

3. Resolve the lock by selecting an action:

Table 715. Lock actions

Action	Description
View Request	Displays the process log for the process that contains the lock. You can use the **Actions** field on the displayed pane to see the name of the process step that is causing the lock.
Release	Releases the lock, which enables the associated process to continue processing.

If the HCL DevOps Deploy (Deploy) server and or agents go down while a locked process is running, Deploy automatically restores any interrupted processes along with any locks they might contain after service is restored.

Acquire Lock on page 2466

Release Lock on page 2483

System properties

System properties are global variables for the server.

System properties are available on the **Settings** tab: click **Settings > Properties**.

References to system properties are similar to the following example:

```
${p:system/propertyName}
```

If you create a `SUCCESS` system variable , for example, you would refer to it as in the following example:

```
echo ${p:system/SUCCESS}
```

Output in this case:

```
SUCCESS
```

System settings

System settings allows you to manage global settings for components, clean up, password requirement, security, mail-server, and much more.

Example

The following tables list the settings for several system-wide settings for the server.

Table 716. General settings

Field	Description
External Agent URL*	Specify the URL that the HCL DevOps Deploy (Deploy) server provides to agents as their point of contact. When an agent wants to contact the server, it retrieves this URL and opens a connection on it. This URL must point to the HTTP or HTTPS port of the server.
External User URL*	Specify the URL that users enter to connect to the Deploy server. The URL is also used when creating a notification template.
Message of the Day	A custom notification message that is displayed when users log in to the dashboard. This field supports standard Markdown syntax, which you can use to include formatted headings, bold text, numbered or bulleted lists, inline code blocks, and internal or external hyperlinks.
Validate Agent IP	When enabled, the agent IP and host name are validated against values that are used the first time that the agent is connected to the Deploy server.
Create Default Children for Plugins	When enabled, empty groups are created when plug-ins use the auto discovery feature.
Default Locale	Select a default language for the user interface.
Default Snapshot Lock Type	Determines the default lock type when users create snapshots. Lock types are the following values: **Only Component Versions**, **Only Configuration**, or **Component Versions and Configuration**. The default value is **Component Versions and Configuration**. Changes are effective after the server is restarted.
Require a Comment For Process Design Changes	When enabled, prompts users to provide a comment when a process design is updated.
Enable Maintenance Mode	When enabled. stops activities on the server so you can run important tasks that require the server to be idle.

Table 717. Component settings

Field	Description
Components copy to CodeStation by default	When enabled, newly created components copy artifacts to CodeStation by default. You can change this setting on individual components even when this option is enabled.
Enforce Deployed Version Integrity	When enabled, deployed component version artifacts cannot be changed.
Automatic Version Import Check Period (seconds)*	Specify the time-period (in seconds) between the times that Deploy polls components for new versions. If this value is changed, the server must be restarted before the change becomes effective. You can set this value to 15 seconds or higher.
Use Agent Tag For Integration	When enabled, allows agent that is identified by a specific tag to import component versions. If this setting is selected, the **Agent Tag for version imports** field is shown. Otherwise, the **Agent for Version Imports** field is displayed. For information about tagging objects, see Adding tags to objects on page 2521
Agent for Version Imports	Specify the agent that is used to import component versions. The agent must have access to component artifacts. The agent becomes the default agent for new components. This value can be overridden when a component is created. This field is displayed if the **Use Agent Tag for Integration** toggle button is set to Off. To import artifacts from the server location, install an agent in the same location and specify that agent.
Version Import Records to Retain	Specify the number of version import records to retain during cleanup. Default is 100.
Enable Safe Edit of Component Processes	When enabled, you can test component processes before making them available in normal environments. You can make updates to your component process, test those updates safely, and then promote to a new version when you are ready.
Require Approval to Promote	When enabled, any draft component process must be approved by an authorized user before it can be promoted and used in deployments.

Table 717. Component settings (continued)

Field	Description
Component Process	
Allow Process Locking	When enabled, users with 'Manage Process Lock' permission can lock component processes for editing. Users can also force unlock a process locked by another user.
Require Process Locking	When enabled, users will not be able to edit component processes without locking the process first.
Server Storage Display '100%' Size (MB)	Define the size in megabytes of '100%' storage in the dashboard server storage display. This setting only affects the dashboard display and does not enforce a limit for artifact uploads.

Table 718. Artifact cleanup settings

Field	Description
Daily Cleanup Start Time*	Enter the time when versions are cleaned. The value must be an integer from 0 (midnight) to 23 (11 pm). To preview the component versions that are scheduled for cleaning, click **Preview Version Cleanup**. See Cleaning up component versions on page 2136.
Default Application Snapshot Retention (days)*	Enter the number of days application snapshots are kept by default. A value of `-1` means that they are kept indefinitely. Component and environment settings can override this setting.
Default Version Retention for Component (days)*	Enter the number of component versions to keep by default. A value of `-1` specifies that all are kept. Component settings can override this setting.
Default Number of Versions to Retain for Component*	Enter the number of versions to retain for each component.
Default Version Retention for Environment (days)*	Enter the number of environment versions to keep by default. A value of `-1` specifies that all are kept. Environment settings can override this setting.
Default Number of Versions to Retain for Environment*	Enter the number of versions to retain for each environment.

Table 718. Artifact cleanup settings (continued)

Field	Description
Archive Path	Specify the path where the compressed file that contains the archived component versions is written. If this field is blank, the compressed file is not written, and no archive is kept.
Preview Version Cleanup	Click **Preview Version Cleanup** to see the versions that are archived using the current settings. See Cleaning up component versions on page 2136.

Table 719. Process history cleanup settings

Field	Description
Daily Cleanup Start Time	Specify the time that the daily cleanup process starts.
Daily Cleanup Duration (hours)	Specify the number of hours that the cleanup process runs daily.
Enable Deployment History Cleanup	When enabled, deployment history files are reduced. See Cleaning up deployment history files on page 2133.
Days to Retain Deployment History	Enter the number of days to retain deployment history. This setting can be overridden with the related environment setting.
Enable Generic Process History Cleanup	When enabled, the generic process history files are set to delete as per the **Days to Retain Generic Process History** setting.
Days to Retain Generic Process History	Enter the number of days to retain generic process history. This setting can be overridden with the related environment setting.
Enable Process Step Log Cleanup	When enabled, the process step log cleanup starts. The process step logs are deleted according to the values that you set without deleting other history records.
Days to Retain Process Step Logs	Enter the default number of days to retain process step logs for generic processes not associated with deployments, and for environments if the number of days is not specified directly in the environment settings. Valid range is 0 or greater.

Table 720. Audit Log settings

Field	Description
Enable Audit Log Entries for Read Events	This option is disabled by default on new installation. When disabled, no READ events are recorded in the audit log.
Enable Audit Log Cleanup	When enabled, audit log entries older than the number of days specified in the **Days to Retain Audit Log Entries** field are removed beginning at the time specified by the **Daily Cleanup Start Time** field. See Configuring log rotation settings on page 3002. Deleting audit logs from **Settings > Audit Log > Cleanup Log** creates a log entry of event type Audit Log Cleanup that are non-deletable.
Daily Cleanup Start Time	If **Enable Audit Log Cleanup** is enabled, specify the time the audit log cleanup starts. The default value is 12:00 AM.
Days to Retain Audit Log Entries	If **Enable Audit Log Cleanup** is enabled, specify the number of days that audit log records are retained. The default value is 30.

Table 721. Password requirement settings

Field	Description
Minimum Password Length*	Define the minimum length for passwords.
Require Uppercase Characters in Passwords	When enabled, passwords must contain at least one uppercase character.
Require Lowercase Characters in Passwords	When enabled, passwords must contain at least one lowercase character.
Require Special Characters in Passwords	When enabled, passwords must contain at least one special character.
Require Number Characters in Passwords	When enabled, passwords must contain at least one numeric character.
Require Password to be Unique From User Information	When enabled, passwords must not match username, actual name, or configured email.

Table 722. Security settings

Field	Description
Discovery Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Auto Discovery Steps to expire. The value must be 300 seconds or more.

Table 722. Security settings (continued)

Field	Description
Configure Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Auto Configure Steps to expire. The value must be 300 seconds or more.
Version Import Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for Version Import Steps to expire. The value must be 300 seconds or more.
Plugin Step Auth Token Expiration Delay(seconds)	Specify the delay in seconds for auth tokens that are created for plug-in steps to expire. The value must be 300 seconds or more.
Use Default Auth Token Restriction if not specified	When enabled, the default authentication token restriction for processes that are created in Deploy is used. For these versions, the default token is applied to the most current process version but not other versions. For more information, see Restricting authentication tokens on page 2223.
Require Token Restriction	When enabled, the None option is removed from the Auth Token Restriction drop-down when creating or editing an authentication token. This makes Auth Token Restriction a required field, but the user can still set a highly permissive token restriction.
"Remember me" duration (hours)	Specify the number of hours a user can optionally be remembered and remain logged in.
Maximum Login time (hours)	Define the maximum duration (in hours) a user can stay logged in. When set, it forcibly disconnects the remote users from server when the logon hours expires. This setting overrides the **"Remember me" duration (hours)** setting. You can enter `0` or a negative value to disable the setting.
Logout should invalidate all "Remember Me" cookies	When enabled, invalidates all "Remember Me" cookies for a user when they explicitly log out.
Default Teams for New Objects	Select **All Teams Available to User** to add all teams that are available to user by default when a new object is created. When set to None, no teams are assigned to the users when new objects are created. Users can override this setting while creating objects.

Table 722. Security settings (continued)

Field	Description
Trusted proxy list	Enter a regular expression pattern to match IP of the trusted proxy servers. This value affects all servers. You must restart the servers for the changes to reflect. If left blank, the proxy headers are not trusted from incoming connections, which further may affect auth token IP restriction validation and IP logging.
User Idle Days to Lock	Specify the number of days after the user's last login date before locking the user account. You can enter 0 to disable user account locking.
User Idle Days to Delete	Specify the number of days after the user's last login date before deleting the user account. You can enter 0 to disable user account deletion.
Preview Idle User Lock	Click **Preview Idle User Lock** to load the information about user accounts that will be locked or deleted.
Realm for Bearer Authentication	Select an authentication realm to be used for the bearer authentication.

Table 723. Mail server settings

Field	Description
Mail Server Host	Enter the host name of the mail server that is used for notifications. Deploy can send notifications to users based on user-configured trigger events (to set up notifications, see Creating Notifications in a Notification Scheme on page 2081). Deploy requires an external SMTP mail server to send messages. To disable notifications, leave the field blank.
