HCLSoftware

HCL DevOps Loop 2026.08 (2.0.2.1) User Documentation

Release date: 14 August 2026

Special notice

Before using this information and the product it supports, read the information in Notices on page mmmccxcii.

Contents

Chapter 1. Release Notes..... 5
What's New..... 5
Defect fixes..... 19
Known issues..... 20
Chapter 2. System Requirements..... 25
Hardware..... 26
Operating systems and containers..... 26
Host prerequisites..... 27
Supported software..... 29
Chapter 3. Getting Started..... 30
Overview of DevOps Loop..... 30
User interface..... 30
Accessibility features..... 36
Chapter 4. Administration..... 37
Configuration of external databases for the capabilities in DevOps Loop..... 37
Configuring an external database for Plan and Control..... 37
Configuring an external database for Deploy..... 39
Configuring an external database for Build..... 41
Configuring an external database for Test..... 42
Configuring an external database for Measure and Release..... 43
Configuring external access to the Plan PostgreSQL database..... 44
Installation of DevOps Loop..... 45
Installing DevOps Loop on IBM Cloud Kubernetes Service (IKS)..... 46
Installing DevOps Loop on Kubernetes Service (K8S)..... 49
Installation of DevOps Loop on Google Kubernetes Engine (GKE)..... 56
Installing DevOps Loop on a RHEL system for a demo setup..... 59
Installation of DevOps Loop on Amazon Web Services (AWS)..... 62
Installation of DevOps Loop in an air-gapped environment..... 69
Managing DevOps Loop features after installation..... 76
License management and user administration..... 77
DevOps Loop licensing information..... 78
Enabling the social sign-up and social login for DevOps Loop..... 80
Revoking a license..... 81
User access and administration using Keycloak..... 81
About user roles and access permissions..... 83
Backup and restoration of DevOps Loop..... 84
Backing up DevOps Loop data..... 85
Restoring DevOps Loop data..... 86
Private CA and self-signed certificate support..... 87
Configuring trusted certificates in DevOps Loop..... 88
Upgrading DevOps Loop..... 90
Integrations in DevOps Loop..... 93
AI provider integration for Loop Genie - Tech Preview..... 94
Harbor integration overview..... 104
DevOps Loop MCP server..... 111
Getting started with the DevOps Loop MCP server..... 112
DevOps Loop MCP server configuration in VS Code..... 127
Connecting Claude to the DevOps Loop MCP server..... 130
Configuring an external MCP server in a teamspace..... 130
Teamspace management..... 132
Creating a teamspace..... 132
Adding or inviting members to a teamspace..... 134
Joining a teamspace as an invited member..... 135
Removing a member from a teamspace..... 135
Uninstalling DevOps Loop..... 136
Uninstalling DevOps Loop from IBM Cloud Kubernetes Service (IKS)..... 136
Uninstalling DevOps Loop from Kubernetes Service (K8S)..... 137
Chapter 5. Working with Loops..... 139
Loop management..... 139
Creating a loop..... 140
Capabilities and resources configured during loop creation..... 142
Viewing loop details..... 145
Adding members to a loop..... 145
Removing a member from a loop..... 146
Disabling a loop..... 147
Enabling a loop..... 147
Loop Segments overview..... 148
Learning Loop overview..... 151
Creating a Loop with preloaded example data..... 152
Dashboards and insights..... 154
Viewing dashboards..... 155
Editing dashboards..... 155
AI-powered search..... 156

Chapter 1. Release notes for DevOps Loop 2026.08 (2.0.2.1)

This document includes information about the features introduced, a product overview, and installation instructions, as well as contact information of HCL Customer Support for this version of HCL DevOps Loop.

Product description

DevOps Loop is a cloud-based continuous integration platform. DevOps Loop is built on modern, cloud-native technologies that enables product teams to plan, code, test, build and deploy the applications efficiently. DevOps Loop provides a holistic view of the progress in the DevOps cycle, allowing teams to track development, monitor workflows, and manage releases effectively. For more information, see Overview of DevOps Loop on page 30.

What's new

You can find information about the features introduced, enhancements, or other changes in DevOps Loop. See What's New on page 5.

Product download and installation

If you have purchased the licenses to use the product, you can download the entitled software packages from HCL Harbor container registry.

For instructions about installing the product software, see Installation of DevOps Loop on page 45.

Known issues

For the list of known issues that are identified in this version and the previously published known issues that are still applicable, see Known issues on page 20.

Contacting HCL support

- For technical assistance, contact HCL Customer Support.
- Before you contact HCL support, you must gather the background information that you might need to describe your problem. When you describe a problem to an HCL Support specialist, be as specific as possible and include all relevant background information so that the specialist can help you solve the problem efficiently. To save time, know the answers to these questions:
    - What software versions were you running when the problem occurred?
    - Do you have logs, traces, or messages that are related to the problem?
    - Can you reproduce the problem? If so, what steps do you take to reproduce it?
    - Is there a workaround for the problem? If so, be prepared to describe the workaround.

What's New

You can find information about the features introduced, enhancements, or other changes made in HCL DevOps Loop.

What's New in DevOps Loop 2026.08 (2.0.2.1)

Release date: 14 August 2026

Ther are no new features in this release of DevOps Loop.

What's New in DevOps Loop 2026.06 (2.0.2)

Release date: 09 July 2026

The following table lists the new features, enhancements, or other changes made in DevOps Loop:

Feature title	Description
Azure OpenAI integration for Loop Genie	You can now configure Azure OpenAI as AI provider in Loop Genie, that enables AI-powered workflows through Microsoft Azure services. See Configuring AZURE OpenAI integration on page 98.
External MCP server support in Loop Genie	You can now connect Loop Genie to external MCP servers that enable integration with third-party tools and services through the Model Context Protocol. See Configuring an external MCP server in a teamspace on page 130.
Harbor integration in DevOps Loop	You can configure Harbor as an integrated capability during DevOps Loop installation to provide container image storage, vulnerability scanning, and image management capabilities. See Harbor integration overview on page 104.
Updated user interface	You can experience a refreshed user interface across DevOps Loop with updated page designs that provide a more consistent, modern, and accessible user experience.
Demo data for segments in Learning Loop	You can now create a complete sample DevOps environment with preloaded data across the Plan, Control, Build, Deploy, and Test capabilities. The Learning Loop includes frontend and backend segments with ready-to-use repositories, build pipelines, and deployments that demonstrate end-to-end DevOps workflows. This environment enables hands-on practice without impacting production systems. See Learning Loop overview on page 151.
Enhanced Loop Genie - Tech Preview	Loop Genie now uses an enhanced ReAct execution model that dynamically determines the next action required to satisfy your request, evaluates results after each step, and invokes additional tools as needed, while displaying full tool activity (names, parameters, execution status, and results) inline for complete transparency. See Loop Genie overview - Tech Preview on page 3277.
Plan	
Code Genie support	The Code Genie feature provides an end-to-end integration within the Loop environment that allows you to generate source code directly from a work item. See Code implementation with AI on page 158.
Control	

Feature title	Description
Code Genie support	Control repositories created for Loops are now automatically configured to enable AI-assisted code reviews through Code Genie and the Copilot dev container. You can now use interactive code suggestions across your team during code reviews. See AI code reviewing with Code Genie on page 224.
Deploy	
Azure OpenAI support for Deployment Genie	Added support for Azure OpenAI LLM integration in Deployment Genie for AI-assisted failure analysis. See Configuring the AI settings on page 2117.
Locking snapshot in process step	Added a new built-in step for locking snapshots in generic, application, and component processes to ensure deployment audit requirements. See Creating snapshots on page 2383.
Exporting the draft process	Added the ability to export draft component processes in JSON and YAML formats for review workflows. See Exporting specific component processes on page 2300.
Amazon S3 archiving	Added native support for archiving component versions to Amazon S3 buckets with configurable policies and IAM authentication. See Archiving version artifacts to Amazon S3 on page 2122.
Deployment reports enhancements	The deployment reports are enhanced as follows: • Support for selecting multiple applications and environments simultaneously. • Added approver information. • Added **Snapshot** and **Description** of the deployment request process columns. See Deployment reports on page 2547.
Plugin page enhancements	The Plugin page is enhanced as follows: • The **View Documentation** option is added to the plug-in pages for direct access to plug-in documentation. • The **Installed plugins** page now highlights plug-ins with newer versions available. See Installing plug-ins from the Web UI on page 2560.

Feature title	Description
Message of the Day formatting	Added CommonMark markdown formatting support (bold, links, lists, headers, code blocks) to the **Message of the Day** system settings. See System settings on page 2086.
Enhanced MCP tools	Added the following MCP tools: • **GetDeploymentFailedSteps**: Retrieves information on failed deployment steps. • **GetStepOutput**: Accesses step execution logs and output. • **SearchStepOutputRegex**: Searches step output using RE2-protected regex patterns. • **SearchStepOutputHangs**: Identifies long intervals between log output lines. See Using the Deploy MCP tools on page 2994.
Dependent generic process exclusion	Added an option to exclude dependent generic processes from the import operation. See Importing and exporting generic processes on page 2452.
Additional truststore for server	Added support for an additional server truststore that is used alongside the JVM default truststore. It helps in storing keys specific to webhooks, email, and other TLS clients. See Keystores configuration on page 2164.
Test	
AI-powered test generation with Test Genie in Test Hub	You can now use Test Genie to automatically generate test assets within Test. By providing natural language instructions and connecting to a supported AI provider, you can accelerate your test creation process. While test steps are being generated, you can view AI interactions and session logs on the progress page. After the test generation is complete, you can view the generation metrics. See Test creation with Test Genie on page 780, Creating a Web UI test with Test Genie on page 781, and Modifying a Web UI test created by using Test Genie on page 783.
Support for the Anthropic AI provider	You can now add and manage the Anthropic AI provider on the **Cloud Credentials** page in Test. You can then use Anthropic to generate tests by using Test Genie, or to populate schema generator configurations when auto-assigning generators and configurations to each field in a data definition. See Management of cloud credentials on page 1115, Test creation with Test Genie on page 780, and Auto-assigning generators and AI-provided data configurations to data definitions in the Schema View on page 1009.
Personal agents for local test execution and debugging	You can now download, install, and start a personal agent directly from the **Test Editor** page. A personal agent is a local agent that provides a dedicated, isolated runtime

Feature title	Description
	environment to run Web UI tests and suites directly on your local machine so that you can visually observe UI interactions in real time and identify the exact point of test failure. See Management of the personal agent on page 1095, Installing and starting the personal agent on page 1096, and Stopping or unregistering the personal agent on page 1100.
MCP support for authentication	MCP clients can now dynamically register with the authorization server (Keycloak) without requiring an offline token to be passed through the authentication header. When you connect to an MCP server endpoint in Test to access server-side tools directly from MCP clients, such as VS Code, you must provide your credentials to authenticate the connection. See Configuration of an MCP server endpoint on page 756 and Configuring an MCP server endpoint in VS Code on page 757.
Support for local repository creation and asset management	You can now create standalone local repositories without a remote repository reference. These local repositories operate the same way as the remote repositories, and they can optionally be connected to an empty remote repository at a later point for synchronization. See Adding a repository to a team space on page 1031.
Support for running server test assets and server suite assets on device clouds	You can now run server test assets and server suite assets on Android or iOS devices that are available through supported device clouds, such as BrowserStack Cloud, LambdaTest Cloud, and pCloudy Cloud. See Running server test assets by using a cloud credential on page 1326 and Configuring a run of a Web UI test to run by using a cloud credential on page 1354.
Customization of environments with profile overrides	You can now configure profile overrides in custom environments so that you can easily change the target profile without changing your test script. When you run a test or a suite with a profile override, the default profile, such as a specific browser or emulated device, is substituted with a different target profile, such as a cloud-native device or an alternative browser. See Test environments on page 869, Creating an environment on page 870, and Modifying an environment on page 872.
Device emulation support on Safari for Web UI tests	You can now record and play back Web UI tests on the Safari browser in the device emulation mode. You can use the Phone (X-Large) and Tablet (X-Large) options that are available for Safari on Mac. See Web UI test creation on page 769.
Support for downloading the agent from the project's Agents and Intercepts page	You can now download DevOps Test Runtime from the **Agents and Intercepts** page after navigating to your project from the initial team space. See Installing and registering DevOps Test Runtime agents on page 1087.
Support for recording and playback of jQuery UI controls	You can now record and play back tests for supported jQuery UI controls. The Smartshot view includes a **Filter by jQuery** option that helps you identify supported jQuery UI controls when editing tests. See Editing a Web UI test on page 793.
Support for conditional flow control actions in Web UI tests	You can now use conditional flow control actions such as **If, While, and Do-while** directly in Web UI test steps. These actions support smartshots and use the same

Feature title	Description
	decision logic as verification points, so that you can perform steps based on the presence or state of a UI widget. The **Pause** step is renamed to **Wait** and now supports both **UI** and **General** modes. See Adding an If step on page 816, Adding a While step on page 818, Adding a Do-While step on page 821, and Adding a Wait step on page 802.
Support for moving or deleting tests with dependent assets	You can now move or delete tests along with their dependent assets. Assets that are referenced exclusively by a test are processed together with the test, while shared assets remain unaffected. References to shared assets are updated automatically to prevent any impact on the test run. See Test navigator panel on page 761.
Support for multi-select actions in Test Navigator	You can now select multiple assets in the Test Navigator and perform actions, such as editing, moving, and deleting, on all selected assets, which makes asset management more efficient. See Test navigator panel on page 761.
Easy navigation in Test Editor to access the failed and error steps in the suites	When you play back test suites in **Test Editor**, the three color-coded boxes display the counts of passed steps, failed steps, and errors. You can now view the step details of the first failed step or the step with an error by clicking the respective color-coded box. See Running a suite sequentially on page 834 and Running a suite concurrently on page 835.
Support for viewing individual test results in Test Editor	You can now select and view individual test results directly within **Test Editor**. Result information is displayed in **Test Editor**, and step-level results are highlighted when the selected result matches the current version of the test. See Running a Web UI test on page 785.
Support for viewing configuration details in functional reports and test logs	You can now view configuration details directly in the functional report and test log. Configuration nodes for tests and modules display the initial variable values and dataset information to provide better visibility into the configuration used during test runs. Variable information is displayed in a more streamlined format to improve report readability and analysis. See Test logs on page 1523 and Viewing a Functional Report on page 1511.
Support for generating negative test data from data definitions	You can now generate negative test data from data definitions to validate error handling and input validation scenarios. You can configure the type and amount of negative data that is generated, preview the generated data, and create datasets that combine invalid values, optionally, combined with valid data to support more effective, comprehensive testing. See Generating negative test data for a data definition on page 1015.
Build	
UI Modernization	The user interface has been improved for better navigation and usability.

Feature title	Description
Support for Repository-based configuration files	You can now store Job as Code (JAC) configuration files, such as `<config_file>.json` or `<config_file>.yaml`, anywhere within your source code repository. When configuring a Job as Code step, you can specify the path to the configuration file relative to the repository root. During execution, the plugin retrieves the file from the branch that triggered the build and dynamically generates the build workflow. See Creating Job templates using the Job as Code plugin on page 378.
Measure	
Added Data retention policy	Product administrators can now configure data retention policy to archive or permanently delete historical data for the resource types, such as versions, builds, or issues. You can provide the retention period across VSM, team, or application scopes to optimize database performance, reduce UI clutter, and simplify compliance management.
Enhanced User Interface	The user interface is enhanced for better navigation and usability.
Enhanced MCP token exchange time	The Model Context Protocol (MCP) workflow is enhanced by adding a cache layer. This helps make MCP integration more responsive and reliable.
Added support for Jira, Jenkins, and GitHub	The Analytics dashboards can now display the data for Jira, Jenkins, and GitHub.
Code	
Updated user interface	The interface is refined to reflect a more intuitive user experience, featuring improved navigation and dark theme support.
Code Genie: AI-assisted development and PR reviews	You can now use the AI providers, including but not limited to GitHub Copilot and IBM Bob, to automate pull request workflows and Plan work item implementation with AI-powered code generation, security scanning, and AI-agent code review.
Enhanced extension registry support	You can now configure private extension registries for secure, administrator-controlled extension management with centralized configuration and on-premises hosting support.

You can find information about the features introduced, enhancements, or other changes made in the previous versions of DevOps Loop in the following sections.

- What's New in DevOps Loop 2026.03 (2.0.1) on page 12
- What's New in DevOps Loop 2025.12 (2.0.0) on page 15
- What's New in DevOps Loop 2025.09 (1.0.3) on page 16
- What's new in DevOps Loop 2025.06 (1.0.2) on page 18
- What's new in DevOps Loop 2025.03 (1.0.1) on page 19

What's New in DevOps Loop 2026.03 (2.0.1)

Release date: 13 April 2026

The following table lists the new features, enhancements, or other changes made in DevOps Loop:

Feature title	Description
AWS platform support	You can now install DevOps Loop on AWS. See Installation of DevOps Loop on Amazon Web Services (AWS) on page 62.
Support for loop segments	You can manage multiple microservices within a single loop by creating independent segments with dedicated resources and integrations. See Loop Segments overview on page 148.
Enhanced Loop Genie - AI Assistant	You can now use predefined tasks from the **Tasks** tab to automate workflows and perform common DevOps operations. You can also review or reuse past interactions from the **History** tab within a unified workspace. See Loop Genie overview - Tech Preview on page 3277.
New loop dashboards	You can now see three new dashboards available for your loop - Delivery dashboard, Quality and Security dashboard, and Productivity dashboard. See Dashboards and insights on page 154.
Dashboard enhancements	You can now view the Issue flow rate visualization, which replaces Issue Created vs. Issue Closed and includes total outstanding open issues, eliminating the need for a separate Total open issues chart. You can also view Lead time and Cycle time by calculated using the median (in days) for accurate insights. See Dashboards and insights on page 154.
Plan	
Support for the Plan MCP server	The Model Context Protocol (MCP) server is integrated to connect with AI-powered development environments (such as GitHub Copilot in VS Code), which enables management of DevOps Plan through natural language prompts by using MCP tools, helping in streamlining developer workflows. See Plan MCP endpoint and tools on page 115.
Control	
Support for the Control MCP server	DevOps Control enables AI-driven development by integrating AI agents through the MCP server. Through this integration, you can perform DevOps operations, including repository (create, fork, search) and code management (create/update/delete files, retrieve contents, manage branches), and collaboration workflows (creating, approving, and merging pull requests) by using natural language commands, with support for AI IDEs such as Visual Studio Code. See Control MCP endpoint and tools on page 119.

Feature title	Description
Support for Trivy security scan	DevOps Control repositories created in a loop are now automatically configured with Trivy security scanning, which runs on every pull request before code reaches the main branch. This feature automatically checks for vulnerabilities and misconfigurations, so that teams can enforce severity-based merge protection.
Git credential manager	After any Loop upgrade, you should remove cached credentials from the previous use of Git Credential Manager. See Managing Git authentication for developers.
Git credential manager update	You must remove cached credentials from previous use of Git Credential Manager after upgrading Loop to ensure proper authentication. See Managing Git authentication for developers.
Code	
Support for Log Viewer	You can now use Log Viewer in Code to view, filter, and download logs from dev containers and teamspaces for easier troubleshooting.
Support for Extension Registry - Tech Preview	The Extension Registry is a tech preview feature for configuring local extension registries, so that you can control and publish approved extensions for teamspaces.
Support for Code Genie	The Code Genie feature now automates pull request workflows in Control repositories providing actionable insights, and automatically approving or rejecting PRs.
Build	
Support for the Build MCP server	You can now connect to the Build MCP server from external MCP clients such as VS Code and Claude Desktop to retrieve and update build resources directly from the external clients.
Test	
Support for downloading the agent from the Agents and Intercepts page	You can now download the DevOps Test Runtime from the **Agents and Intercepts** page to install and register the system as a local agent for playing back Web UI tests. See Installing and registering DevOps Test Runtime agents on page 1087.
Support for device emulation	You can now use the device mode of browsers to record and run tests or suites. Test Hub supports a set of device profiles for phones and tablets of four different sizes. Depending on the device size that you select, the device opens in Edge or Chrome browser. See Web UI test creation on page 769, Recording a Web UI test on page 771, Running server test assets on page 1321, Running server suite assets on page 1329, and Running server test assets on an agent on page 1324.
Support for running UI tests across multiple browsers in a single run	You can now run Web UI tests across multiple browsers in a single test run. This feature allows you to configure multiple browser environments and run the test against them simultaneously, helping you validate application behavior across different

Feature title	Description
	browsers more efficiently. See Running suites on multiple browsers and devices on page 839.
Support to define custom environments for test runs	You can now define custom environments to manage sets of variables such as application URLs and user credentials. When you run a test by using the environment, the variables defined in the environment dynamically replace the values within your test script. See Test environments on page 869, Creating an environment on page 870, and Modifying an environment on page 872.
Support for wildcard patterns to include or exclude multiple tests or suites for a test run	You can now use wildcard patterns to include or exclude multiple tests or suites by their name for a test run. You can configure the suite to select tests or suites by adding wildcard patterns. You can use a single asterisk (*) to match items within the same folder, or double asterisks (**) to match items in multiple subdirectories. See Running multiple suites or tests by using the wildcard pattern on page 837.
Support for individual results for test run as part of a suite	You can now view results for child tests that run as part of a parent suite. Each child test generates its own result, making it easier to review failures. These results are listed in the Results tab, where you can identify failed tests and analyze their results. See Test suite management on page 829 and Test results and reports on page 1501.
Support for viewing the run status of the asset during publishing	You can now view the run status of assets when reviewing changes on the **Changes** page before publishing. Each executable asset displays a colored status indicator in the parent row, so that you can view the most recent run result for that specific revision of the asset. See Publishing all changes in an Edit branch on page 1023.
Enhanced test repair experience	You can now repair tests by using the **Show Result** option. You can view the result details, including run status, duration, statistics, and reasons for failures. You can analyze results and verify step details without switching back to edit mode. See Viewing step-level results and updating tests on page 789.
Enhanced smartshots access to update tests	You can now access additional smartshots to update the test by using the **Replace Smartshot** option in the step details pane. The **Result Smartshots** section displays smartshots from the last test run, and the **Application Smartshots** section displays all previously captured smartshots for the application. See Viewing step-level results and updating tests on page 789.
Support for multiple dataset configurations in server assets	You can now configure multiple datasets for server test assets, such as Tests and Suites to assign dataset values to test variables during the test run. This feature supports dynamic data usage during test runs by allowing additional datasets to populate test variables, enabling subsequent steps to use unique and data-driven values. See Multiple datasets in tests and test suites on page 866.

What's New in DevOps Loop 2025.12 (2.0.0)

Release date: 12 January 2026

The following table lists the new features, enhancements, or other changes made in DevOps Loop:

Feature title	Description
GKE platform support	You can now install DevOps Loop on Google Kubernetes Engine, with full support for Filestore NFS, DNS configuration, load balancers, and Helm-based installation. See Installing DevOps Loop on Google Kubernetes Engine (GKE) on page 58.
Learning Loop enhancements	Learning Loop now provides an automated CI/CD demonstration flow from code changes to build, deployment, and a live updated webpage served through a new NgineX web server pod with a unique URL for each loop. See Learning Loop overview on page 151.
Support for DevOps Loop MCP server integration	You can now integrate the DevOps Loop MCP server with external MCP clients such as VS Code and Claude Desktop to retrieve and update loop resources directly from those tools. See Connecting Claude to the DevOps Loop MCP server on page 130.
Enhanced Loop Genie with multi-agent workflow engine	Loop Genie now uses a multi-agent workflow engine that can perform multi-step automation, run complex tasks, and produce well-formatted responses by using models such as **Claude Desktop**, **OpenAI**, and **Gemini**.
Support for a centralized Loop Details page	You can now view all loop configuration details in one place through the new **Loop Details** page, including linked resources and team members, with options to add additional test projects and repositories. See Loop Genie overview - Tech Preview on page 3277.
AI provider support for Loop Genie	You can now configure AI providers such as Claude Desktop and Gemini in DevOps Loop to enhance the AI capabilities of Loop Genie. See Configuring Claude integration on page 99, Configuring Gemini integration on page 101.
UI and accessibility enhancements	DevOps Loop UI is now improved with consistent color schemes, fonts, pagination, and alignment which provides a uniform and accessible user experience.
Enhanced search capabilities	The Search feature has been enhanced with new capabilities that make it easier to find and understand information across your loops. You can now search multiple artifact types including issues, builds, tool requests, commits, and deployments. You can also filter results by selecting a loop. See AI-powered search on page 156.
Support for mixed licensing tiers	As an administrator, you can now assign users to different licensing tiers: Essential, Standard, or Premium with access and feature availability automatically adjusted based on the selected tier. Non-admin users receive a tier during onboarding, and admin users automatically receive the highest tier available. See DevOps Loop licensing information on page 78.
Plan	

Feature title	Description
UI enhancements for query links and work item subscriptions	You can now copy query links to the clipboard and more easily subscribe other users to work items.
Enhancements to Schema Designer	You can now apply new schema revisions directly to your application, including adding and editing record-type Fields, Actions, and States.
Code	
Viewing metrics in the running dev containers	You can now get real-time visibility into key dev container resource metrics to help optimize performance. See Working with dev containers on page 169.
Support for automated SSH authentication by using the Open with DevOps Code UI option	You can now securely clone a Control Git repository by using the DevOps Code UI with SSH authentication. See Authenticating with DevOps Code UI on page 192.
Support for temporary GitHub Copilot in dev containers	You can now configure a dev container to support GitHub Copilot for AI-powered code suggestions and chat assistance. See Installing GitHub Copilot in dev containers on page 223.
Build	
Automatic Build agent configuration	Build agents are now automatically configured and added to the agent pool during the teamspace initialization.

What's New in DevOps Loop 2025.09 (1.0.3)

Release date: 31 October 2025

The following table lists the new features, enhancements, or other changes made in DevOps Loop.

Feature title	Description
Support for installation of DevOps Loop in an air-gapped environment	You can install DevOps Loop in environments without internet access. See Installation of DevOps Loop in an air-gapped environment on page 69.
Support for private CA and self-signed certificates	You can now configure DevOps Loop to trust private or self-signed certificates. See Private CA and self-signed certificate support on page 87.
Support for backup and restoration of DevOps Loop data	You can now back up and restore DevOps Loop data by using Velero and Minio for disaster recovery and upgrades. See Backup and restoration of DevOps Loop on page 84.
Support for upgrading DevOps Loop	You can now upgrade DevOps Loop with support for restoring configurations and resources if needed. See Upgrading DevOps Loop on page 90.

Feature title	Description
Support for Learning Loop with built-in sample data	You can now use sample data for Build, Control, Deploy, and Plan by enabling Learning Loop for training and experimentation without affecting production data. See Learning Loop overview on page 151.
Support for IBM watsonx integration for Loop Genie	You can now integrate IBM watsonx in DevOps Loop to enhance the AI capabilities of Loop Genie. See Configuring IBM watsonx integration on page 102.
Enhanced Loop Genie AI assistant - Tech Preview	You can now use Loop Genie as an intelligent, chat-based assistant to manage teamspace users, loops, and perform control actions such as creating branches or managing pull requests. New features also include voice interaction and improved tracking capabilities. See Loop Genie overview - Tech Preview on page 3277, Prompt references for Loop Genie on page 3286.
Support for customizing Dashboards	You can now edit dashboards, swap panels, clone panels, and add titles directly within DevOps Loop, which provides enhanced customization and visibility. See Dashboards and insights on page 154.
Support for Search across issues	You can now search for issues such as epics, defects, and stories across loops and teamspaces. Search results include issue metadata, associated URLs, and AI-generated summaries with results filtered by your access permissions. See AI-powered search on page 156.
Support for loop enabling or disabling functionality	You can now enable or disable loops. Disabling a loop moves it to a **Disabled** tab and stops associated plugins and webhooks, while re-enabling the loop restores all previously disabled functionality. See Disabling a loop on page 147 and Enabling a loop on page 147.
Support for Build integration	Build is now automatically set up during loop and teamspace creation, which streamlines resource setup and CI/CD steps.
Support for UI and accessibility enhancements	You can now experience improved UI consistency across DevOps Loop, including updated color schemes, fonts, pagination, and alignment which provides a uniform and accessible user experience.
Support for removing members from Teamspaces and Loops	You can now remove members from loops, which automatically removes them from all associated capabilties of DevOps Loop. After you remove members from loops, you can also remove the members from their teamspaces. See Removing a member from a loop on page 146 and Removing a member from a teamspace on page 135.
Measure	
Support for integration with Measure to export test execution metrics	You can now integrate Test Hub with Measure by using a webhook and specify additional parameters related to the test run so that you can view the summary metrics of the test run in the Measure dashboard. The results are categorized based on the type of test – Functional, Unit tests, API, and Performance.

Feature title	Description
Code	
Support for launching Dev Containers via URL	You can now launch Dev Containers directly from a shared URL in DevOps Code, not just from the landing page, enabling quicker access and simplified collaboration.
Support for viewing running Dev Containers	A new Running Containers tab is available on the landing page to show active Dev Containers in DevOps Code for improved visibility and management.
Display of Dev Container descriptions in UI	Each Dev Container tile on the landing page now displays its description, helping users understand the container's purpose before launching it.
Inclusion of sample Dev Containers in new teamspaces	Each newly created teamspace is now prepopulated with a set of sample Dev Containers, enabling users to explore and start development quickly without manual setup.
Support for Git device code authentication	You can now authenticate Git operations using device code authentication on page 196, ideal for secure or restricted environments.
Support for embedding preinstalled extensions in Dev Container images	As an admin, you can now embed extensions directly into Dev Container images, ensuring they are preinstalled at launch - ideal for air-gapped environments without access to online extension registries on page 181.

What's new in DevOps Loop 2025.06 (1.0.2)

The following section lists the new features, enhancements, or other changes made in DevOps Loop:

Feature title	Description
Support for teamspace creation	You can now create teamspaces for your teams in DevOps Loop and the linked teamspaces in all the integrated applications such as DevOps Plan, DevOps Control, DevOps Code, DevOps Test, DevOps Deploy, DevOps Measure, and DevOps Release. See Teamspace management on page 132, Creating a teamspace on page 132, and Adding or inviting members to a teamspace on page 134.
Support for OpenSearch dashboards	You can now view the visualization of the data that is gathered through the DevOps activities in the integrated applications. See Dashboards and insights on page 154.
Integration of AI providers - Tech Preview	You can now integrate AI providers such as OpenAI and Ollama to enable Loop Genie to search and summarize the project data in a loop. See AI provider integration for Loop Genie - Tech Preview on page 94, Configuring OpenAI integration on page 97, Configuring Ollama integration on page 103.
Integration of Loop Genie - Tech Preview	You can now use the Loop Genie chatbot to answer your queries related to the project in a loop. See Interacting with Loop Genie on page 3281.
Revoking licenses	You can now revoke licenses for users when they are no longer required in a project. See Revoking a license on page 81.

Feature title	Description
Integration of Build	You can now configure and use DevOps Build as part of the platform for managing continuous integration and build processes.
Support for custom dev containers	DevOps Code now supports custom dev containers. A teamspace owner can configure the dev containers accessible to the members. The configuration is based on the Dev Containers specification. You can push specifications of Dev containers to a Control Git repository to version the containers.
Support for a new landing page	DevOps Code now includes a new landing page. From the landing page, you can select the teamspace that you want to work and choose the branch from where you can fetch the available dev containers. You can launch, open, or terminate Dev containers directly from this landing page.

What's new in DevOps Loop 2025.03 (1.0.1)

The following section lists the features, enhancements, or other changes made in DevOps Loop:

Feature title	Description
Integration of DevOps Code	You can now use DevOps Code (Code) as part of the platform. Code is a cloud-based integrated development environment for creating and managing your code. See Code on page 159.

Defect fixes

You can find the defects that are fixed in this version of HCL DevOps Loop.

Defects fixed in DevOps Loop 2026.08 (2.0.2.1)

The defects fixed in DevOps Loop 2026.08 (2.0.2.1) are as follows:

ID	Description
NEXUS00006400	Previously, DevOps Code deployments in the AirGapLab environment failed with an image pull error because the Alpine image path was incorrect. This problem is fixed.
NEXUS00006417	Previously, repeated Google API references during Loop page loads caused UI slowness. This problem is fixed.
NEXUS00006553	Previously, external font API dependencies affected support for air-gapped environments. This problem is fixed.

Known issues

You can find the known issues that are identified in this version of HCL DevOps Loop.

Known issues in DevOps Loop 2026.08 (2.0.2.1)

The following known issue is identified in this release:

ID	Description
NEXUS00006751	When you create a teamspace by using an email ID that is exactly 12 characters long, the operation might fail at the Measure phase because the MongoDB 5.9.2 package incorrectly treats the email value as an ObjectId. In this case, the teamspace might be created in Velocity, but the overall teamspace creation task does not complete successfully. To work around this problem, you must avoid using email IDs that are exactly 12 characters long.
NEXUS00006817	When you run tests through Deploy in an HCL DevOps Loop in an air-gapped environment, the tests might fail because the HCL DevOps Test Hub plugin version 4.3 does not work correctly with the Test Hub integration. To work around this problem, navigate to Deploy and update the HCL DevOps Test Hub plugin to version 5.0 to run Test Hub tests successfully.

Known issues from earlier versions

The known issues identified in the earlier versions of DevOps Loop that are still applicable are as follows:

ID	Description	Identified in version	Resolved in version
NEXUS00006323	When you install IBM DevOps Loop version 2.0.2 by using the default IBM entitled registry, DevOps Code dev containers that use the GitHub Copilot extension image or Trivy images might fail to start because the image registry is not configured correctly for the generated image specification. To work around this problem, you must update the `IMAGE_REGISTRY` environment variable in the `devops-code-container-mgr` deployment after the installation is complete by following these steps: 1. From a workstation where the Kubernetes cluster is configured and the `kubectl` command is available, run the following command: `kubectl edit deployment devops-code-container-mgr -n devops-loop`	2.0.2	2.0.2.1

ID	Description	Identified in version	Resolved in version

	2. In the image deployment configuration, update the `IMAGE_REGISTRY` environment variable value with the following:
	`env:`
	`- name: IMAGE_REGISTRY`
	`  value: cp.icr.io/cp`
	3. Save the changes and exit the editor that opened when you ran the `kubectl edit` command.
	Kubernetes restarts the `devops-code-container-mgr` pod after the deployment configuration is updated.
	
	After the pod restrarts, you can create DevOps Code dev containers by using the GitHub Copilot extension image and Trivy images successfully. If you run the DevOps Loop installation script again, you must repeat this configuration change.
	
	Alternatively, before rerunning the installation, you must update the `ibm-devops-loop/charts/ibm-devopscode/templates/helper-deployment.yaml` template to set the `IMAGE_REGISTRY` value correctly.		

NEXUS0000 6321	The demo installation scripts that are included with DevOps Loop 2.0.2 contain incorrect configuration values. As a result, the scripts might fail or produce unexpected results unless they are corrected before execution.
	
	To work around this problem, you must make the following changes before running the demo installation scripts:
	1. Update the Loop chart version to the correct value:
	`LOOP_CHART_VERSION=2.0.200`
	2. Correct the `JSONPath` command by removing the extra closing brace (`)`).
	Replace:
	`-o jsonpath="{.data.valkey-password}" | base64 -d)`
	with
	`-o jsonpath="{.data.valkey-password}" | base64 -d`
	After making these changes, you must rerun the demo installation scripts.
		2.0.2	2.0.2.1

ID	Description	Identified in version	Resolved in version
NEXUS0005995	When you upgrade the DevOps Loop platform to version 2.0.2, existing 2.0.1 Learning Loops continue to use the Ecological Payments sample application and do not include the new Loop Genie tasks that are introduced in version 2.0.2. The **Upgrade Loop** option is not available for loops that were created in version 2.0.1. To work around this problem, you must create a new Learning Loop after upgrading to DevOps Loop 2.0.2 to use the **CycleShop** sample application and the latest Loop Genie tasks and tools.	2.0.2	
NEXUS0006310	When teamspace creation fails, and you select **Cancel and Retry Later**, the failed teamspace is expected to appear in a red ribbon for later retry. Instead, the page becomes unresponsive. To work around this problem, you must sign in with a different user account and create the Teamspace again.	2.0.2	2.0.2.1
NEXUS0006264	When you use Loop Genie to list the available loops, the request might fail because of a tool or domain metadata validation issue. As a result, Loop Genie might not display the available loops. Currently, there is no workaround for this problem.	2.0.2	
NEXUS0006216	When you use Loop Genie, the first request in a new session might fail with an internal server error because of API rate limiting. Although model validation completes successfully, the initial request might not be processed. To work around this problem, you must retry the request after a short interval. If the problem persists, you must start a new Loop Genie session and try the request again.	2.0.2	
NEXUS0006225	When you use Loop Genie in a long chat session, the conversation context might not be summarized correctly as the model context window approaches its limit. As a result, Loop Genie might not respond as expected or stop processing requests. To work around this problem, you must start a new Loop Genie session and continue your conversation there.	2.0.2	
NEXUS0	When a user is assigned an **unsupported Keycloak group and Measure/Release role combination**, the system does not display a	2.0.2	

ID	Description	Identified in version	Resolved in version
0005427	clear authorization error. Instead, the user might experience one of the following behaviors: • Repeated login redirect/loop during authentication • Inability to load Measure or Release pages • No explicit error message indicating invalid role mapping To work around this problem: 1. Ensure the user is assigned a supported Keycloak group. 2. Verify the user is mapped to a valid Measure/Release role combination. 3. For users added to the Users group in Keycloak, use the authorization feature in Measure or Release to assign the required permissions. 4. Re-login after correcting the configuration.		
NEXUS0005067	When you run the list test command, the response returns only the count of projects instead of detailed test information such as test names, IDs, or metadata. In some cases, the returned data might also be inaccurate. Also, when you run a test prompt, the system might return a **test asset file not found** error even when the correct project ID and test name are provided, indicating an issue in locating or mapping the specified test file. Currently, there is no workaround for this problem.	2.0.2	
NEXUS0006206	When you access the `/teamspaces` or `/teamspaces/{id}/tasks` API endpoints in an IHD environment, you might experience slow response times. Currently, there is no workaround for this problem.	2.0.2	
NEXUS0006316	The Jenkins data is not available in the **Deployment by Environment Name** chart in Analytics Dashboards. Currently, there is no workaround for this problem.	2.0.2	2.0.2.1

ID	Description	Identified in version	Resolved in version
NEXUS0000 4133	When you use IBM watsonX, it might not provide proper responses for multistep workflows. The issue is currently observed only with workflows involving multiple steps. Single-step workflows work as expected. To work around this problem, you must use IBM watsonX only for single-step workflows until the issue is resolved.	2.0.0	
NEXUS0000 3275	When an administrator is added to a loop by another administrator before logging into Measure for the first time or before creating their own Loop, the administrator cannot log in to Measure. To work around this problem, you must log in to Measure as another administrator (for example, the one who created the loop) and assign the global *Product Administrator* role to the administrator who cannot log in.	1.0.3	

Chapter 2. System Requirements for DevOps Loop 2026.08 (2.0.2.1)

This document includes information about hardware and software requirements for HCL DevOps Loop.

Notwithstanding the Terms of Use users of this site are permitted to copy and save the reports generated from this tool for such users own internal business purpose. No other use shall be permitted.

Hardware

You can find information about the hardware requirements for HCL DevOps Loop.

The following table lists the requirements to run DevOps Loop on the Kubernetes Service (K8S) or IBM Cloud Kubernetes Service (IKS) platform.

Resource	**Requirement**	**Notes**
Number of worker nodes	4	If you are using Ollama, worker nodes must have at least 32Gib memory.
Processor	8 CPUs per node	
Memory	64 GiB total In addition, you might require 200 MB for each DevOps Code Dev Container used by a user.	
Disk space	256 GiB In addition, you might require 20 GB for each DevOps Code Dev Container used by a user.	
Network	1 Gbps

Operating systems and containers

You can find details about the supported operating systems and containers for HCL DevOps Loop.

Contents

- Bit version support on page 27
- Operating systems on page 27
- Container Platforms on page 27

Bit version support

Bitness	Description
64-Exploit	The product or part of the product runs as a 64-bit application in the 64-bit platforms listed as supported.

Operating systems

Operating system	Hardware	Bitness	Notes
RHEL 8.8	x86-64	64-Exploit	
RHEL 8.10	x86-64	64-Exploit	
RHEL 9.1	x86-64	64-Exploit	
RHEL 9.2	x86-64	64-Exploit	
RHEL 9.4	x86-64	64-Exploit	

Container Platforms

You can find details about the supported container platforms.

Platform	Version	Note
Kubernetes Service (K8S)	1.33	The storage class must support ReadWriteOnce (RWO) and ReadWriteMany (RWX).

Chapter 3. Getting Started

HCL DevOps Loop is a platform designed to support the full DevOps lifecycle. The Getting Started section introduces key concepts and walks through the initial steps to help new users begin working with the platform.

Before exploring the capabilities or performing tasks, ensure that the DevOps Loop is installed and properly configured. See Installation of DevOps Loop on page 45.

Overview of DevOps Loop

HCL DevOps Loop is a unified platform that brings every stage of the software development lifecycle into a continuous feedback loop. It connects teams, processes, and applications across planning, coding, testing, releasing, deploying, and measuring to deliver software faster, with greater visibility and governance.

DevOps Loop is built on cloud-native technologies that support CI/CD at scale and enhance automation with Loop Genie. This AI-powered assistant that provides search results across applications in the Loop and accelerates workflows and helps accelerate delivery.

With dashboards and analytics, DevOps Loop provides real-time insights into progress, quality, and delays across the toolchain. These insights help teams track value creation, enhance decision-making, and continuously improve delivery.

Enterprises can install DevOps Loop on IBM Red Hat OpenShift, IBM Cloud Kubernetes Service (IKS), Kubernetes Service (K8S), Google Kubernetes Engine (GKE), Amazon Web Services (AWS), and Air-Gapped environments to achieve flexibility and scalability across environments.

In addition to its platform-wide features, DevOps Loop includes a suite of integrated capabilities such as **Plan, Code, Control, Build, Test, Release, Deploy, Measure, and Harbor**(if enabled) which work together to support every stage of the software development lifecycle.

For security and compliance, DevOps Loop offers role-based access control so administrators can manage permissions and enforce governance across projects.

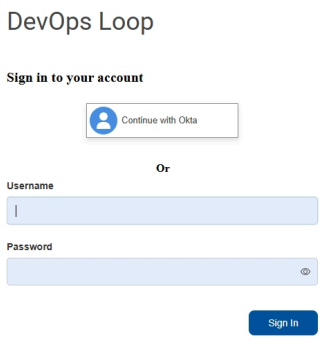
To learn more about the specific capabilities, see Capabilities of DevOps Loop on page 158.

User interface

You can find an overview of the HCL DevOps Loop user interface.

Login page

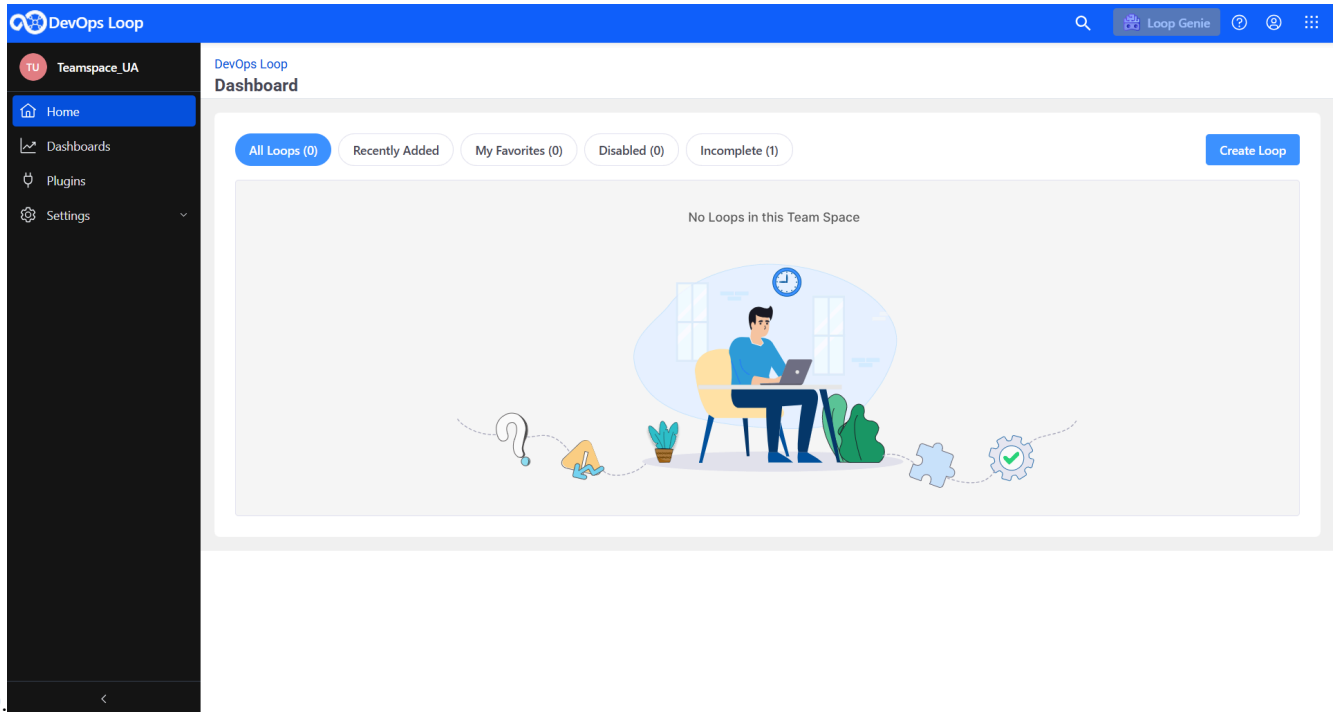
The login page provides an option to sign in to the DevOps Loop



platform.

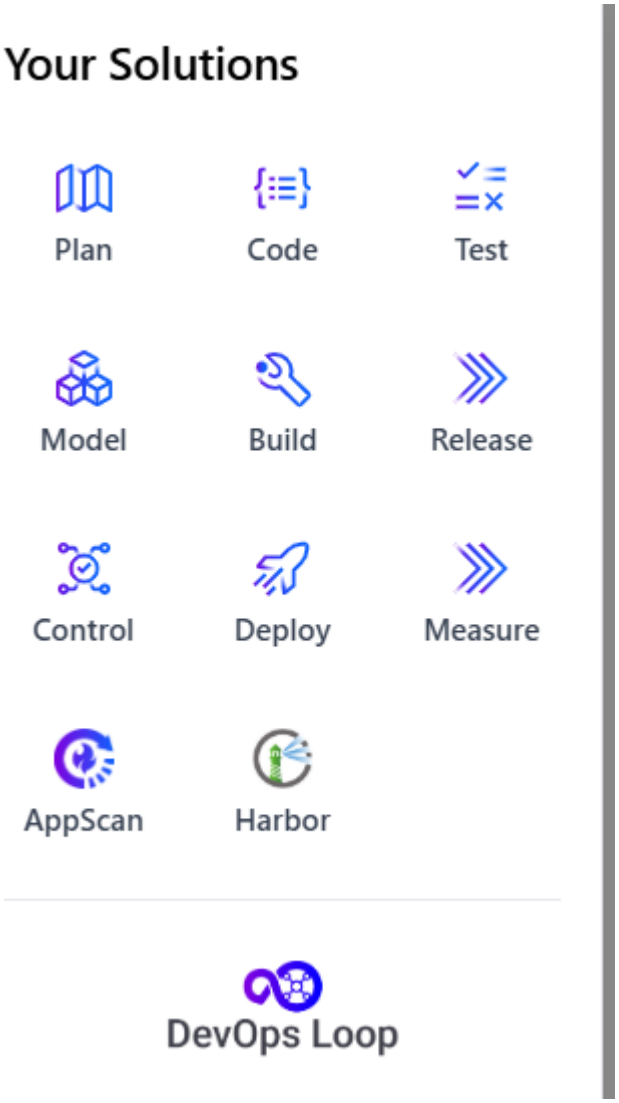
Home page

Within your Teamspace, you can create a loop to begin setting up your DevOps workflow. See Loop management on page 139.



Capability selector

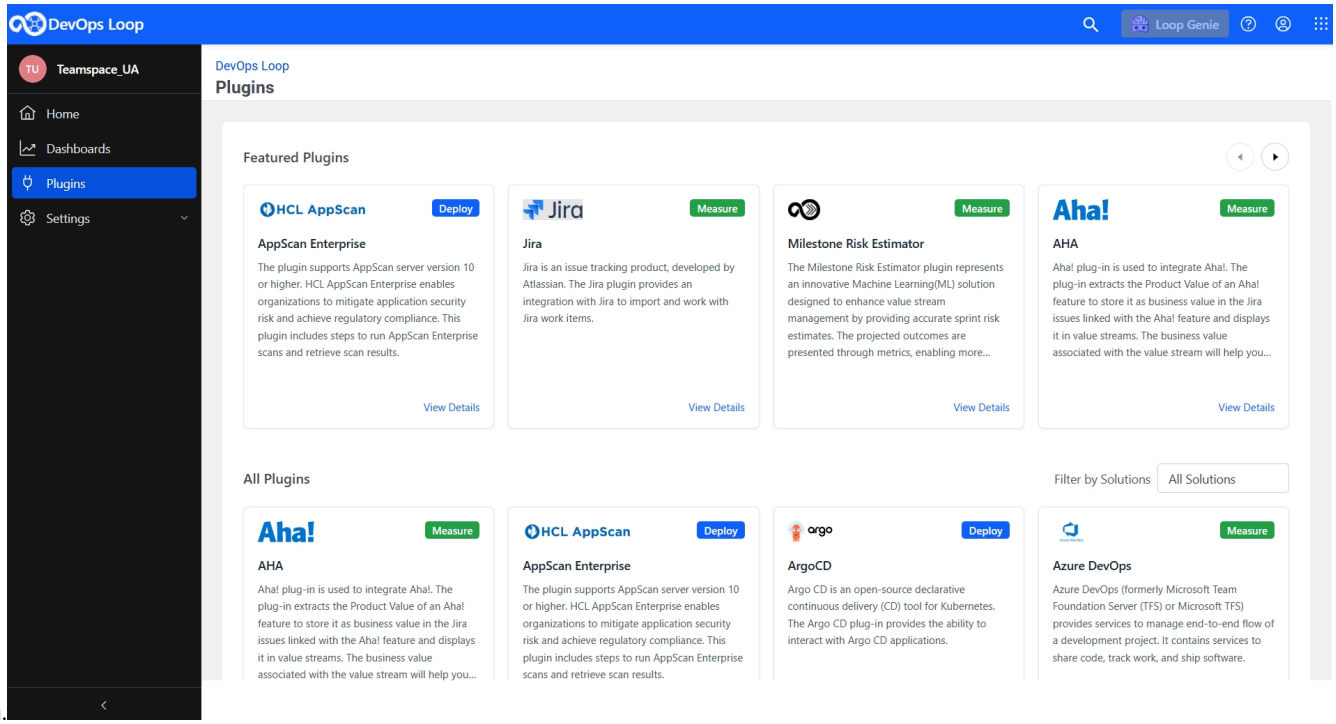
By using the capability selector icon , you can quickly access all DevOps Loop capabilities, such as Plan, Code, Test, Build, Release, Control, Deploy, Measure and Harbor (if enabled) from a single menu.



Plugins

The sidebar provides the **Plugins** option for you to navigate to the **Toolchain Engineering** page that lists the **Featured plugins** and **All plugins** sections. You can choose a plugin that is

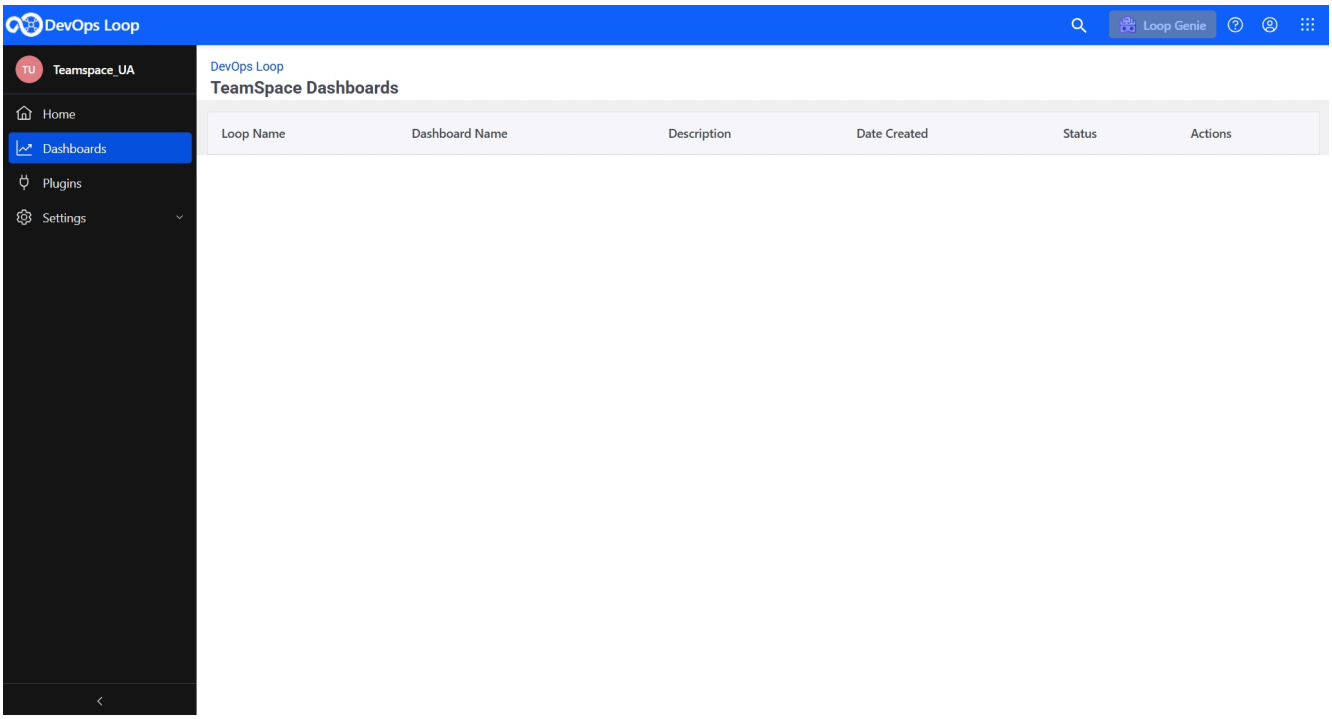
required for a specific solution from the **All plugins** section and click to download the



plugin.

Dashboards

The Dashboards page provides a centralized view where teams can access, filter, and manage all their DevOps Loop dashboards.



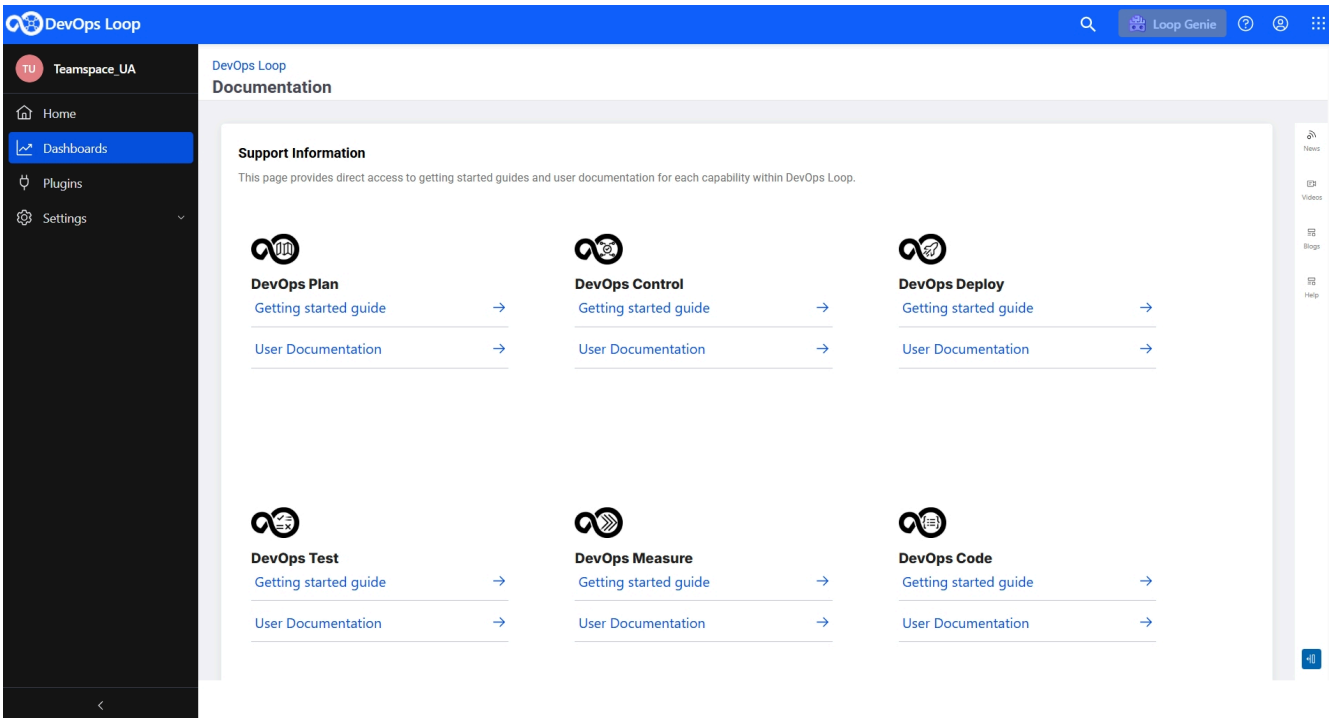
Settings

The sidebar provides you the option to administer users through the **User Administration** page and manage integrations through the **Installed Integrations** page. See Revoking a license on page 81 and Integrations in DevOps Loop on page 93.

Help

You can click the **Help** icon to quickly access the product information and documentation resources.

You can select **Documentation** option in the **Help** menu to view getting-started guides and detailed user documentation for every capability within DevOps Loop.



Global Search

The search option 
helps you to find information across multiple capabilities. You can search across a wide set of artifact types, including issues, builds, tool requests, commits, and deployments, and you can filter results by loop or by category to quickly narrow your search.

Profile

The **Profile** displays the logged-in user's information and provides the option to log out of DevOps Loop.

To log out, you can click the profile icon , and then click **Logout**. The following logout page is displayed.

You can click **Login** to log in again.

Accessibility features

Accessibility features help users who have physical disabilities, such as visual and hearing impairment, or limited mobility, to use the software products successfully.

Accessibility compliance

The product documentation is published by using Oxygen XML WebHelp Responsive. To understand the accessibility compliance status for Oxygen XML WebHelp Responsive, refer to WebHelp Responsive VPAT Accessibility Conformance Report.

Accessing UI elements

DevOps Loop supports navigation in the UI by using different methods such as a mouse, keyboard, or touchpad.

You can use the keyboard keys such as **Tab**, arrow keys such as **UP**, **DOWN**, **LEFT**, and **RIGHT** to navigate to the different pages in the **Navigation** pane or to the different action labels in the right pane on the UI.

Chapter 4. Administration

This section provides information on administration, installation, configuration, and integrations and teamspace management.

Configuration of external databases for the capabilities in DevOps Loop

DevOps Loop capabilities use databases to store configuration data, execution results, and operational information. In the default configuration, some capabilities deploy internal databases as part of the Helm installation. However, you can configure the capabilities to use external databases that are managed outside the Kubernetes cluster.

By configuring external databases, you can use the existing enterprise database infrastructure, apply centralized backup and security policies, and manage the database lifecycle independently from the DevOps Loop platform.

Each capability in DevOps Loop supports external database configuration through Helm parameters or configuration files that are referenced during installation. You can configure the following capabilities to use external databases:

- **Plan** – Supports an external PostgreSQL database.
- **Control** – Supports an external PostgreSQL database.
- **Deploy** – Supports external relational databases such as MySQL, Db2, Oracle, or SQL Server.
- **Build** – Uses the same MySQL database configured for Deploy.
- **Test** – Supports an external PostgreSQL database.
- **Measure and Release** – Uses an external MongoDB database.

You can configure external databases for one or more capabilities by updating the DevOps Loop installation script and Helm configuration before running the installation.

If multiple capabilities require external databases, you can configure all required database settings in the installation script at the same time and run the DevOps Loop installation once. During installation, the Helm charts read the configured parameters and connect the corresponding capabilities to their external databases.

After the installation completes, the capabilities run in the Kubernetes cluster while using the specified external databases for storing application data.

Configuring an external database for Plan and Control

You can configure an external PostgreSQL database for the Plan capability in DevOps Loop and provide the database connection details in the Helm chart so that Plan connects to the external database instead of using the default PostgreSQL service included with the chart.

Before you begin

You must have completed the following tasks:

- Prepared the external PostgreSQL instance, and ensured that it is accessible from the Kubernetes cluster.
- Ensured that the database user has permissions for insert, update, delete, select, and schema modifications (create, alter, drop tables and indexes).
- Ensured that the Kubernetes cluster can reach the database host and port.
- Ensured that the following information is available:
  - `Database host name or IP address`
  - `Database port (default: 5432)`
  - `Database name`
  - `Database user name`
  - `Database password`

About this task

You must update the installation script so that Plan connects to the external database. The modifications include defining database variables, creating a Kubernetes secret for the database credentials, and passing the database parameters to Helm during installation.

1. Add the required external database variables at the beginning of the installation script:

   ```
   PLAN_DB_HOST=<database-host>
   PLAN_DB_PORT=5432
   PLAN_DB_NAME=plan_db
   PLAN_DB_USER=plan_user
   PLAN_DB_PASSWORD=<database-password>
   ```

   These variables define the connection details for the external PostgreSQL database used by Plan.

2. Set the Helm parameter `postgresql.enabled=false` to ensure the deployment does not create a database automatically.
3. Create a `devopsplan.yaml` file that defines the external database connection, tenant datastore, and disables the internal PostgreSQL service:

   ```
   ## Spring datastore settings (PostgreSQL)
   ibm-devopsplan-prod:
     spring:
       datastore:
         url: "jdbc:postgresql://${PLAN_DB_HOST}:${PLAN_DB_PORT}/${PLAN_DB_NAME}"
         username: ${PLAN_DB_USER}
         password: ${PLAN_DB_PASSWORD}

   ## Tenant datastore settings (PostgreSQL)
     tenant:
       datastore:
         server: ${PLAN_DB_HOST}
         dbname: ${PLAN_DB_NAME}
         username: ${PLAN_DB_USER}
         password: ${PLAN_DB_PASSWORD}

   ## Optional SMTP settings
     global:
   ```

```
    platform:
      smtp:
        sender: ${EMAIL_FROM_ADDRESS}
        host: ${EMAIL_SERVER_HOST}
        port: ${EMAIL_SERVER_PORT}
        username: ${EMAIL_SERVER_USERNAME}
        password: ${EMAIL_SERVER_PASSWORD}

  postgresql:
    enabled: false

## CONTROL external database settings
  control:
    postgresql:
      host: "CONTROL_DB_HOST"
      dbName: "CONTROL_DB_NAME"
      username: "CONTROL_DB_USER"
      password: "CONTROL_DB_PASSWORD"
    postgresql:
      enabled: false
```

4. Update the Helm install or upgrade command to use the external database by including the `devopsplan.yaml` file:

```
helm upgrade devops-loop oci://hclcr.io/launch-helm/hcl-launch-plan-prod \
  --install \
  --namespace ${NAMESPACE} \
  -f devopsplan.yaml
```

Results

After you run the installation script, DevOps Loop is installed, and the Plan capability connects to the external PostgreSQL database by using the parameters defined in the script and the `devopsplan.yaml` file

What to do next

You must install DevOps Loop to apply the configuration. See Installation of DevOps Loop on page 45.

Configuring external access to the Plan PostgreSQL database on page 44

Configuring an external database for Deploy

You can configure an external database for the Deploy capability in DevOps Loop and provide the database connection details in the Helm chart so that Deploy connects to the external database instead of creating one within the cluster.

Before you begin

You must have completed following tasks:

- Prepared the external PostgreSQL instance, and ensured that it is accessible from the Kubernetes cluster.
- Ensured that the database user has permission to access the database.
- Ensured that the Kubernetes cluster can reach the database host and port.
- Ensured that the required JDBC driver is available for the database.

- The following information is available:
  - `Database type (MySQL, Db2, Oracle, or SQL Server)`
  - `Database host name or IP address`
  - `Database port`
  - `Database name`
  - `Database user name`
  - `Database password`

About this task

You must update the installation script so that Deploy connects to the external database. The modifications include defining database variables, creating a Kubernetes secret for the database credentials, and passing the database parameters to Helm during installation.

1. Add the required external database variables to the beginning of the installation script:

   ```
   DB_TYPE=mysql
   DB_HOST=<database-host>
   DB_PORT=3306
   DB_NAME=deploydb
   DB_USER=dbuser
   DB_PASSWORD=<database-password>
   DB_SECRET=ucd-db-secret
   ```

   These variables define the connection details for the external database used by Deploy.

2. Create a Kubernetes secret for the database password.

   ```
   kubectl create secret generic ${DB_SECRET} \
     --namespace ${NAMESPACE} \
     --from-literal=dbpassword="${DB_PASSWORD}"
   ```

   The Deploy server reads the database password from this secret during initialization.

3. Set the Helm parameter `database.createDatabase=false` to ensure the deployment does not create a database automatically.
4. Update the `HELM_OPTIONS` in the script to include the external database connection parameters:

   ```
   HELM_OPTIONS="${HELM_OPTIONS} \
   --set hcl-launch-server-prod.database.type=${DB_TYPE} \
   --set hcl-launch-server-prod.database.hostname=${DB_HOST} \
   --set hcl-launch-server-prod.database.port=${DB_PORT} \
   --set hcl-launch-server-prod.database.name=${DB_NAME} \
   --set hcl-launch-server-prod.database.username=${DB_USER} \
   --set hcl-launch-server-prod.database.createDatabase=false \
   --set hcl-launch-server-prod.secret.name=${DB_SECRET} \
   --set hcl-launch-server-prod.database.fetchDriver=true"
   ```

Note: Add the following Helm parameter to ensure the Deploy server automatically downloads the required JDBC driver:

```
--set hcl-launch-server-prod.database.fetchDriver=true
```

Results

After you run the installation script, DevOps Loop is installed, and the Deploy capability connects to the external database by using the parameters defined in the script.

What to do next

You must install DevOps Loop to apply the configuration. See Installation of DevOps Loop on page 45.

Configuring an external database for Build

You can configure Build to use the same external MySQL database that is used by Deploy. When using an external database, the Build Helm chart must be configured to connect to the existing MySQL instance instead of creating a database inside the Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Ensured that the external MySQL database used by Deploy is available and accessible from the Kubernetes cluster.
- Ensured that the following information is available:
  - `MySQL host name or IP address`
  - `MYSQL port`
  - `Database name`
  - `Database user name`
  - `Database password`
- Ensured that the database user has permission to access the required database.
- Ensured that the Kubernetes cluster is connected to the MySQL server.
- Esnured that a Kubernetes secret containing the database password exists in the deployment namespace.

1. Add variables for the external MySQL database in the installation script:

   ```
   MYSQL_HOST=<mysql-host>
   MYSQL_PORT=3306
   DATABASE_NAME=<database-name>
   DATABASE_USER=<database-user>
   BUILD_DB_SECRET=build-secret
   ```

   These variables define the connection details for the external MySQL database used by the Build.
2. Create a Kubernetes secret that contains the database password by running the following command:

```
BUILD_DB_PASSWORD=<DATABASE_PASSWORD>
kubectl create secret generic build-secret -n devops-loop --from-literal=dbpassword="$BUILD_DB_PASSWORD"
```

#☺ **Important:** The `BUILD_DB_PASSWORD` must match the password assigned to the MySQL user.

3. Add the following Helm values to the `HELM_OPTIONS` section of the installation script. These parameters configure the Build Helm chart to use the external database.

```
--set hcl-devops-build.externalDB.enabled=true \
--set hcl-devops-build.externalDB.hostname=<MYSQL_HOST> \
--set hcl-devops-build.externalDB.port=<MYSQL_PORT> \
--set hcl-devops-build.externalDB.database=<DATABASE_NAME> \
--set hcl-devops-build.externalDB.user=<DATABASE_USER> \
--set hcl-devops-build.secret.name=build-secret
```

Results

After you run the installation script, DevOps Loop is installed and the Build capability connects to the external MySQL database by using the credentials stored in the Kubernetes secret.

What to do next

You must install DevOps Loop to apply the configuration. See Installation of DevOps Loop on page 45.

Configuring an external database for Test

You can configure an external PostgreSQL database for the Test capability in DevOps Loop and provide the database connection details in the Helm chart so that Test connects to the external database instead of using the PostgreSQL instance that is installed in the cluster by default.

Before you begin

You must have completed the following tasks:

- Prepared the external PostgreSQL instance, and ensured that it is accessible from the Kubernetes cluster.
- Ensured that the database user has permissions for insert, update, delete, select, and schema modifications (create, alter, drop tables and indexes).
- Ensured that the Kubernetes cluster can reach the database host and port.
- Ensured that the following information is available:
  - `Database host name or IP address`
  - `Database port (default: 5432)`
  - `Database name`
  - `Database user name`
  - `Database password`

About this task

You must update the installation script so that the Test capability connects to the external database. The modifications include defining database variables and passing the database parameters to Helm during installation.

1. Add the required external database variables to the beginning of the installation script:

```
TEST_DB_HOST=<database-host>
TEST_DB_PORT=5432
TEST_DB_NAME=testhubdb
TEST_DB_USER=postgres
TEST_DB_PASSWORD=<database-password>
TEST_CA_SECRET=<ca-secret-name>   # Optional, if using self-signed certificates
```

   These variables define the connection details for the external PostgreSQL database used by the Test.

2. Update the `HELM_OPTIONS` in the script to include the external database connection parameters:

```
HELM_OPTIONS="${HELM_OPTIONS} \
--set hcl-devops.postgresql.external=true \
--set hcl-devops.postgresql.hostname=${TEST_DB_HOST} \
--set hcl-devops.postgresql.port=${TEST_DB_PORT} \
--set hcl-devops.postgresql.username=${TEST_DB_USER} \
--set hcl-devops.postgresql.existingPassword=${TEST_DB_PASSWORD}"
```

   Note: By default the `sslmode` is set to `verify-full`.

   If the database uses a self-signed certificate, add the following parameter:

```
--set hcl-devops-prod.global.privateCaBundleSecretName=${TEST_CA_SECRET}
```

Results

After you run the installation script, DevOps Loop is installed and the Test capability connects to the external PostgreSQL database by using the parameters defined in the script.

What to do next

You must install DevOps Loop to apply the configuration. See Installation of DevOps Loop on page 45.

Configuring an external database for Measure and Release

You can configure Measure and Release to use an external MongoDB database by creating a Kubernetes secret to store the database connection URL and updating the Helm chart to reference this secret.

Before you begin

You must have completed following tasks:

- Ensured a running MongoDB instance is available.
- Ensured that the following information is available:
  - `MONGO_HOST`
  - `MONGO_PORT`
  - `Mongo_DATABASE`
  - `Mongo_USER`
  - `Mongo_PASSWORD`
- Ensured that the database user has the permission to access the required database.

1. Create a Kubernetes secret `mongodb-url-secret` in the target namespace, storing the MongoDB connection URL as the password.

```
MONGO_HOST=<mongo-host>
MONGO_PORT=3306
MONGO_DATABASE=<database-name>
MONGO_USER=<database-name>
MONGO_PASSWORD=<password>
MONGO_URL="mongodb://${MONGO_USER}:${MONGO_PASSWORD}@${MONGO_HOST}:${MONGO_PORT}/${MONGO_DATABASE}"

kubectl create secret generic mongodb-url-secret --namespace ${NAMESPACE} \
  --from-literal=password="${MONGO_URL}"
```

2. Add the following to the `HELM_OPTIONS` section of the installation script to reference the MongoDB secret:

```
--set hcl-ucv-prod.secrets.database=mongodb-url-secret
```

Results

After you run the installation script, DevOps Loop is installed, and the Measure and Release capabilities use the external MongoDB instance through the Kubernetes secret.

What to do next

You must install DevOps Loop to apply the configuration. See Installation of DevOps Loop on page 45.

Configuring external access to the Plan PostgreSQL database

You can configure external PostgreSQL access during installation by using a Helm upgrade.

About this task

When you install DevOps Loop by using the internal DevOps Plan PostgreSQL database and need to access it from DevOps Plan Designer or other supported PostgreSQL tools (such as pgAdmin 4), you must enable PostgreSQL access and configure the exposed port during installation or upgrade.

1. Use the following options with the Helm install or Helm Upgrade command:

```
--set hcl-devopsplan-prod.postgresql.enableExternalAccess=true \
--set hcl-devopsplan-prod.postgresql.service.exportPort=30106
```

2. Use the following details to connect to the PostgreSQL database:
    - **Host:** `global.domain`
    - **Port:** `30106`
    - **Database:** `postgres`
    - **Username:** `postgres`
3. Run the following command to retrieve the password:

```
kubectl get secret --namespace devops-loop devopsplan-postgresql \
-o jsonpath="{.data.tenant-datastore-password}" | base64 -d; echo
```

Note: You must ensure the namespace is set to `devops-loop`.

Results

You have configured external access to the Plan PostgreSQL database.

What to do next

You can view the connection details from the DevOps Plan UI. See Viewing connection details from the DevOps Plan UI on page 45.

Viewing connection details from the DevOps Plan UI

After you configured the external access to the Plan PostgreSQL, you can view the connection details from the DevOps Plan UI.

1. Open the **Tenant Management** page.
2. Select the required **Tenant**.
3. In the **TeamSpace** panel, select the **Details** tab.
4. Click **Show connection properties**.
5. View the PostgreSQL connection details for the selected TeamSpace.

Results

You have viewed the connection details from the DevOps Plan UI.

Installation of DevOps Loop

To get started working with HCL DevOps Loop, you must first install the platform in your environment.

You can install DevOps Loop on the following supported platforms:

- IBM Cloud Kubernetes Service (IKS)
- Kubernetes Service (K8S)
- Google Kubernetes Enigine (GKE)
- Amazon Web Services (AWS)
- Air-Gapped Environment

Note: Before you get started with the installation, review the requirements for configuring external databases for DevOps Loop capabilities. See Configuration of external databases for the capabilities in DevOps Loop on page 37.

Optional components

DevOps Loop supports optional components such as Harbor.

To enable Harbor during installation, set:

```
HARBOR_ENABLED=true
```

For prerequisites, configuration parameters, verification, and troubleshooting for Harbor, see Installing DevOps Loop with Harbor integration on page 107 and Troubleshooting Harbor integration.

For additional installation parameters, see Additional Helm parameters on page 76.

If you encounter issues during the installation or upgrade process, see Troubleshooting DevOps Loop installation and upgrade.

Installing DevOps Loop on IBM Cloud Kubernetes Service (IKS)

You can find information about the tasks that you can perform to install HCL DevOps Loop on IBM Cloud Kubernetes Service (IKS) by using a newly created cluster. You can use the Helm chart to perform the installation.

Before you begin

You must have completed the following tasks:

- Read and understood System Requirements for DevOps Loop 2026.08 (2.0.2.1) on page 25.
- Installed the following CLI tools:
  - Kubectl
  - IBM Cloud CLI
- Installed Helm on the system from which you access the Kubernetes cluster. For more information, refer to Installing Helm.
- Set up a Kubernetes cluster. For more information, refer to Getting started with IBM Cloud Kubernetes Service.
- Set up the Secrets Manager in your Kubernetes Service cluster. For more information refer to IBM Cloud Secrets Manager.
- Obtained valid public certificates issued by trusted Certificate Authorities (CAs). Also, read and understood about managing certificates and secrets. For more information refer to Managing TLS and non-TLS certificates and secrets.

1. Navigate to **Cluster Management > Clusters > Overview > Actions > Connect via CLI** in your IBM Cloud account and associate the kubectl context with your cluster.
2. Navigate to **Cluster Management > Clusters > Ingress > Ingress Controllers (ALB)** and note down the IP address of the public ingress controller.

3. Navigate to **Cluster Management > Clusters > Ingress > Domain** and note down the region in the domain name of your cluster, which is in the format, `<cluster_name-id>.<region>.containers.appdomain.com`.
4. Click **Create** in the **Domain** tab and perform the following steps:
    a. Provide a domain name in the format, `<custom_name>.<region>.containers.appdomain.com`, by using the region noted down in the previous step.
    b. Provide the IP address of the public ingress controller noted down in step 2 on page 46.
    c. Set the domain as the default domain.

    Note: If you do not set this as the default domain, you must delete and re-create the domain to set it as the default domain.

5. Make the certificate and key available as a Kubernetes secret in the Kubernetes namespace that you use for DevOps Loop.

    Note: If a helm lookup error occurs on a secret, likely the certificate was not imported to the Loop namespace.

    To correct this error, import the certificate into your namespace: `ibmcloud ks ingress secret create --cluster <cluster_name_or_ID> --cert-crn <crn> --name <secret_name> --namespace <namspace>`

    You must use the IBM Secrets Manager to manage the life cycle of the certificate. You must also note down the name of the secret that contains the TLS certificate and key. For more information, refer to https://cloud.ibm.com/docs/containers?topic=containers-secrets&interface=ui#tls-custom.
6. Perform the following steps to install Emissary-ingress in your cluster:
    a. Run the following commands to set the Ambassador Edge Stack Helm chart:

    ```
    helm repo add datawire https://app.getambassador.io
    helm repo update
    ```

    b. Run the following commands to create a namespace and install the Ambassador Edge stack:

    ```
    kubectl create namespace emissary && \
    kubectl apply -f https://app.getambassador.io/yaml/emissary/3.9.1/emissary-crds.yaml
    kubectl wait --timeout=90s --for=condition=available deployment emissary-apiext -n
     emissary-system
    ```

    c. Run the following command to create `emissary-ports.yaml`:

    ```
    cat <<EOF > emissary-ports.yaml
    service:
      ports:
        - name: https
          port: 443
          targetPort: 8443
          #nodePort: <optional>
        - name: http
          port: 80
          targetPort: 8080
          #nodePort: <optional>
        - name: deploy-wss
    ```

```
      port: 7919
      targetPort: 7919
      #nodePort: <optional>
    - name: control-ssh
      port: 9022
      targetPort: 9022
      #nodePort: <optional>
EOF
```

d. Install Emissary-ingress by running the following command:

```
helm install emissary-ingress --namespace emissary datawire/emissary-ingress -f
 emissary-ports.yaml && \
kubectl -n emissary wait --for condition=available --timeout=90s deploy
 -lapp.kubernetes.io/instance=emissary-ingress
```

7. Note down the domain name for your cluster, which is in the format, `<custom_name>.<region>.containers.appdomain.com`.
   You can navigate to **Containers > Cluster Management > Clusters > Ingress > Domains** in the IBM Cloud console or run the following command to list the domains in your cluster:

```
ibmcloud ks ingress domain ls --cluster <CLUSTER_NAME>
```

8. Perform the following steps to access the HCL Harbor container registry:
   a. Get a key to the HCL Harbor container registry.
   b. Log in to HCL Harbor container registry with the HCL ID and password that are associated with the entitled software.
   c. Copy the pre-generated CLI secret from the **User Profile** page.
   d. Create the following three secrets in the target namespace to pull images from the HCL Harbor container registry:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=<Harbor User ID> \
    --docker-password=<CLI secret> \
    --docker-server=hclcr.io
```

Note: Secrets are namespace-specific and they are required to install DevOps Plan.

9. Run the following command to view the `README.md` file:

```
helm show readme oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201
```

10. Optional:
11. Update the following parameters and the other required parameters in the script in the Helm README with the correct values:
    - DOMAIN
    - TLS_CERT_SECRET_NAME
    - RWO_STORAGE_CLASS=nfs-client
    - RWX_STORAGE_CLASS=nfs-client

    For DOMAIN and TLS_CERT_SECRET_NAME, you must provide the values noted down in the previous steps.

12. Run the script in the Helm README for K8 installation.

    Note: If the installation fails due to timeout, run the installation script again.

13. Perform the following steps to enable non-HTTP and additional special services:
    a. Run the following command to display the IP of the L4 load balancer installed as part of DevOps Loop:

    ```
    kubectl get svc --namespace emissary emissary-ingress -o
     jsonpath='{.status.loadBalancer.ingress[0].ip}'
    ```

    b. Perform the following steps to create a new domain by using the IP of the L4 load balancer:
        i. Navigate to **Cluster Management > Clusters > Ingress > Domains >** .
        ii. Copy the default domain name.
        iii. Click **Create**.
        iv. Enter `service-<copied_domain_name>` in **Name**.
        v. Enter the IP of the L4 load balancer in **IP address**.
        vi. Click **Create**.

    You can also run the following command from CLI:

    ```
    ibmcloud ks ingress domain create --cluster CLUSTER [--crn CRN] [--is-default] [--domain
     DOMAIN] [--hostname HOSTNAME] [--ip IP] [--output OUTPUT] [--domain-provider PROVIDER] [-q]
     [--secret-namespace NAMESPACE] [--zone ZONE]
    ```

    Note: You must ensure that the domain created in this step is not the default domain.

Results

You have installed DevOps Loop on IKS by using a newly created cluster.

Installing DevOps Loop on Kubernetes Service (K8S)

You can find information about the tasks that you can perform to install HCL DevOps Loop on Kubernetes Service (K8S). You can use the Helm chart to perform the installation.

Before you begin

You must have completed the following tasks:

- Read and understood System Requirements for DevOps Loop 2026.08 (2.0.2.1) on page 25.
- Installed the Kubernetes CLI tool, Kubectl.
- Installed Helm on the system from which you access the Kubernetes cluster. For more information, refer to Installing Helm.
- Set up a Kubernetes cluster. For more information, refer to Kubernetes Documentation.
- Read and understood administering a cluster and managing TLS certificates in a cluster. For more information, refer to Administer a Cluster and Manage TLS Certificates in a Cluster.
- Set up the cert-manager in your Kubernetes cluster. For more information refer to Kubernetes documentation.

About this task

You can select one of the following methods to install DevOps Loop on K8S:

- Installing on a K8S cluster that has load balancer resources available on page 50
- Installing on a K8S cluster with an upstream L7 load balancer on page 52
- Installing on a K8S cluster that has an upstream L7 load balancer and expects data to be re-encrypted on page 54

Installing on a K8S cluster that has load balancer resources available

Before you begin

You must have completed the following tasks:

- Ensured your cluster supports L4 load balancer resources.
- Ensured that an external fully qualified domain name with a certificate signed by a well-known CA or an intermediary is available.

1. Associate the kubectl context with your cluster by using the following commands:

```
kubectl config set-context <context_name> --namespace=<namespace-name> --cluster=<cluster-name>
 --user=<user-name>
kubectl config use-context <context-name>
```

2. Obtain the certificate and key for the domain that you use for DevOps Loop.
3. Make the certificate and key available as a Kubernetes secret in the Kubernetes namespace that you use for DevOps Loop.

   You should use the cert-manager or any standard mechanism to manage the life cycle of the certificate. You must also note down the name of the secret that contains the TLS certificate and key.
4. Perform the following steps to install Emissary-ingress in your cluster:
   a. Run the following commands to set the Ambassador Edge Stack Helm chart:

```
helm repo add datawire https://app.getambassador.io
helm repo update
```

   b. Run the following commands to create a namespace and install the Ambassador Edge stack:

```
kubectl create namespace emissary && \
kubectl apply -f https://app.getambassador.io/yaml/emissary/3.9.1/emissary-crds.yaml
kubectl wait --timeout=90s --for=condition=available deployment emissary-apiext -n
 emissary-system
```

   c. Perform the following step to create emissary-ports.yaml:

```
cat <<EOF > emissary-ports.yaml
service:
  ports:
    - name: https
      port: 443
      targetPort: 8443
      #nodePort: <optional>
    - name: http
      port: 80
      targetPort: 8080
      #nodePort: <optional>
    - name: deploy-wss
      port: 7919
```

```
      targetPort: 7919
      #nodePort: <optional>
     - name: build-wss
      port: 7920
      targetPort: 7920
      #nodePort: <optional>
    - name: control-ssh
      port: 9022
      targetPort: 9022
      #nodePort: <optional>
EOF
```

d. Install Emissary-ingress:

```
helm install emissary-ingress --namespace emissary datawire/emissary-ingress -f
 emissary-ports.yaml && \
kubectl -n emissary wait --for condition=available --timeout=90s deploy
 -lapp.kubernetes.io/instance=emissary-ingress
```

5. Open the ports in your firewall to the external ports and the node ports configured in the previous step.
   You can run the following command to determine the node ports if they are configured automatically:

```
kubectl get svc emissary-ingress --namespace emissary -o jsonpath='{range .spec.ports[*]}{.name}:
 {.nodePort}{"\n"}{end}'
```

6. Perform the following steps to access the HCL Harbor container registry:
   a. Get a key to the HCL Harbor container registry.
   b. Log in to HCL Harbor container registry with the HCL ID and password that are associated with the entitled software.
   c. Copy the pre-generated CLI secret from the **User Profile** page.
   d. Create the following three secrets in the target namespace to pull images from the HCL Harbor container registry:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=<Harbor User ID> \
    --docker-password=<CLI secret> \
    --docker-server=hclcr.io
```

Note: Secrets are namespace-specific and they are required to install DevOps Plan.

7. Run the following command to view the `README.md` file:

```
helm show readme oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201
```

8. Update the following parameters and the other required parameters in the script in the Helm README with the correct values:
   - DOMAIN
   - TLS_CERT_SECRET_NAME
   - RWO_STORAGE_CLASS=nfs-client
   - RWX_STORAGE_CLASS=nfs-client

   For DOMAIN and TLS_CERT_SECRET_NAME, you must provide the values noted down in the previous steps.

9. Run the script in the Helm README for K8 installation.

   Note: If the installation fails due to timeout, run the installation script again.

10. Perform the following steps to enable non-HTTP and additional special services:
    a. Configure the DNS to route traffic from a second FQDN that is service-<DOMAIN> to the L4 load balancer that you created as a prerequisite.

       The DOMAIN value is the same as the value used in the helm chart.

    b. Configure your L4 node balancer to forward the ports configured in 4.c on page 50 and determined in 5 on page 51 to your cluster.

Installing on a K8S cluster with an upstream L7 load balancer

Before you begin

You must have completed the following tasks:

- Ensured that the external L7 load balancer and cluster support for L4 load balancer resources are available.
- Ensured that an external fully qualified domain name with a certificate signed by a well-known CA or an intermediary is available.

1. Perform the following steps to install Emissary-ingress in your cluster:
   a. Run the following commands to set the Ambassador Edge Stack Helm chart:

   ```
   helm repo add datawire https://app.getambassador.io
   helm repo update
   ```

   b. Run the following commands to create a namespace and install the Ambassador Edge stack:

   ```
   kubectl create namespace emissary && \
   kubectl apply -f https://app.getambassador.io/yaml/emissary/3.9.1/emissary-crds.yaml
   kubectl wait --timeout=90s --for=condition=available deployment emissary-apiext -n
    emissary-system
   ```

   c. Perform the following step to create emissary-ports.yaml:

   ```
   cat <<EOF > emissary-ports.yaml
   service:
     type: LoadBalancer  #Set to NodePort when using an external L4 load balancer
     ports:
       - name: http
         port: 80
         targetPort: 8080
         #nodePort: <optional>
       - name: deploy-wss
         port: 7919
         targetPort: 7919
         #nodePort: <optional>
       - name: control-ssh
         port: 9022
         targetPort: 9022
   ```

```
      #nodePort: <optional>
EOF
```

d. If the support for load balancer resources is not available in your cluster, edit the `emissary-ports.yaml` to change the type to NodePort.

An external L4 load balancer is required in this installation scenario.

e. Install Emissary-ingress:

```
helm install emissary-ingress --namespace emissary datawire/emissary-ingress -f
 emissary-ports.yaml && \
kubectl -n emissary wait --for condition=available --timeout=90s deploy
 -lapp.kubernetes.io/instance=emissary-ingress
```

2. Open the ports in your firewall to the node ports configured in the previous step.
You can run the following to determine the node ports if they are configured automatically:

```
kubectl get svc emissary-ingress --namespace emissary -o jsonpath='{range .spec.ports[*]}{.name}:
 {.nodePort}{"\n"}{end}'
```

3. Perform the following steps to access the HCL Harbor container registry:
   a. Get a key to the HCL Harbor container registry.
   b. Log in to HCL Harbor container registry with the HCL ID and password that are associated with the entitled software.
   c. Copy the pre-generated CLI secret from the **User Profile** page.
   d. Create the following three secrets in the target namespace to pull images from the HCL Harbor container registry:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=<Harbor User ID> \
    --docker-password=<CLI secret> \
    --docker-server=hclcr.io
```

Note: Secrets are namespace-specific and they are required to install DevOps Plan.

4. Run the following command to view the `README.md` file:

```
helm show readme oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201
```

5. Update the following parameters and the other required parameters in the script in the Helm README with the correct values:
   - DOMAIN
   - RWO_STORAGE_CLASS=nfs-client
   - RWX_STORAGE_CLASS=nfs-client

   For DOMAIN, you must provide the values noted down in the previous steps.

6. Add the following parameter to the ADDITIONAL_HELM_OPTIONS section:

```
--set platform.emissary.l7Depth=<number_of_hops_to_load_balancer>
```

By default the value is set to 0, which indicates that there is no upstream load balancer. You must set the value to 1 for a single hop to a direct upstream load balancer.

7. Run the script in the Helm README for K8 installation.
8. Perform the following steps to enable non-HTTP and additional special services:
    a. If the load balancer resources are available in your cluster, then run the following command to determine the IP of the L4 load balancer:

    ```
    kubectl get svc --namespace emissary emissary-ingress -o
     jsonpath='{.status.loadBalancer.ingress[0].ip}'
    ```

    If the load balancer resources are not available, then configure an external L4 load balancer to open the non-http/https ports in the `emissary-ingress.yaml` to direct traffic to your cluster.

    b. Configure the DNS to route traffic from a second FQDN that is service-<DOMAIN> to the L4 load balancer that you created as a prerequisite.

    A certificate is not required for this domain. The DOMAIN value is the same as the value used in the helm chart.

Installing on a K8S cluster that has an upstream L7 load balancer and expects data to be re-encrypted

Before you begin

You must have completed the following tasks:

- Ensured that the external L7 load balancer, and cluster support for L4 load balancer resources or an external L4 load balancer are available.
- Ensured that an external fully qualified domain name with a certificate signed by a well-known CA or a self-signed certificate is available as required.

1. Obtain a certificate and key that covers all the nodes in your cluster through a Subject Alternative Name (SAN).
2. Configure your L7 load balancer to trust the certificate for the nodes in your cluster.

    Note: A health check endpoint is available at `/automation/healthz` for your load balancer to reference for health checks.

3. Make the certificate and key available as a Kubernetes secret in the Kubernetes namespace that you use for DevOps Loop.
    You must use the cert-manager or any standard mechanism to manage the life cycle of the certificate. You must also note down the name of the secret that contains the TLS certificate and key.
4. Perform the following steps to install Emissary-ingress in your cluster:
    a. Run the following commands to set the Ambassador Edge Stack Helm chart:

    ```
    helm repo add datawire https://app.getambassador.io
    helm repo update
    ```

b. Run the following commands to create a namespace and install the Ambassador Edge stack:

```
kubectl create namespace emissary && \
kubectl apply -f https://app.getambassador.io/yaml/emissary/3.9.1/emissary-crds.yaml
kubectl wait --timeout=90s --for=condition=available deployment emissary-apiext -n
 emissary-system
```

c. Perform the following step to create emissary-ports.yaml:

```
cat <<EOF > emissary-ports.yaml
service:
  type: LoadBalancer # NodePort if no LoadBalancer resources are available in your cluster
  ports:
    - name: https
      port: 443
      targetPort: 8443
      #nodePort: <optional unused if type Nodeport>
    - name: http
      port: 80
      targetPort: 8080
      #nodePort: <optional unused if type Nodeport>
    - name: deploy-wss
      port: 7919
      targetPort: 7919
      #nodePort: <optional unused if type Nodeport>
    - name: control-ssh
      port: 9022
      targetPort: 9022
      #nodePort: <optional unused if type Nodeport>
EOF
```

d. If no load balancer resources are available in your cluster, edit the `emissary-ports.yaml` to change the type to NodePort.

An external L4 load balancer is required in this installation scenario.

e. Install Emissary-ingress:

```
helm install emissary-ingress --namespace emissary datawire/emissary-ingress -f
 emissary-ports.yaml && \
kubectl -n emissary wait --for condition=available --timeout=90s deploy
 -lapp.kubernetes.io/instance=emissary-ingress
```

5. Open the ports in your firewall to the node ports configured in the previous step.
   You can run the following to determine the node ports if they are configured automatically:

```
kubectl get svc emissary-ingress --namespace emissary -o jsonpath='{range .spec.ports[*]}{.name}:
 {.nodePort}{"\n"}{end}'
```

6. Perform the following steps to access the HCL Harbor container registry:
   a. Get a key to the HCL Harbor container registry.
   b. Log in to HCL Harbor container registry with the HCL ID and password that are associated with the entitled software.
   c. Copy the pre-generated CLI secret from the **User Profile** page.
   d. Create the following three secrets in the target namespace to pull images from the HCL Harbor container registry:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=<Harbor User ID> \
    --docker-password=<CLI secret> \
    --docker-server=hclcr.io
```

Note: Secrets are namespace-specific and they are required to install DevOps Plan.

7. Run the following command to view the `README.md` file:

```
helm show readme oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201
```

8. Update the following parameters and the other required parameters in the script in the Helm README with the correct values:
    - DOMAIN
    - TLS_CERT_SECRET_NAME
    - RWO_STORAGE_CLASS=nfs-client
    - RWX_STORAGE_CLASS=nfs-client

   For DOMAIN and TLS_CERT_SECRET_NAME, you must provide the values noted down in the previous steps.

9. Run the script in the Helm README for K8 installation.
10. Perform the following steps to enable non-HTTP and additional special services:
    a. If the load balancer resources are available in your cluster, then run the following command to determine the IP of the L4 load balancer installed as part of DevOps Loop:

```
kubectl get svc --namespace emissary emissary-ingress -o
 jsonpath='{.status.loadBalancer.ingress[0].ip}'
```

    If the load balancer resources are not available, then configure an external L4 load balancer to open the non-http/https ports in `emissary-ingress.yaml` to direct traffic to your cluster.

    b. Configure the DNS to route traffic from a second FQDN that is service-<DOMAIN> to the L4 load balancer that you created as a prerequisite.

    A certificate is not required for this domain. The DOMAIN value is the same as the value used in the helm chart.

Installation of DevOps Loop on Google Kubernetes Engine (GKE)

You can find information about tasks that you can perform to install DevOps Loop on Google Cloud Platform (GCP) by using the Google Kubernetes Engine (GKE) service.

Related information

Preparing GCP infrastructure for installing DevOps Loop on GKE on page 57

Installing DevOps Loop on Google Kubernetes Engine (GKE) on page 58

Preparing GCP infrastructure for installing DevOps Loop on GKE

You must set up the required Google Cloud Platform (GCP) infrastructure including DNS, a global static IP address, and RWX Storage, before deploying DevOps Loop on Google Kubernetes Engine (GKE).

Before you begin

You must have completed the following tasks:

- Ensured that your GCP environment includes the required roles and APIs:
  - The service account used for the GKE cluster must have the `roles/file.serviceAgent` IAM role.
  - Enabled the following APIs at the project level:
    - `file.googleapis.com`
    - `gkehub.googleapis.com`

      These APIs and permissions are required for filestore provisioning, CSI driver operations, and certificate management within GKE.

1. Perform the following steps to configure DNS and network resources:
   a. Create a host name in Cloud DNS for the DevOps Loop application.
   b. Reserve a **global static IPv4 address** in the same GCP project.
   c. Create a DNS A record that maps the domain name to the global static IP address.

   For example:
   - Name: `<host-name>`
   - Type: `A`
   - Value: `<GLOBAL_STATIC_IP>`

   Note: DNS must resolve and must be visible from the public internet or at least from GCP checkers for GKE-managed certificate provisioning to succeed.

2. Perform the following steps to configure `RWX StorageClass` for DevOps Loop:

   a. Create a custom `RWX StorageClass` with the following requirements:

      - Minimum 1 TiB storage
      - Provisioner: `filestore.csi.storage.gke.io`
      - VPC: must match the VPC network used by your GKE cluster

   Note: A custom `StorageClass` is required so filestore volumes are created within your cluster's VPC. Otherwise, GCP-provided filestore classes attempt provisioning under the default network.

3. Verify available `StorageClasses` by running the following command:

```
kubectl get storageclass
```

Results

You have prepared the required Google Cloud Platform (GCP) infrastructure for deploying DevOps Loop on Google Kubernetes Engine (GKE).

What to do next

You can now proceed with installing DevOps Loop on GKE.

Installing DevOps Loop on Google Kubernetes Engine (GKE)

You can install HCL DevOps Loop on a newly created GKE cluster by using the Helm chart.

Before you begin

You must have completed the following tasks:

- Read and understood System Requirements for DevOps Loop 2026.08 (2.0.2.1) on page 25.
- Gained access to the cluster and installed the following tools:
  - Kubectl
  - Google Cloud SDK and Google Cloud CLI
- Installed Helm on the system from which you access the Kubernetes cluster. For more information, refer to Installing Helm.
- Set up a Kubernetes (GKE) cluster under the platform - Google Kubernetes Engine (GKE) and Image type - Container-Optimized OS with containerd (cos_containerd). For more information, refer to Create a cluster and deploy a workload in the Google Cloud console.

  Note: Ensured that you have enabled the Filestore CSI driver and Cloud Storage Fuse CSI driver while creating the cluster to use the GCP CSI driver storage class.

- Prepared the required infrastructure in Google Cloud Platform (GCP). See Preparing GCP infrastructure for installing DevOps Loop on GKE on page 57.
- Ensured that you have the following details:
  - **DOMAIN (FQDN)** – the hostname you created in Cloud DNS for the Loop installation.
  - **STATIC_IP_ADDRESS** – the global static IP mapped to the DNS A record.
  - **NAMESPACE** – the target Kubernetes namespace (for example: `devops-loop`).

1. Run the following command to download the `GKE-Infra-Setup.sh` script from the Helm chart to provision and configure the load balancer with a Google managed certificate.

   ```
   (TMP_DIR=$(mktemp -d) && \
   helm pull hcl-helm/hcl-devops-loop --untar --untardir "$TMP_DIR" --version 2.0.201 > /dev/null 2>&1 && \
   sh "$TMP_DIR/hcl-devops-loop/scripts/GKE/GKE-Infra-Setup.sh" && \
   rm -rf "$TMP_DIR")
   ```

   This command downloads and copies, and runs the `GKE-Infra-Setup.sh` script in your temporary directory.

After you run the script, wait for certificate provisioning to complete. This process can take 10–60 minutes, depending on your cluster and DNS configuration.

2. Perform the following steps to access the IBM Entitled Registry:
    a. Log in to the **My IBM Container Software Library** using the ID and password associated with your entitled software.
    b. Navigate to the Entitlement keys section and select **Copy key** to copy your IBM Entitled Registry entitlement key to you clipboard.
    c. Create a secret in the target namespace named `hcl-entitlement-key` to pull images from the HCL Harbor container registry:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=<Harbor User ID> \
    --docker-password=<CLI secret> \
    --docker-server=hclcr.io
```

3. Run the following command to add the repository:

```
helm repo add hclsoftware
https://us-artifactory1.nonprod.hclpnp.com/artifactory/hclsoftware-helm-dev --force-update
```

4. Run the following command to view the `README.md` file:

```
helm show readme hclsoftware-helm/hclsoftware-devops-loop
```

5. Update the following parameters in the Helm installation script with the correct values:
    - DOMAIN - the FQDN created in Cloud DNS
    - TLS_CERT_SECRET_NAME – Leave it blank to use the GCP-managed certificate.
    - RWO_STORAGE_CLASS=`standard-rwo` OR `premium-rwo` as required.
    - RWX_STORAGE_CLASS=custom storage class name you have created previously for RWX under the filestore csi driver. (e.g.: `custom-rwx`)
6. Run the script in the Helm README for installing DevOps Loop on GKE.

    If the installation fails due to a timeout, run the installation script again.

Results

You have installed DevOps Loop on Google Kubernetes Engine (GKE).

What to do next

You can add users and manage user access by logging in to the Keycloak instance that is installed with DevOps Loop. See User access and administration using Keycloak on page 81.

Installing DevOps Loop on a RHEL system for a demo setup

Disclaimer: In this demo setup, DevOps Loop is deployed on a RHEL-based system with minimum hardware and software specifications. This demo setup is intended solely for evaluation purposes and might not accurately represent the performance, reliability, or feature set of the full production environment. The demo setup might not

include enhanced security configurations typical of production systems. No warranty is implied regarding uptime, support, or continuity of access.

You can find information about the tasks that you can perform to install HCL DevOps Loop on a Red Hat Enterprise Linux (RHEL) system for a demo setup.

Before you begin

You must have completed the following tasks before running the infrastructure setup script:

- Verifed that the RHEL system on which you are deploying DevOps Loop meets the following minimum requirements:
  - Operating system: RHEL 9.4 or later
  - Disk space: 300 GB
  - RAM: 64 GB
  - CPU: 16 Core
- Registered your RHEL system by using the subscription manager.

```
subscription-manager register
```

- (Recommended) Created a snapshot of your VM before running the infrastructure setup script.
- Obtained the user credentials of the licensed Docker account.

Note: If you do not provide the licensed Docker account credentials, the system might take approximately 6 hours to become operational.

1. Run the following command to download and extract the DevOps Loop Helm chart and scripts:

```
helm pull oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201 --untar
```

2. Set the following environment variables:

```
export USERNAME=<docker_username>
export PASSWORD=<docker_password>
```

Note: The `<docker_username>` and `<docker_password>` are your Docker Hub credentials. If these values are not set, you are prompted to log in during script execution.

3. Run the following `RHEL9-K8S-Infra-Setup.sh` script:

```
hcl-devops-loop/scripts/demo/RHEL9-K8S-Infra-Setup.sh 2>&1 | tee infra-setup.log
```

4. Run the following command to create a namespace:

```
kubectl create namespace devops-loop
```

5. Perform the following steps to access the HCL Harbor container registry:
   a. Log in to the HCL Harbor container registry using your HCL ID and password by selecting the **LOGIN VIA OIDC PROVIDER** authentication method.
   b. Copy the **CLI secret** by opening your **User Profile** from the top right corner of the page.

This value serves as the password for the `docker-registry` secret creation command.

c. Create an `imagePullSecret` to authenticate and pull images from the HCL Entitled Registry.

Note: Secrets are namespace-scoped and must be created in each namespace where you plan to install DevOps Loop.

Use the following command to create an `imagePullSecret` named `hcl-entitlement-key`:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --docker-username=<username> \
    --docker-password=<password> \
    --docker-server=hclcr.io
    --namespace devops-loop \
```

For example:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --docker-username=xxxx@hcl.com \
    --docker-password=AOve4CzW2Hs0yCnuQxxxxxxvX \
    --docker-server=hclcr.io
    --namespace devops-loop \
```

6. Update the following values in the `HCL-devops-Install.sh` script:

```
LICENSE_SERVER=<port>@<hostname_or_IP>
EMAIL_SERVER_HOST=<smtp_host>
EMAIL_SERVER_PORT=<smtp_port>
EMAIL_FROM_ADDRESS=<sender_email>
EMAIL_SERVER_USERNAME="<smtp_username>
EMAIL_SERVER_PASSWORD="<smtp_password>
```

7. Run the installation script:

```
./HCL-devops-Install.sh
```

After the successful installation, the following URLs are displayed:

Application URL: `https://<system_IP_address>.nip.io`

Keycloak URL to add users: `https://<system_IP_address>.nip.io/auth`

Note: If you are installing DevOps Loop on a computer that is newly set up, then the installation might fail sometimes. If the installation fails, to resolve the issue, you must uninstall the application by running the `uninstall.sh` script and then reinstall it.

Note: If the installation fails due to a timeout, you must run the installation script again.

8. **Optional:** Run the following command to check whether all the pods are running:

```
kubectl get pods -n devops-loop
```

9. Open a browser and enter the application URL to get started with DevOps Loop.

10. Run the following command to log out of Docker to remove any cached authentication tokens, after completing the DevOps Loop installation:

    ```
    docker logout
    ```

    This command removes the login credentials for `https://index.docker.io/v1/` and cleans up Docker credentials stored in the cache (for example, `/root/.docker/config.json`). Logging out is recommended for security, as Docker authentication tokens are otherwise retained on the system.

    Note:

    - When you run DevOps Loop on a RHEL-based system for an extended period (approximately 30 days), you might need to restart the Calico DaemonSet to ensure continued creation of new loops and Kubernetes pods (for example, when running tests in Test Hub).

      This behaviour is due to Kubernetes security tokens used by the Calico networking component are rotated periodically. In some RHEL demo environments, the updated token is not automatically picked up, and a restart ensures the networking components recognize the refreshed credentials.

      To perform this maintenance step, you must run the following command:

      ```
      kubectl rollout restart daemonset calico-node -n kube-system
      ```

      Restarting the Calico DaemonSet is safe and ensures normal system operation during extended demo periods.

    - Use the following script to recover a Kubernetes node that is experiencing full disk usage:

      a. Locate the recovery script in the repository:

      `ibm-devops-loop/scripts/demo/Recover-K8s-Node.sh`

      b. Run the script on the affected Kubernetes node.

    This script cleans logs, caches, and unused containers to free up disk space and restore node functionality.

Results

You have installed DevOps Loop on a RHEL system for a demo setup.

What to do next

You can onboard users to DevOps Loop. See User access and administration using Keycloak on page 81. After the user is onboarded, you can add the user to teamspaces and loops.

Installation of DevOps Loop on Amazon Web Services (AWS)

You can find information about tasks that you can perform to install DevOps Loop on AWS by using the Elastic Kubernetes Service (EKS).

Preparing AWS infrastructure for installing DevOps Loop on AWS

You must set up the required AWS infrastructure, including Amazon Elastic Kubernetes Service (EKS), storage, and load balancers, before installing DevOps Loop.

Prerequisites

You must have ensured that the following tasks are completed:

- Installed the following AWS tools on the deployment machine:
  - AWS CLI
  - kubectl
  - Helm v3.10 or later
  - eksctl
- Verified cluster access by running the following command:

  ```
  kubectl get nodes
  ```
- Created a VPC with public and private subnets in at least 2 availability zones. Recommended CIDR for example, `VPC CIDR: 10.x.x.x/22`

  Subnet usage:
  - Public subnets: Used for Application Load Balancer (ALB)
  - Private subnets: Used for worker nodes
  - Private subnets: Used for EFS mount targets
- Tagged the subnets correctly for Kubernetes and AWS Load Balancer Controller by using the following values:
  - **Public subnets**

    ```
    kubernetes.io/cluster/<cluster-name> = shared
    kubernetes.io/role/elb = 1
    ```
  - **Private subnets**

    ```
    kubernetes.io/cluster/<cluster-name> = shared
    kubernetes.io/role/internal-elb = 1
    ```

    Note: These tags allow the AWS Load Balancer Controller to automatically discover the correct subnets when creating Application Load Balancers (ALB) and Network Load Balancers (NLB). Without these tags, the load balancer provisioning fails.

About this task

You must perform these AWS infrastructure tasks in the following sequence before installing DevOps Loop.

1. Set up the Amazon EKS cluster on page 64
2. Configure storage (EBS and EFS) on page 64
3. Install the AWS Load Balancer Controller on page 66

4. Configure DNS and TLS on page 67
5. Configure ingress and load balancing on page 67
6. Configure DNS records on page 68

Set up the Amazon EKS cluster

1. Create an Amazon EKS cluster with the following recommended configuration:
    - Node capacity: 8 vCPU, 32 GB memory
    - Multiple worker nodes for high availability
2. Create an **IAM role** for worker nodes and attach the following AWS managed policies:
    - `AmazonEKSWorkerNodePolicy`
    - `AmazonEC2ContainerRegistryReadOnly`
    - `AmazonEKS_CNI_Policy`
3. Create a **security group** to allow traffic within the VPC for communication between:
    - Load balancers
    - Worker nodes
    - Internal Kubernetes services
    - Storage (EFS, EBS)

    Note: Ensure that you deploy worker nodes in private subnets, and use public subnets only for internet-facing load balancers.

4. Enable IAM roles for Service Accounts (IRSA) by enabling the OpenID Connect (OIDC) provider for the cluster by running the following command:

```
eksctl utils associate-iam-oidc-provider \
  --cluster <cluster-name> \
  --approve
```

Note: IRSA is required for components such as the **EFS CSI Driver**, **EBS CSI Driver**, and **AWS Load Balancer Controller**.

Configure storage (EBS and EFS)

1. Perform the following steps to install the Amazon EBS CSI Driver (RWO Storage):
    a. Create an IAM role for EBS CSI Driver:
        - Attach the AWS managed policy: `AmazonEBSCSIDriverPolicy`.
        - Trust Relationship: The role must trust the EKS OIDC provider and allow the service account: `kube-system:ebs-csi-controller-sa`.
    b. Enable the **EBS CSI Driver Add-on**.

During installation, select the IAM role created in the previous step and enable the add-on. This action installs the CSI controller in the `kube-system namespace`.

c. Verify the installation by running the following command:

```
kubectl get pods -n kube-system | grep ebs
```

d. Configure the default StorageClass:
The cluster uses the `gp3 storage class` backed by Amazon EBS.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: gp3
  annotations:
    storageclass.kubernetes.io/is-default-class: "true"
provisioner: ebs.csi.aws.com
parameters:
  type: gp3
  fsType: ext4
reclaimPolicy: Delete
volumeBindingMode: WaitForFirstConsumer
allowVolumeExpansion: true
```

This storage class is used for workloads requiring ReadWriteOnce (RWO) volumes.

2. Perform the following steps to create an Amazon EFS for shared storage:

a. Create an EFS filesystem by selecting the same VPC used by EKS.

b. Configure mount targets in all Availability Zones used by worker nodes.

c. Create one mount target per Availability Zone where nodes run: AZ-1 → mount target , AZ-2 → mount target, AZ-3 → mount target.

d. Configure security group - Attach a security group to the EFS mount targets as follows. This allows worker nodes to mount the filesystem.

```
Allow NFS access -  Port: 2049 Protocol: TCP Source: EKS node security group
```

3. Perform the following steps to install the EFS CSI Driver (RWX storage):

a. Create an IAM role for EFS CSI Driver (RWX storage)
   - Attach the AWS managed policy: `AmazonEFSCSIDriverPolicy`.
   - Trust Relationship: The role must trust the EKS OIDC provider and allow Kubernetes the service account: `kube-system:efs-csi-controller-sa`.

b. Enable the **EFS CSI Driver Add-on** from the Amazon EFS CSI Driver console and select the **IAM role** created for the EFS CSI driver in the Add-on.

c. Verify the installation by running the following command:

```
kubectl get pods -n kube-system | grep efs
```

d. Create a StorageClass.

Note: Reference the EFS filesystem ID in the EFS StorageClass to enable dynamic provisioning using the EFS CSI driver. For example:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: efs-sc
provisioner: efs.csi.aws.com
parameters:
  provisioningMode: efs-ap
  fileSystemId: <EFS-FILESYSTEM-ID>
  directoryPerms: "700"
reclaimPolicy: Delete
volumeBindingMode: Immediate
```

e. Verify the storage classes by running the following command:

```
kubectl get storageclass
```

Expected output: `gp3 & efs-sc`

f. Confirm the CSI driver pods by running the following command:

```
kubectl get pods -n kube-system | grep csi
```

Install the AWS Load Balancer Controller

Perform the following steps to install the AWS Load Balancer Controller:

a. Create an IAM policy.

```
AWSLoadBalancerControllerIAMPolicy
```

b. Create an IAM role associated with the service account:

```
kube-system:aws-load-balancer-controller
```

c. Install the AWS Load Balancer Controller via Helm:

```
helm repo add eks https://aws.github.io/eks-charts
helm repo update
helm install aws-load-balancer-controller eks/aws-load-balancer-controller \
  -n kube-system \
  --set clusterName=<cluster-name> \
  --set serviceAccount.create=false \
  --set serviceAccount.name=aws-load-balancer-controller
```

This controller automatically provisions AWS load balancers based on Kubernetes resources.

Configure DNS and TLS

1. Create domains by using AWS services

   Note: Use **Amazon Route 53** and **AWS Certificate Manager (ACM)** to configure domains.

2. Create and configure the following hosted zones in Route 53:
   - A public hosted zone (for example, `looptest.xxxx.com`)

   This hosted zone is used as the application domain and enables routing through the Application Load Balancer (ALB).
   - A private hosted zone (for example, `service-looptest.xxxx.com`)

   This hosted zone is used to route traffic to the Network Load Balancer (NLB) for the Loop application.

   Note: Ensure that the domain name includes the `service-` prefix. Make a note of the domain names, as they are required during DevOps Loop installation.

3. Request a certificate using the AWS Certificate Manager (ACM) for public domain (for example: `looptest.xxxx.com`).

   After creating the certificate, make a note of the **Certificate ARN**, as it is required for configuring the Application Load Balancer (ALB).

Configure ingress and load balancing

1. Run the following command to download and run the AWS infrastructure setup script:

```
(TMP_DIR=$(mktemp -d) && \
helm pull hclsoftware/ibm-devops-loop --untar --untardir "$TMP_DIR" --version 2.0.200 > /dev/null 2>&1
 && \
sh "$TMP_DIR/ibm-devops-loop/scripts/AWS/AWS_Emissary_LB_TLS_infra_setup.sh" && \
rm -rf "$TMP_DIR")
```

   Note: This command downloads the DevOps Loop Helm chart, extracts it to a temporary directory, runs the infrastructure setup script, and removes the temporary files after execution.

2. Verify the actions performed by the script.

   The `AWS_Emissary_LB_TLS_infra_setup.sh` script performs the following actions:
   - Creates the **Emissary namespace**
   - Installs **Emissary Ingress** using Helm
   - Creates an **Application Load Balancer (ALB)** for HTTPS traffic
   - Creates an **internal Network Load Balancer (NLB)** with access restricted to the VPC CIDR range for TCP services
   - Configures the required Kubernetes **Ingress resources and Services**

   After running the script, AWS might take 5 - 15 minutes to provision the ALB and NLB. You can verify the creation of ingress resources and services by running the following command:

```
kubectl get ingress -n emissary-system
kubectl get svc -n emissary-system
```

Configure DNS records

1. Obtain the DNS names of the Application Load Balancer (ALB) and Network Load Balancer (NLB) after running the infrastructure script.
2. Create **A records** in **Amazon Route 53** to map your domains:
    - Map the application domain (for example: `looptest.xxxx.com`) to the ALB DNS name.
    - Map the service domain (for example: `service-looptest.xxxx.com`) to the NLB DNS name.

Results

After completing these steps, the required AWS infrastructure is ready, including the EKS cluster, storage, load balancers, and DNS configuration.

What to do next

You must now install DevOps Loop. See Installing DevOps Loop on AWS on page 68.

Installing DevOps Loop on AWS

After you have prepared the infrastructure, you can install DevOps Loop on a newly created EKS cluster by using the Helm chart.

Before you begin

You must have completed the following tasks:

- Gained access to the cluster and installed the following tools:
    - AWS CLI
    - kubectl
    - eksctl
- Installed Helm on the system from which you access the Kubernetes cluster. For more information, refer to Installing Helm.
- Set up an EKS cluster on AWS Elastic Kubernetes Service. For more information, refer to Create an Amazon EKS cluster.
- Prepared the required infrastructure in AWS. See Preparing AWS infrastructure for installing DevOps Loop on AWS on page 63.

1. Log in to the **My IBM Container Software Library** using the ID and password associated with your entitled software.
2. Navigate to the **Entitlement keys** section and select **Copy key** to copy your IBM Entitled Registry entitlement key to your clipboard.
3. Create a secret key in the target namespace `ibm-entitlement-key` to pull images from the IBM Entitled Registry:

```
kubectl create secret docker-registry ibm-entitlement-key \
    --namespace [namespace_name] \
    --docker-username=cp \
```

```
    --docker-password=<EntitlementKey> \
    --docker-server=cp.icr.io
```

4. Run the following command to add the Helm repository:

```
helm pull oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201 --untar
```

5. Run the following command to view the `README.md` file:

```
cat hcl-devops-loop/README.md
```

6. Update the following parameters in the Helm installation script with the appropriate values:
   - `DOMAIN` the FQDN created in Cloud DNS.
   - `TLS_CERT_SECRET_NAME` Leave it blank to use the AWS-managed certificate.
   - `RWO_STORAGE_CLASS=gp2` OR `gp3` as created in the pre-requisite steps.
   - `RWX_STORAGE_CLASS=efs-sc` (The EFS storage class created for RWX access).
7. Run the script in the Helm README for installing DevOps Loop on AWS.

Note: If the installation fails due to a timeout, run the installation script again.

Results

You have installed DevOps Loop on AWS EKS.

What to do next

You can add users and manage user access by logging in to the Keycloak instance that is installed with DevOps Loop. For more details, see User access and administration using Keycloak.

Installation of DevOps Loop in an air-gapped environment

An air-gapped environment is a network or system isolated from the public internet, typically for security or compliance reasons. In such environments, all external resources must be imported manually. DevOps Loop supports air-gapped installations by providing scripts and configurations to transfer required resources into your private environment.

Some deployments operate without internet access, requiring all container images, plugins, and dependencies to be preloaded into a private registry.

Scripts and configurations for Air-gapped installation

DevOps Loop provides the `airgap.sh` script along with Helm configuration parameters to support air-gapped setups.

Parameter	Description	Example value
`global.imageRegistry`	Private registry for product images	`registry.local:5000/devops-loop`
`global.externalImageRegistry`	Private registry for unqualified/public images. The `airgap.sh` script places qualified and unqualified images in the same image repository, you can separate them if required.	`registry.local:5000/public`

Parameter	Description	Example value
`airgap.sh`	Script to list or copy required images to private registry	`./airgap.sh -|`

The `airgap.sh` script provides the following capabilities:

- Lists all the container images required by DevOps Loop (using `-l` option).
- Copies images from public registries to a private or internal registry.

Learning Loop in an air-gapped environment

Learning Loop sample applications use npm to install JavaScript dependencies during the build process. In an air-gapped environment, the public npm registry is unavailable. As a result, build steps such as `npm ci` fail unless the required npm packages are made available through an internal npm registry.

Before disconnecting the environment from the internet, populate an internal npm registry with all packages required by the Learning Loop sample applications and update the application lockfiles to reference the internal registry. After this preparation is complete, Learning Loop builds can run entirely within the air-gapped environment. For more information, see Preparing Learning Loop applications for an air-gapped environment on page 74.

Note: This preparation is required only for Learning Loop applications that use npm packages. Standard DevOps Loop installation images are handled separately by the `airgap.sh` script.

Preparing images and resources for an air-gapped installation

Before you begin the air-gapped installation of DevOps Loop, you must prepare all the required container images and resources. In an air-gapped environment, external repositories are not accessible, and therefore, you must collect and transfer all required assets to your internal registry or offline storage.

Before you begin

You must have completed the following tasks:

- Gained administrative privileges on the target Kubernetes namespace and the airgap container registry.
- Downloaded the DevOps Loop Helm chart and it is accessible.
- Downloaded the `airgap.sh` script and ensured that it is available in the DevOps Loop Helm chart.
- Installed the `skopeo` utility on your local machine and authenticated with the required image registries.

- Allocated sufficient disk space to save product images and plugin files for transfer to the air-gapped environment.

Note: Product images consume approximately 50 GB or more of disk space in your internal/air-gapped image registry.

About this task

You must perform the following tasks in sequence to prepare for an air-gapped installation:

1. Copy DevOps Loop images by using a jump server on page 71 OR

   Copy DevOps Loop images by using file-based transfer on page 71
2. Prepare MongoDB for an air-gapped installation on page 72
3. Prepare MySQL JDBC driver on page 72

Copy DevOps Loop images by using a jump server

Copy DevOps Loop images directly to the internal registry by using a jump server. You can use this method when a system can connect to both the public internet and the air-gapped image registry.

Run the following command to copy the images directly to the internal registry:

```
sh ./hcl-devops-loop/scripts/airgap/airgap.sh -r hcl-devops-loop -d registry.local:5000/devops-loop
```

Results

DevOps Loop images are copied directly to the internal image registry.

OR

Copy DevOps Loop images by using file-based transfer

Copy DevOps Loop images to an air-gapped environment by using file-based image archives. You can use this method when no system has access to both the public internet and the air-gapped environment.

1. Run the following command on a machine with internet access:

   ```
   sh hcl-devops-loop/scripts/airgap/airgap.sh -r hcl-devops-loop -d loopimagesdir -x save -y
   ```
2. Transfer the `loopimagesdir` directory to a machine inside the air-gapped environment.
3. Run the following command to load the images into the internal registry:

   ```
   sh ibm-devops-loop/scripts/airgap/airgap.sh -r ibm-devops-loop -d airgap.registry.io/loopimages -s
    loopimagesdir -x load
   ```

Results

DevOps Loop images are available in the internal air-gapped image registry.

Prepare MongoDB for an air-gapped installation

You must prepare MongoDB for air-gapped installation by making the required Helm chart available locally and updating the configuration to use images from your internal registry.

1. Download and extract the MongoDB Helm chart version 14.13.0 from Bitnami Helm Charts into the same directory as the expanded `ibm-devops-loop` Helm chart.
2. Update the installation script as follows:
   - Set `MONGO_IMAGE_REPO=registry.local:5000/devops-loop`.
   - Replace `bitnami/mongodb` with `mongodb` in the `helm upgrade --install` command.

Prepare MySQL JDBC driver

The DevOps Deploy server, installed as part of DevOps Loop, creates a MySQL database to store various artifacts. In an air-gapped environment, the installation cannot automatically download the required JDBC driver. You must make the driver available manually before starting the DevOps Loop installation.

1. Download the required MySQL JDBC driver and make it accessible within the air-gapped environment.
2. Write a bash script, named `script.sh` that copies the JDBC driver from a location accessible from your cluster to `${UCD_HOME}/ext_lib/`.
3. Store the script `script.sh` in a YAML file describing a Kubernetes ConfigMap.
   The Kubernetes ConfigMap is defined for copying the JDBC driver to your Persistent Volume (PV) during the chart installation process.
   Here is an example ConfigMap YAML file that copies a MySQL .jar file from a web server using `wget`:

   ```
   kind: ConfigMap
   apiVersion: v1
   metadata:
     name: user-script
   data:
     script.sh: |
       #!/bin/bash
       echo "Running script.sh..."
       if [ ! -f ${UCD_HOME}/ext_lib/mysql-jdbc.jar ] ; then
         echo "Copying file(s)..."
         wget -L -O mysql-jdbc.jar http://webserver-example/mysql-jdbc.jar
         mv mysql-jdbc.jar ${UCD_HOME}/ext_lib/
         echo "Done copying."
       else
         echo "File ${UCD_HOME}/ext_lib/mysql-jdbc.jar already exists."
       fi
   ```

4. Create the ConfigMap in your cluster by running the following command:

   ```
   oc create configmap <map-name> <data-source>
   ```

5. Reference the ConfigMap name in Helm by using the following command:

   ```
   hcl-launch-server-prod.extLibVolume.configMapName
   ```

Results

You have copied all required DevOps Loop images and prepared the necessary resources, including MongoDB and the MySQL JDBC driver. Your internal registry or offline storage now contains all required artifacts.

What to do next

You can begin the air-gapped installation of DevOps Loop. See Installing DevOps Loop in an air-gapped environment on page 73.

Installing DevOps Loop in an air-gapped environment

After preparing the required images, plugins, and JDBC drivers in your air-gapped registry or offline storage, you can begin installing DevOps Loop in an air-gapped environment by using Helm.

Before you begin

You must have completed the following tasks:

- Preloaded images and resources. See Preparing images and resources for an air-gapped installation on page 70.
- Ensured that you have administrative privileges on the Kubernetes namespace where DevOps Loop will be installed.
- Installed and configured Helm on your system.
- Gained access to the airgap image containing the preloaded images.

1. Modify the `ADDIITIONAL_HELM_OPTIONS` variable in the DevOps Loop installation script, to set the following Helm values to point to your airgap registry:

```
--set global.imageRegistry=registry.local:5000/devops-loop
--set global.externalImageRegistry=registry.local:5000/devops-loop
--set platform.velocity.plugins.plan.image=ucv-ext-compass:1.2.2
--set platform.velocity.plugins.control.image=hclcr.io/accelerate/ucv-ext-control:1.1.1
--set platform.velocity.plugins.test.image=hclcr.io/accelerate/ucv-ext-onetest-server:1.0.32
--set platform.velocity.plugins.deploy.image=hclcr.io/accelerate/ucv-ext-launch:5.1.1
--set platform.velocity.plugins.build.image=hclcr.io/accelerate/ucv-ext-build:1.1.2
--set platform.velocity.plugins.yaml.image=hclcr.io/accelerate/ucv-ext-yaml-executor:0.0.13
```

2. Edit the DevOps Loop installation script to use the locally downloaded and expanded DevOps Loop Helm chart.
   For **OpenShift (OCP)** installations, no further changes to the installation script are required.
   For **Kubernetes (K8s)** installations, you must locate the `helm upgrade --install` command at the end of the installation script and replace `ibm-helm/ibm-devops-loop` with `ibm-devops-loop`.
3. Follow the DevOps Loop installation instructions based on your environment.

Results

You have installed DevOps Loop in the air-gapped environment.

What to do next

Before installing additional plug-ins, ensure the required images are available in your internal or air-gapped environment:

- If you want to install Measure plug-in images that are not included in the standard DevOps Loop set, download them from their public repositories (such as docker.io or hclrc.io) and upload them to your internal or air-gapped image registry.
- If you want to install Deploy plug-ins that are not included in the standard set, download them from their public repositories to local storage, then upload them to the DevOps Deploy server.

Preparing Learning Loop applications for an air-gapped environment

Before running Learning Loop applications in an air-gapped environment, prepare an internal npm registry with the required npm packages and update the application lockfiles to use the internal registry. This preparation enables `npm ci` and subsequent builds to complete without accessing the public npm registry.

Before you begin:

Ensure that you have completed the following tasks:

- Installed DevOps Loop in an air-gapped environment. See Installing DevOps Loop in an air-gapped environment on page 73.
- Configured an internal npm registry that is accessible from the DevOps Loop build environment.
- Verified that the environment has temporary internet access to download npm packages.
- Installed npm client.
- Installed and configured `kubectl` with access to the DevOps Loop namespace.

Procedure for environments with temporary internet access

1. Clone the Learning loop frontend and backend repositories to a machine that has internet access.

   ```
   git clone <frontend-repository-url> ${LOOP_NAME}-frontend
   git clone <backend-repository-url> ${LOOP_NAME}-backend
   ```

2. Install and configure an internal npm registry that can be reached by the DevOps Loop build agents.

   For example, to install Verdaccio:

   ```
   sudo npm install -g verdaccio
   ```

   Configure the registry to proxy requests to the public npm registry while internet access is available, and then start the service.

3. Copy the frontend and backend repositories to the DevOps Loop build pod:

   ```
   kubectl -n devops-loop cp "${FRONTEND_REPO_PATH}/." \
   devops-build-agent-0:/tmp/${LOOP_NAME}-frontend
   ```

   ```
   kubectl -n devops-loop cp "${BACKEND_REPO_PATH}/." \
   devops-build-agent-0:/tmp/${LOOP_NAME}-backend
   ```

4. Connect to the build pod and configure npm to use the internal registry:

```
npm config set registry "${REGISTRY_URL}"
npm config set replace-registry-host always
npm config set omit-lockfile-registry-resolved true
```

5. Regenerate the `package-lock.json` file for each repository.

```
rm -f package-lock.json
npm install --package-lock-only --ignore-scripts
```

   Verify that the regenerated lockfiles do not reference the public npm registry.

6. Run the following command for each Learning Loop repository while internet access is still available:

```
npm ci
```

   This command downloads all required dependencies and stores them in the internal npm registry for later use.

7. Copy the regenerated `package-lock.json` files back to the cloned repositories. Commit the updated lockfiles to a feature branch and push the branch to your source control repository.

   For example:

```
git checkout -b chore/internal-registry-lockfile
git add package-lock.json
git commit -m "Regenerate package-lock.json for internal npm registry"
git push -u origin chore/internal-registry-lockfile
```

   Create and merge a pull request for both the frontend and backend repositories.

8. Remove any proxy or uplink configuration from the internal npm registry, after all required npm packages have been downloaded.
9. Disconnect the environment from the internet.
10. Run the Learning Loop build.

    Verify that the build completes successfully and that npm ci retrieves all required packages from the internal npm registry without attempting to access the public npm registry.

Procedure for fully air-gapped environments

If the target environment does not have internet access at any stage, prepare the required npm packages on a connected staging machine before deploying them to the air-gapped environment.

1. Install and configure an internal npm registry on a staging machine with internet access, .
2. Configure the registry to proxy requests to the public npm registry.
3. Prepare the Learning Loop application manifest files (`package.json` and `package-lock.json`).
4. Regenerate the `package-lock.json` files and run `npm ci` for the frontend and backend applications to populate the internal npm registry with all required npm packages.
5. Remove any proxy or uplink configuration from the internal npm registry so that it operates in offline mode.
6. Export the registry data and the application manifest files.

7. Transfer the exported registry data and application manifest files to the air-gapped environment by using your organization's approved transfer method.
8. Import the registry data into the internal npm registry in the air-gapped environment.
9. Configure the DevOps Loop build environment to use the internal npm registry.
10. Run a Learning Loop build and verify that `npm ci` installs the required packages from the internal npm registry without requiring internet access.

The Learning Loop applications are configured to use the internal npm registry, and builds can run successfully in the air-gapped environment without requiring access to the public npm registry.

Managing DevOps Loop features after installation

After you install HCL DevOps Loop, you can manage and customize certain features based on your requirements.

During the installation of DevOps Loop, if you did not use any Helm parameters, you can still use those parameters even after installation is complete.

You can use the helm upgrade command to enable or disable server features after the installation of DevOps Loop is complete.

The sample code is to enable the Egress policy that restricts traffic to private IP addresses by retaining the values of other parameters that you used during the installation.

Similarly, you can use the other additional Helm parameters to enable or disable features based on your requirements. See Additional Helm parameters on page 76.

Additional Helm parameters

You can find the information about Helm parameters that you can use during the installation of HCL DevOps Loop.

As a system administrator, you must complete the additional configuration for the capabilities by using Helm parameters. Each Helm parameter that is specific to the solution is prefixed by its Helm chart name as follows:

- Plan: `hcl-devopsplan-prod`
- Test: `hcl-devops`
- Deploy: `hcl-launch-server-prod`
- Measure: `hcl-velocity`

For example, to configure a property in Plan, use the following command:

```
bash
--set hcl-devopsplan-prod.property=value
```

You can run the following commands to view the required parameters:

- Plan: helm show readme hcl-helm/hcl-devopsplan-prod # DevOps Plan
- Deploy: helm show readme hcl-helm/hcl-launch-server-prod # DevOps Deploy

- Test: helm show readme hcl-helm/hcl-devops # DevOps Test
- Measure and Release: helm show readme hcl-helm/hcl-velocity # DevOps Velocity

License management and user administration

After you install DevOps Loop, you must manage licenses, users, and authentication to control access to platform resources.

License management

During installation, you can configure licensing information by using the license server settings that are provided in the Helm chart. For more information, see DevOps Loop licensing information on page 78.

The **User Administration** page displays license consumption information for the tenant. Administrators can view license usage across configured license tiers and manage user license assignments.

The **Licenses** section displays:

- The available license tiers.
- The total number of licenses in each tier.
- The number of licenses that are currently assigned.
- The number of licenses that remain available.

License usage information is updated automatically when user license assignments are modified.

User administration

As part of administration, you can add users to DevOps Loop and assign roles in Keycloak. For more information, see User access and administration using Keycloak on page 81 and Enabling the social sign-up and social login for DevOps Loop on page 80.

You can use the default user management capabilities that are provided by the platform or manage users through the configured identity provider.

An administrator can manage users within a tenant. A tenant represents an organization within which multiple TeamSpaces can be created, and each TeamSpace can contain multiple Loops.

To access user administration, click **Settings** > **User Administration**.

Tenant information

The top section of the **User Administration** page displays summary information about the tenant, including:

- Tenant name
- Tenant ID
- Creation date
- Number of TeamSpaces

- Number of Loops
- Number of users

Managing users

The user list displays all users that belong to the tenant. You can perform the following actions:

- Browse users within the tenant.
- Search for users by name or email address.
- Filter users by TeamSpace.
- Filter users by Loop.
- Assign or modify a user's license tier.

Select a user from the list to view detailed user information.

User details

When you select a user, the details pane displays information about the user, including:

- User name
- Email address
- Assigned role
- Associated TeamSpaces
- Associated Loops

This information helps administrators review user access and license assignments across the tenant.

Roles

User roles are managed through Keycloak and are reflected in DevOps Loop. The assigned role for a user is displayed in the user details pane.

For information about managing users and roles in Keycloak, see User access and administration using Keycloak on page 81.

DevOps Loop licensing information

You can find the details of licensing that HCL DevOps Loop supports.

DevOps Loop supports the following 3 tiers of license:

- **Essentials** (Tier 1): Plan, Control and Code
- **Standard** (Tier 2): Plan, Control, Code, Build, Test, Deploy and Harbor (if enabled).
- **Premium** (Tier 3): Plan, Control, Code, Test, Build, Deploy, Measure, Release and Harbor (if enabled).

Each tier is defined by the number of capabilities that are included in the DevOps Loop platform.

Licenses are consumed when the admin assigns them, and only released when the admin explicitly revokes them or DevOps Loop is uninstalled. License tier re-assignments may take up to 15 minutes to reflect.

By default, non-admin users must be assigned a tier before logging in, while admin users automatically receive the highest available tier. This per-user tier assignment allows different access levels to be enforced for different users, providing flexibility in license management.

Configuration

When you purchase one of these tiers, you must map the licenses to My HCLSoftware (MHS). MHS is a cloud-based web application that helps to manage software entitlements and licenses. When you install DevOps Loop, you must specify the License server URL and ID, which are configured only through the Helm chart. For more information about managing licenses for your product, refer to the following resources:

- My HCLSoftware
- Managing HCL Local License Server or Managing HCL Cloud License Server

License allocation

You must run the following command to retrieve information on the licensing allocation:

curl --cacert /path/to/your/certificate.crt https://FQDNhostname:LLSport/v1/licensepools/poolID

Sample output:

```
{
  "id": "MyPoolID",
  "features": {
    "DevOpsAutomationEssentials": {
      "total": 100,
      "leased": 0,
      "available": 100,
      "name": "DevOps Automation Essentials User"
      }
    }
}
```

When you run the command to retrieve the current license allocations, depending on the tier that you have opted for, the following values are displayed:

- **DevOpsAutomationEssentials**
- **DevOpsAutomationStandard**
- **DevOpsAutomationPremium**

The license feature names that are used by the License server are different from the product name.

Usage

After the Admin user creates a user, when the user logs in to DevOps Loop, then one license of the highest available tier is consumed. The user can access the products that are included in the licensing tier that is purchased.

DevOps Loop provides a user interface to view and manage licensing. You can revoke or assign a user's license through the **User Administration** page. See License management and user administration on page 77 and Revoking a license on page 81.

Troubleshooting

You can view the licensing logs for troubleshooting by running the following command:

```
kubectl logs <licensing_pod_name> -n <namespace>
```

Where, the *namespace* is defined by the Helm installation. You can find the *licensing_pod_name* by running the following command:

```
kubectl get pods -n <namespace>
```

The pod name that contains 'licensing' in the name is listed.

Enabling the social sign-up and social login for DevOps Loop

You can enable social authentication for users to sign up and log in to HCL DevOps Loop by using a social network account. The Keycloak admin can configure this social sign-up in the Keycloak UI.

Before you begin

You must have completed the following tasks:

- Installed DevOps Loop.
- Assigned the role of a Keycloak Administrator.
- Copied the URL of the Keycloak UI, username, and password on completion of the installation of the platform.
- Obtained the credentials to access the dashboard of a social identity provider to configure the delegation of authentication to a social media account.
- Read and understood Integrating identity providers.

About this task

The social sign-up link on the **Login** page of DevOps Loop is not visible when you install DevOps Loop by using the default values. The sign-up link is hidden to provide enhanced security to the platform. You can enable the sign-up link on the **Login** page when you want to provide self-registration of users in DevOps Loop.

The following procedure describes steps to be performed to enable the **Sign up** link by using Keycloak UI.

1. Log in to the Keycloak Admin Console.
2. Click **Identity providers** from the left navigation pane.
3. Select an identity provider under the **Social** section.
   The configuration page for the selected identity provider is displayed.
4. Enter the configuration details.
   The fields in the configuration page depend on the social identity provider that you have selected.
5. Click **Add** to apply the changes.

Results

You have enabled the social sign-up link on the **Login** page of DevOps Loop.

What to do next

You must add the self-registered users to the **Users** group in the Keycloak Admin Console. See User access and administration using Keycloak on page 81.

Related information

Keycloak

Revoking a license

Each user is assigned a license when they log in to the DevOps Loop for the first time. As an admin, you can revoke the assigned license if the user is no longer part of the platform.

1. Log in to DevOps Loop.
2. Navigate to **Settings > User Administration**.
   The **User Administration** page and all the users are displayed. You can search for a user by their name or email ID if the list is long.
3. Select **None**from the **Tier** option next to the username.

   A confirmation dialog is displayed.
4. Click **Yes, Revoke**.

Results

You have revoked the assigned license for a user.

User access and administration using Keycloak

HCL DevOps Loop uses Keycloak (https://www.keycloak.org/) to manage and authenticate users. You can manage user access by logging in to the Keycloak instance that is installed with DevOps Loop.

Keycloak uses the concept of a realm to manage and authenticate users. When you install DevOps Loop, a realm called *platform* is created for you in Keycloak. All server users belong to this realm and when they log in to DevOps Loop, they log into that realm.

As an administrator, it is important to consider the following points about the platform administration:

- To begin with, there is no administrator for DevOps Loop.

  Such an administrator is required for accessing additional functions, which include claiming ownership of projects and unarchiving them. However, you can assign administrative privileges to any user. You must assign the privilege by adding the admin role to the user in Keycloak.

- You must add a user that you want to be the administrator in Keycloak by logging in to the Keycloak Admin Console at `https://<fully-qualified-dns-name>/auth/`.

  Note: Do not use that admin user to perform non-administration tasks. Instead, add another user.

  The default username for the Keycloak administrator is `keycloak`. The password is randomly generated when the software is installed. You can see the password by using the following kubectl command:

  ```
  kubectl get secret -n <namespace> <helm name>-keycloak -o jsonpath="{.data.password}" | base64 --decode;
   echo
  ```

- After you add the user that you want to be the administrator for DevOps Loop, you must make that user the administrator.

  In the Keycloak Admin Console, on the **Users** page, you can search and select the user that you want to make an administrator. Then, in the **Groups** tab, you can add the user to the **Admins** group.

- All users must have the **Users** group assigned to them to access DevOps Loop.

  In the Keycloak Admin Console, on the **Users** page, you can search and select a user, and then in the **Groups** tab, you can add the user to the **Users** group.

  For more information about assigning user roles, see Groups in the Keycloak documentation.

Now that you are the platform administrator, it is important to consider the following points about the default user management and authentication:

- Minimum password length is 8 characters
- Email verification of new users is turned off
- The Forgot Password feature is turned on by default but no instructions are sent to the user to reset their password
- Forgotten user passwords are changed by you if you do not enable Keycloak to send instructions to reset a password

Note: If a user is added through the user management of HCL DevOps Plan, then that user must have the **Users** or **Admins** group assigned in the Keycloak Admin Console to get access to DevOps Loop.

You can review the following sections about changing the default authentication controls.

Email settings

The default status of the Forgot Password switch is ON in the *devops-automation* realm. However, as an administrator, you must enable Keycloak to send an email to the user with instructions to reset their password. If you want to verify an email, you must also enable Keycloak to send an email to the user to verify their email address.

You must provide SMTP server settings for Keycloak to send an email. After you log in to the Keycloak Admin Console, see Email Settings in the Keycloak documentation.

Then, to set up the email verification, see Forgot Password in the Keycloak documentation.

Password policy

The *devops-automation* realm has a password policy where the minimum length of a password is 8. As an administrator, you can update password policies in Keycloak.

After you log in to the Keycloak Admin Console, see Password Policies in the Keycloak documentation.

User password

When you create a user, you must create credentials for the user by clicking the **Set password** button in the **Credentials** tab. Then, you must share the username and password with the user. While setting the password, if the **Temporary** slider button is set to **On**, then the user must set a new password before logging in to the platform.

If you did not enable Keycloak to send instructions to a user about how to reset a password, you must use the Keycloak Admin Console to change their password for them.

After you log in to the Keycloak Admin Console, see User Credentials in the Keycloak documentation.

User deletion

When a user is inactive or no longer needs to access the platform, you can delete that user.

After you log in to the Keycloak Admin Console, see Deleting Users in the Keycloak documentation.

About user roles and access permissions

Users have different roles and access levels on the platform and in integrated capabilities, depending on their tasks and the settings in each application.

Two types of roles are supported in HCL DevOps Loop: admin and user. Admin users can create teamspaces and loops.

Role	Permissions
Admin	Admins have full permission for the following features in the platform: • User administration • Integration • Teamspace management • Loop management • Loop Genie • Dashboards
User	Users have view permission for the following features in the platform:

Role	Permissions
	• View loops that the user is a part of • Switch to the application • Loop Genie • Dashboards

Notes:

- Loop creator is granted the highest permissions for the resources in the integrated applications that are created by the loop. The other invited users are granted basic access. The loop creator can elevate the other users' access as required.
- If you are an admin user in the platform but a loop member, in Deploy, you will be given the same privileges as the loop creator. For information on roles and permissions in Deploy, see DevOps Loop: Deploy security management.

Backup and restoration of DevOps Loop

You must back up HCL DevOps Loop data before you uninstall the current version of DevOps Loop. You must back up the data to avoid data loss or inaccessibility.

A backup creates a copy of your data and stores it in secondary storage. You can use this copy to recover if the original data is lost or becomes inaccessible.

A restore copies backed-up data from secondary storage back to its original location, making it available again.

You must back up and restore the data when you perform the following tasks:

- Move the existing environment to a new system.
- Change the name of the release or namespace that you used during the installation of DevOps Loop.
- Minimize the downtime of DevOps Loop during disaster recovery.

Tools supporting backup and restoration

DevOps Loop uses the following open source tools to perform backup and restore operations:

- **Velero**: It is a Kubernetes native backup and restore tool that captures and restores Kubernetes resources, persistent volumes, and application state. Velero also supports disaster recovery and migration scenarios between clusters.
- **MinIO**: It is an S3 compatible object storage system used as the backup storage target for Velero. MiniO stores the backups created by Velero and enables you to retrieve them for restore operations.

Velero is installed in your Kubernetes cluster and configured to use MinIO or any other S3-compatible storage backend.

Note: MinIO is provided here as an example S3-compatible storage solution for reference purposes only.

To install Velero and MiniO in your cluster, you must run the following script:

```
./ibm-devops-loop/scripts/backup-restore/install-minio.sh
./ibm-devops-loop/scripts/backup-restore/install-velero.sh
```

After installing MinIO, run the port-forward commands to make it accessible on your local machine:

```
```bash
kubectl port-forward --address 0.0.0.0 pod/minio -n loops-minio 9000:9000 9090:9090
```

Then, use the MinIO Web UI (http://localhost:9090) to create a bucket (for example, "loops-backup") to store Velero backups.

Backing up DevOps Loop data

You can back up DevOps Loop by using Velero and Minio to support disaster recovery and upgrade scenarios.

Before you begin

You must have completed the following tasks:

- Ensured that all DevOps Loop services are running and in a healthy state.
- Gained administrative privileges.
- Installed Velero and configured with an S3-compatible storage backend (MinIO or AWS S3). See Tools supporting backup and restoration on page 84.
- Locally saved the Helm values for your current DevOps Loop deployment.

About this task

DevOps Loop utilizes both block and file storage, allowing the back up process to support CSI snapshots and fs-volume backups.

"

Important: If DevOps Loop pods that use file storage for fs-volume backups are not labeled, Velero will not include their data in the backup, which could result in incomplete or inconsistent backup data.

"

1. Run the following command to label DevOps Loop pods that use file storage for fs-volume backups:

   ```
   ./ibm-devops-loop/scripts/backup-restore/annotate-pods.sh
   ```
   ```

Note: If your DevOps Loop deployment only uses block storage volumes (CSI snapshots), you can skip this step.

2. Export the Helm configuration of your DevOps Loop deployment to a local file by running the following command:

```
helm get values devops-loop -n devops-loop > devops-loop-values-backup.yaml
```

3. Run a Velero backup of the DevOps Loop namespace, including PVCs, PVs, and Secrets, using the following command:

```
velero backup create devops-loop-backup \
  --include-namespaces devops-loop \
  --include-resources persistentvolumeclaims,persistentvolumes,secrets \
  -n velero
```

4. Run the following command to verify the backup status to ensure it completed successfully:

```
velero backup describe devops-loop-backup --details
```

5. **Optional** Backup any external databases with their native backup tools to ensure data consistency.
6. Optional: Check the status and logs of your restore jobs to troubleshoot any issues:

```
# Check backup status
velero get backup

# Describe specific backup
velero describe backup <backup-name>

# View backup logs
velero backup logs <backup-name>
```

Results

You have created a backup of the DevOps Loop namespace and Helm values for disaster recovery or upgrade scenarios.

Restoring DevOps Loop data

You can restore DevOps Loop from a backup created with Velero and Helm values after a disaster recovery event or a failed upgrade.

Before you begin

You must have completed the following tasks:

- Ensured that the Kubernetes environment hosting DevOps Loop is running and accessible.
- Gained administrative privileges
- Installed Velero and configured with an S3-compatible storage backend (MinIO or AWS S3). See Tools supporting backup and restoration on page 84.
- Locally saved the Helm values for your current DevOps Loop deployment.

About this task

DevOps Loop utilizes both block and file storage, allowing the restore process to support CSI snapshots and fs-volume backups.

“

Important: If DevOps Loop pods that use file storage were not labeled during backup, their data will not be restored, which could result in incomplete or inconsistent recovery.

”

1. Run the following command to restore the DevOps Loop namespace from the Velero backup:

```
velero restore create --from-backup devops-loop-backup
```

2. Verify that the restore is completed successfully by running the following command:

```
velero restore describe devops-loop-backup --details
```

3. Reinstall or upgrade DevOps Loop using the saved Helm values if necessary:

```
helm upgrade --install devops-loop devops-loop-chart -n devops-loop -f devops-loop-values-backup.yaml
```

Note: If persistent volumes are larger than the default Helm chart sizes, override them using `--set` options during reinstall.

4. **Optional**: Restore any external databases used by DevOps Loop using their native restore tools to ensure data consistency.
5. Restart DevOps Loop to ensure all services reflect the restored state:

```
kubectl rollout restart deployment devops-loop -n devops-loop
```

6. Optional: Check the status and logs of your restore jobs to troubleshoot any issues:

```
# Check all restores
velero get restore

# Describe a specific restore
velero describe restore <RESTORE_NAME>

# View restore logs
velero restore logs <RESTORE_NAME>
```

Results

You have restored the DevOps Loop namespace, including all CSI snapshots and fs-volume backups, and any external databases (if applicable).

Private CA and self-signed certificate support

A private Certificate Authority (CA) is an organization-specific service that issues and manages digital certificates for use within an enterprise’s private network. These certificates secure communication between internal applications and services.

By default, self signed or privately signed certificates are not automatically trusted by clients because they are not included in the public trust stores used by operating systems and browsers.

DevOps Loop supports configuring and trusting such private CA or self-signed certificates so that secure connections to internal systems can be established.

During installation or upgrade, DevOps Loop reads CA certificates from a Kubernetes secret specified by the Helm parameter `global.privateCaBundleSecretName`. These certificates are then added to internal trust store of DevOps Loop so that integrations and plugins can establish encrypted, trusted connections to systems that use private CA or self-signed certificates.

You can also reference the same secret using `global.ibmCertSecretName` when using self-signed certificates to simplify configuration.

Related information

Configuring trusted certificates in DevOps Loop on page 88

Configuring trusted certificates in DevOps Loop

You can configure DevOps Loop to use private CA and self-signed certificates by creating or updating a Kubernetes secret with a PEM certificate bundle.

Before you begin

You must have completed the following tasks:

- Ensured that you have the administrator privileges to the Kubernetes namespace where DevOps Loop will be installed.
- Ensured that the private CA is available in a PEM format (`.pem`).

Note: In the scenarios below, `mycacrt.pem` is used as a sample PEM file name for a private CA or combined certificate bundle. You must replace `mycacrt.pem` with the actual name and path of your PEM file.

Perform any of the following actions based on the scenario:

Scenario	Action	Notes
No certificate provided (auto-generate self-signed)	Perform the following steps: a. Set `SELF_SIGNED=true` in the DevOps Loop installation script. The script generates `key.pem` and `cert.pem` valid for 365 days with SAN for `$DOMAIN`.	No manual secret creation is required. The certificate is generated automatically.

Scenario	Action	Notes
	The script creates a Kubernetes secret named in `devops-loop-tls-secret` containing `ca.crt=cert.pem`, `tls.crt=cert.pem`, and `tls.key=key.pem`. The script also sets `global.hclCertSecretName=devops-loop-tls-secret`, so that it is used to terminate TLS for the DevOps Loop instance.	

Using a private CA certificate bundle	Perform the following steps:
	
	a. Combine multiple CA/intermediate certificates if needed:
	`cat rootCA1.pem rootCA2.pem > mycacrt.pem`
	b. Create the secret:
	`kubectl create secret generic privateca-secret --from-file=ca.crt=/path/to/mycacrt.pem -n devops-loop`
	c. Edit the `ADDITIONAL_HELM_OPTIONS` variable in the DevOps Loop installation script to add:
	`--set global.privateCaBundleSecretName=privateca-secret -set hcl-devops-prod.ingress.cert.selfSigned=true`
	
	The helm value
	`hcl-devops-prod.ingress.cert.selfSigned=true`
	is needed to work-around an issue with the latest shipping version of DevOps Test when using TLS certificates signed by a private CA.
		Used when internal services are signed by a private CA. The `ca.crt` key is mandatory.

Updating an existing CA or self-signed certificate	Perform the following steps: a. To prevent the need to manually restart pods, create a new secret with the updated certificate in the secret: `kubectl create secret generic privateca2-secret \ --from-file=ca.crt=/path/to/mycacrt.pem -n devops-loop`	

Scenario	Action	Notes

	b. Edit the `ADDITIONAL_HELM_OPTIONS` variable in the DevOps Loop installation script to add:
	`--set global.privateCaBundleSecretName=privateca2-secret -set hcl-devops-prod.ingress.cert.selfSigned=true`
	The helm value
	`hcl-devops-prod.ingress.cert.selfSigned=true`
	is needed to work around an issue with the latest shipping version of DevOps Test when using TLS certificates signed by a private CA.	

Results

You have configured DevOps Loop to use the specified trusted certificates.

What to do next

You must run the DevOps Loop installation script. See Installation of DevOps Loop on page 45.

Upgrading DevOps Loop

After you complete the required backup and pre-upgrade tasks, you can upgrade DevOps Loop to a newer version.

Before you begin

Ensure that you have completed the following tasks:

- Backed up DevOps Loop. See Backing up DevOps Loop on page 84.
- Ensured that you have access to the Kubernetes cluster and the Helm CLI.
- Verified that the Helm chart repository is reachable from your environment.
- Deleted any existing namespaces that are used by Code dev containers running in user namespaces, when applicable.

About this task

You can upgrade DevOps Loop by using one of the following methods:

- **Manual Helm upgrade** - Use this method to upgrade the DevOps Loop platform without enabling Harbor.
- **Installation script upgrade** - Use this method if you want to enable Harbor during the upgrade. Configure the Harbor parameters before you run the installation script.

Note: Upgrading the DevOps Loop platform updates the platform components only. Existing loops are not modified and continue to use their existing sample data, tasks, and Loop Genie TASKS repository and velocity plugins. To use the sample applications, tasks, and Loop Genie capabilities that are introduced in version 2.0.2, create a new loop after the platform upgrade.

Upgrade DevOps Loop without Harbor

1. Run the following commands to set environment variables for the upgrade:

```
HELM_NAME=devops-loop
NAMESPACE=devops-loop
LOOP_CHART_VERSION=2.0.201
```

2. Run the following command to initialize the additional Helm options:

```
export ADDITIONAL_HELM_OPTIONS="--set option1=value1 --set option2=value2"
```

3. Run the following command to retrieve the existing Helm values:

```
helm get values ${HELM_NAME} \
  --namespace ${NAMESPACE} \
  > user_input_values.yaml
```

4. Retrieve the existing Helm values again to verify the configuration by running the following command:

```
ADDITIONAL_HELM_OPTIONS=${ADDITIONAL_HELM_OPTIONS:-}
helm get values ${HELM_NAME} --namespace ${NAMESPACE}
```

5. Run the following command to upgrade DevOps Loop:

```
helm upgrade "${HELM_NAME}" oci://hclcr.io/devops-automation-helm/hcl-devops-loop \
  --namespace ${NAMESPACE} \
  --version=${LOOP_CHART_VERSION} \
  -f user_input_values.yaml \
  ${ADDITIONAL_HELM_OPTIONS}
```

6. Run the following command to verify that all the DevOps Loop pods and components are running:

```
kubectl get pods -n devops-loop
```

You have upgraded DevOps Loop without enabling Harbor.

Upgrade DevOps Loop with Harbor enabled

1. Login to the HCL container registry:

```
helm registry login hclcr.io \
  --username <username> \
  --password <password>
```

2. Run the following command to download the Helm chart:

```
helm pull oci://hclcr.io/devops-automation-helm/hcl-devops-loop --version 2.0.201 --untar
```

3. Set the following variables:

```
Set the environment variables
export HELM_NAME=devops-loop
export NAMESPACE=devops-loop
```

4. Run the following command to create the HCL Container Registry image pull secret:

```
kubectl create secret docker-registry hcl-entitlement-key \
    --docker-username=<accountID>
    --docker-password=<entitlementKey> \
    --docker-server=hclcr.io
    -n ${NAMESPACE}
```

5. Create the Harbor object storage secret by running the following command:

```
kubectl create secret generic harbor-s3-secret \
  -n ${NAMESPACE} \
  --from-literal=accesskey=<ACCESS_KEY> \
  --from-literal=secretkey=<SECRET_KEY>
```

6. Run the following command to export the current Helm values:

```
helm get values ${HELM_NAME} \
  -n ${NAMESPACE} \
  > user_input_values.yaml
```

7. Update the installation script (`hcl-devops-loop/scripts/HCL-loop-XXX-install.sh`) with the following changes:
    - Add placeholders and instructions for the required environment-specific details, including:
        - Domain name
        - License information
        - TLS certificate details
        - Storage class configuration
        - Update both Helm upgrade commands in the installation script to include the user values file:

          ```
          -f user_input_values.yaml
          ```

          This ensures that all user-specific configuration is applied consistently during both Helm upgrade operations.

   For example:

```
helm upgrade --install ${HELM_NAME} \
  oci://hclcr.io/devops-automation-helm/hcl-devops-loop \
  --version ${LOOP_CHART_VERSION} \
  -f user_input_values.yaml \
  --set harbor.enabled=false \
  --hide-notes \
  --timeout 30m \
  -n ${NAMESPACE} || return 1

helm upgrade --install ${HELM_NAME} \
  oci://hclcr.io/devops-automation-helm/hcl-devops-loop \
  --version ${LOOP_CHART_VERSION} \
  -f user_input_values.yaml \
  ${HARBOR_HELM_OPTIONS} \
  --hide-notes \
```

```
  --timeout 30m \
  -n ${NAMESPACE} || return 1
```

8. Update the installation script with the required Harbor configuration:

```
HARBOR_ENABLED=true
HARBOR_S3_BUCKET=<bucket>
HARBOR_S3_REGION=<region>
HARBOR_S3_ENDPOINT=<endpoint>
HARBOR_TRIVY_STORAGE_CLASS=<storage-class>
HARBOR_OIDC_ADMIN_GROUP=<group>
```

9. Run the modified installation script for upgrade.

   For example:

```
bash HCL-loop-K8s-install.sh
```

10. Run the following command to verify that the Harbor pods are running:

```
kubectl get pods -n ${NAMESPACE}
```

11. To confirm that Harbor is accessible and the URL is active, open a web browser and navigate to:

```
https://harbor.<DOMAIN>
```

You have upgraded DevOps Loop with Harbor enabled.

Troubleshooting DevOps Loop installation and upgrade

Related information

Troubleshooting Harbor integration

Integrations in DevOps Loop

DevOps Loop provides a set of integrations to extend the platform's capabilities and connect your loops to external systems and intelligent tools. These integrations enable you to automate tasks, enhance productivity, and interact with loop resources from outside the DevOps Loop interface.

AI provider integration

DevOps Loop supports AI-assisted features through external AI providers such as **OpenAI**, **Claude Desktop**, **Gemini**, **IBM watsonx**, and **Ollama**. When configured, these integrations enable Loop Genie to generate summaries, insights, and contextual information across work items, build results, deployments, and other supported capabilities.

MCP server integration

The MCP server (Model Context Protocol Server) allows external MCP-compatible tools such as **VS Code (Copilot)** and **Claude Desktop** to connect directly to DevOps Loop. Through this integration, you can query, retrieve, and modify loop resources from supported external tools. For more information, see DevOps Loop MCP server on page 111.

AI provider integration for Loop Genie - Tech Preview

Disclaimer:

This release contains access to the AI provider configurations for Loop Genie feature in HCL DevOps Loop as a Tech Preview. The Tech Preview is intended for you to view Loop Genie's capabilities by integrating with major LLM providers such as OpenAI, Claude Desktop, Gemini, IBM watsonx, and Ollama and provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL provides the information without obligation of support and "as is" without warranty of any kind.

You can configure AI providers such as **OpenAI**, **AZURE OpenAI**, **Claude Desktop**, **Gemini**, **IBM watsonx**, and **Ollama** with DevOps Loop. Configuring any one of these providers activates Loop Genie for your environment. Only one provider can be active at a time.

Loop Genie relies on external AI providers to power natural language understanding, multi-agent orchestration, and conversational task execution. By configuring an AI provider, you enable Loop Genie to process prompts, retrieve and summarize data, and perform supported actions across your DevOps Loop environment.

Loop Genie becomes available once at least one AI provider is configured and active. Switching providers immediately changes which LLM Loop Genie uses for processing prompts. All provider configurations remain saved even when disabled.

With at least one AI provider configured, Loop Genie can:

- Interpret natural language prompts
- Execute multi-step, multi-capability queries
- Retrieve data such as issues, repositories, branches, and commit history
- Perform supported automation tasks (For example: create work items, create branches, list repositories, edit files, manage pull requests)
- Produce structured, readable output
- Provide context-aware responses within a conversational thread.

You can manage integrations that are configured in HCL DevOps Loop by editing, deleting, enabling, or disabling them as required.

You can use the following options on the **Integrations** page:

Actions	Description
Search for an integration	You can search for an integration that is added by entering the name in the **Search plugin** field when the list of integrations is lengthy.
Enable or disable a provider	You can enable or disable an AI provider by clicking the toggle button in the **Provider** column. At any point in time, only one provider can be enabled. Other providers in the list are disabled automatically.
Edit an integration	You can modify the integration details by clicking in the **Actions** column.
View an integration	You can view the integration details by clicking in the **Actions** column.
Delete an integration	You can delete an integration when it is no longer required by clicking in the **Actions** column.

Prerequisites for setting up AI providers for Loop Genie

When you want to configure an AI provider such as OpenAI, IBM watsonx, Gemini, Claude or Ollama with HCL DevOps Loop, ensure that the prerequisites are met.

Requirements for OpenAI integration

Ensure the following steps are completed before integrating OpenAI with DevOps Loop:

1. **Create an OpenAI account**: Sign up on OpenAI's platform and obtain API access.
2. **Generate an API key**: Navigate to the OpenAI dashboard and create a secret API key for authentication.
3. **Install OpenAI library**: Use Python or another programming language to install the OpenAI package.

Requirements for AZURE OpenAI integration

Ensure the following steps are completed before integrating AZURE OpenAI with DevOps Loop:

1. **Create a Model Deployment**
    a. **Sign In:** Log into the Azure Portal.
    b. **Open Resource:** Click on your Azure OpenAI resource from your dashboard.
    c. **Launch Studio:** Select **Go to Azure AI Foundry portal** (or Azure OpenAI Studio).
    d. **Go to Deployments:** Click **Deployments** in the left navigation menu.
    e. **Start Deployment:** Select **+ Deploy model**, then click **Deploy base model**.
    f. **Choose Model:** Select your preferred model (for example, **gpt-4o**) and click **Confirm**.
    g. **Name & Save:** Type a **Deployment name**, click **Deploy**, and save the name for your setup.

Requirements for Claude Desktop integration

Ensure the following steps are completed before integrating Claude Desktop with DevOps Loop:

1. **Create an Claude account**: Sign up on Claude's platform and obtain API access.
2. **Generate an API key**: Navigate to the Claude dashboard and create a secret API key for authentication.
3. **Install Claude library**: Use Python or another programming language to install the Claude Desktop AI package.

Requirements for Gemini integration

Ensure the following steps are completed before integrating Gemini with DevOps Loop:

1. **Create an Gemini account**: Sign up on Gemini's platform and obtain API access.
2. **Generate an API key**: Navigate to the Gemini dashboard and create a secret API key for authentication.
3. **Install Gemini library**: Use Python or another programming language to install the Gemini package.

Requirements for IBM watsonx integration

Ensure that you have the following details:

1. API Key
2. Project ID
3. Endpoint URL

Requirements for Ollama integration

Ensure the following steps are completed before integrating Ollama with DevOps Loop:

1. **Install Ollama**: Download the installer and install it.

   You must have read and understood the system requirements for each model of Ollama. for more information, refer to https://ollama.com.

2. **Download a model**: Download the required large language model (LLM) such as Llama 2 or Mistral.
3. **Set up Python environment**: Create and activate a virtual environment and install dependencies.

   Note:

   If you are using the Ollama instance that is bundled with DevOps Loop, you must follow these steps:

   a. Enable the instance in the Helm chart by setting the value to `true` in the `values.yaml` file:

   ```
   llama:
       enabled: true
   ```

   b. Specify the required large language model (LLM) name in the Helm chart by providing the values in the `values.yaml` file:

   ```
   llama:
       ollama:
   ```

```
models:
pull:
    - <model name>
    - <model name>
run:
    - <model name>
    - <model name>
```

Where, the pull command is used to download a model, and the run command is used to run the model.

Configuring OpenAI integration

You can configure the OpenAI integration in HCL DevOps Loop to connect to the provider and use Loop Genie services.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Completed the steps to prepare your OpenAI account for integration with DevOps Loop. See Requirements for OpenAI integration on page 95.

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click **Add Integration**.
   The **Add Integration** pane is displayed with the **Overview** tab.
3. Enter a name to identify the integration in **Name**.
4. Select **Open AI** from the **Provider** list.
5. Select one of the following options in the **Credential Type** list:
   - API Key: Go to step 6 on page 97.
   - Password: Go to step 7 on page 97.
6. Enter the API key of the AI provider account to authenticate the connection in **API Key**.
7. Enter the details in the following fields:
   - Username
   - Password
   - Confirm Password
8. Click **Next**.
   The **Configure** tab is displayed.
9. Perform the following steps in the Configure tab to set the parameters:
   a. Enter the **API Endpoint** URL used by your OpenAI account.
   b. Select **Chat** in **Mode** to set the mode of communication.
   c. Select an LLM to be used from the **Model** list.
   d. Enter the **Organization ID** configured in your OpenAI account for your organization.
   e. Enter the **Project ID** configured in your OpenAI account for your organization.

f. Enter one or more **Stop Sequences** to define where the model should stop generating text. For example: `"stop"` or `"end"`.
g. Use the **Temperature** slider to control the creativity of the response:
    - Lower values produce more precise, consistent answers.
    - Higher values produce more creative or varied output.
h. Set the **Max Length** slider to define the maximum number of tokens the model can generate.
i. Use the **Top P** slider to adjust the diversity of the output:
    - Lower values focus on the most likely words.
    - Higher values allow more varied responses.
j. Set the **Frequency Penalty** slider to reduce repetition of words or phrases.
    - Higher values result in less repetitive output.
k. Set the **Presence Penalty** slider to encourage the model to introduce new topics rather than repeating previous ones.
l. Set the **Best Of** slider to choose how many internal responses the model generates before returning the best one.

10. Click **Save** to apply the configuration.

Results

You have configured the OpenAI integration with DevOps Loop.

Configuring AZURE OpenAI integration

You can configure the AZURE OpenAI integration in HCL DevOps Loop to connect to the provider and use Loop Genie services.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Created an Azure OpenAI account.
- Created and deployed the required Azure OpenAI model deployment. See Requirements for AZURE OpenAI integration on page 95.
- Ensured that you have the following details:
    - Deployment Name
    - API Endpoint URL
    - API Version

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click the **Add Integration** button.

The **Add Integration** pane is displayed with the **Overview** tab.

3. Enter a name to identify the integration in **Name**.
   For example: AZURE
4. Select **AZURE OpenAI** from the **Provider** list.
5. Select one of the following options in the **Credential Type** list:
   - API Key: Go to step 6 on page 99.
   - Password: Go to step 7 on page 99.
6. Enter the API key of the AI provider account to authenticate the connection in **API Key**.
7. Enter the details in the following fields:
   - Username
   - Password
   - Confirm Password
8. Click **Next**.
   The **Configure** tab is displayed.
9. Perform the following steps in the Configure tab to set the parameters:
   a. Enter the **API Endpoint** URL used by your Azure OpenAI account.

      For example: https://qadevopsplan.openai.azure.com

   b. Select **Chat** in **Mode** to set the mode of communication.
   c. Enter the **Deployment Name**.

      The deployment name is the Azure OpenAI model deployment that you want DevOps Loop to use.

   d. **Optional:** The **Embedding Deployment Name** field is disabled, which is the default setting, and DevOps Loop uses **Keyword (BM25) search**. To enable semantic search, update the frontend ConfigMap to configure the embedding model. After it is enabled, the **Embedding Deployment Name** field is displayed in the integration UI. Enter the deployment name of your Azure OpenAI embedding model in this field.
   a. Enter the **API Version**.
10. Click **Save**.

Results

You have configured the AZURE OpenAI integration with DevOps Loop.

Configuring Claude integration

You can configure the Claude integration in HCL DevOps Loop to enable Loop Genie services by connecting to the Claude Desktop provider.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Completed the steps to prepare your Claude Desktop account for integration with DevOps Loop. See Prerequisites for setting up AI providers for Loop Genie on page 95.

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click **Add Integration**.
   The **Add Integration** pane is displayed with the **Overview** tab.
3. Enter a name to identify the integration in **Name**.
4. Select **Claude** from the **Provider** list.
5. Select one of the following options in the **Credential Type** list:
   - API Key: Go to step 6 on page 100.
   - Password: Go to step 7 on page 100.
6. Enter the API key of your Claude account to authenticate the connection in **API Key** and go to step 8 on page 100.
7. Enter the details in the following fields:
   - Username
   - Password
   - Confirm Password
8. Click **Next**.
   The **Configure** tab is displayed.
9. Perform the following steps in the **Configure** tab to set the parameters:
   a. Enter the **API Endpoint** URL used by your Claude account.
      - URL = https://api.anthropic.com
   b. Select **Chat** in **Mode** to set the mode of communication.
   c. Select an LLM to be used from the **Model** list.
   d. Enter the **Organization ID** configured in your Claude account for your organization.
   e. Enter the **Project ID** configured in your Claude account for your organization.
   f. Enter one or more **Stop Sequences** to define where the model should stop generating text.

      For example: `"stop"` or `"end"`.

   g. Use the **Temperature** slider to control the creativity of the response:

      - Lower values produce more precise, consistent answers.
      - Higher values produce more creative or varied output.

   h. Set the **Max Length** slider to define the maximum number of tokens the model can generate.
   i. Use the **Top P** slider to control the diversity of the generated output:

      - Lower values focus on the most likely words.
      - Higher values allow more varied responses.

   j. Set the **Frequency Penalty** slider to reduce repetition of words or phrases.
      - Higher values result in less repetitive output.

k. Set the **Presence Penalty** slider to encourage the model to introduce new topics rather than repeating previous ones.
l. Set the **Best Of** slider to choose how many internal responses the model generates before returning the best one.

10. Click **Save** to apply the configuration.

Results

You have configured the Claude with DevOps Loop.

Configuring Gemini integration

You can configure Gemini integration in HCL DevOps Loop to connect to the provider and use Loop Genie services.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Completed the steps to prepare your Gemini account for integration with DevOps Loop. See Requirements for Gemini integration on page 96.

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click **Add Integration**.
   The **Add Integration** pane is displayed with the **Overview** tab.
3. Enter a name to identify the integration in **Name**.
4. Select **Gemini** from the **Provider** list.
5. Select one of the following options in the **Credential Type** list:
   - API Key: Go to step 6 on page 101.
   - Password: Go to step 7 on page 101.
6. Enter the API key of your Gemini account to authenticate the connection in **API Key** and go to step 8 on page 101.
   - Name = `Google_API_Key`
   - Value = `AIzaSyDySjxBpUlHqUhdIvh6VnXbxOYBJ5wout4`
7. Enter the details in the following fields:
   - Username
   - Password
   - Confirm Password
8. Click **Next**.
   The **Configure** tab is displayed.
9. Perform the following steps in the **Configure** tab to set the parameters:
   a. Enter the **API Endpoint** URL used by your Gemini account.
      - URL = https://generativelanguage.googleapis.com
   b. Select **Chat** in **Mode** to set the mode of communication.
   c. Select an LLM to be used from the **Model** list.

d. Enter the **Organization ID** configured in your Gemini account for your organization.
e. Enter the **Project ID** configured in your Gemini account for your organization.
f. Enter one or more **Stop Sequences** to define where the model should stop generating text. For example: `"stop"` or `"end"`.
g. Use the **Temperature** slider to control the creativity of the response:
    - Lower values produce more precise, consistent answers.
    - Higher values produce more creative or varied output.
h. Set the **Max Length** slider to define the maximum number of tokens the model can generate.
i. Use the **Top P** slider to adjust the diversity of the output:
    - Lower values focus on the most likely words.
    - Higher values allow more varied responses.
j. Set the **Frequency Penalty** slider to reduce repetition of words or phrases.
    - Higher values result in less repetitive output.
k. Set the **Presence Penalty** slider to encourage the model to introduce new topics rather than repeating previous ones.
l. Set the **Best Of** slider to choose how many internal responses the model generates before returning the best one.

10. Click **Save** to apply the configuration.

Results

You have configured the Gemini integration with DevOps Loop.

Configuring IBM watsonx integration

You can configure the IBM watsonx integration in HCL DevOps Loop to connect to the provider and use Loop Genie services.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Ensured that you have details such as API Key, Project ID, and Endpoint URL.

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click **Add Integration**.
   The **Add Integration** pane is displayed with the **Overview** tab.
3. Perform the following steps in the **Overview** tab:
    a. Enter a name to identify the integration in the **Name** field.
    b. Select **Watson X** in the **Provider** list.

c. Select the API key in the **Credentials** list.

d. Enter the API Key in the **API Key** field.

e. Click **Next**.

The **Configure** tab is displayed.

4. Perform the following steps in the **Configure** tab:

a. Enter the API Endpoint URL in the **API Endpoint** field.

b. Enter the release version of the IBM watsonx.ai model in the **Version** field to specify the model to which DevOps Loop should connect.

c. Select a **Model** from the list.

d. Enter the project ID in the **Project ID** field.

e. Enter the string to be used to stop the generation of text by AI in the **Stop Sequences** field.

For example, you can set "stop" or "end" as the stop sequence.

f. Select a **Decoding** method from the list to control how the model generates output.
The following options are available:
- **Greedy:** Produces the most likely next token at each step for straightforward output.
- **Sample:** Randomly selects from probable next tokens, resulting in more varied and creative responses.

g. Use the **Repetition Penalty** slider to control how much the model discourages repeating the same tokens in its output:
For example: A higher value, for example, 1.5, makes more different responses. A lower value, for example, 1.0, allows natural repetition of words.

h. Specify the minimum number of tokens in the **Min Token** for the response.

i. Specify the maximum number of tokens in the **Max Token** for the response.

j. Click **Save**.

Results

You have configured the IBM watsonx integration with DevOps Loop.

Configuring Ollama integration

You can configure the Ollama integration in HCL DevOps Loop to connect to the provider and use Loop Genie services.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Completed the steps to prepare your Ollama account for integration with DevOps Loop. See Requirements for Ollama integration on page 96.

1. Click **Settings > Installed Integrations**.
   The **Installed Integrations** page is displayed.
2. Click **Add Integration**.
   The **Add Integration** pane is displayed with the **Overview** tab.
3. Enter a name to identify the integration in **Name**.
4. Select **Ollama** from the **Provider** list.
5. Click **Next**.
   The **Configure** tab is displayed.
6. Enter the URL of the AI provider in the **API Endpoint** field.
7. Select **Chat** in **Mode** to set the mode of communication.
8. Select an LLM to be used from the **Model** list.
9. Click **Save**.

Results

You have configured Ollama integration with DevOps Loop.

Harbor integration overview

Harbor is an integrated capability in DevOps Loop that provides an OCI-compliant container registry, vulnerability scanning, image signing, and image management capabilities.

DevOps Loop and Harbor are installed together in one installation process. You must set the `HARBOR_ENABLED=true` parameter when installing DevOps Loop.

Harbor capabilities

Harbor provides the following capabilities when it is integrated with DevOps Loop:

- Container image storage and distribution
- Role-based access control
- Vulnerability scanning through Trivy
- OpenID Connect (OIDC) authentication through Keycloak
- Image replication and lifecycle management
- Image bootstrapping support

Architecture

Harbor uses the following services and infrastructure components when it is integrated with DevOps Loop:

- Keycloak for authentication and supplies group claims
- PostgreSQL for metadata storage
- Valkey for caching
- S3-compatible object storage for image artifacts
- Kubernetes persistent storage for Harbor services

Authentication

Harbor uses the same Keycloak realm and single sign-on session as DevOps Loop. You can authenticate through the configured identity provider and can access Harbor without maintaining separate credentials.

Prerequisites for Harbor integration

You must ensure that the required Kubernetes platform components, storage configuration, object storage, DNS, TLS, and dependency secrets are available before you install DevOps Loop with Harbor integration.

Kubernetes platform components

The Kubernetes cluster must be accessible and configured with the required tooling for deployment. You must ensure that your Kubernetes environment includes the required platform components.

Before deploying DevOps Loop, ensure that your Kubernetes environment meets the following prerequisites:

- Helm and kubectl access are configured.
- Emissary ingress controller is installed and available.
- Image pull secrets are configured for the required container images.
- A dedicated namespace for DevOps Loop deployment is available.
- If you are deploying DevOps Loop on **OpenShift**, ensure that a cluster administrator is available to configure the required Harbor **Security Context Constraints (SCC)** before Harbor is enabled.

These components support application deployment, ingress routing, and container image access during installation.

DNS configuration for Harbor

You must create a DNS entry for the Harbor endpoint in your DNS provider.

Example values:

- Name: `harbor.<DOMAIN>`
- Type: A or CNAME
- Value: <IP_ADDRESS or LOAD_BALANCER_ENDPOINT>

Ensure that the DNS record is resolvable from the cluster environment and external clients. This configuration is required for Harbor access and OIDC authentication flows.

TLS configuration for Harbor

You must ensure that a valid TLS certificate is available for secure access to Harbor.

The certificate must include the Harbor hostname, for example, `harbor.<DOMAIN>`.

You can use a wildcard certificate, such as `*.example.com` or a SAN certificate that covers both DevOps Loop and Harbor endpoints.

TLS configuration must be compatible with the existing DevOps Loop Ingress setup.

Storage configuration for Harbor

You must ensure that the following storage classes are available in the Kubernetes cluster:

- A `ReadWriteOnce` (RWO) storage class for standard persistence.
- A `ReadWriteMany` (RWX) storage class for Trivy vulnerability scanning.

You must verify the available storage classes by running the following command:

```
kubectl get storageclass
```

The RWX storage class must support shared access across multiple pods and be compatible with Trivy scanning requirements.

Object storage configuration for Harbor

You must ensure that an S3-compatible object storage system is available. Supported storage providers are as follows:

- AWS S3
- IBM Cloud Object Storage
- Google Cloud Storage (HMAC-enabled)
- MinIO
- Other S3-compatible storage systems

You must ensure that the following configuration values are available:

- Bucket name
- Region
- Endpoint URL
- Access key
- Secret key

These values are required for configuring Harbor registry storage.

Note: If you use Google Cloud Storage as the object storage backend, you must configure HMAC keys because Harbor requires S3-compatible authentication. You must also run the `gcloud storage buckets update ... --no-uniform-bucket-level-access` command to disable Uniform Bucket-Level Access.

Harbor dependency secrets

The following secrets are required during Harbor installation:

- `devops-loop-valkey`
- `devops-loop-postgresql`

These secrets are automatically created during the DevOps Loop installation.

The Harbor installation validates the availability of these secrets before it proceeds.

You have prepared all the required prerequisites for installing DevOps Loop with Harbor integration.

You can now proceed with installing DevOps Loop with Harbor integrated. See Installing DevOps Loop with Harbor integration on page 107.

Installing DevOps Loop with Harbor integration

You can configure Harbor as an integrated capability during DevOps Loop installation to provide container image storage, vulnerability scanning, and image management capabilities.

Before you begin

You must have completed the prerequisites tasks. See Prerequisites for Harbor integration on page 105.

1. Create the object storage secret.

   ```
   kubectl create secret generic harbor-s3-secret \
     -n devops-loop \
     --from-literal=accesskey='<ACCESS_KEY>' \
     --from-literal=secretkey='<SECRET_KEY>'
   ```

   Verify that the secret is created:

   ```
   kubectl get secret harbor-s3-secret -n devops-loop
   ```

2. **Optional:** Configure MinIO if you use MinIO as the object storage provider.
   - Install MinIO.
   - Create a bucket, for example, `loopharbor`.
   - Ensure that the bucket is accessible.

   If you deploy DevOps Loop in an air-gapped environment, ensure that the required container images are available in your internal registry before you install Harbor. After the installation is complete, you can bootstrap commonly used images into Harbor by using the bootstrap script.

3. Set the following parameter to configure Harbor with DevOps Loop:

Enable or disable Harbor:

```
HARBOR_ENABLED=true
HARBOR_S3_BUCKET=<BUCKET_NAME>
HARBOR_S3_REGION=<REGION>
HARBOR_S3_ENDPOINT=<S3_ENDPOINT>
HARBOR_TRIVY_STORAGE_CLASS=<RWX_STORAGE_CLASS>
```

Optional parameter:

```
HARBOR_OIDC_ADMIN_GROUP=<group-name>
```

Default admin group: `harbor-admins`.

Note: You can customise the Harbor admin group name in the optional parameter in case, the group name is not provided during the installation, the group will be created with the default name harbor-admins. Users who require Harbor system administrator access must be members of that Keycloak group.

4. **Optional**: Perform the following steps to configure the Harbor Security Context Constraints (SCC) if you are installing DevOps Loop on OpenShift:
   a. Apply the Harbor SCC that is provided with the installation.

   ```
   scripts/harbor/openshift/harbor-scc.yaml
   ```

   b. Run the helper script to apply the SCC and bind it to the Harbor service account:

   ```
   scripts/harbor/openshift/apply-harbor-scc.sh \
     --namespace devops-loop \
     --service-account harbor \
     --scc-name harbor-uid-10000-devops-loop
   ```

   The Harbor SCC is not installed automatically by Helm because it is stored under `scripts/harbor/openshift/` rather than the Helm `templates/ directory`. Before Harbor is enabled, the installer verifies that the SCC exists and is correctly bound to the Harbor service account.

   Note: If `https://harbor.<DOMAIN>` is not resolvable in your OpenShift environment, set `HARBOR_EXTERNAL_URL` to a DNS-resolvable OpenShift router wildcard URL.

5. Run the installation script in the Helm README for installing DevOps Loop.
   For example: `bash <Install-script>.sh`

   The installer performs the following tasks:

   - Deploys DevOps Loop.
   - Validates prerequisites.
   - Validates secrets.
   - Installs Harbor when enabled.
   - Configures OIDC.
   - Configures ingress and HTTPS.

Note: When `HARBOR_ENABLED=true`, the installer uses a two-phase Helm installation process. The Helm release history can show an initial revision with an Install status and a later revision with an Upgrade status. This behavior is expected.

6. Run the following command to verify that the Harbor pods are running:

   ```
   kubectl get pods -n devops-loop | grep harbor
   ```

   The output must include the following Harbor pods:

   - `harbor-core`
   - `harbor-jobservice`
   - `harbor-nginx`
   - `harbor-portal`
   - `harbor-registry`
   - `harbor-trivy`

Results

You have installed DevOps Loop with Harbor enabled.

What to do next

You can perform the following tasks:

- Access Harbor from the DevOps Loop. See Accessing Harbor from DevOps Loop on page 109.
- Import images into Harbor. See Importing and validating images in Harbor registry on page 110.

Accessing Harbor from DevOps Loop

You can access Harbor from the DevOps Loop when it is configured with DevOps Loop installation.

Before you begin

You must have completed the following tasks:

- Installed Harbor and ensured it is running in the `devops-loop` namespace.
- Esnured that you are signed in to DevOps Loop.

1. Select the application launcher icon .
   The application launcher displays the DevOps Loop capabilities.
2. Select **Harbor**.
   The Harbor login page opens in a new tab.
3. Select **LOGIN VIA OIDC PROVIDER**.
4. Authenticate by using your Keycloak credentials.

Harbor uses the same Keycloak realm and single sign-on session as DevOps Loop.

Note: Logging out of Harbor clears the Harbor application session. It does not log the user out of DevOps Loop. If the DevOps Loop or Keycloak SSO session is still active, clicking Login with Keycloak in Harbor again may automatically log in the same user without asking for credentials.

To force a credential prompt, the user must also log out fromDevOps Loop or Keycloak, clear browser cookies, use an incognito/private browser session, or use a separate browser profile

Results

You can access Harbor from the application launcher and sign in through OIDC.

Managing Users

Assign users to a project

Importing and validating images in Harbor registry

You can import images into Harbor to preload repositories with commonly used container images.

Before you begin

You must have completed the following tasks:

- Installed Harbor and ensured it is accessible. See Accessing Harbor from DevOps Loop on page 109.
- Installed skopeo on the system where you run the bootstrap script.

1. Update the bootstrap image list.

   Edit the `scripts/harbor/bootstrap-images.txt` file in the following format:

   ```
   source_image target_project target_repository target_tag
   ```

   For example:

   ```
   docker://docker.io/library/nginx:latest devops nginx bootstrap
   docker://docker.io/library/alpine:latest devops alpine bootstrap
    docker://docker.io/library/busybox:latest devops busybox bootstrap
   ```

2. Run the bootstrap script.

   ```
   DOMAIN=<DOMAIN> \
   NAMESPACE=devops-loop \
   RELEASE=devops-loop \
   scripts/harbor/bootstrap-images.sh
   ```

3. Verify that the imported images are available in Harbor.
4. Validate image push and pull operations:

```
docker login harbor.<DOMAIN>
docker tag nginx:latest harbor.<DOMAIN>/devops/nginx:test
docker push harbor.<DOMAIN>/devops/nginx:test
docker pull harbor.<DOMAIN>/devops/nginx:test
```

5. Perform the following steps to verify vulnerability scanning:
    a. Open Harbor.
    b. Navigate to the project that contains the uploaded image.
    c. Enable **Automatically scan images on push** for the project if it is not already enabled.
    d. Push a container image to the project.
    e. Verify that Harbor displays the vulnerability scan results for the image.

   Harbor scans the image by using Trivy and displays the detected vulnerabilities.

Results

You have imported the specified images into Harbor and they are available for use.

DevOps Loop MCP server

The DevOps Loop Model Context Protocol (MCP) server provides a standardized interface so that external MCP clients can interact with DevOps Loop and perform supported operations.

The MCP-compatible clients, such as Visual Studio Code (through MCP extensions) and Claude Desktop, can use this interface to query, retrieve, and modify loop resources directly from their development or AI-assisted environments.

By using the MCP server, you can access DevOps Loop capabilities without switching between interfaces. It enforces secure and controlled access by honoring the permissions defined in DevOps Loop.

The server maintains session security through a 30-minute idle timeout. If no activity occurs during this period, the session expires and requires reauthentication. After initial configuration, MCP client settings are stored persistently. MCP clients then reconnect automatically in subsequent sessions.

The MCP server offers a set of domain-specific tools that allow external clients to perform the following operations:

- Managing loops
- Accessing tenant and teamspace information
- Querying analytics data
- Performing deployment and build operations
- Managing repositories and pull requests
- Interacting with planning and test resources

Each tool defines its required inputs and expected outputs, ensuring consistent and predictable interactions.

Related information

Getting started with the DevOps Loop MCP server on page 112

Getting started with the DevOps Loop MCP server

Use the Loop MCP endpoint to fetch and manage loop platform entities, including loops, teamspaces, users, and loop analytics.

Each DevOps Loop capability, which includes Loop platform, Plan, Measure, Control, Deploy, Build, and Test exposes a dedicated MCP endpoint. You must configure your MCP client with the appropriate endpoint URL based on the capability that you want to access.

After you configure the endpoint, the MCP client establishes a session with the DevOps Loop MCP server and makes the available tools accessible within the client interface.

DevOps Loop MCP endpoint

You can use the following endpoint to connect to the DevOps Loop MCP server:

```
https://<loop_hostname>/loop/mcp
```

MCP tools available in DevOps Loop

After an MCP client is connected to DevOps Loop, it can access a set of tools offered by DevOps Loop. These tools provide controlled access to loop resources across the loop server, tenant server, and analytics services. Each tool specifies its required inputs and expected output.

Use these tools when you need loop and teamspace administration, user membership, or cross-domain analytics queries. Do not use these tools for Plan work item lifecycle updates, repository pull request actions, build execution control, deployment execution, or test execution.

Parameter conventions:

- `teamspace_id` and `loop_id` must be valid UUID values.
- `user` must be a valid email address.
- For analytics date filters, use `YYYY-MM-DD`.
- For filtered searches, pass only supported filter keys for the target entity.

Table 1. Loop-related tools

MCP Tools	Description	Input	Output
loop_get_all_loops	Fetch all loops in a teamspace.	teamspace_id	List of loops that you are a member of.
loop_get_all_loop_users	Fetch all users in a loop.	loop_id, teamspace_id	List of users who are part of the loop.

Table 1. Loop-related tools (continued)

MCP Tools	Description	Input	Output
loop_add_user_to_loop	Add a user to a loop.	loop_id, teamspace_id, user (email)	Confirmation that the user was added to the loop.
loop_add_test_project_to_loop	Add a test project to a loop.	teamspace_id, loop_id, project_name, project_description	Details of the test project created in the loop.
loop_add_control_repo_to_loop	Add a control repository to a loop.	teamspace_id, loop_id, repo_name	Details of the control repository added to the loop.

Table 2. Loop tenant-related tools

Tools	Description	Input	Output
loop_get_all_tenants	Fetch all tenants.	None	List of all tenants
loop_get_all_teamspace_users	Fetch all users in a teamspace.	teamspace_id	List of users in the teamspace
loop_get_all_teamspaces	Fetch all teamspaces.	None	List of all teamspaces
loop_invite_user_to_teamspace	Invite a user to a teamspace.	teamspace_id, user (email)	Confirmation that the user was invited to the teamspace

Table 3. Loop analytics-related tools

Command	Description	Input	Output
analytics_search_work_items	Searches work items by using filters.	teamspace_id, loop_id, optional filters	List of work items matching the filters.
analytics_get_work_item_status	Retrieves status for work items.	teamspace_id, loop_id, filters	List of work item statuses.
analytics_count_work_items	Counts work items by using filters.	teamspace_id, loop_id, filters	Count of work items matching the filters.
analytics_get_story_points	Retrieves story point analytics.	teamspace_id, loop_id, owner, date filters	Story point analytics data.
analytics_get_recent_and_old_work_items	Retrieves recent and oldest work items.	teamspace_id, loop_id, optional filters	List of work items ordered by time.

Table 3. Loop analytics-related tools (continued)

Command	Description	Input	Output
analytics_search_commits	Search commits by creator, date, repo, etc.	teamspace_id, loop_id, filters	List of commits matching the filters.
analytics_search_pull_requests	Attribute-based PR search.	teamspace_id, loop_id, filters	List of pull requests matching the filters.
analytics_count_pull_requests	Count PRs by creator, repo, status, or month.	teamspace_id, loop_id, filters	Count of pull requests matching the filters.
analytics_get_recent_and_old_pull_requests	Retrieves time-ordered pull requests.	teamspace_id, loop_id, filters	List of pull requests ordered by time.
analytics_search_builds	Searches builds by using filters.	teamspace_id, loop_id, filters	List of builds matching the filters.
analytics_count_builds	Counts builds by creator, status, or month.	teamspace_id, loop_id, filters	Count of builds matching the filters.
analytics_get_recent_and_old_builds	Retrieves recent and oldest builds.	teamspace_id, loop_id, filters	List of builds ordered by time.
analytics_search_deployments	Search deployments with filters.	teamspace_id, loop_id, filters	List of deployments matching the filters.
analytics_count_deployments	Counts deployments by status, creator, or month.	teamspace_id, loop_id, filters	Count of deployments matching the filters.
analytics_get_recent_and_old_deployments	Retrieves recent and oldest deployments.	teamspace_id, loop_id, filters	List of deployments ordered by time.
analytics_field_values	Retrieves available values for discoverable fields of an analytics entity before applying filters.	entity, teamspace_id, loop_id, optional fields	Lists of available field values, unsupported fields, and fields containing blank values.

Plan MCP endpoint and tools

Use Plan MCP tools to create, read, update, and organize Agile planning data, including work items, projects, releases, sprints, approvals, and metadata.

Plan MCP endpoint

You can use the following endpoint to connect to the Plan MCP server:

```
https://<loop_hostname>/plan/mcp
```

MCP tools available in Plan

Use these tools when you need planning operations, such as managing work items, assigning ownership, linking hierarchy, setting sprint or release values, or listing projects, releases, and sprints. Do not use these tools for repository or pull request actions, build execution, deployment execution, test execution, or value stream analytics reporting.

Parameter conventions:

- `applicationName` must match an accessible Plan application exactly.
- `teamspaceId` is required for scoped operations and must be a valid UUID.
- Resolve `teamspaceId` by using `plan_getDevopsPlanApplications` when missing.
- Use `YYYY-MM-DD` for date values such as startDate and endDate.
- Use positive integers for `pageNumber` and `pageSize`.

Tools	Description	Input	Output
plan_deleteWorkitem	Deletes an existing work item from the specified Plan application.	applicationName, workItemId, teamspaceId	Confirmation that the work item was successfully deleted.
plan_fetchWorkitem	Retrieves detailed information for a specific work item by its ID.	workItemId, teamspaceId, applicationName	A record containing all available details for the specified work item.
plan_getAgileApprovals	Retrieves a list of existing Agile approval records from a Plan application.	applicationName, teamspaceId	A list of approval records.
plan_getAgileReleases	Retrieves a list of existing Agile Releases from a Plan application.	applicationName, teamspaceId	A list of Agile releases.
plan_getAgileSprints	Retrieves a list of existing Agile Sprints from a Plan application.	applicationName, teamspaceId	A list of Agile sprints.

plan_getAgileWorkitems	Retrieves Agile work items, supporting sprint and release filtering.	applicationName, teamspaceId, optional filters	A list of Agile work items matching the filters.
plan_getAvailableAgileWorkItemTypes	Retrieves a list of existing Agile work item types for a specific project.	applicationName, teamspaceId, project	A list of Agile work item types.
plan_getDevopsPlanApplications	Retrieves all DevOps Plan applications available to the current user.	None	A list of accessible Plan applications, including name and teamspaceId.
plan_getProjectsInAgileApplication	Retrieves all projects from a specified Plan application.	applicationName, teamspaceId	Project details, including ID, name, and description.
plan_getWorkItemMetaData	Retrieves read-only Work Item Metadata (schema and field definitions).	applicationName, teamspaceId	Work Item Metadata schema (field names, types, allowed values, etc.).
plan_getWorkItemStatesAndStateTransitions	Retrieves all available work item state transitions in the specified Plan application.	applicationName, teamspaceId	Detailed transition information (Action name, Destination state, Source states).
plan_addChildToParentWorkitem	Adds/links a child work item to a parent work item.	applicationName, parentWorkItemId, childWorkItemId, teamspaceId	Confirmation of successful linking.
plan_addCommentToWorkitem	Adds a comment to a work item.	applicationName, workItemId, comment, teamspaceId	Confirmation that the comment was added.
plan_addSubscriberToWorkitem	Adds a subscriber to a work item.	applicationName, workItemId, username, teamspaceId	Confirmation that the user was added as a subscriber.
plan_assignOwnerToWorkitem	Assigns or reassigns an owner to a work item.	applicationName, workItemId, owner, teamspaceId	Confirmation that the owner was successfully assigned.

plan_changeResolutionOfWorkitem	Changes the Resolution field of a work item.	applicationName, workItemId, resolution, teamspaceId	Confirmation that the resolution was changed.
plan_changeStateOfWorkitem	Changes or sets the State field of a work item.	applicationName, workItemId, state, teamspaceId	Confirmation that the state was changed.
plan_createAgileWorkitem	Creates a new Agile work item.	applicationName, title, type, project, teamspaceId	Details of the newly created work item.
plan_modifyAgileWorkitem	Modifies an existing Agile work item.	applicationName, workItemId, teamspaceId	Confirmation that the work item was successfully modified.
plan_removeSubscriberFromWorkitem	Removes a subscriber from a work item.	applicationName, workItemId, username, teamspaceId	Confirmation that the user was removed as a subscriber.
plan_setPlannedReleaseOfWorkitem	Sets the PlannedRelease field of a work item.	applicationName, workItemId, plannedRelease, teamspaceId	Confirmation that the planned release was set.
plan_setSprintForWorkitem	Sets the Sprint field of a work item.	applicationName, workItemId, sprint, teamspaceId	Confirmation that the sprint was set.
plan_setStoryPointsForWorkitem	Sets the StoryPoints field of a work item.	applicationName, workItemId, storyPoints, teamspaceId	Confirmation that the story points were set.
plan_setWorkitemStartAndEndDates	Sets both StartDate and EndDate fields of a work item.	applicationName, workItemId, startDate, endDate, teamspaceId	Confirmation that the start and end dates were set.
plan_addComponentToProject	Adds or links a component to an existing Agile project.	applicationName, teamspaceId, project, component	Confirmation that the component was added to the project.

plan_addReleaseToProject	Adds, links, or associates an existing release to an existing Agile project.	applicationName, teamspaceId, project, releaseName	Confirmation that the release was associated with the project.
plan_addSprintToProject	Adds, links, or associates an existing sprint to an existing Agile project.	applicationName, teamspaceId, project, sprintName	Confirmation that the sprint was associated with the project.
plan_addSprintToRelease	Adds, links, or associates an existing sprint to an existing Agile Release.	applicationName, teamspaceId, releaseIdentifier, sprintName	Confirmation that the sprint was associated with the release.
plan_addWorkItemTypeToProject	Adds or links a work item type to an existing Agile project.	applicationName, teamspaceId, project, workItemType	Confirmation that the work item type was added to the project.
plan_createAgileProject	Creates a new Agile project in the specified Plan application.	applicationName, teamspaceId, projectName	Details of the newly created project.
plan_createAgileRelease	Creates a new Agile Release in the specified Plan application.	applicationName, teamspaceId, releaseName	Details of the newly created release.
plan_createAgileSprint	Creates a new Agile Sprint in the specified Plan application.	applicationName, teamspaceId, sprintName	Details of the newly created sprint.
plan_modifyAgileRelease	Renames and/or updates an existing Agile Release.	applicationName, teamspaceId, releaseIdentifier	Confirmation that the release was successfully modified.
plan_modifyAgileSprint	Renames an existing Agile Sprint and/or updates its start and end dates within the specified Plan application.	applicationName, teamspaceId, sprintIdentifier	Confirmation that the sprint was successfully modified.
plan_removeComponentFromProject	Removes or unlinks or dissociates an existing Component from an existing	applicationName, teamspaceId, project, component	Confirmation that the component was

	Agile project within the specified Plan application.		removed from the project.
plan_removeReleaseFromProject	Removes or unlinks or dissociates an existing Release from an existing Agile project within the specified Plan application.	applicationName, teamspaceId, project, releaseName	Confirmation that the release was removed from the project.
plan_removeSprintFromProject	Removes or unlinks or dissociates an existing Sprint from an existing Agile project within the specified Plan application.	applicationName, teamspaceId, project, sprintName	Confirmation that the sprint was removed from the project.
plan_removeSprintFromRelease	Removes or unlinks an existing Sprint from an existing Agile Release within the specified Plan application.	applicationName, teamspaceId, releaseIdentifier, sprintName	Confirmation that the sprint was removed from the release.
plan_removeWorkItemTypeFromProject	Removes or unlinks or dissociates an existing work item type from an existing Agile project within the specified Plan application.	applicationName, teamspaceId, project, workItemType	Confirmation that the work item type was removed from the project.

Control MCP endpoint and tools

Use Control MCP tools to manage source control resources and collaboration workflows, including repositories, branches, files, commits, and pull requests.

MCP endpoints

You can use the following endpoint to connect to the Control MCP server:

```
https://<loop_hostname>/control/mcp
```

MCP tools available in Control

Use these tools when you need repository content updates, branch management, pull request operations, or repository search and discovery. Do not use these tools for planning entities, build execution, deployment execution, test execution, or value stream analytics reporting.

Parameter conventions:

- `owner` and `repo` are required for repository-scoped operations.
- `index` is the pull request number and must be a positive integer.
- `filePath` must be a repository-relative path.
- `sha` is required for safe file updates.
- Use positive integers for pagination fields such as `page`, `pageSize`, or `page_size`.

Tools	Description	Input	Output
control_approve_pull_request	Approves a pull request.	owner, repo, index	Confirmation that the pull request was approved.
control_assign_pull_request	Assigns a pull request to a user.	owner, repo, index, assignee(control username)	Confirmation that the pull request was assigned to the user.
control_create_branch	Creates a branch.	owner, repo, branch, old_branch	Confirmation that the branch was successfully created.
control_create_file	Creates a file.	owner, repo, filePath, content, message, branch_name	Confirmation that the file was successfully created and committed.
control_create_pull_request	Creates a pull request.	owner, repo, title, body, head, base	Details of the created pull request.
control_create_repo	Creates a repository in personal account or organization.	name	Details of the created repository.
control_delete_branch	Deletes a branch.	owner, repo, branch	Confirmation that the branch was successfully deleted.
control_delete_file	Deletes a file.	owner, repo, filePath, message, branch_name	Confirmation that the file was successfully deleted.
control_fork_repo	Creates a fork of a repository.	user, repo	Details of the forked repository.
control_get_dir_content	Retrieves a list of entries in a directory.	owner, repo, ref, filePath	List of directory entries (files and directories).

control_get_file_content	Retrieves file content and metadata.	owner, repo, ref, filePath	File content and metadata.
control_get_mcp_server_version	Retrieves the Control MCP server version.	None	Control MCP Server Version.
control_get_pull_request_by_index	Retrieves a pull request by index.	owner, repo, index	Details of the specified pull request.
control_list_branches	Lists branches.	owner, repo	List of branches in the repository.
control_list_my_repos	Lists repositories for the authenticated user.	page, pageSize	List of repositories.
control_list_pull_request_comments	Lists all comments from a pull request (includes general comments and code review comments).	owner, repo, index	List of pull request comments.
control_list_repo_commits	Lists repository commits.	owner, repo, page, page_size	List of repository commits.
control_list_repo_pull_requests	Lists repository pull requests.	owner, repo	List of repository pull requests.
control_merge_pull_request	Merges pull request.	owner, repo, index, merge_title	Confirmation that the pull request was successfully merged.
control_search_org_teams	Searches organization teams.	org, query	List of organization teams.
control_search_repos	Searches repos.	keyword	List of repositories matching the search criteria.
control_search_users	Searches users.	keyword	List of users matching the search criteria.
control_update_file	Updates a file.	owner, repo, filePath, sha, content, message, branch_name	Confirmation that the file was successfully updated and committed.

control_get_my_user_info	Retrieves authenticated user information.	None	User's information.
control_get_user_orgs	Retrieves organizations associated with the authenticated user.	None	List of organizations.
control_get_user_pending_approvals	Lists pending approvals for the authenticated user.	None	List of pending approvals.

Deploy MCP endpoint and tools

Use Deploy MCP tools to execute and monitor application deployments by listing applications, snapshots, environments, and deployment processes.

Deploy MCP endpoint

You can use the following endpoint to connect to the Deploy MCP server:

```
https://<loop_hostname>/deploy/mcp
```

MCP tools available in Deploy

Use these tools when you need to deploy an application snapshot to an environment and monitor deployment status. Do not use these tools for build orchestration, repository pull request actions, planning updates, or test execution.

Parameter conventions:

- `applicationId` scopes application-level listing and deployment operations.
- `applicationProcessId`, `snapshotId`, and `environmentId` are required to start a deployment.
- `requestId` is required to query deployment status.
- Use IDs returned by list operations and treat them as opaque values.

Tools	Description	Input	Output
deploy_snapshot_to_environment	Deploys a snapshot to a target environment.	applicationId, applicationProcessId, snapshotId, environmentId	Confirmation of successful deployment and deployment details.
get_deployment_status	Retrieves the status of a previously requested application deployment.	requestId	The status and results of the requested application deployment.
list_application_environments	Lists the environments for a specific application.	applicationId	List of application environments with names and IDs.

list_application_processes	Lists the deployment processes for a specific application	applicationId	List of deployment processes with names and IDs for the application.
list_application_snapshots	Lists the snapshots for a specific application.	applicationId	List of snapshots for a specific application.
list_applications	Lists applications.	None	List of all available applications.

Build MCP endpoint and tools

Use Build MCP tools to trigger and inspect CI build executions, including projects, workflows, build runs, logs, and retries.

Build MCP endpoint

You can use the following endpoint to connect to the Build MCP server:

```
https://<loop_hostname>/build/mcp
```

MCP tools available in Build

Use these tools when you need to run a build, inspect build details, retrieve build logs, or restart a failed build run. Do not use these tools for deployment execution, test execution, repository pull request actions, or planning data management.

Parameter conventions:

- `project_id` is required for project-scoped build operations.
- `process_id` is required to trigger a process build.
- `build_life_id` is required to fetch run details, logs, or restart a build run.
- Use only IDs returned by Build list endpoints; treat identifiers as opaque values.

Tools	Description	Input	Output
build_list_projects	Lists all projects in DevOps Build.	None	List of projects in DevOps Build.
build_list_workflows	Lists all workflows for a specific project in DevOps Build.	project_id	List of workflows for the specified project.
build_trigger_process_build	Triggers a new build for a specific process in a project using the process trigger API.	project_id, process_id	Request ID for tracking the triggered build.

build_list_build_lives	Lists all build lives for a specific project in DevOps Build.	project_id	List of all build lives for the specified project.
build_get_build_life_info	Retrieves detailed information about a build life in DevOps Build.	build_life_id	Detailed information about the specified build life.
build_get_build_life_logs	Retrieves logs for a specific build life in DevOps Build.	build_life_id	Logs for the specified build life.
build_restart_build_life	Restarts a build run by using the build life ID in DevOps Build.	build_life_id	Confirmation that the build life was successfully restarted.

Test MCP endpoint and tools

Use Test MCP tools to execute tests and retrieve test results in DevOps Test Hub, including project discovery, test listing, test run initiation, and result lookup.

Test MCP endpoint

You can use the following endpoint to connect to the Test MCP server:

```
https://<loop_hostname>/test/mcp
```

MCP tools available in Test

Use these tools when you need to run tests, list tests in a branch, or fetch test outcomes and details. Do not use these tools for build orchestration, deployment execution, repository pull request actions, or planning updates.

Parameter conventions:

- `projectId` is required for all project-scoped operations.
- `branch` must be a valid branch name in the target project.
- `assetId` identifies the test asset to execute.
- `resultId` identifies an execution result for detailed lookup.
- Use IDs from prior list and get responses; do not infer IDs.

Tools	Description	Input	Output
testhub__get_projects	Retrieves a list of projects available in DevOps Test Hub.	None	List of available projects.

testhub__list_tests	Retrieves a list of tests in DevOps Test Hub for a specific project and branch.	projectId, branch	List of tests for the specified project and branch.
testhub__run_test	Runs a test in a specific project.	projectId, assetId, branch	Details of the executed test, including execution ID.
testhub__get_result_by_id	Retrieves the test run result and detailed result data.	projectId, resultId	Test execution result and detailed data.
testhub__get_results	Retrieves test result summaries for multiple executions in DevOps Test Hub.	projectId, branch	Test result summaries for multiple executions.

To configure MCP endpoint in VS Code, See Configuring an MCP server endpoint in VS Code on page 757.

Measure MCP endpoint and tools

Use Measure MCP tools to query value stream and engineering metrics, including workflows, deployments, builds, gate checks, and trend-based reporting.

MCP endpoint

You can use the following endpoint to connect to the Measure MCP server:

```
https://<loop_hostname>/velocity/mcp
```

MCP tools available in Measure

Use these tools when you need analytics, KPI trends, value stream reporting, or workflow health insights. Do not use these tools to modify planning records, execute builds, run deployments, run tests, or manage repository pull requests.

Parameter conventions:

- `tenantId` is required for tenant-scoped queries.
- `workflowId` is required for workflow-scoped metrics and statistics.
- `id` is the application identifier for application-by-ID queries.
- For date filters, use `YYYY-MM-DD` unless the endpoint requires ISO date-time.
- Use positive integers for pagination fields when supported.

Tools	Descriptions	Inputs	Output

Measure_applicationByIdQuery	Fetches application details for a given application ID or all applications for a tenant.	id, tenantId	Application details for the given ID or a list of all applications for the tenant.
Measure_workflowQuery	Retrieves detailed information for a specific Value Stream.	workflowId	Detailed information for the specific Value Stream/Workflow.
Measure_teamspacesForTenantQuery	Fetches teamspace information for a given tenant.	tenantId	List of teamspace information for the given tenant.
Measure_teamsForCurrentUserQuery	Fetches the tenant ID associated with the current user.	None	The tenant ID associated with the current user.
Measure_buildsQuery	Retrieves build metrics to analyze build success rates, commits, pull requests, and deployments against builds.	None	Build metrics and related data (success rates, commits, PRs, deployments).
Measure_workflowsForTenantQuery	Retrieves all workflows (VSM or value streams) and their details associated with a specific tenant.	tenantId	List of all workflows (VSM or value streams) and their associated details for the tenant.
Measure_metricsQuery	Retrieves metrics data based on specified filters and pagination options.	None	Metrics data based on the specified filters.
Measure_deploymentsQuery	Retrieves deployment data with related builds, issues, and pull requests to analyze release frequency.	None	Deployment data, including associated Builds, Issues, and PRs.
Measure_latestWorkflowGateChecksQuery	Retrieves the latest value stream workflow gate checks to verify whether quality gates are passing.	None	The latest workflow gate checks status.

Measure_workflowStatsByIdQuery	Retrieves key statistics for a specific workflow (value stream).	workflowId	Detailed key statistics for the specific workflow (value stream).

DevOps Loop MCP server configuration in VS Code

You can connect **Visual Studio Code** (VS Code) with GitHub Copilot to the DevOps Loop MCP server to run MCP-based queries that retrieve and update loop resources directly from VS Code. After the connection is established, the MCP server configuration is saved and remains available across VS Code sessions.

You can add the DevOps Loop MCP server in VS Code by using one of the following methods:

- By using the command palette. See Adding the DevOps Loop MCP server in VS Code by using the command palette on page 127.
- By editing the MCP configuration file. See Adding the DevOps Loop MCP server in VS Code by editing the MCP configuration file on page 128.

Adding the DevOps Loop MCP server in VS Code by using the command palette

You can use the VS Code command palette to quickly add the DevOps Loop MCP server without manually editing configuration files.

Before you begin

You must have completed the following tasks:

- Ensured that you have installed VS Code and the GitHub Copilot extension.
- You must have a valid MCP server endpoint URL. For example: `https://hostname/loop/mcp`

1. Open **VS Code**.
2. Open the **Command Palette**.
   - Windows/Linux: Ctrl+Shift+P
   - macOS: Cmd+Shift+P
3. Search and select **MCP: Add Server**.
4. Choose **HTTP** as the server type when prompted for the transport type.
   The DevOps Loop MCP server uses HTTP-based transport.
5. Enter the **MCP Server URL** in the **URL** field.
   VS Code automatically generates the required `mcp.json` configuration.
6. Enter a name for the server.

   For example: Loop MCP server.
7. Select the location to save the configuration:
   - **Global** – Makes the MCP server available in all VS Code workspaces.
   - **Workspace** - Makes the MCP server available only in the current workspace.

- **Workspace** – Makes the MCP server available only in the current folder/project.

  Note: Selecting **Workspace** automatically creates a `.vscode` folder and generates a `mcp.json` file inside it.

8. Select **Workspace** to save the configuration for the current workspace.
   VS Code creates a `.vscode` folder and generates an `mcp.json` file if they do not already exist.

Results

You have added the DevOps Loop MCP server to VS Code and is available in the MCP Servers view.

What to do next

After adding the DevOps Loop MCP server, you can view and manage the configured MCP server in VS Code. You can start the MCP server and complete the authentication process before using the MCP tools. See Viewing and managing MCP servers in VS Code on page 129.

Adding the DevOps Loop MCP server in VS Code by editing the MCP configuration file

You can manually configure the DevOps Loop MCP server by editing the `mcp.json` configuration file in your workspace.

Before you begin

You must have completed the following tasks:

- Ensured that you have installed VS Code and the GitHub Copilot extension.
- You must have a valid MCP server endpoint URL. For example: `https://hostname/loop/mcp`

1. Open **VS Code**.
2. Open any project in VS Code.
3. Create a new folder named `.vscode` at the root of the workspace, if not present.
4. Create a file named `mcp.json` inside the `.vscode` folder.
5. Paste the MCP configuration JSON. For example:

```
{
  "servers": {
    "loop-mcp": {
      "url": "https://hostname/loop/mcp",
      "type": "http"
    }
  },
  "inputs": []
}
```

6. Replace the `hostname` with your actual DevOps Loop server hostname.
7. Optional: To connect to a specific DevOps Loop capability, update the URL to the corresponding MCP endpoint.
   Each capability, such as Plan, Measure, Control, Build, Deploy, and Test, provides a dedicated MCP endpoint.
8. Save the `mcp.json` file.

Results

The DevOps Loop MCP server configuration is added to VS Code and is available in the MCP Servers view.

What to do next

After adding the DevOps Loop MCP server, you can view and manage the configured MCP server in VS Code. You can start the MCP server and complete the authentication process before using the MCP tools. See Viewing and managing MCP servers in VS Code on page 129.

Viewing and managing MCP servers in VS Code

After you add the DevOps Loop MCP server, you can view and manage the MCP server in VS Code.

Before you begin

You must add an MCP server in VS Code. See Adding the DevOps Loop MCP server in VS Code by using the command palette on page 127 or Adding the DevOps Loop MCP server in VS Code by editing the MCP configuration file on page 128.

1. Open VS Code.
2. Click the **Settings** icon in the chat interface.
   The **Agent Customizations** window is displayed.
3. Select **MCP Servers**.
   The configured MCP servers are displayed.
4. Right-click the MCP server you want to manage and select one of the following actions:
   - Click **Start Server** to start the MCP server.
   - Click **Stop Server** to stop the MCP server.
   - Click **Enable Server** to make the MCP server available for use.
   - Click **Disable Server** to prevent the MCP server from being used.
   - Click **Show Configuration** to view the configuration of the added MCP server.
5. When prompted, authenticate with the MCP server:
   a. Click **Allow** when VS Code displays a notification indicating that the MCP server requires authentication.
   b. Click **Open** when prompted to open an external website.
   c. Sign in to DevOps Loop by using your credentials.
   d. Review the consent request and click **Yes** to grant access.

   After successful authentication, the available MCP tools are displayed.

   Note: MCP server sessions expire after 30 minutes of inactivity. If no tool calls occur during this period, you must authenticate again before using the MCP server.

Results

You can view the status of configured MCP servers and manage their availability from the **MCP Servers** view. Authenticated MCP servers are available for use in VS Code.

Connecting Claude to the DevOps Loop MCP server

You can connect Claude to the DevOps Loop MCP Server and use it as a connector to retrieve and update loop resources.

Before you begin

You must have completed the following tasks:

- Ensured that Claude is installed and you have an active **Claude Pro subscription** (minimum).
- Obtained the MCP Server URL. For example: `https://hostname/loop/mcp`

1. Open the **Claude** application.
2. Navigate to **Settings > Connectors**.
3. Click **Add custom connector**.
   The **Add custom connector** window is displayed.
4. Enter the name of the connector. For example: Loop MCP server
5. Enter the MCP server URL in the **Remote MCP server URL** field.
6. Click **Add**.
   The MCP server is now added and listed on the **Connectors** page.
7. Click the **Connect** button next to the newly added Loop MCP server entry.

   Claude Desktop redirects you to the **DevOps Loop** login page.
8. Sign in with your DevOps Loop credentials.

   A consent screen is displayed requesting access to MCP tools, loop APIs (used internally for tool execution), and basic profile and role information.
9. Click **Yes** to approve and complete the connection.

   After successful authentication, Claude displays the list of available MCP tools provided by the DevOps Loop MCP Server. See Getting started with the DevOps Loop MCP server on page 112.

   Note: The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session will expire and you will be prompted to re-authenticate.

Results

You have successfully connected Claude to the DevOps Loop MCP Server.

Configuring an external MCP server in a teamspace

You can configure an external MCP server in DevOps Loop to connect to external MCP services and make them available to all loops in a teamspace.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Ensured that you must have a valid MCP server endpoint URL.

1. Navigate to **Settings** > **Installed Integrations**.
   The Installed Integrations page is displayed.
2. Click the **MCP** tab.
3. Click **Add Server**.
   The **Add Server** pane is displayed.
4. Enter a name to identify the MCP server in the **Name** field.
   For example, `GitHub MCP Server`.
5. Select the appropriate domain from the **Domain** list.

   Note: Each MCP server belongs to a Domain. Only one MCP server can be enabled for a Domain at a time. If you are adding a new MCP server to an existing domain, ensure that other MCP servers of the same domain are disabled.

   Note: If you select **Others** in the **Domain** list, the MCP server name is used as the domain value for that MCP server.

6. Enter the MCP server endpoint URL in the **Server URL** field.
7. Keep **OAuth** selected as the **Credential Type**.
8. **Optional**: Enter the client ID in the **Client ID** field.
9. **Optional**: Enter the client secret in the **Client Secret** field.
10. Click **Save**.

    The OAuth authentication window is displayed.

11. Complete the OAuth authentication process.
    The MCP server is added to DevOps Loop within a teamspace.
12. Use the toggle switch in the **Manage External MCP** list to enable the MCP server.

    Note: Newly added MCP servers are disabled, which is the default setting. If AI integration is inactive, the MCP server cannot be enabled.

Results

The MCP server is added to the Manage External MCP list. When the MCP server is enabled, it is available to all loops within the teamspace.

What to do next

The teamspace members can authenticate and use the MCP server through Loop Genie.

Teamspace management

A teamspace in HCL DevOps Loop is a secure, dedicated environment designed for multiple teams to work independently within a single shared DevOps Loop installation.

When you create a teamspace in DevOps Loop, the platform automatically provisions corresponding components for all integrated applications. Each component is provisioned with a corresponding name that reflects the Teamspace, ensuring consistency and seamless integration across all the applications.

The following table lists the configuration of each integrated application within the teamspace provisioning:

Application	Description
Plan	A new teamspace is created.
Control	An organization is created.
Code	A teamspace is created.
Deploy	A team is created.
Test	A teamspace is created.
Measure	A teamspace and a default team are created.

You can manage and switch between multiple teamspaces by clicking the **Switch Teamspace** icon . The following options are available to help you create and manage team spaces in DevOps Loop:

Action	Icon	Description
Create a teamspace		Select **Create TeamSpace** to create a team space within DevOps Loop.
Invite members to a teamspace		Select **Edit Teamspace** to add members to the teamspace.

These configurations provide your team with a fully integrated DevOps environment, streamlining collaboration, automation, and traceability across the software delivery lifecycle.

Adding or inviting members to a teamspace on page 134

Joining a teamspace as an invited member on page 135

Creating a teamspace

You can create a teamspace in HCL DevOps Loop to provide your team with a dedicated, secure workspace that automatically spans across all the capabilities like Plan, Control, Code, Build, Test, Deploy, and Measure.

Before you begin

Ensure that the following prerequisites are completed:

- You are added to the **User** group in **Keycloak**.
- Ensure that you have administrative privileges in DevOps Loop.

1. Log in to DevOps Loop.
2. Click the **Teamspace** button in the left navigation panel.
3. Click **+ Create TeamSpace** in the **Switch Teamspace** panel.

   Result

   The Create Teamspace page is displayed along with the **Define Teamspace** and **Invite Members** tabs.
4. Perform the following steps in the **Define Teamspace** tab.
   a. Provide a name in **Enter TeamSpace Name**. The maximum character limit is 20.
   b. **Optional**: Provide a brief description of the teamspace in **Description**.
5. Click **Next**.

   Result

   The **Invite Members** tab is displayed.
6. Perform the following steps in the **Invite Members** tab.
   a. Click **Add External Members**.
   b. Search members with a valid email address or select them from the dropdown list and click **Add**.
   c. Type the email address of the members who are not in the Keycloak user directory and click **Add**.

   Note: You can enable or disable the teamspace access for the added members in a teamspace.

   - If the members already exist in the Keycloak user directory, they are directly added as members in the teamspace.
   - If the members do not exist in the Keycloak user directory, an invitation email is automatically triggered after the teamspace is created.

     Note: You can add multiple members to your invite list.
7. Click **Create TeamSpace**.

   The Teamspace setup progress page is displayed, showing each phase of the setup. DevOps Loop begins provisioning the TeamSpace across all integrated capabilities.

Note: A Control repository is added to Build, and a webhook is set up in Control to synchronize data between Control and Build.

If an error occurs during teamspace creation, an error message is displayed with options to **Retry** or **Cancel and retry later**. Click **Retry** to attempt the operation again. If the problem persists, check the tenant server pod logs and the logs for the associated product components to obtain additional information.

Note: The error badge indicates that the teamspace setup is incomplete or has configuration issues.

For a visual walkthrough of creating a teamspace watch the following video:
../videos/creating%20a%20teamspace.mp4

Results

You have created a teamspace, which is provisioned across all the capabilities of DevOps Loop. Additionally, the loop creation is enabled.

Related information

Joining a teamspace as an invited member on page 135

Removing a member from a teamspace on page 135

Adding or inviting members to a teamspace

You can add existing members or invite new members to join a teamspace in DevOps Loop by using the **Edit Teamspace** option.

Before you begin

- You must be a teamspace owner.

1. Log in to DevOps Loop.
2. Select the teamspace in which you want to add members.
3. Click **Edit Teamspace**.

   Result

   The **Edit members** pane is displayed.
4. Perform the following steps in the **Invite Members** tab.
   a. Search members with a valid email address or select them from the dropdown list and click **Add**.
   b. Type the email address of the members who are not in the Keycloak user directory and click **Add**.
5. Click **Update Members**.

If the members already exist in the Keycloak user directory, they are directly added to the corresponding teamspaces across all integrated applications.
If the members do not exist in the Keycloak user directory, an invitation email is automatically triggered to join the teamspace.

Results

You have added members to your teamspace. If the members are not part of DevOps Loop, an invitation email is sent to them to join the teamspace.

Joining a teamspace as an invited member

You can join a teamspace in DevOps Loop when you receive an invitation from a teamspace owner. The invitation email includes a link to update your account and access the DevOps Loop.

Before you begin

You must have completed the following tasks:

- Confirmed that you have received an invitation email from DevOps Loop.
- Ensured that you are not signed in with another account in the same browser session.

1. Open the invitation email sent by DevOps Loop.
2. Click the **Link to account update** link in the email.
   The account update page is displayed in a new browser tab.

   Note: If you are already signed in with another DevOps Loop account in your default browser, open the link in a different browser or in an incognito or private window in your default browser.

3. Click **Click here to proceed**.
4. Type **New password** and **Confirm password** and click **Submit**.
5. Type the **Email id**, **First name**, and **Last name** on the account setup page.
6. Click **Submit**.
   You are added to the invited teamspace.

Related information

Teamspace management on page 132

Removing a member from a teamspace

You can remove a member from a teamspace when they no longer need access.

Before you begin

You must have completed the following tasks:

- Ensured that you have administrative privileges in DevOps Loop.
- Ensured that the member is removed from all associated loops before removing from the teamspace.

1. Log in to DevOps Loop.
2. Select the teamspace from which you want to remove a member.
3. Click **Edit Teamspace**.

   The **Edit Members** pane is displayed.

4. Click the Delete icon next to the member you want to remove in the Members List section.
5. Click**Update Members**.

Results

The member is removed from the teamspace.

Adding or inviting members to a teamspace on page 134

Uninstalling DevOps Loop

You can safely uninstall DevOps Loop from your environment, ensuring that all resources and data are properly removed.

Note: For demo setups and air-gapped environment, follow the same Kubernetes service uninstall procedures used for your platform.

Uninstalling DevOps Loop from IBM Cloud Kubernetes Service (IKS)

To reinstall HCL DevOps Loop when an ongoing installation fails, you can uninstall DevOps Loop and its components from theIBM Cloud Kubernetes Service (IKS) cluster.

Before you begin

You must have completed the following tasks:

- Installed DevOps Loop.
- Closed DevOps Loop, any open web browsers, and all other applications that are enabled by DevOps Loop.
- Ensured that, if applicable, existing namespaces used by Code dev containers running in user namespaces are deleted before starting the upgrade.
- **Optional**: Backed up data from the previous version of DevOps Loop.

1. Navigate to **Cluster Management > Clusters > Overview > Actions > Connect via CLI** in your IBM Cloud account and switch context to your cluster.
2. Run the following command to uninstall DevOps Loop:

   ```
   helm uninstall $HELM_NAME -n $NAMESPACE
   ```

   Where,

   ```
   NAMESPACE=devops-loop
   HELM_NAME=devops-loop
   ```

   The PersistentVolumeClaims and PersistentVolumes that were created during the installation are not deleted automatically. If you reinstall DevOps Loop, the user data is reused unless you specifically delete those volumes.
3. Run the following command to delete everything, including the user data contained in claims and persistent volumes:

   ```
   kubectl delete namespace $NAMESPACE
   ```

Results

You have uninstalled DevOps Loop from the IKS cluster.

Uninstalling DevOps Loop from Kubernetes Service (K8S)

To reinstall HCL DevOps Loop when an ongoing installation fails, you can uninstall DevOps Loop and its components from the Kubernetes Service (K8S) cluster.

Before you begin

You must have completed the following tasks:

- Installed DevOps Loop.
- Closed DevOps Loop, any open web browsers, and all other applications that are enabled by DevOps Loop.
- Ensured that, if applicable, existing namespaces used by Code dev containers running in user namespaces are deleted before starting the uninstall.

1. Switch to your K8S cluster by using the following command:

   ```
   kubectl config use-context <context-name>
   ```
2. Run the following command to uninstall DevOps Loop:

   ```
   helm uninstall $HELM_NAME -n $NAMESPACE
   ```

   Where,

   ```
   NAMESPACE=devops-loop
   HELM_NAME=devops-loop
   ```

   Note: User-specific DevContainer namespaces are not removed automatically when DevOps Loop is uninstalled. These namespaces are created outside of the DevOps Loop Helm release and therefore are not deleted when the Helm release is removed.

After uninstalling DevOps Loop, review the cluster for any DevContainer namespaces that are no longer required and delete them manually:

```
kubectl delete namespace <devcontainerNamespace>
```

DevContainer namespace names are derived from the user's email address, with special characters converted to Kubernetes-compatible character sequences. For example, the email address `xyz@example.com` is converted to the namespace `xyz-40-example-2e-com`.

The PersistentVolumeClaims and PersistentVolumes that were created during the installation are not deleted automatically. If you reinstall DevOps Loop, the user data is reused unless you specifically delete those volumes.

3. Run the following command to delete everything, including the user data contained in claims and persistent volumes:

```
kubectl delete namespace $NAMESPACE
```

Results

You have uninstalled DevOps Loop from the K8S cluster.

Chapter 5. Working with Loops

A loop is a workflow that connects DevOps activities of your team from planning and development through build, deployment, testing, and release phases.

You can find information about creating and managing loops, learning loop, managing members, and using dashboards to monitor progress across all capabilities of DevOps Loop.

Loop management

The loop consists of several interconnected phases that ensure continuous software development, testing, deployment, and monitoring.

Loop creation ensures seamless integration between development and operations, leading to faster and more reliable DevOps workflow. The following changes take place as a result of loop creation:

- Provisions your planning, source control, testing, deployment, and metrics tools for a ready-to-use project environment.
- Connects all capabilities by installing and configuring essential plugins, webhooks, repositories, and integrations for real-time data sharing and visibility.
- Provides access to a unified dashboard and links for direct access to each application.
- Adds users in each capability and sets specific access rights across all applications.

Overall, loop creation reduces the time and manual effort required to configure and maintain your development toolchain so that you can focus on innovation.

You can explore loop capabilities by enabling Learning Loop option. This allows you to learn and practice workflows by working with sample projects, work items, and configurations without starting from an empty setup. See Learning Loop overview on page 151.

Managing loops

You can use the following options on the **Home** page:

Actions	Description
View all the loops	The **All loops** tab lists all the loops within your teamspace.
View the recently added loops	The **Recently Added** tab lists the recently added loops within your teamspace.
View My favorites	The **My Favorites** tab lists the loops that are marked as favorite within your teamspace.
View Disabled loops	The **Disabled** tab lists the loops that are disabled within your teamspace.
View the incomplete loops	The **Incomplete** tab lists all the incomplete loops within your teamspace. You can click **Retry** to complete the creation of the loop.

Actions	Description
Search loops	You can search for a loop by clicking the icon and entering the name in the **Search Loops** field when the list of loops is lengthy.
Create a loop	You can create a new loop by clicking the **Create Loop** button.
Edit a loop	You can modify the list of team members who can access the loop by clicking the **Settings** icon .
Mark as favorite	You can mark a loop as a favorite to make it easier to find by clicking the **Add to favorites** icon .
Open Loop Genie	You can interact with Loop Genie and send your queries related to the loop by clicking the button.
View dashboards	You can view the overview and detailed dashboards for the loop by clicking
View loop details	You can view loop details such as configuration details and its linked resources, such as test projects and control repositories, by clicking the **Loop Details** option on the loop.

Creating a loop

You can create a loop to build a pipeline of tasks across the integrated capabilities in HCL DevOps Loop.

Before you begin

Ensure that the following prerequisites are completed:

- You are added to the **User** group in **Keycloak**.
- Created a teamspace or a member of an existing teamspace.
- Read and understood the information in About user roles and access permissions on page 83.

About this task

When you create a loop, DevOps Loop creates specific resources in each of the applications and also, installs and configures the required plugins. During the loop creation, when the plugins are installed and configured, personal access tokens are created in **Plan**, **Control**, and **Test**. On loop creation, the respective users are added to the specific resources in each of the capabilities.

1. Click **Teamspace > <teamspace_name>** to navigate to your teamspace.
2. Click **Create Loop** on the home page of your teamspace.
   The **Define Loop** tab is displayed.
3. Perform the following actions in the **Define Loop** tab:

a. Enter a loop name.

> **Note:** The first five characters for the loop name must always be unique, and they should not be reused while creating another loop.

b. **Optional**: Enter details about the loop in **Description**.
c. **Optional**: Enable the **Learning Loop** option to prepopulate the loop with demo data for exploring workflows and practicing tasks.

4. Click **Next**.
   The **Invite Members** tab is displayed.
5. **Optional**: Perform the following actions in **Invite Members** tab.
   a. Click Add External Members.
   b. Enter the email ID of the team member to be added to the loop in **Search members**.
   c. Click **Add**.
6. Click **Next**.
   The loop setup process begins. A progress view displays the status of each capability being initialized. Once all the capabilities are fully initialized, the loop is successfully created.
   For details about the capabilities and resources configured during loop creation, see Capabilities and resources configured during loop creation on page 142.

   What to do next: After the loop is created, DevOps Loop automatically provisions the required resources and integrations across all capabilities. You can begin using these resources based on your workflow needs.

   The following examples show common actions you may perform after creating a loop. These are **optional** and depend on the tasks you want to complete within the loop:
   - View the Dashboard to see summaries and statuses of the activities through visualizations. See Dashboards and insights on page 154.
   - Create components and applications in DevOps Deploy. See Creating components in Deploy for a loop and Creating applications in Deploy for a loop.
   - For Control integration, create a file named `input.txt` under the repository in Control.

   For a visual walkthrough of creating a loop watch the following video:
   ../videos/creating%20a%20loop.mp4

Capabilities and resources configured during loop creation

When you create a loop, the platform automatically provisions resources, installs and configures plugins, generates tokens, establishes integrations, and assigns appropriate permissions to the loop creator and invited members across multiple capabilities.

Capability-specific resources and configurations

Capability or Plugin	Configuration during loop creation
Plan	• Creates an application in the same teamspace where the loop is created. • Sets up email notifications for work item changes. • Names the application using the first five characters of the loop name.
Control	• Creates a repository with the same name as the loop in the organization associated with the teamspace.
Code	• No resources are created at this stage.

Build	• Creates a team with the following convention: `<TeamspaceName~LoopName>`.
	• Creates the following templates:
	  ◦ Project
	  ◦ Process
	  ◦ Source
	  ◦ Jobs
	• Creates a job template with basic CI/CD steps.
	• Creates the **Deploy** and **Control** integrations.
	• Creates the main project with the naming convention **TeamSpace~Loop:LoopName** (The UI displays this convention as **TeamSpace~Loop**) and configures it using the Process and Source templates.
	 Note: A project is associated with only one loop.

Test	Creates a project with the same name as the loop within the teamspace.

Capability or Plugin	Configuration during loop creation
Deploy	• Creates an application with the same name as the loop and a team named <TeamspaceName~LoopName>. • Creates three empty environments: Development, QA, and Production. • Creates a template pipeline and an empty application process.
Plan Plugin	• Installs and configures the Plan plugin in Measure. • Installation occurs once; configuration occurs with each loop. • Generates a personal access token in Plan which is used to configure the Plan Plugin for Plan-Measure connection. • Auto-synchronizes every 5 minutes. • Default version: 1.2.7
Build Plugin	• Installs and configures the Build plugin in Measure. • Installation occurs once; configuration occurs with each loop. • Auto-synchronizes every 5 minutes. • Default version: 1.1.5
Control Plugin	• Installs and configures the Control plugin in Measure. • Installation occurs once; configuration occurs with each loop. • Generates a personal access token in Control which is used to configure the Control Plugin for Control-Measure connection. • Auto-synchronizes every 5 minutes. • Default version: 1.1.3
Deploy Plugin	• Installs and configures the Deploy plugin in Measure during the first loop creation. • Generates a personal access token in Deploy which is used to configure the Deploy Plugin for Deploy-Measure connection. • Auto-synchronizes every 5 minutes. • Default version: 5.1.1
Test Plugin	• Installs and configures the Test plugin in Measure. • Installation occurs once; configuration occurs with each loop.

Capability or Plugin	Configuration during loop creation
	• Generates an offline user token in Test which is used to configure the Test Plugin for Test-Measure connection. • No auto-synchronization. • Default version: 1.0.32
Control–Plan Integration	• Links repository changes (pull requests, commits, branch creation) in Control to work items in Plan. • Pull request titles and branch names should start with the work item ID for proper syncing. • Changes appear in the SCM Event section of the work item in Plan. • A personal access token in Plan configures a webhook in Control.
Test–Plan Integration	• Creates work items in Plan from Test Hub via integration. • A personal access token in Plan is used for setup. • Verify by opening your Test Hub project and navigating to Manage Integration > Change Management.
Test–Control Integration	• Maps the repository created in Control to the Test Hub project associated with the loop. • View it in Test Hub under Manage Configuration > Repositories. • Enables Test Hub to pull test assets from Control.
Measure	• Creates a team <TeamspaceName~LoopName Team> and adds the creator/admin with full permissions. • Creates a value stream and pipeline associated with the team, using application data from Deploy by using the YAML plugin in Measure.
Analytics	• Creates dashboards in Opensearch for the newly created loop.
Loop Genie	• Creates a repository in Control with the naming convention `<loop_name>~TASKS`. • PredefinedTask files are uploaded in the TASKS repository.

Capability or Plugin	Configuration during loop creation
Branch Protection	• Configures branch protection on the Control repository's main branch

Access and Permissions

The loop creator is granted the highest permissions for all resources in the integrated capabilities. Invited users are given only basic permissions by default when they join a loop. They can manually elevate their own permissions through the UI for any resource as needed.

Viewing loop details

You can use the **Loop Details** page to view a complete overview of a loop, including its key configuration and resource information.

When you want to view a loop's configuration details and its linked resources, such as test projects and control repositories, select the **Loop Details** option on the loop. Each resource includes metadata such as its name, URL, and creation date, making it easy to understand how the loop is structured and which assets it relies on.

From the **Loop Details** page, you can add additional test projects and control repositories as needed, so that you can expand or update the loop's configuration without leaving the page.

The page also includes a team members section. Here, you can view all the members who are part of the loop, along with their role (Admin or Team Member), their email ID, and the other loops they belong to. You can search through the list of members or make updates using the available edit capabilities, helping you keep membership aligned with your project requirements.

Related information

Adding members to a loop on page 145

Adding members to a loop

You can add members to a loop who are already part of your teamspace so they can collaborate and stay updated within it.

Before you begin

You must have completed the following tasks:

- Created a loop.
- Ensured that you have administrative privileges in DevOps Loop.
- Ensured that the member is already added to the teamspace.

1. Log in to DevOps Loop.
2. Click **Teamspace > <teamspace_name>** to navigate to your teamspace.
3. Click **Loop Details** option in the Loop card for which you want to add members.

The **<Loop name> Details** page is displayed.

4. Navigate to **Team Members** tab and click **Edit Members** button.
   The **Edit Members** pane and list of members in your teamspace is displayed.
5. Type the email address in the **Search** bar or select the member from the list and click **Add**.
6. Click **Update Members**.

Results

The member is added to the loop and its capabilities.

Related information

Removing a member from a loop on page 146

Removing a member from a loop

You can remove a member from a loop when they no longer need access.

Before you begin

You must have completed the following tasks:

- Created a loop.
- Ensured that you have administrative privileges in DevOps Loop.

About this task

When you remove a member from a loop, the member is also removed from all connected capabilities within that loop.

1. Log in to DevOps Loop.
2. Select the loop from which you want to remove the member on the **All Loops** tab.
3. Click the Settings icon and select **Edit**.

   The **Loop Members** pane is displayed.

4. Select the member in the **Members List** section, and click the **Delete** icon .
5. Click **Save**.
   The member is removed from the loop and its capabilities.

Related information

Adding members to a loop on page 145

Disabling a loop

You can disable a loop to pause its activities and stop updates. You can enable it again from the **Disabled** tab whenever you need it.

Before you begin

You must have completed the following tasks:

- Created a loop.
- Ensured that you have administrative privileges in DevOps Loop.

About this task

When you disable a loop, the following connected capabilities within that loop are impacted:

- **Plan**: Emails, alerts, and search functions for work item updates are disabled.
- **Control**: The Plan-Control webhook is deactivated and all the information in the events (such as pull request, branch creation etc) stop flowing from Control to Plan.
- **Measure**: Data flow from Control, Plan, Test and Build is interrupted and therefore value streams and dashboards no longer receive updates.

1. Log in to DevOps Loop.
2. Navigate to the loop that you want to disable from the **All Loops** tab.
3. Click the Settings icon in the loop which you want to disable
4. Select **Archive Loop** option.

   The loop is disabled and moved to the **Disabled** tab.

Related information

Enabling a loop on page 147

Enabling a loop

You can enable a loop to restore its activities and allow updates to flow again.

Before you begin

You must have completed the following tasks:

- Created a loop.
- Disabled the loop you want to enable.
- Ensured that you have administrative privileges in DevOps Loop.

About this task

When you enable a loop, the following connected capabilities are restored:

- **Plan** – Emails, alerts, and search functions for work item updates are re-enabled.
- **Control** – The webhook is activated and all the events such pull request, branch creation etc starts flowing from Control to Plan.
- **Measure** – Data flow from **Control**, **Plan**, **Test** and **Build** resumes, and therefore value streams and dashboards receive updates.

1. Log in to DevOps Loop.
2. Select the Loop that you want to enable from the **Disabled** tab.
3. Click the Settings icon and select **Enable**.

   The loop is enabled and appears in the **All Loops** tab.

Related information

Disabling a loop on page 147

Loop Segments overview

When a loop contains multiple microservices, you can add loop segments to manage each microservice independently. Each segment creates a dedicated set of resources and integrations for that microservice.

These resources support the development lifecycle of the microservice and can include items such as:

- A dedicated control repository
- A separate plan component
- Supporting test and build integrations

Each segment behaves like a sub-loop and provides capabilities that are specific to a microservice.

A segement:

- Supports its own build and validation flow
- Tracks changes specific to the microservice
- Remains connected to the overall application lifecycle

You can use segments when you are working with multiple microservices in a single application, each microservice needs separate repositories, builds or testing processes. Segments help maintain clear separation between microservices without creating multiple loops for each microservice.

For example: You build an e-commerce application using a microservices architecture, such as frontend service, order service, and payment service. All these microservices belong to the same application and share a common delivery lifecycle, so you create one Loop to represent the overall application. However, you create a **Segment** for each microservice inside the parent loop. For example, you create a segment named **Order Service**.

A loop can contain multiple segments and each segment contributes to the overall value stream.

Related information

Adding a loop segment on page 149

Adding a loop segment

You can add a loop segment within a loop to manage a microservice that requires its own repositories, builds, and integrations.

Before you begin

Ensure that the following tasks are completed:

- Created a teamspace or a member of an existing teamspace.
- Created a loop.

About this task

Segments are used when an application contains multiple microservices that require independent repositories, builds, and testing processes. Each segment represents a microservice within the loop.

1. Click **Loop Details** option in the loop card for which you want to add a loop segment.
2. Click **Add connection > Loop segment** in the **Loop Connections** tab.
   The **Add Loop Segment** panel is displayed.
3. Enter a Segment name in **Name** field.

   Segment name must be at least 3 characters long.
4. **Optional:** Enter additional details in **Description**.
5. Click **Add Segment**.

   The system begins the segment setup process and displays a progress view that shows the status of each initialization task. During this process, the system performs the following actions:

Figure 1. Capability-specific resources and configurations created in segment

Capability or Plugin	Configuration during segment creation
Plan	◦ Creates a plan component.
Control	◦ Creates a repository with the same name as the segment name in the organization associated with the teamspace. ◦ Applies branch protection rules to the repository.
Build	◦ Creates a project with the naming convention **TeamSpace~Loop:LoopName:SegmentName** and configures it using the Process and Source templates. **Note:** A project is associated with only one loop or segment. ◦ Creates a job template with basic CI/CD steps for the segment. ◦ The segment process is added as dependency within the process of the main project of the loop. ◦ The main project build is trigerred only when we have at least one version built for all the segments in the loop.
Test	◦ Creates a project with the name as **LoopName-SegmentName**within the teamspace. ◦ Configures Control repository in the created project. ◦ Configures webhook to upload test results to measure. ◦ Configures Plan integration in the created project.
Deploy	◦ Creates a component in Deploy with the name as **LoopName-SegmentName** within the application.
Build Plugin	◦ Updates the Build plugin configuration in Measure to add the newly created project for the segment.
Control Plugin	◦ Updates the Control plugin configuration in Measure to add the newly created repository for the segment.
Control–Plan Integration	◦ Links repository changes (pull requests, commits, branch creation) in Control to work items in Plan. ◦ Pull request titles and branch names should start with the work item ID for proper syncing. ◦ Changes appear in the SCM Event section of the work item in Plan. ◦ A personal access token in Plan configures a webhook in Control.

After all tasks are completed, the segment is successfully created and appears under the **LoopName Loop Segments** section in the **Loop Connections** tab.

Learning Loop overview

Learning Loop provides preloaded sample data across multiple DevOps Loop capabilities. It helps you learn and practice workflows by exploring sample projects, work items, repositories, build pipelines, deployments, and tests without starting from an empty setup.

Learning Loops use a sample application that consists of frontend and backend microservices. The application components are organized into segments, which contain the source code, build configurations, deployment configurations, and test assets required to demonstrate an end-to-end DevOps workflow.

The Learning Loop, with its preloaded sample data, helps you explore and understand the following DevOps Loop features:

- Understand how events flow between capabilities. For example, a commit in Control triggers a build in Build and a deployment in Deploy.
- View a consistent end-to-end implementation of DevOps Loop capabilities for demonstrations, evaluations, and training.
- Explore how DevOps Loop manages multi-component applications through segments.
- Experiment with features and configurations in a non-production environment.

Learning Loops include an automated deployment experience for a sample application. Code changes flow through the complete pipeline from source control to build, deployment, and testing. The sample application consists of frontend and backend services that are managed independently through segments while remaining connected within the same Learning Loop.

Segments in Learning Loops

A segment is a sub-loop that represents an individual application component within a Learning Loop.

Learning Loops use segments to organize and manage multi-component applications. When a Learning Loop is created, DevOps Loop automatically provisions separate frontend and backend segments.

Each segment contains the following resources:

- Source code repository
- Build configuration
- Deployment configuration
- Test assets

Segments help you manage and deploy application components independently while maintaining visibility across the complete application lifecycle.

Scope

A Learning Loop creates resources across the following DevOps Loop capabilities:

- **Plan** - Creates a project with releases, sprints, and work items.
- **Control** - Creates and populates frontend and backend source code repositories with sample application code and deployment artifacts.
- **Build** - Creates projects, processes, and jobs for frontend and backend segments. Requires a manual step to configure an active agent.
- **Deploy** - Creates deployment resources and processes for frontend and backend segments. Backend services are deployed to Kubernetes, while frontend artifacts are published through the Learning Webserver.

Key characteristics

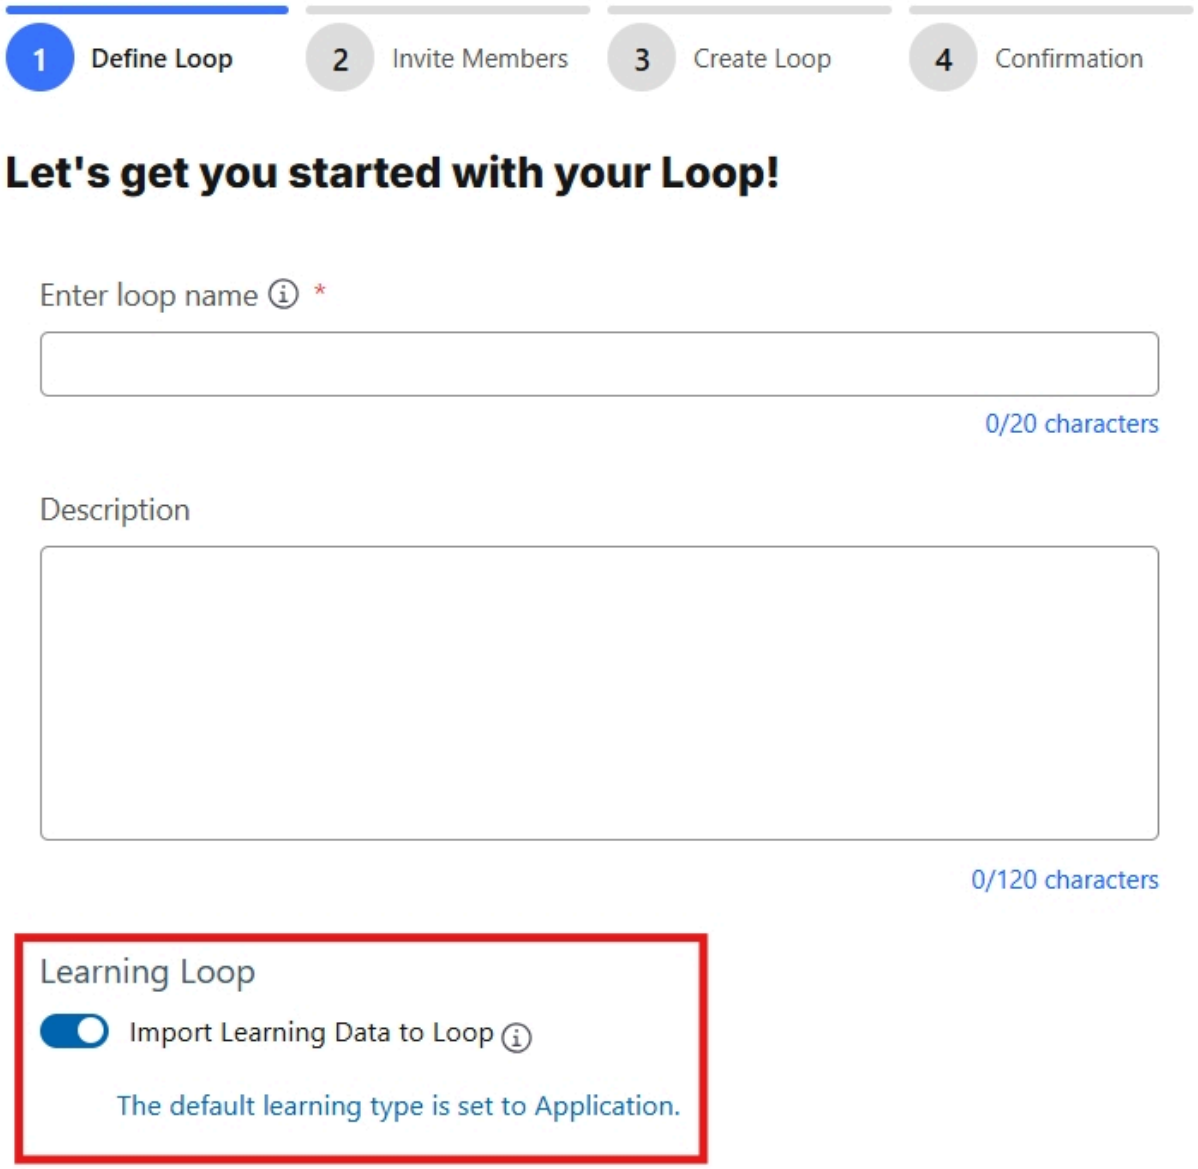
- Built for learning and exploration, not for use in production environments.
- Some manual steps, such as configuring build agents, are required.
- After the configuration, the end-to-end workflow is automated across Control, Build, Deploy, and Test.
- After the sample data is loaded, you can edit or extend it to fit your own configurations.
- Learning Loops support multi-component application architectures through frontend and backend segments.
- The frontend application is hosted through the Learning Webserver and is accessible through a unique URL generated for each Learning Loop.
- Each Learning Loop receives its own backend deployment and temporary database instance.

Note: The temporary database is not persistent and is reset if the backend deployment is restarted.

Creating a Loop with preloaded example data

When you want to explore DevOps Loop capabilities and learn how workflows operate across Plan, Control, Build, Deploy, and Test, you can use the Learning Loop option to preload sample data with pre-configured projects, repositories, build pipelines, deployments, and test assets.

1. Log in to DevOps Loop.
2. Click **Create Loop**.
3. Enter the required loop details, such as the **Loop Name** and **Description**.
4. Enable the **Learning Loop** option.



When you select the **Learning Loop** option, DevOps Loop automatically provisions a sample application and the associated resources and configurations across the Plan, Control, Build, Deploy, and Test capabilities.

The following resources and configurations are created:

- Frontend and backend segments.
- Source code repositories populated with sample application code.
- Build configurations for frontend and backend services.
- Deployment configurations for frontend and backend services.
- A hosted frontend application.
- A unique URL for accessing the Learning Loop application.

5. Navigate to **Test** and execute the test manually.
   The test result is displayed in the **Execution** tab.

Results

You have successfully created a Learning Loop with a sample application, pre-configured frontend and backend segments, and sample data across DevOps Loop capabilities.

Dashboards and insights

The dashboard consolidates data from all capabilities, such as Plan, Code, Control, Build, Test, Release, and Deploy, by offering a centralized view of the status. Dashboards are available with both summary and detailed perspectives, and they filter information specific to each loop.

After you created a loop, five dashboards for each subscription tier are automatically provisioned and linked directly to the workspace of each loop. These dashboards are universally visible, irrespective of the user's licensing tier. You can see tier-specific differences in the dashboard because of the depth and variety of data sources through integrated applications for a specific tier. The default dashboards are preconfigured and available for immediate use.

For advanced analytics, DevOps Loop includes a milestone risk assessment feature, which requires an optional plug-in.

Dashboard types

You can view the following dashboards for each loop in your teamspace:

Table 4. Available Dashboards in a loop

Dashboards	Description
Overview	The **Overview** dashboard provides a high-level summary of loop activity, including issues, team workload, test results, builds, and deployments.
Detailed	The **Detailed** dashboard provides more granular insights, such as issues, pull requests and commits, builds, deployments, test metrics, and timeline performances.
Delivery	The **Delivery** dashboard provides information about Lead Time, Cycle Time, Dev Cycle Time, Deployment Counts, Throughput, Distribution, Deployment Frequency, and Lead Time to Change.
Quality and Security	The **Quality and Security** dashboard provides the information about Functional Tests, Unit Tests, and API Tests.

Data authorization

All the dashboard data is displayed based on your loop membership and access rights. You can only see information for loops in which you are a member, so that sensitive data remains secure and collaboration across teams stays controlled.

Viewing dashboards

You can view the dashboards for the loops in your teamspace. The dashboards display key metrics such as issues, workloads, builds, deployments, milestones, lead time, and cycle time.

Before you begin

You must be a member of the loop.

About this task

You can view the data only for the loops you are a member of, and the information displayed is restricted based on your access rights.

1. Click the **Dashboards** tab in the navigation panel.
   The **Dashboards** page is displayed.
2. Select the dashboard from the **Dashboard name** column.

Results

The selected dashboard with metrics and data is displayed.

Related information

Editing dashboards on page 155

Dashboard types on page 154

Editing dashboards

You can customize the dashboard view by applying filters and selecting specific metrics such as test results, build history, or deployment status to focus on the data most relevant to your loop.

Before you begin

You must have completed the following tasks:

- Created a loop.
- Ensured you have administrative privileges.

1. Click the **Dashboards** tab.
   Result
   The **Dashboards** page is displayed.
2. Click the **Edit** icon .
3. Use any of the following options to edit the dashboard:

Option	Description
Full Screen	Expands the dashboard to full-screen mode for easier viewing.
Share	Shares the dashboard view with other users in the following format • Embed code • Permlinks
Clone	Creates a copy of the selected widget within the dashboard layout.
Swap	Allows for swapping the position of widgets within the dashboard layout.
Add	Adds new panels or widgets to the dashboard.
Cancel	Cancels the current edit operation.
User Margin Between Panels	Adjusts spacing between panels in the dashboard.
Show Panel Titles	Toggles panel titles on or off.
Add Filters	Applies a filter to the data to be displayed in the dashboard.

4. Click **Save** to save the changes.
5. Click **Refresh** to update the dashboard view with the latest data.

Results

You have customized the dashboard to focus on the metrics and information that are most important to your loop.

AI-powered search

When you want to search work items, records, and related data in DevOps Loop, you can use the search bar to locate information across multiple capabilities. You can search across a wide set of artifact types, including issues, builds, tool requests, commits, and deployments, and you can filter results by loop or by category to quickly narrow your search.

You can search for epics, defects, and stories across Plan, and the results are presented as interactive cards that include metadata. From these cards, you can directly access associated URLs for pull requests (PRs), commits, and builds, making it easy to move from search results to action.

You can generate AI summaries of search results to quickly understand the context of work items, issues, and related data. These summaries are generated for the top five results on each page, helping accelerate decision-making by providing quick insights as you navigate through your results.

Note: AI summaries are available only if the OpenAI or watsonx integration is enabled in DevOps Loop. If neither integration is enabled, DevOps Loop will not generate summaries.

Search results are automatically filtered based on your access rights. You will only see documents and records associated with loops of which you are a member, ensuring that sensitive data remains secure and collaboration across teams is controlled. This ensures that results are fully scoped to the current user, preventing visibility into team spaces you do not belong to.

Chapter 6. Capabilities of DevOps Loop

HCL DevOps Loop provides an integrated suite of capabilities such as Plan, Code, Control, Build, Test, Release, Deploy, Measure and Harbor (if enabled) to manage every stage of the software development lifecycle within a connected, continuous loop.

Each capability is designed for a specific purpose, but together they form a continuous feedback cycle, helping teams plan, build, deploy, and measure value efficiently.

Plan

Plan is a change management software application within the DevOps Loop that supports seamless ticket creation, tracking, and comprehensive issue management. With customizable workflow automation, it helps teams to streamline and adapt processes to meet their unique business requirements while preparing work for the next stages of the loop.

For more details refer to the Plan Documentation.

Code implementation with AI

The Code Genie feature provides an end-to-end integration within the Loop environment, allowing you to generate source code directly from a work item. By coordinating between DevOps Plan, Code, and Control products, Code Genie automates the transition from a descriptive task to a functional Pull Request (PR).

Before you begin

Code Genie leverages AI to translate work item details into actionable coding instructions. It analyses the Description and Conversation (comments) fields of a work item to determine the requirements for code generation. The tool then triggers a background process in which an AI-powered dev container applies the requested changes and submits them as a PR in the designated Control repository.

Before you begin, ensure that you have:

- AI requirement: You must have an AI integration enabled to use the Generate function for coding instructions. For more information, see the *Artificial Intelligence integration* topic in Plan Documentation.
- CLI token: For a CLI token, see Manage Coding CLI on page 215.
- Branching strategy: Use a branching strategy on page 233 with a protected main branch.
- Processing time: Code generation is not instantaneous. After clicking Implement in DevOps Plan, it might take some time for the PR to appear in Control.
- Manual review required: While Code Genie generates the code, ensure that a reviewer must still manually review and merge the PR to ensure quality and security.
- Branch protection: Standard branch protection rules in Control still apply, preventing unauthorized code from being pushed directly to protected branches.
- Unsaved instructions: If you close the slide-out panel before clicking Implement, any manually entered or AI-generated instructions that have not been submitted will be lost.

About this task

1. Open the work item: Navigate to the desired work item in DevOps Plan in full view mode.
2. Launch Code Genie: Click the Code Genie button located in the record toolbar.
3. Select repository: In the slide-out panel, select the appropriate Control repository from the dropdown menu. This action automatically loads the relevant dev container and coding guidelines.
4. Prepare coding instructions:
    - AI generation: Click **Generate** to let the AI create instructions based on the work item's description and comments.
    - Manual entry: Alternatively, type specific instructions or prompts directly into the text area.
5. Implement: Click the **Implement** button to initiate the background generation process.
6. Verify the PR: Navigate to the Control UI to view the automatically generated PR. You can review the files changed and any automated security scans that are run by Trivy.
7. Monitor in DevOps Plan: Return to the work item in the DevOps Plan and check the SCM events tab to verify that the PR is reflected there.

Results

Upon successful completion, Code Genie generates a complete PR in the linked Control repository. This PR includes the implemented code files based on your instructions and is ready for manual review and merging by assigned reviewers.

Code

Code is a cloud-based browser IDE on page 180 in a dev container on page 161 that is part of HCL DevOps Loop, allowing developers to write, compile, build, and debug code directly in the browser without requiring local setup.

Built on Visual Studio Code, Code offers pre-configured tools, extensions, and libraries, along with support for custom extensions. It includes a file system, terminal, and tools for debugging and testing while integrating with remote source control repositories for secure version control.

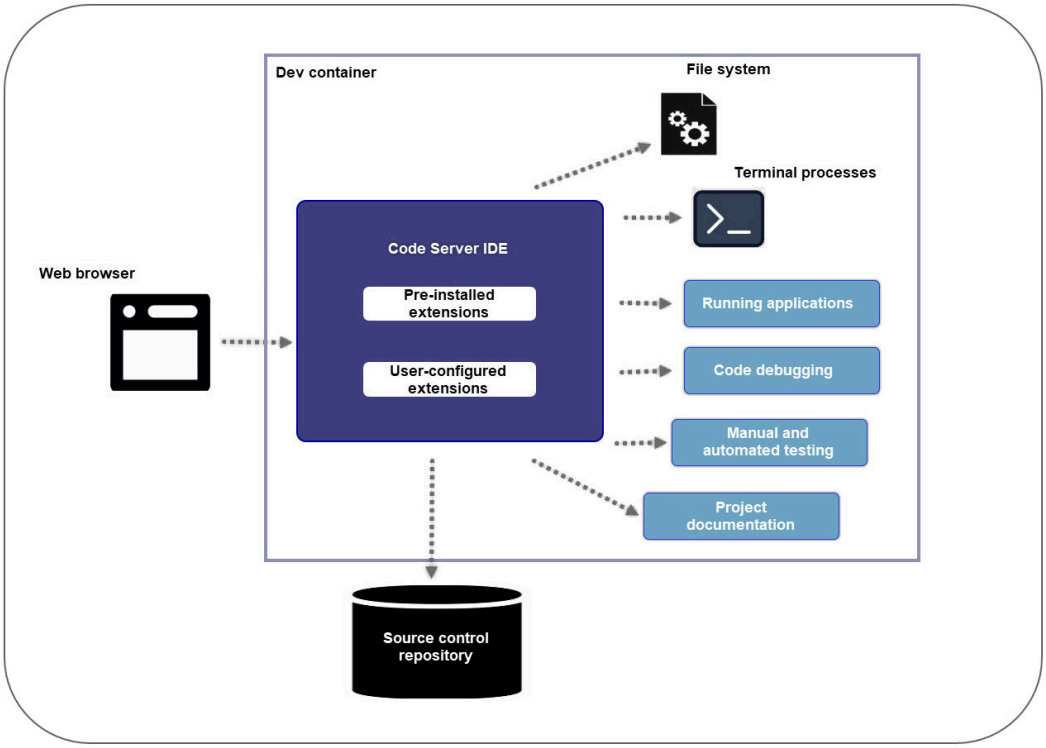
Continue reading to learn how Code enhances your development experience and integrates with DevOps Loop.

Code overview

Code is a cloud-based integrated development environment on HCL DevOps Loop, with which you can write, compile, build, and debug software applications in a so-called **dev container**, accessible directly from a web browser. The editor provides a completely configured development environment with preinstalled extensions, tools, and libraries. You can start coding without the need to set up the environment on your local machine.

Architecture

The general architecture of the Code platform is shown in the following image.



Code provides personal **dev containers** that are configured for members of a teamspace. By using each dev container, you can write, build, and debug your code in an integrated environment without affecting the work of other users in the team. Each container is isolated for a specific user to prevent conflicts with different project setups. Additionally, you can also customize the individual dev container to meet your specific needs, by ensuring that all the necessary extensions and libraries are available for use.

The dev container integrates essential tools and processes, with the web browser serving as an interface for accessing the browser IDE on page 180, supporting coding, debugging, version control, and more.

Visual Studio Code-based environment

The browser development environment is based on Visual Studio Code, which means that almost all features the latter provides are also available in Code. For more information, refer to Visual Studio Code documentation.

The development environment includes preinstalled extensions on page 181. However, you can also add custom extensions to suit project needs. It includes a file system for file management, a terminal for command-line operations, and tools for application execution, debugging, testing, and maintaining documentation.

Source control integration

Code integrates with remote source control repositories, ensuring secure, accessible version control and project continuity across sessions. Code offers built-in support for Git repositories (for example, repositories stored in https://help.hcl-

software.com/devops/plan/3.0.3/oxy_ex-1/control/content/index.en-us.html). Other types of source control repositories are supported by means of extensions that you can install into the dev container.

Accessing Code

To learn how to access the Code feature, see DevOps Loop user interface on page 30.

Related information

Git authentication for dev containers on page 191

Accessing dev containers

You can switch to your teamspace to access team-specific dev containers and their pre-configured settings.

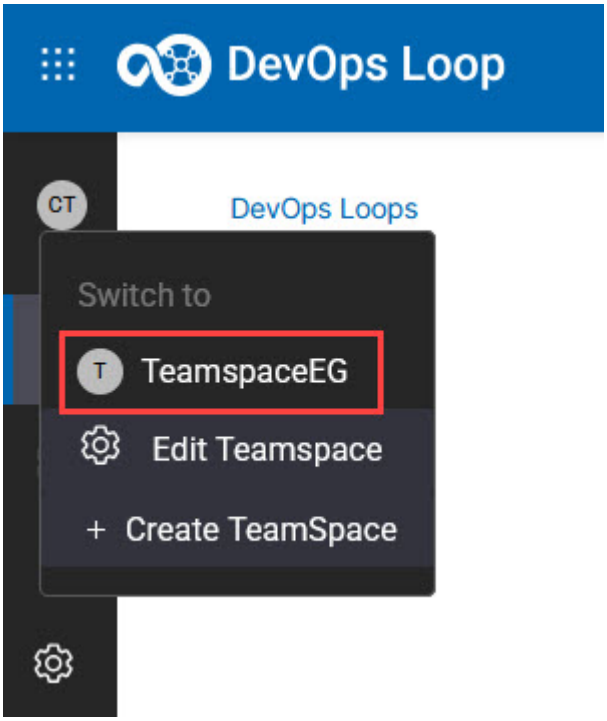
About this task

Upon login, you can navigate using two tabs: **Running Dev Containers** and **Other Dev Containers**.

If you have an assigned teamspace, you can launch preconfigured dev containers - such as Starter, Java, Python, or C++ - directly from the **Other Dev Containers** tab. Once launched, you can manage these running dev containers in the **Running Dev Containers** tab. You can find full details in the Working with dev containers on page 169 guide.

To access your team-specific dev containers:

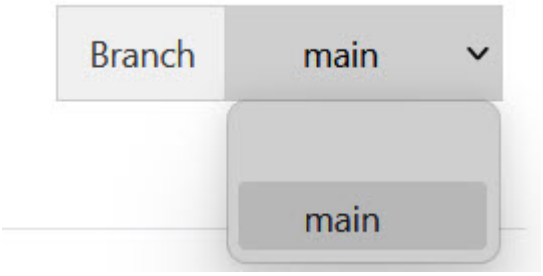
1. Click the switch teamspace button in the top-left corner.



2. Select the appropriate teamspace created by your team admin.

Note: If you do not see any teamspace listed, it means you have not been added yet. Contact your team admin to request access to a teamspace.

You can also switch to a different branch (other than main) using the Branch menu in the upper right corner of the IDE. The branch switch menu is visible only in **Other Dev Containers** tab. This allows for versioning dev containers, which lets a development environment evolve together with the application it creates.



Dev containers

You can use this information to understand why and when to choose between available dev containers. You should choose the Starter container when you need basic tasks, or a preconfigured container when your project requires a customized environment (like Node.js or Java) assigned by an administrator.

Starter dev container

The **Starter** dev container provides a basic environment designed for essential tasks like text editing and cloning Git repositories. It includes the **DevOps Code** extension, which offers commands for seamless integration with tools like DevOps Plan on page 217.

This container is available to all users, regardless of teamspace membership. After logging into Code, you will find **Starter** under the **Other Dev Containers** tab. Once launched, it moves to the **Running Dev Containers** tab.

The following video demonstrates two scenarios: one for users without a teamspace, and one for users within a teamspace.

../videos/starter-userspace-not-userspace.mp4

To launch the Starter container, go to the Code landing page and click the **Let's Go** button on the **Starter** container tile. Alternatively, to copy a direct link to the container, click the copy link button on the tile. You can then paste the link into a web browser address bar to open the container.

Preconfigured dev container

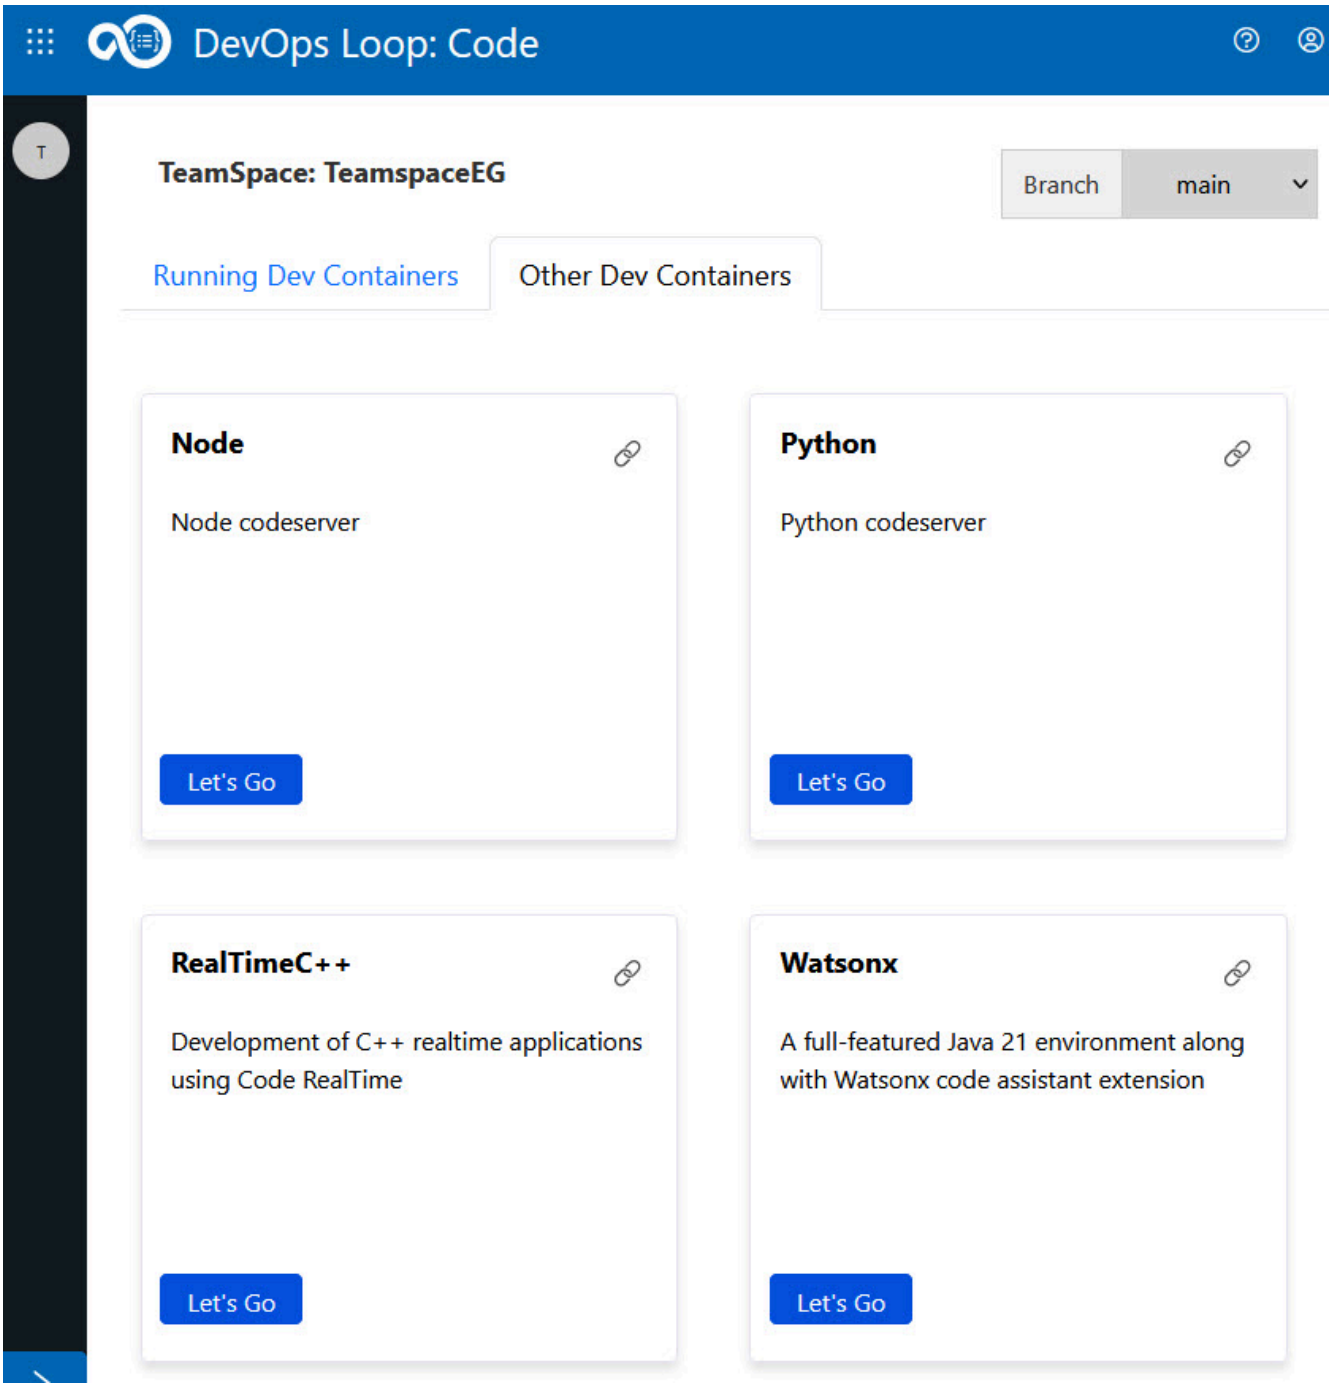
A preconfigured dev container provides a customized development environment tailored to specific project requirements, such as C++, Java, Node, Python, RealTimeC++, Watsonx, etc. A preconfigured dev container is added via a teamspace created and managed by an administrator on page 172.

To access a preconfigured dev container, switch to the teamspace assigned to you by your administrator. Then, select the relevant dev container from the available options. For example, to work in a Node.js environment, click the **Let's Go** button on the Node dev container tile.

Note: If no teamspace appears, it likely means you are not added to one yet. Contact your team admin to request access.

For example only: The image below shows how dev containers appear after switching to an admin-assigned teamspace, such as TeamspaceEG. In this case, you can see preconfigured dev containers alongside the Starter container.

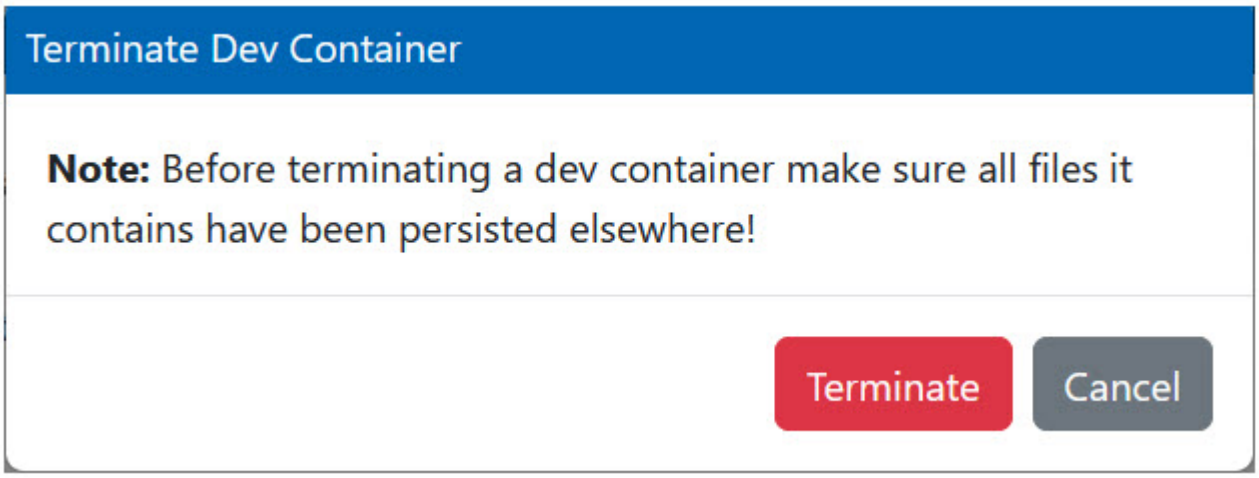
This setup is just an example. The actual teamspace name and available containers might vary.



Note: Administrators can define standard dev containers to ensure consistency across team environments. For more information on configuring dev containers, see the Administrator Guide on page 172.

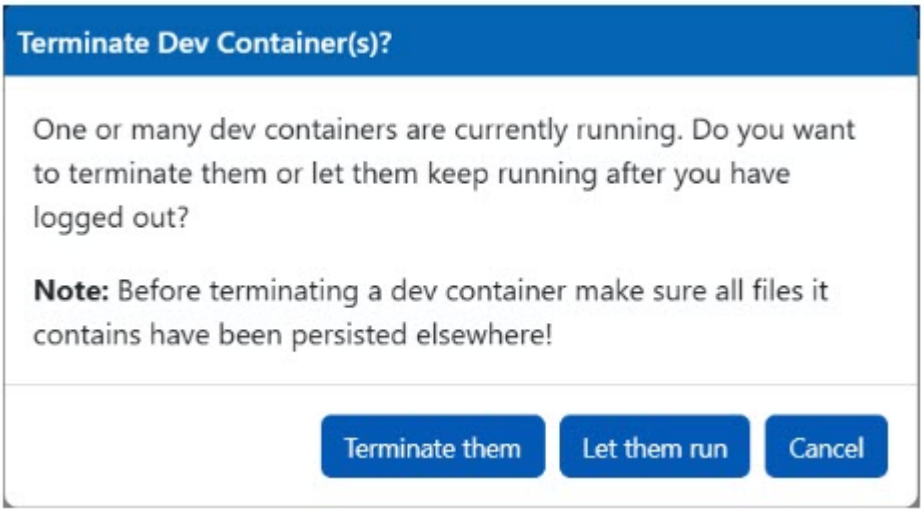
Terminate a dev container

When a dev container starts running, you can see a **Terminate button** on the dev container tile. This action opens the **Terminate Dev Container** dialog.



Important: When you terminate a dev container, all files and unsaved work are deleted. Therefore, you must push your changes to a remote source control repository, such as a Git repository, before termination.

You can also delete all the running dev containers in a namespace by clicking the Logout button, which invokes the **Terminate Dev Container(s)** dialog. When all the dev containers are terminated, the associated user namespace is also deleted.



Viewing logs

Use the Log Viewer in Code when you need to view, filter, or download log output from your dev containers or from Code itself. You can diagnose launch failures, unexpected container behavior, or errors that you want to share with a support team.

Before you begin

You must have completed the following tasks:

- You have opened the Code landing page.
- You are a member of at least one teamspace, if you want to view the container-level logs.

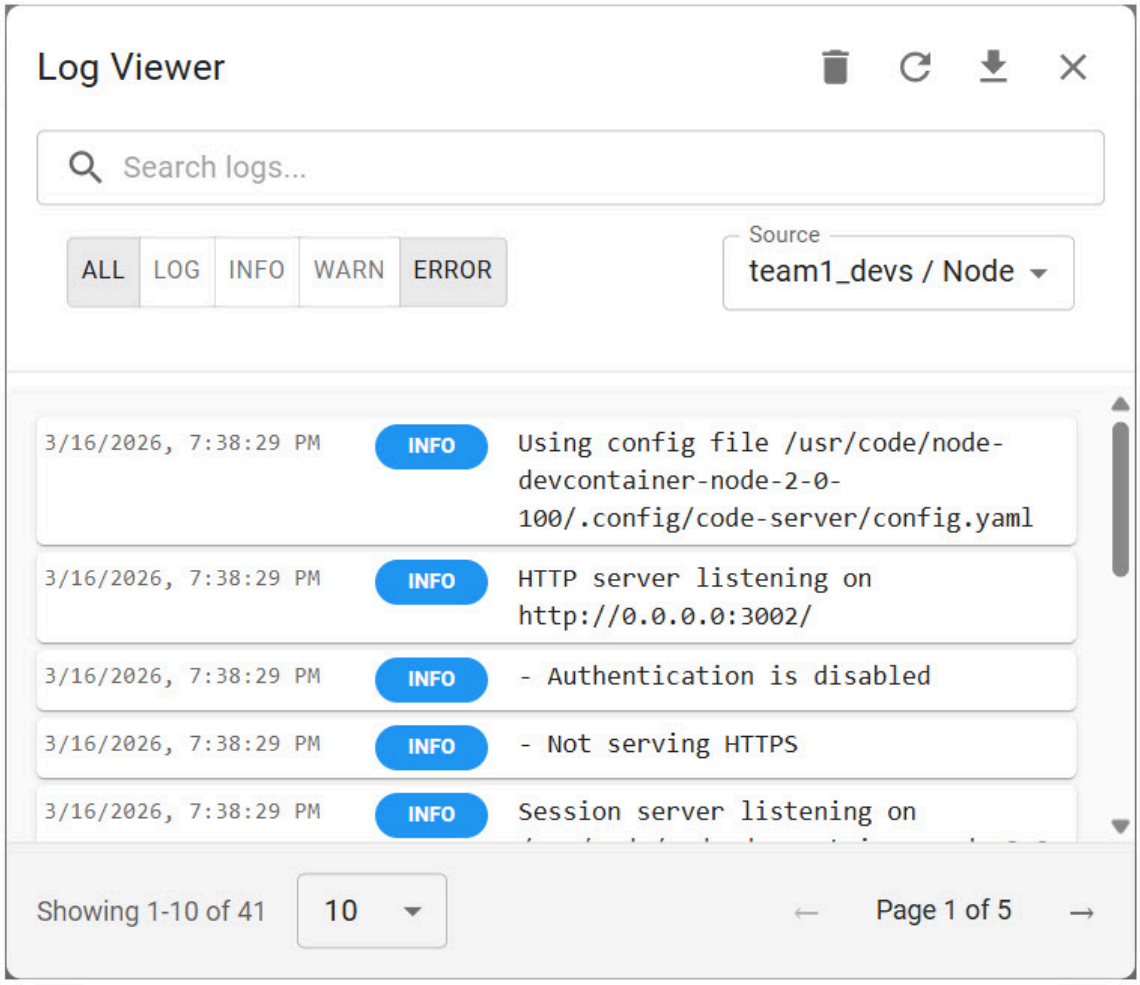
About this task

Log Viewer opens as a panel within the Code interface. You access it from the help menu in the top-right corner of the page. Once open, you can switch between Code logs and dev container logs using the **Source** dropdown, apply severity filters, search log entries by keyword, and download captured logs as a file. The Log Viewer captures **trace logs** from your running dev containers and from Code itself. It does not capture output from applications that run inside the dev containers, for example, the output of a Node.js application.

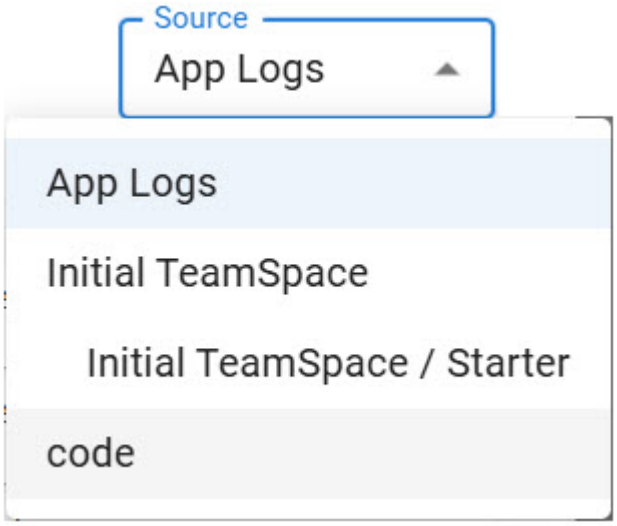
1. Open the Log Viewer:
    a. Onthe Code landing page, click the help icon (top-right).

    b. In the dropdown menu, click **Logs**. The Log Viewer panel opens.
2. Select a **log source**:

a. In the upper-right area of the Log Viewer panel, click the **Source** dropdown.



b. To view logs for a container or containers grouped by their teamspace, select the teamspace name from the **Source** dropdown, then select an individual container if needed.



App Logs show internal logs of Code, not logs from apps inside the dev containers.

3. Filter the **log output**:
   a. In the search bar at the top of the panel where there is the **Search logs...** placeholder, type a keyword to narrow entries by matching text.
   b. Click one or more filter buttons to show only entries of that severity level. The following filters are available:

Button	Description
ALL	Displays all log entries regardless of level.
LOG	Shows log entries without severity levels by using a generic format to record plain-text, non-critical data for simple auditing.
INFO	Shows informational messages about normal operational activity.
WARN	Shows warning-level entries, indicating conditions that might lead to errors.
ERROR	Shows error-level log entries, indicating failures that require attention.

Note: You can enable multiple filters simultaneously. For example, selecting both **WARN** and **ERROR** shows only warning and error entries together.

   c. To load the latest entries, click the **Refresh** icon in the top-right area of the panel.
4. View **log entry details**:

a. Locate the log entry you want to inspect. Each row shows a timestamp, a color-coded level badge (for example, **INFO** or **ERROR**), and a short message.
b. Click the expand arrow on the right side of the row. When expanded, the entry displays sections such as Details, which indicates that the entry is expanded and contains further information, and Context, which provides the namespace and pod name associated with the error.
c. Click the collapse arrow to close the expanded view and return to the compact list.

5. Adjust the number of **displayed entries**:
   a. At the bottom of the panel, click the count selector on the left (default is **10**) and select a different value to change how many entries are shown per page.
   b. Use the arrow controls to move between pages.
6. Download the **logs**:
   a. Click the **Download** icon in the top-right area of the Log Viewer panel.
   b. Save the exported file to your local system.

> **Note:** The download exports only the entries that are currently visible based on your active source and filter selections. Adjust your filters before downloading if you need a specific subset of entries.

Results

You have opened the Log Viewer, selected a log source, applied filters, and reviewed or downloaded log entries from your Code environment. You can now use the log output to identify the cause of issues in your dev containers or share the file with a support team.

What to do next

After you review the log output, consider the following next steps:

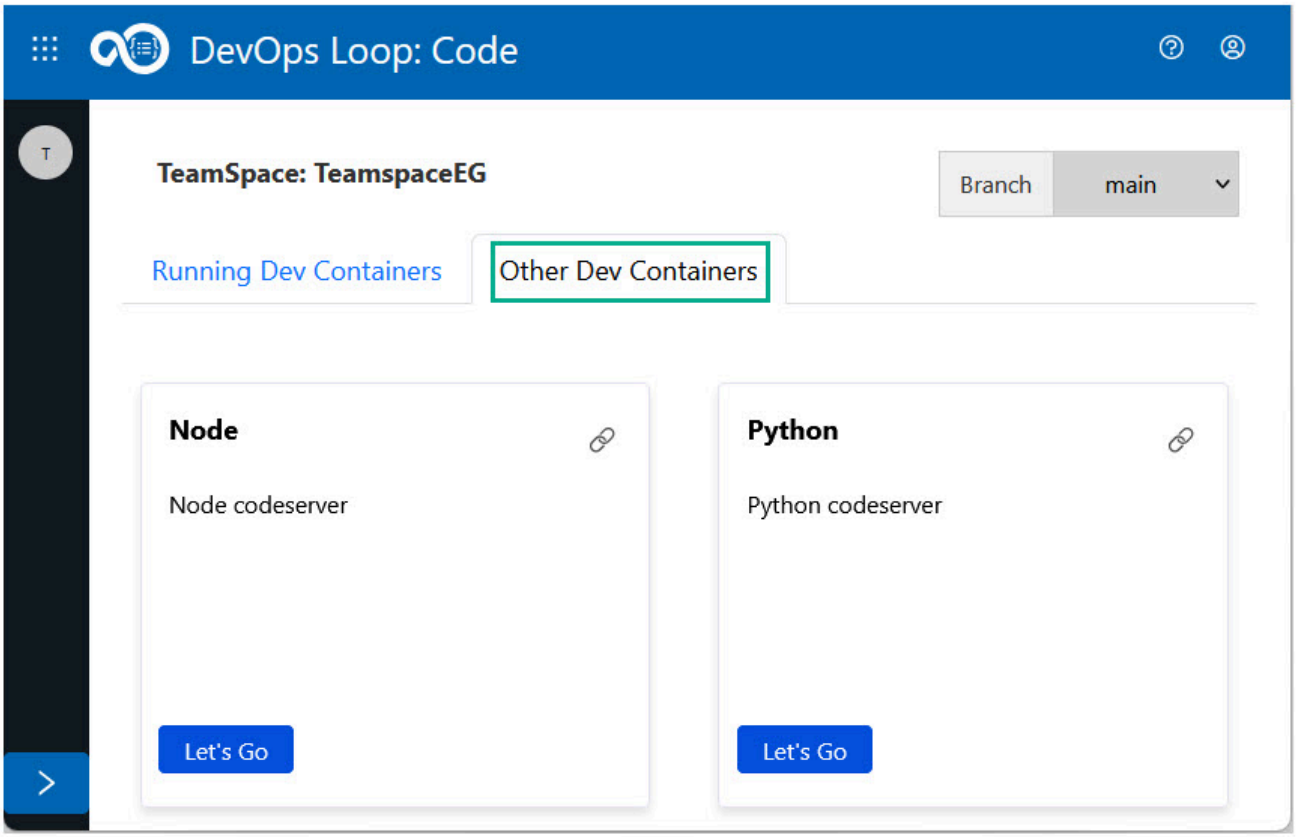
- If you identified an error in the logs, see Configuring dev containers on page 172 to adjust the settings that may be causing the issue.
- If the issue persists, share the downloaded log file with your administrator for further investigation.

Working with dev containers

You can launch a dev container to load your specific development environment and begin active development tasks.

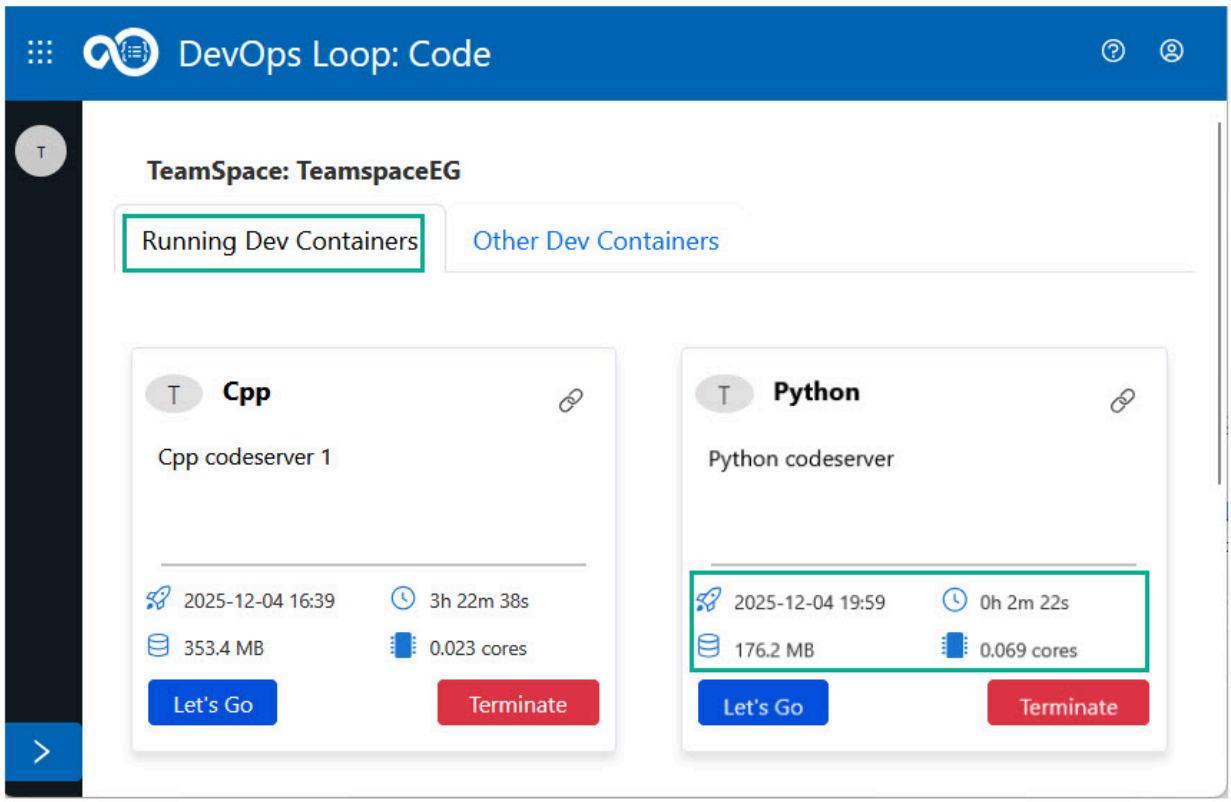
About this task

When you are added to a teamspace, new preconfigured dev containers appear on your landing page under the **Other Dev Containers** tab. Since you have just accessed the workspace for the first time, the **Running Dev Containers** tab will initially be empty. Launching a container moves it to the **Running Dev Containers** tab, where all active environments are managed.



To start working with a dev container:

1. Click the **Let's Go** button on a dev container.
2. The dev container will launch and begin running - this may take some time initially.
3. Once running, the container will move to the **Running Dev Containers** tab.



To optimize performance, Code provides real-time visibility into the resource metrics of your dev containers, such as:

- Launch time and date: The specific date and time the container was started.
- Duration: The total uptime of the container since launch.
- Memory consumption: The real-time RAM usage, measured in Megabytes (MB).
- CPU cores: The number of CPU cores currently utilized by the container.

4. Go to **File** > **Open Folder** to get started, after the Code IDE on page 180 loads.
5. Click **Yes** when prompted with "**Do you trust the authors of the files in this folder?**".
6. Navigate to the workspace directory.
7. You can now start working in your workspace. For example, you can clone a Git repository to populate your workspace with the source code you want to work with.
   Note: This is just a quickstart example. As the environment runs on a VS Code Server, you can install extensions, debug applications with breakpoints and live logs, use terminals and Git integration, and fully customize your dev container with the dependencies you need. Use this as a starting point to explore the full development workflow.

   A video version of the above steps is also available for reference. It demonstrates the full workflow - from accessing Code to running your application in the browser IDE. Watching the video can help you follow along more easily. Learn more about dev containers here on page 162.

   ../videos/new-qs.mp4

Configuring dev containers

As a teamspace admin in Code, you can configure the dev containers so that they are available to the team members.

Before you begin

You must have performed the following tasks:

- Installed Docker and ensured that it is running on your machine.
- Installed Node.js and npm (for Dev Container CLI).
- Created a DockerHub account and enabled it for pushing images.
- Gained access to Control with permission to create repositories.

About this task

You can set up and preconfigure dev containers for users in a teamspace while using Code. You can create and configure the container environment, build an image, publish it to a registry, and make it accessible within the teamspace's configuration repository. These configurations follow the Dev Containers specification and are versioned by pushing them to a Control Git repository.

1. Install the **Dev Container CLI** tool:
   a. Clone the GitHub repository by running the following command:
      ```
      git clone https://github.com/devcontainers/cli.git
      ```
   b. Navigate to the cloned directory and install the following Dev Container CLI:
      ```
      npm install -g @devcontainers/cli
      ```
2. Create the **devcontainer.json** file:
   You can create the devcontainer.json file by defining the metadata such as name, description, build or image source, and runtime Visual Studio Code extensions.
   Here's a **sample devcontainer.json**:
   ```
   {
     "name": "Go Dev Container",
     "description": "A preconfigured Go development environment with code-server support and Go tooling.",
     "build": {
       "dockerfile": "Dockerfile"
     },
     "customizations": {
       "vscode": {
         "extensions": [
           "secure-dev-ops.devops-code",
           "golang.go"
         ]
       }
     }
   }
   ```

Note: In the example above, extensions are specified by their IDs, and will then be downloaded from the Open VSX registry (that is, <publisher.name> format. However, administrators may need to pre-bundle .vsix extension files directly within the dev container image. In such scenarios, especially within

offline environments, you can specify the local .vsix files using a relative path. See Loading extensions from local .vsix files on page 186.

You can also download a sample file here: devcontainer.json

Refer to the Dev Container metadata reference guide to include JSON metadata related to general settings, Docker or Docker Compose-specific options, and tool-specific properties for configuring a devcontainer.js file.

3. Create the **Dockerfile** for custom environment setup:

   You can add a Dockerfile to define the environment and behavior of your development container by specifying the base image, installing tools, setting environment variables, and configuring the container runtime.

   Example **Dockerfile**:

```
FROM ubuntu:20.04
ENV DEBIAN_FRONTEND=noninteractive
RUN apt-get update && \
    apt-get install -y \
        sudo \
        curl \
        git \
        ca-certificates \
        build-essential && \
    apt-get clean

# Install Go
ENV GO_VERSION=1.22.3
RUN curl -fsSL https://go.dev/dl/go${GO_VERSION}.linux-amd64.tar.gz | tar -C /usr/local -xz
ENV PATH="/usr/local/go/bin:${PATH}"
ENV GOPATH="/home/1001/go"
ENV PATH="${GOPATH}/bin:${PATH}"

# Install code-server
RUN curl -fsSL https://code-server.dev/install.sh | sh -s -- --version=4.98.0

# Safe for Ubuntu + RHEL images
RUN chmod -R ug+w /etc/pki/ca-trust/source /etc/pki/ca-trust/extracted || true

RUN useradd -m -u 1001 devuser
USER 1001
WORKDIR /home/1001
CMD ["tail", "-f", "/dev/null"]
```

   Key Commands required for the Dockerfile:

   - FROM: Set the base image.
   - ENV: Set the environment variables.
   - RUN: Install dependencies and clean cache to keep the image lean.
   - USER: Run the container as a non-root user (1001) for security.
   - CMD: Keep the container running by tailing a null file.

To create or customize a Dockerfile for your development container, refer to the official Dockerfile reference. This guide provides detailed explanations and examples of all supported commands. You can also explore dev container documentation for guidance on integrating your Dockerfile into a .devcontainer setup.

Note: If DevOps Loop runs using self-signed certificates or private Certificate Authorities (CAs), the admin must add the line RUN chmod -R ug+w /etc/pki/ca-trust/source /etc/pki/ca-trust/extracted in the Dockerfile before the line USER 1001.

You can download a sample Dockerfile here: Dockerfile

4. Build the **dev container** image:
   Navigate to the root **.devcontainer** directory and run the following command to build the dev container image.

```
devcontainer build --workspace-folder . --image-name sarasonia/go-container:1.0
```

   This command reads the devcontainer.json file and executes the Dockerfile. The syntax should be in the following format:

```
devcontainer build --workspace-folder . --image-name <username>/<container-name>:<tag>
```

   where,
   - **<username>**: Docker Hub username
   - **<container-name>**: your container (repository) name
   - **<tag>**: version (for example, 1.0)
5. Update the **devcontainer.json** file to use the image key:

```
{
  "name": "Go Dev Container",
  "description": "A preconfigured Go development environment with code-server support and Go tooling.",
  "build": {
    "dockerfile": "Dockerfile"
  },
  "image": "sarasonia/go-container:1.0",
  "customizations": {
    "vscode": {
      "extensions": [
        "secure-dev-ops.devops-code",
        "golang.go"
      ]
    }
  }
}
```

6. Push the image to **Docker Hub** registry:
   Login and push.

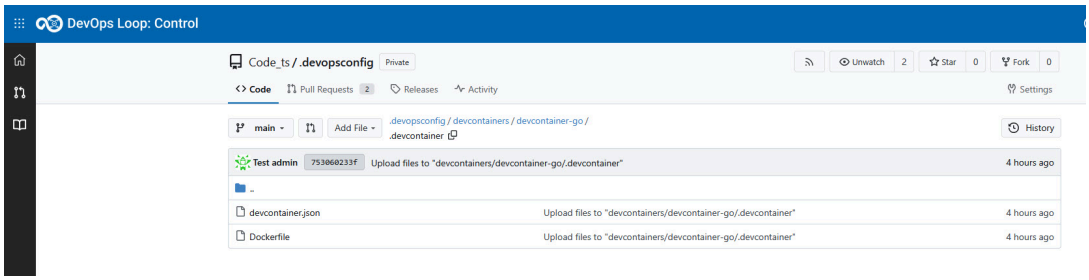
```
docker login
docker push sarasonia/go-container:1.0
```

   After it is pushed, it will be available at: docker.io/devuser/go-container.
7. Access **Control**:

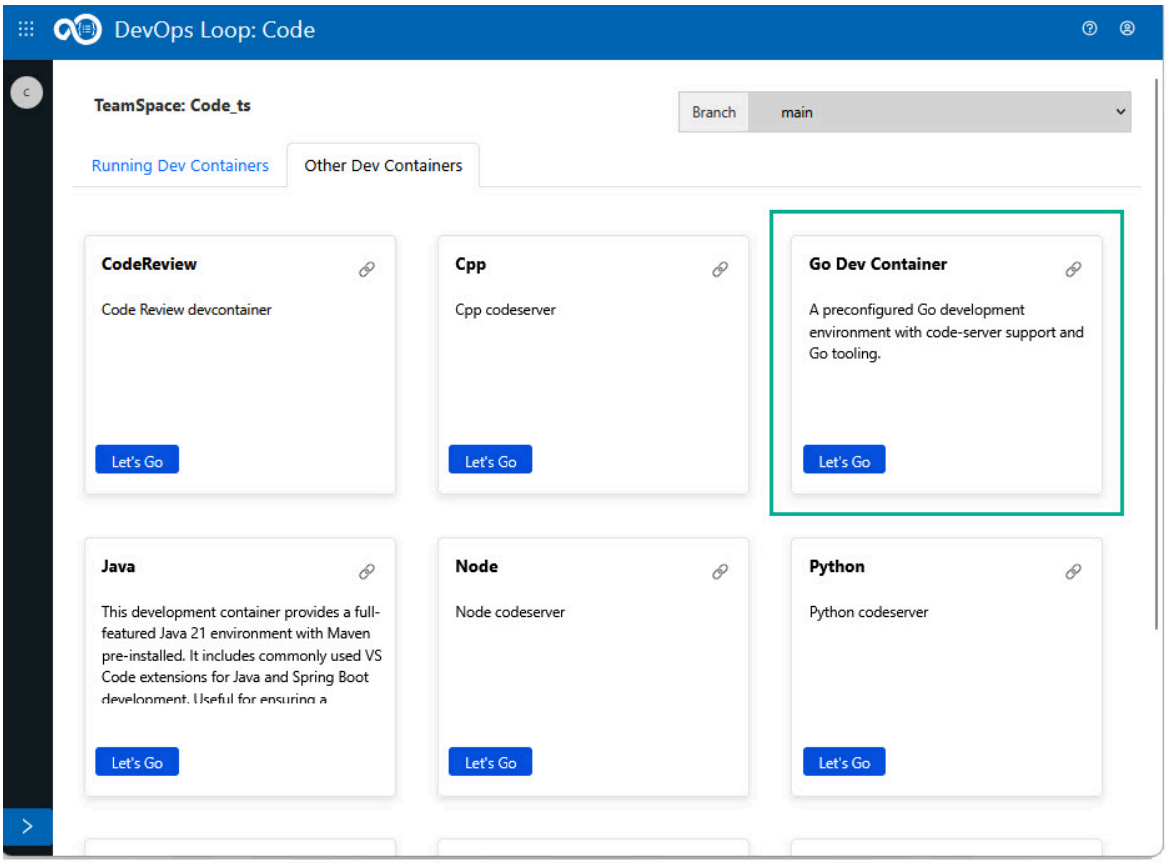
a. Sign in to HCL DevOps Loop. Navigate to your teamspace.
b. Go to the **Control** page. You'll see a repository named .devopsconfig under your teamspace (e.g., TeamspaceEG/.devopsconfig).

8. Upload **devcontainer.json** and **Dockerfile** using Control:
    a. Inside the **.devcontainer** folder of the repo, upload devcontainer.json and Dockerfile.
    b. Commit and push the changes to the main branch.

> **Note:** You can also commit the changes to a different branch other than the main branch. In such a case, you will see different branches on the Branch menu.



9. Start the sample **Go container**:
    a. Go to the Code landing page.
    b. Click the **teamspace** button and switch to your teamspace on page 161. Under **Other Dev Containers**, you will see a new dev container:

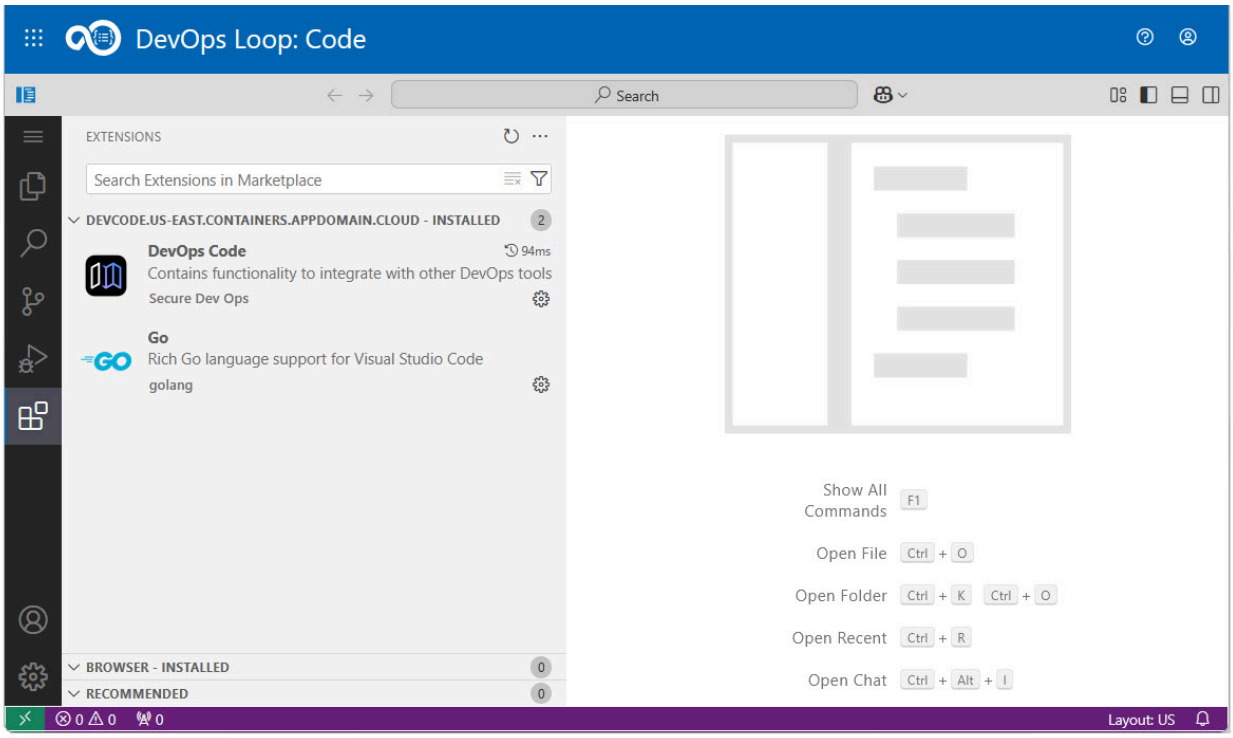


c. Click **Let's Go** to launch the container.

Note: The first-time launch may take a few minutes.

10. View **Visual Studio Code** Extensions:

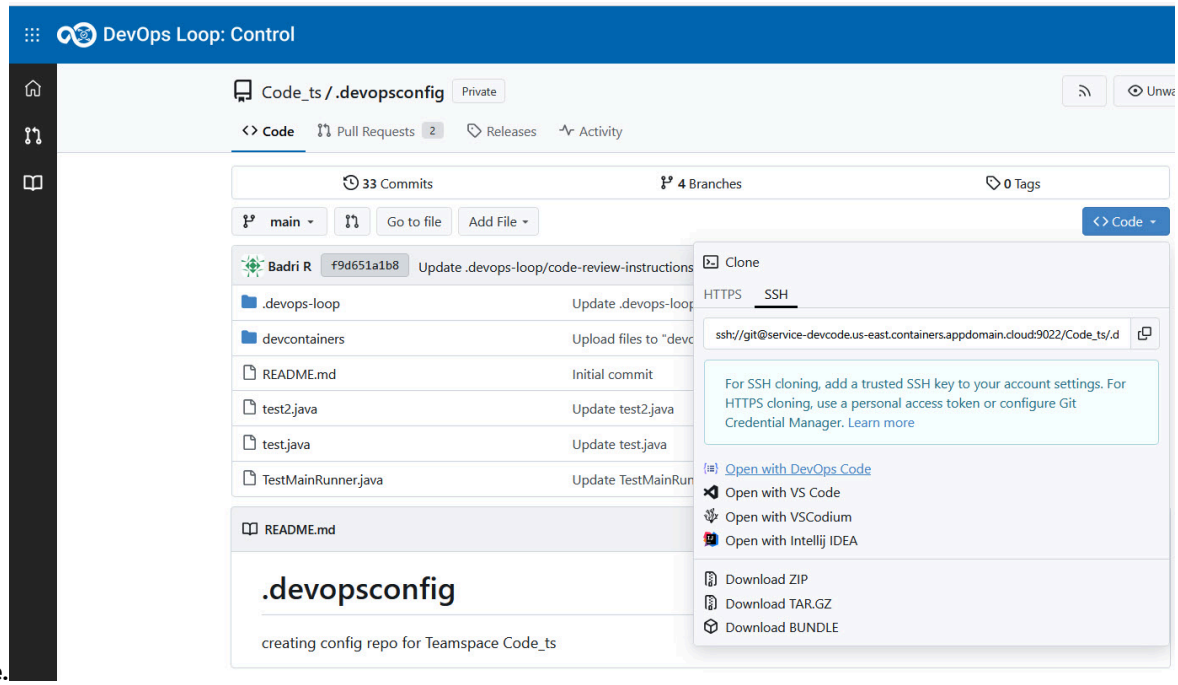
    In the Code IDE instance, click the **Extensions** button to see and verify the extensions you had configured in **devcontainer.json** file.



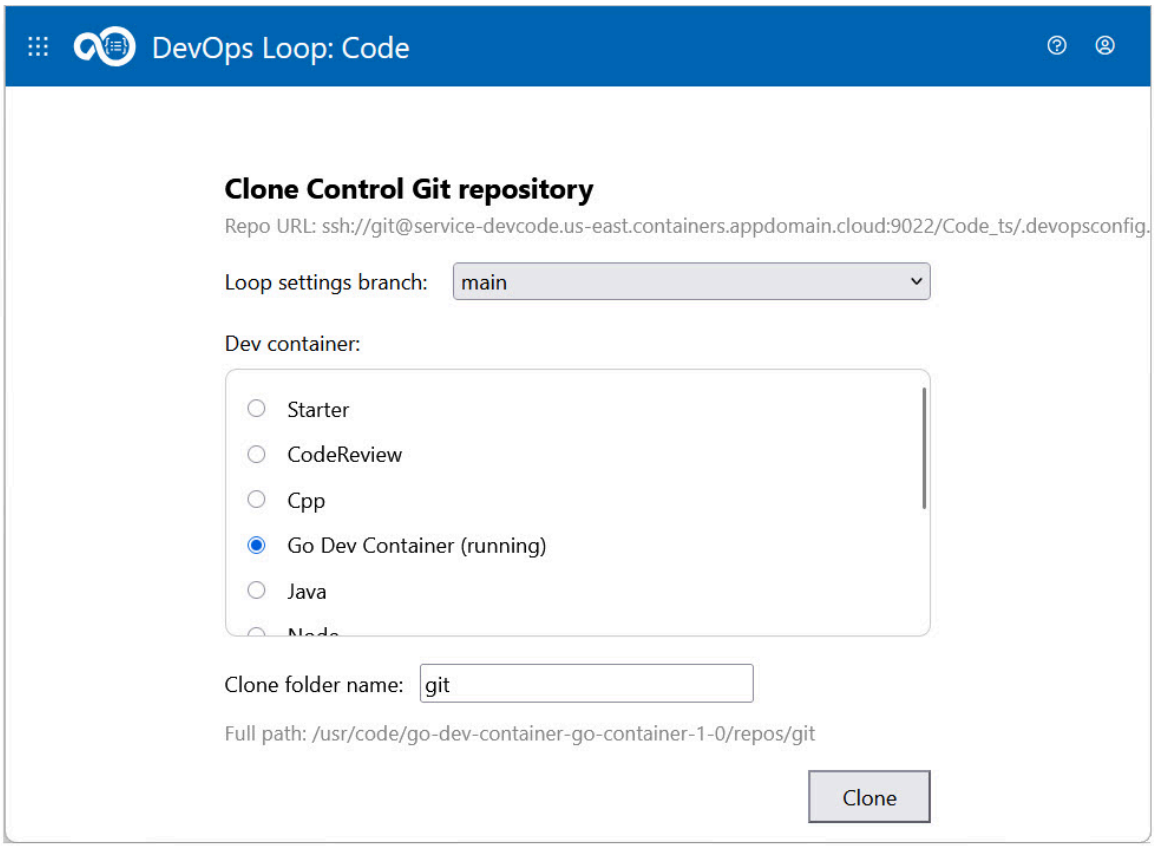
11. Cloning .devopsconfig repo using **DevOps Code**:
    After navigating to the Control page and locating the .devopsconfig repository, you can update your configuration files using the recommended workflow.

    This method is recommended for making multiple changes, as it provides an easier user experience by leveraging the Git functionality within Code.

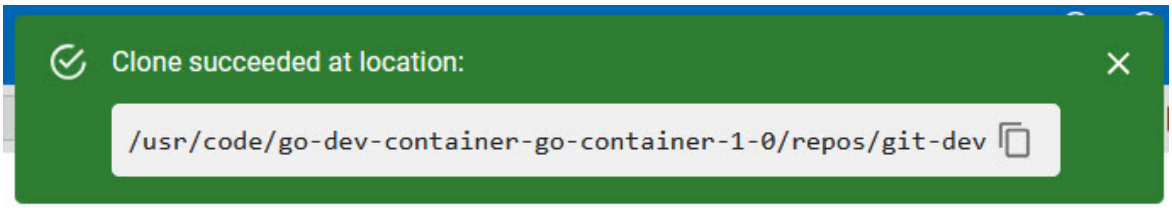
a. Click the **Code** dropdown button next to the repository name, and select **Open with DevOps Code.**



b. This directs to the **Clone Control git repository** page. Here, add the **Loop settings branch**, **Dev container** and a suitable **folder name** for cloning. You can see how the full path changes according to the name you updated in the **Clone folder name** textbox.



c. Click **Clone** to clone the repository. This directs to Code IDE instance. After successful loading of the IDE page, you get a **Clone succeeded at location** message popup. Copy the location.



d. In the Code IDE instance, go to the hamburger menu, select **File** and click **Open Folder**, and paste the location path in the **Go to file** dropdown textbox, and click the **OK** button.
e. Navigate to the devcontainer folder in the left Explorer pane, add/update your devcontainer.json and Dockerfile files, and use the built-in Git tools within **Code** to commit and push the changes to the desired branch of **Control**.

Results

The custom container image has been successfully built and published to the Docker registry. The image is now ready to be configured for use within your teamspace.

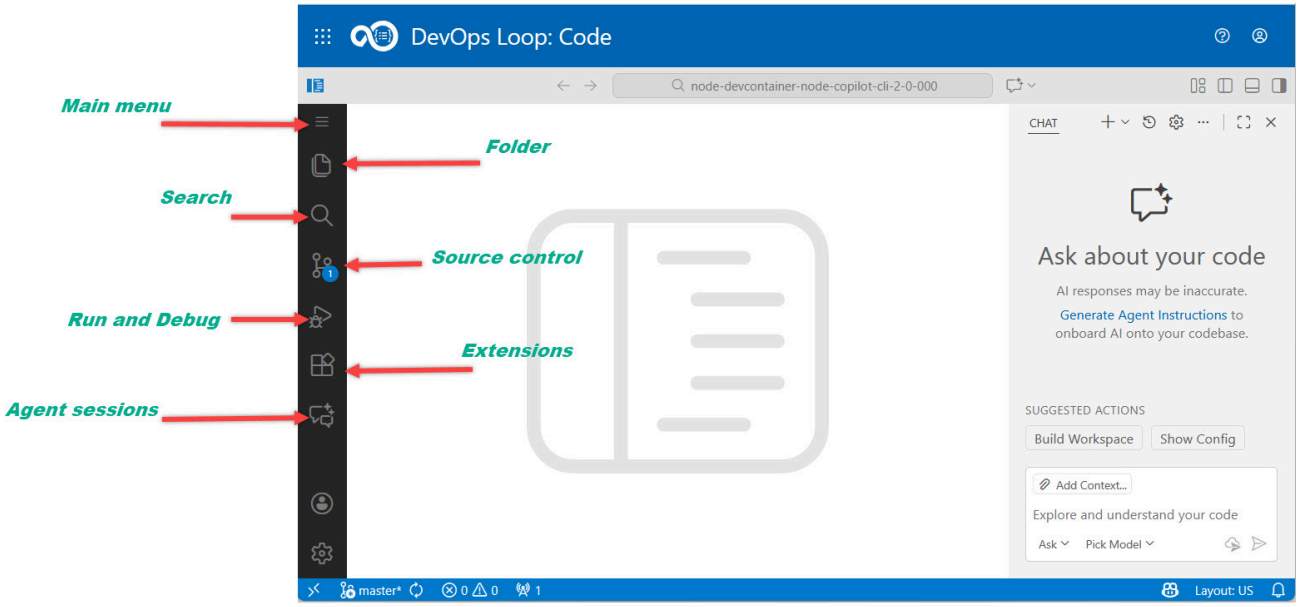
What to do next

- After you configure dev containers for teamspaces, members in a team can launch any dev container directly from their Code landing page.
- If you are working in an air-gapped environment and want to clone repositories correctly, see Fixing Git clone in air-gapped on page 198 environment.

Code IDE user interface

The Code IDE user interface offers key features that are designed to facilitate navigation, file management, source control, debugging, and extension management within the browser IDE.

The following image shows the user interface with a vertical toolbar on the left-hand side of the Code IDE.



The following table lists the main highlights of the Code IDE user interface:

Menu items	Description
Main (hamburger menu)	Opens a collapsible side menu in a dropdown, and includes general menu items such as File, Edit, Selection, View, Go, Terminal, and Help. These menus are mostly the same as those that are present in the main toolbar of Visual Studio Code.
Buttons	
Folder	Opens the Explorer panel that provides tree-like navigation of the workspace structure.
Search	Provides the search and replace functionality for files in the workspace.
Source control	Provides the source control panel from which you can perform commands on Git repositories that are used in your workspace.

Menu items	Description
Run and Debug	Provides common actions for running and debugging applications.
Extensions	Provides a menu to manage extensions.
Agent sessions	Provides a view to manage and monitor ongoing AI-powered autonomous tasks, allowing you to interact with AI agents.

For more information about the UI of the browser IDE, refer to the documentation of Visual Studio Code.

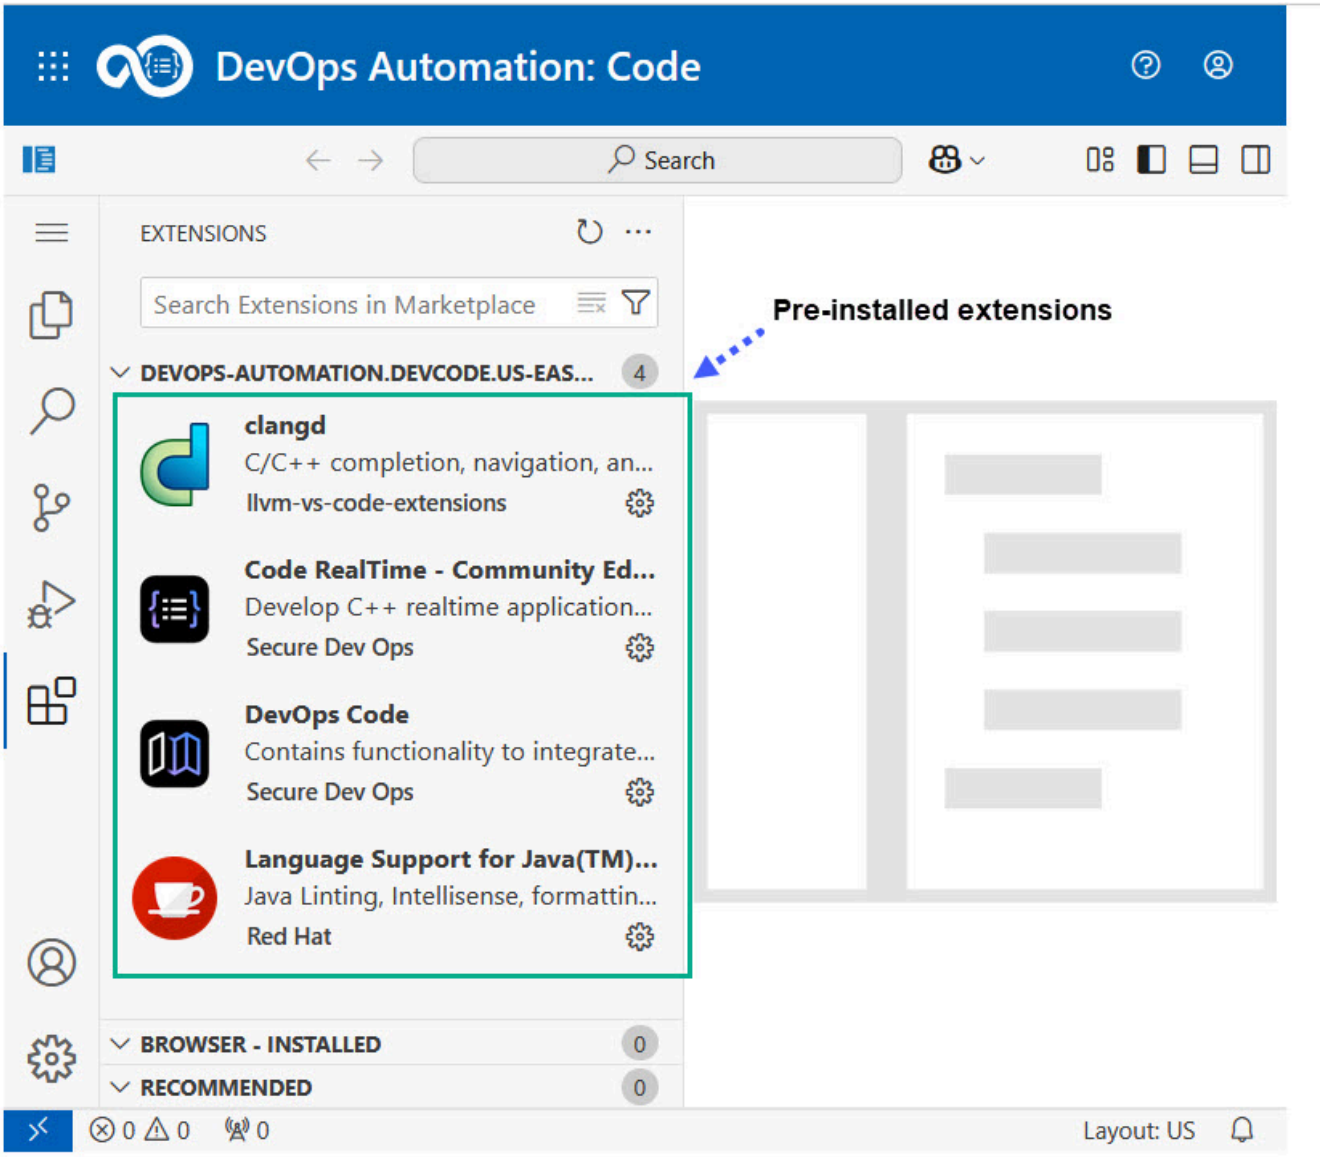
Extensions in dev containers

You can use extensions to specialize the Code IDE, integrating tools for coding, debugging, version control, and more. You can deploy them during initial project setups or to ensure workflow consistency in containerized and offline environments.

Preinstalled extensions

Your administrator can configure dev containers with preinstalled extensions during setup. These extensions are defined in the devcontainer.json file and sourced from the Open VSX Registry. For details on how to configure these in the devcontainer.json, refer to the Administrator Guide on page 172.

The following image shows a simple example of preinstalled extensions available in Code when you launch a dev container.



While working in your browser-based IDE, you can also perform the following tasks:

- Install additional extensions directly from the Open VSX Registry from the Extensions button in the left toolbar of the IDE.
- Install local VSIX files if needed on page 186.
- In an air-gapped environment, install extensions from your organization's configured local extension registry instead of the public Open VSX Registry. For more information, see Configuring extension registry on page 187 and Installing extensions in air-gapped environment on page 190.

File management features

You can transfer files between your local computer and dev container, and simplify your development workflow.

The following section outlines the key features provided by Code for file management:

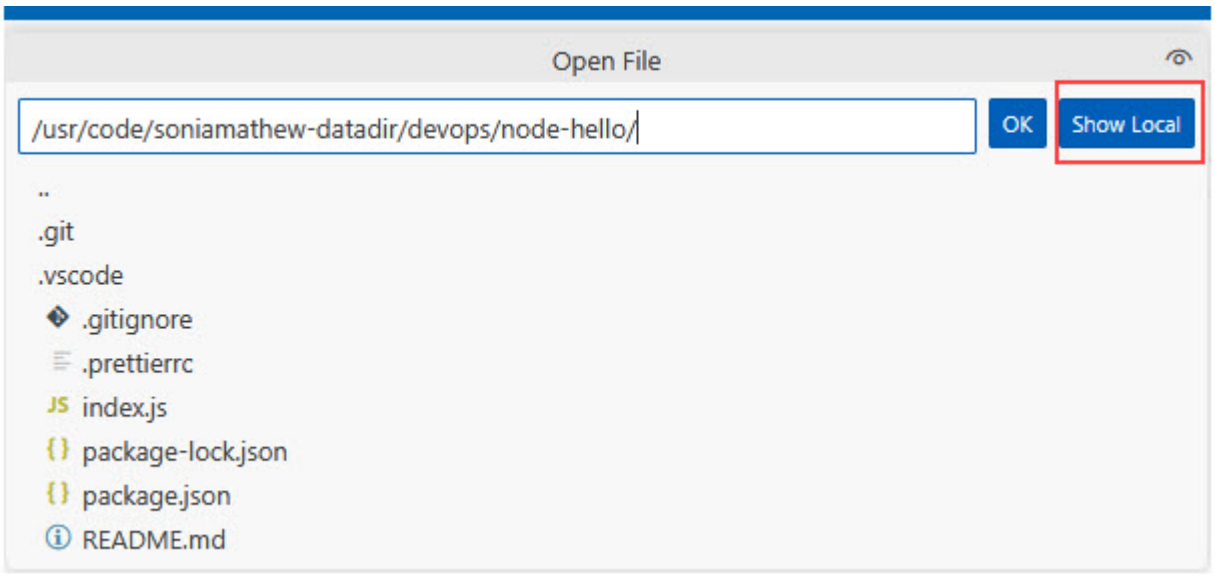
Drag and Drop

Code provides a drag-and-drop feature that simplifies file management, so that you can effortlessly transfer files between your local computer and the dev container. You can simply drag files from your local system and drop them into the Explorer view of the Code IDE to add them to a workspace folder.

../videos/drag-drop.mp4

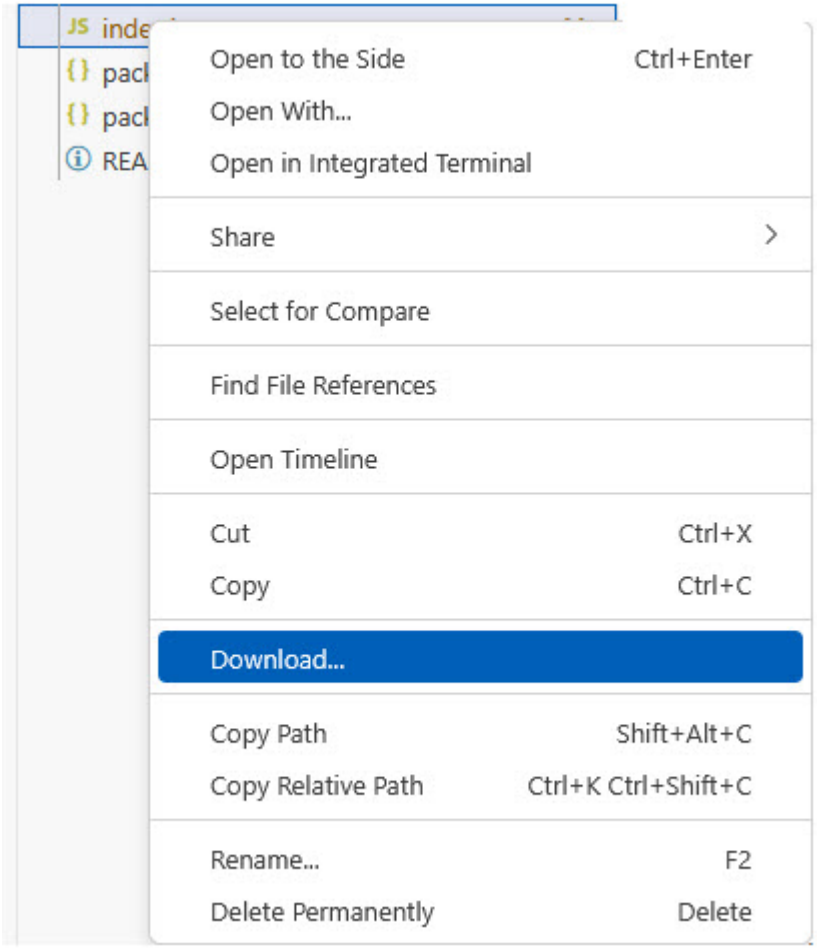
Browse local files

Code provides the **Show Local** button feature, which allows you to browse files from your local machine. This gives you the option to choose between using the file system of your local computer or that of the dev container.



Download

Code provides the **Download** option to easily download files and folders from the server IDE to your local system. Simply right-click on the required file or folder, select the **Download** option, and the file will be transferred to your local machine for backup.



Access applications via automatic port forwarding

You can access applications running within your dev container from your local machine as Code automatically detects and forwards listening ports (7000–8000), to ensure uninterrupted interaction with containerized services.

Note: The dev container uses some ports internally and reserves the port range 7000 - 8000 for your application to use.

When Code detects that an application is running in the dev container and listening on a port, it automatically forwards the port, making it accessible outside the container. For example, you can connect to applications running within the dev container from your local machine.

../videos/auto-port-forwarding.mp4

File system in dev containers

Understanding the file system structure in a dev container helps you organize your work effectively and maintain compatibility across different development environments.

File system tree

You can store your files in or below the /usr/code root directory. This works like a shared directory across all dev containers, ensuring your files remain persistent and accessible.

```
/usr/code/                                    [ROOT DIRECTORY - Shared files
accessible from all dev containers]
│
├── dev-container-1/
│   ├── (your project files)
│   ├── data directory/           [RESERVED - DO NOT MODIFY]
│   └── extension/                [RESERVED - DO NOT MODIFY]
│
├── dev-container-2/
│   ├── (your project files)
│   ├── data directory/           [RESERVED - DO NOT MODIFY]
│   └── extension/                [RESERVED - DO NOT MODIFY]
│
├── dev-container-3/
│   ├── (your project files)
│   ├── data directory/           [RESERVED - DO NOT MODIFY]
│   └── extension/                [RESERVED - DO NOT MODIFY]
│
├── ...
│
└── (additional shared files/repositories)
```

Container-specific directories

You will find each dev container has its own subdirectory under /usr/code where you can create and organize your project files, source code, configurations, and cloned repositories.

You will see two system-managed directories in each container:

- data directory: Contains system-managed data

- extension: Contains system-managed extension files

Note: You must not modify these directories as changes may cause your dev container to malfunction.

Shared files

You can place files directly under /usr/code to make them accessible from any dev container. This is useful for common configurations, shared libraries, or cross-environment projects.

Loading extensions from local `.vsix` files

Using Code, you can install and activate extensions in an offline or air-gapped environment by loading them from local .vsix files specified in the dev container configuration.

About this task

You can load extensions from a local .vsix file by specifying a relative path. This approach allows offline or air-gapped environments to activate extensions and is also necessary for proprietary extensions that should not be published publicly, without requiring access to the Open VSX registry.

1. Place your .vsix extension files into a local folder, such as extensions/ inside a cloned .devopsconfig repository: This allows offline environments to access the extensions without connecting to the Open VSX registry.
2. Reference the local .vsix files in your dev container configuration file (devcontainer.json):

   devcontainer.json example:

   ```
   {
     "name": "Node",
     "description": "Node codeserver environment with offline extensions",
     "build": {
       "dockerfile": "./Dockerfile"
     },
     "customizations": {
       "vscode": {
         "extensions": [
           "IBM.wca-core-1.6.2.vsix",
           "ms-python.python-2025.14.0.vsix"
         ]
       }
     }
   }
   ```

   You can specify the exact version of each extension you want to install and control updates centrally.
3. Update your Dockerfile to copy the extensions folder into the container during build:

   Dockerfile example:

   ```
   FROM mcr.microsoft.com/devcontainers/javascript-node:1-22-bookworm

   ENV DEBIAN_FRONTEND=noninteractive

   RUN apt-get update && \
   ```

```
    apt-get install -y sudo curl git gnupg pass pinentry-tty && \
    apt-get clean

RUN curl -fsSL
 https://github.com/git-ecosystem/git-credential-manager/releases/download/v2.6.1/gcm-linux_amd64.2.6.1.
tar.gz -o gcm.tar.gz \
    && tar -xvf gcm.tar.gz -C /usr/local/bin \
    && rm -rf gcm.tar.gz \
    && git-credential-manager configure

RUN curl -fsSL https://code-server.dev/install.sh | sh -s -- --version=4.103.2

COPY extensions /opt/extensions/

USER 1001

CMD ["tail", "-f", "/dev/null"]
```

This ensures the extensions are installed automatically when the container is set up.

4. Build and run the dev container:
   The extension manager will detect the local .vsix files and install them during container startup.

Results

You have successfully installed and activated extensions in your dev container using local .vsix files. The extensions are now immediately available for use.

What to do next

If you need to manually search for and install additional extensions inside an active air-gapped dev container from your local extension registry, see Installing extensions in air-gapped environment on page 190.

Configuring extension registry

You can configure a local or an on-premises extension registry in Code as an admin to ensure that only approved extensions are available to team members within your teamspace.

Before you begin

Before you begin:

- Gained access to DevOps Control with permission to create repositories.
- Download the required .vsix extension files from a trusted source, or use non-published extension files that you have access to. You can visit the specific extension's page in the Open VSX registry, download the desired stable release's .vsix file. Generally, prerelease versions are also listed in Open VSX and only release versions are recommended for deploying.
- Read Authenticating with DevOps Code UI on page 192.

About this task

An extension registry decides which extensions are available in your teamspace. Regardless of which configuration you choose, only administrators can upload extensions to the registry, and teamspace members can only view and install the extensions that an administrator has approved and published.

There are three ways to configure the registry:

1. **Control repository storage** - Extensions are stored and versioned in the **.devopsconfig Control** repository. Requires a manual commit and push after each deployment.
2. **Persistent Volume Claim (PVC) storage** - Extensions are stored on a persistent volume. Deployment is automated; no commit or push required. The default capacity of the storage is 20 GB.
3. **On-premises Open VSX instance** - Extensions are hosted and managed on your own Open VSX instance.

The following table compares the three configurations:

Table 5. Registry configuration comparison

Configuration	`extensions_gallery` value	`storage_type` value	Commit/push required?
Control repository storage	`local`	`control`	Yes, after every deployment
PVC storage	`local`	`pvc`	No, deployment is automated
On-premises Open VSX	`<your-onprem-openvsx-url>/vscode/gallery/extensionquery`	Not applicable	Not applicable

The **DevOps Code** extension provides commands that you can use as an administrator to deploy and manage extensions within the extension registry. The key commands provided by the **DevOps Code** extension in the cloud IDE are:

- **DevOps Code: Deploy to Extension Registry** - Deploys extension files to the registry.
- **DevOps Code: Fetch from Extension Registry** - Refreshes the registry after new extensions are pushed to the repository.

Note: These commands apply only when `extensions_gallery` is set to `local` (Control repository or PVC storage). They are not applicable when using an on-premises Open VSX instance.

Set Registry Configuration

1. Choose one of the three configurations and update `settings.json` in the repository root accordingly:

   Based on the comparison above, decide whether you want to use Control repository storage, PVC storage, or an on-premises Open VSX instance, then add the corresponding values to `settings.json` as shown below.

   a. Option A - Control repository storage:

   ```
   {
       "extensions_gallery": "local",
   ```

```
    "storage_type": "control"
}
```

b. Option B - Persistent Volume Claim (PVC) storage:

```
{
    "extensions_gallery": "local",
    "storage_type": "pvc"
}
```

c. Option C - On-premises Open VSX instance:

Set `extensions_gallery` to the hosted URL of your Open VSX instance, appended with the `/vscode/gallery/extensionquery` path. The `storage_type` parameter is not applicable for this configuration, since extensions are hosted and managed by your on-premises Open VSX instance rather than by Code.

```
{
    "extensions_gallery": "<your-onprem-openvsx-url>/vscode/gallery/extensionquery"
}
```

d. Supported parameter values:

The `extensions_gallery` parameter supports these values:

- `local`: Uses the administrator-controlled registry (Control repository or PVC storage).
- `disabled`: Prevents the user from installing new extensions from the Code IDE.
- `default`: Uses the public Open VSX registry.
- A URL ending in `/vscode/gallery/extensionquery`: Uses an on-premises Open VSX instance hosted at that URL.

The `storage_type` parameter supports these values:

- `control`: Stores extensions in the .devopsconfig **Control** repository.
- `pvc`: Stores extensions on a persistent volume.

2. Add approved extensions in Code:

Note: This step applies only to local registry configurations (Control repository or PVC storage). It is not applicable when using an on-premises Open VSX instance.

a. Select **Open with DevOps Code** to clone the .devopsconfig Control repository in on page 192 Code.
b. After cloning the main branch of the .devopsconfig repository in Code, create an `extensions` folder in the repository root if one does not exist. Note that you can also create other branches and version the extensions on different branches.
c. Upload the `.vsix` files into the `extensions` folder.

3. Deploy and publish the extensions:

Note: This step applies only to local registry configurations (Control repository or PVC storage). It is not applicable when using an on-premises Open VSX instance.

a. Right-click the `.vsix` file in the Explorer pane and select **Deploy to Extension Registry**.
A dialog confirms that the extension was deployed successfully. If you chose Control repository storage, the extension folder is created inside `extensions` in the Control repository, and the extension is not available to teamspace members until you commit and push the changes. If you chose PVC storage, deployment is automated and the extension becomes available without any further commit or push.

4. If you chose Control repository storage, commit and push the changes to **Control**. Skip this step if you chose PVC storage, where deployment is automated:

a. Commit the following items:
- `extensions` folder
- `settings.json` file

b. Push these changes to the Control repository.
After the push completes, the extension is published to the registry and is available to all team members.

5. Refresh the extension registry:

The registry does not automatically detect new extensions immediately after a push.

a. As an administrator, open the Command Palette and run **DevOps Code: Fetch from Extension Registry** to refresh the registry content and test that the deployment succeeded.
A notification confirms that the registry refresh is complete, and you can search and see the new extension(s). Other teamspace members do not need to run this command; searching for the extension in the Extensions view automatically triggers a rescan and shows the newly deployed extension in the results.

Results

The extensions are now available in the registry. Members in a teamspace can view and install only the extensions that you have added and published.

What to do next

- Install the extensions approved by administrator from the Extensions view in Code.
- Learn how to install extensions manually for air-gapped environment. See Installing extensions in air-gapped environment on page 190.

Installing extensions in air-gapped environment

You can manually install required extensions inside a custom dev container when operating in an air-gapped environment.

Before you begin

Before installing extensions in an air-gapped dev container, review the following prerequisites:

- **Administrator prerequisite:** Ensure that an administrator has configured your local extension registry and published the required extensions. For details, see Configuring extension registry on page 187.
- Ensure that an administrator has configured the custom dev container specification for your teamspace. For details, see Configuring dev containers on page 172.
- Learn how extension installation and lifecycle management work within containers by reading Extensions in dev containers on page 181.
- Familiarize yourself with the layout of the Code browser IDE by reviewing Code IDE user interface on page 180.
- If you prefer to automate extension installation during container builds rather than installing them manually, see Loading extensions from local .vsix files on page 186.

About this task

In an air-gapped environment, custom dev containers (such as a Java dev container) do not automatically install extensions upon launch — except for the DevOps Code extension.

Once an administrator has configured the local extension registry, developers can manually locate and install approved extensions inside their running dev container session.

1. Launch your custom dev container in Code.
2. In the primary sidebar, click the **Extensions** icon to open the Extensions view.
3. Search for the required extension hosted in your local registry and click **Install**.

Results

The selected extensions are now active and operational inside your active dev container session.

Git authentication for dev containers

You can use Git within a dev container to ensure version control and collaboration while keeping your environment isolated.

There are many authentication methods specific to configuring Git in dev containers, including UI feature, personal access tokens and device code authentication.

- DevOps Code UI (Recommended and Easier) on page 192
- Personal Access Token (PAT) on page 195
- Device Code (GPG) on page 196

If you are working in an air-gapped environment, a workaround is required to clone repositories. See Fixing Git clone in air-gapped environment on page 198.

Note: For information on configuring Git credentials using Control Repositories, see Managing Git authentication for developers.

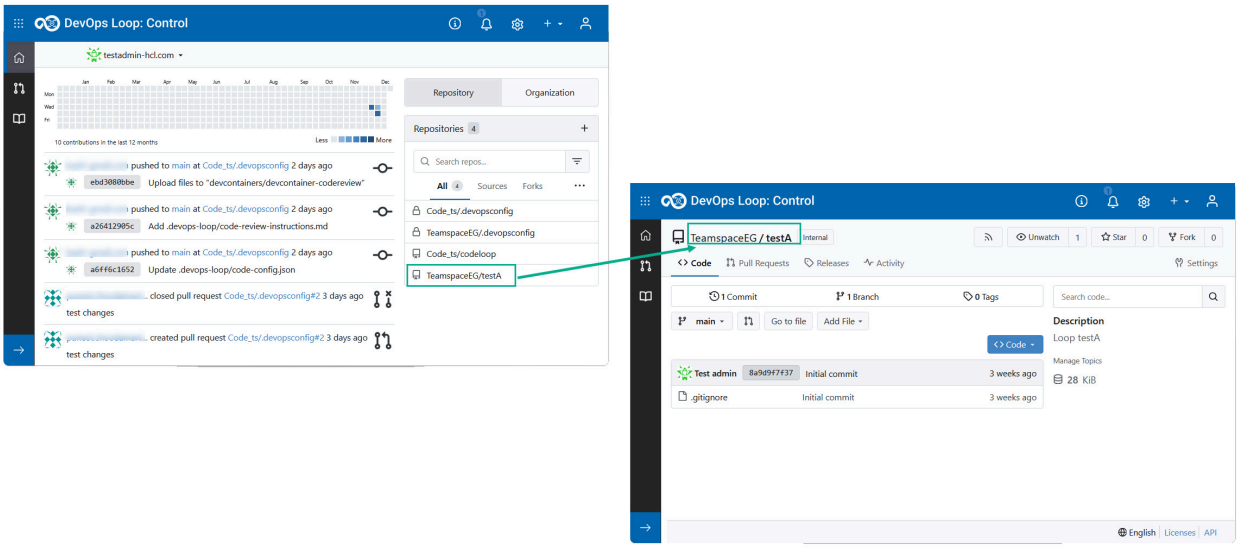
Authenticating with DevOps Code UI (Recommended)

You can create a personal access token in Control, and then use that as your password when authenticating from Code. This type of authentication is based on SSH keys, which are automatically generated for your dev container and registered with Control.

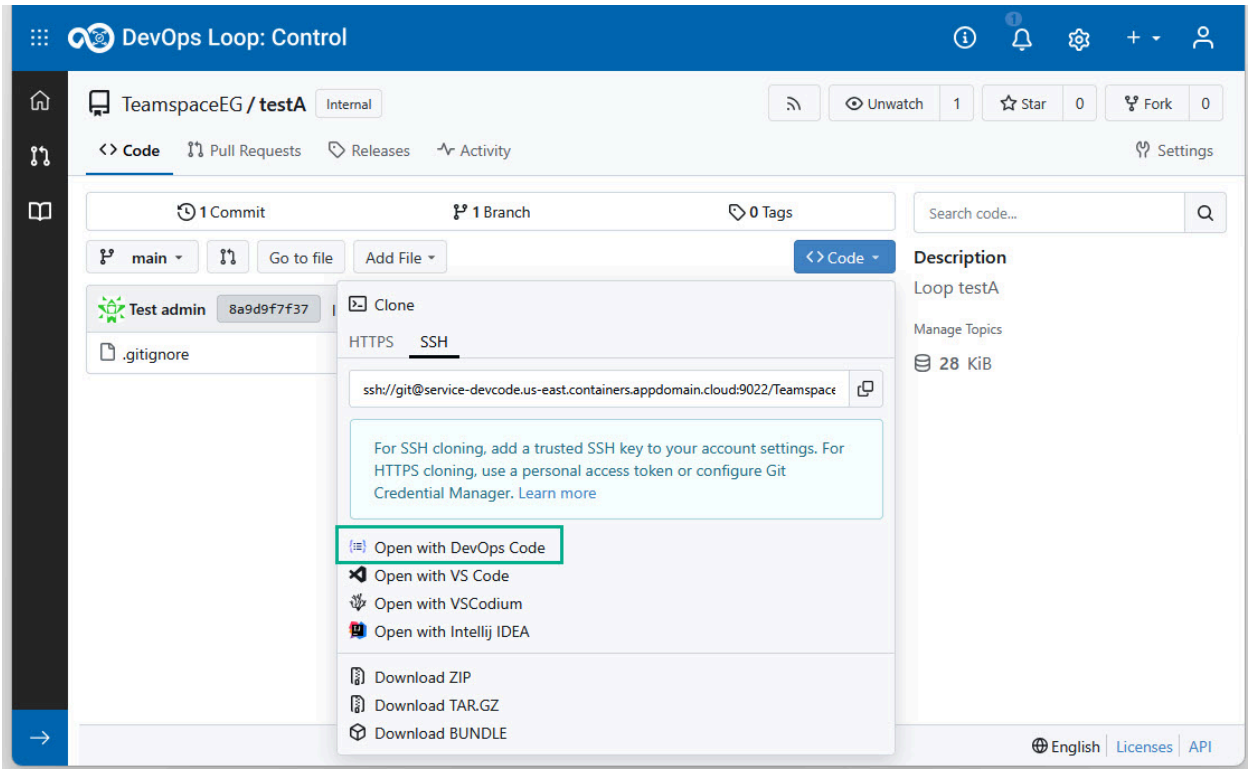
About this task

You can use this procedure to clone a **Control** repository and push changes using **Code**.

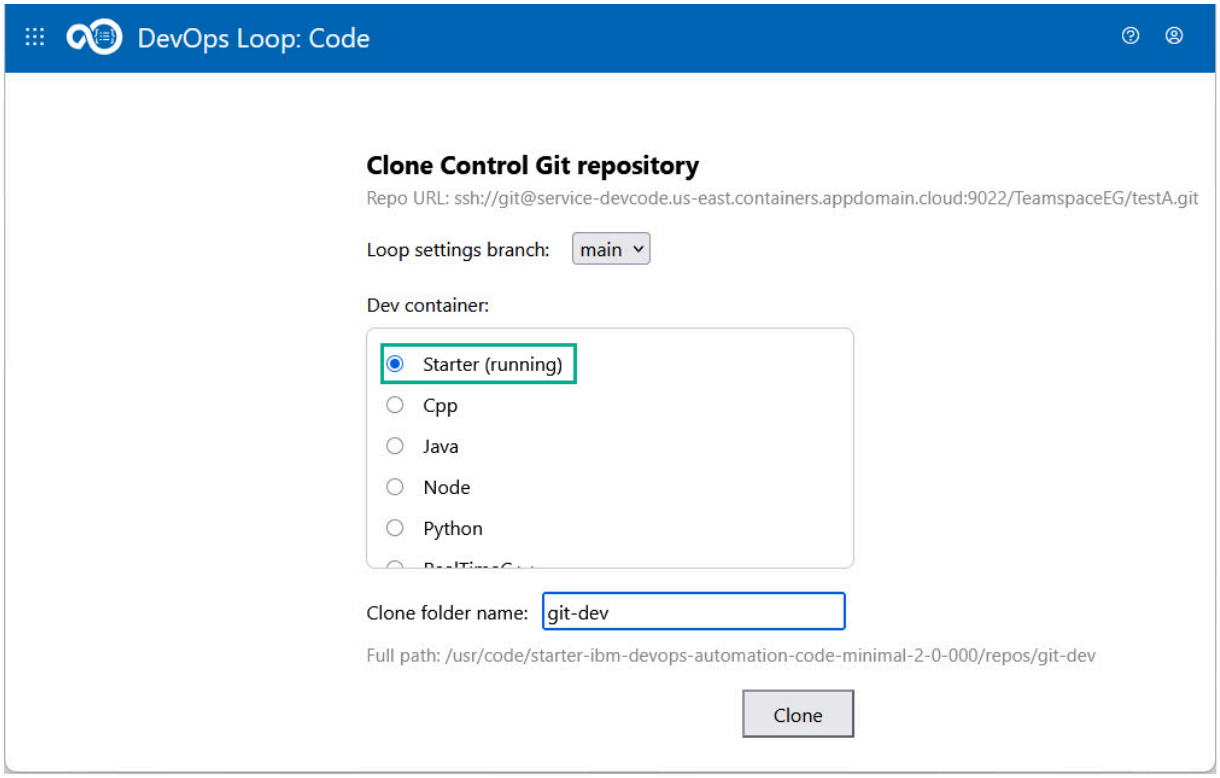
1. Navigate to the Control repository you wish to clone:



2. Click **Open with DevOps Code**.



3. You will be redirected to the **Clone Control Git repository** page.



Configure the repository settings:

a. Select the **Loop settings** branch. This is the branch from where you can fetch available dev containers that you choose to use.
b. Select **Dev container**. The procedure will be faster if you select a dev container that is already running. Otherwise, the dev container will first be launched before beginning a cloning.
c. Enter a valid folder name in the **Clone folder name** field.

> **Note:** The **Full path** field will automatically update on page 184 to reflect the folder name you enter.

d. Click **Clone**. The Code IDE instance will open, and the repository will be cloned.

4. Copy the clone location:
   a. Wait for the IDE page to load completely.
   b. Locate the **Clone succeeded at location** notification popup.

   c. Copy the file path displayed in the message.
   d. Open something from the cloned repository in the Code IDE. Choose one of the following alternatives:
      - Open the repository root folder (which you copied above), or one of its subfolders, as a workspace folder: **File > Open Folder**
      - Add the repository root folder (which you copied above), or one of its subfolders, to a workspace that is already open: **File > Add Folder to Workspace**
      - Open a .code-workspace file from the cloned repository: **File > Open Workspace from File**

5. Commit and push your changes:
   Use the built-in Git source control tools within the IDE to commit your updates and push them to the desired branch.

Authenticating Git with personal access token

You can securely clone a Git repository from your Control system. You can use it as a secure alternative to other Git authentication methods for accessing files in your dev container.

Before you begin

You must have performed the following task:

- Read File system in the dev container on page 184.
- Read How to generate and use Personal Access Token in Control.

About this task

The following method outlines how to clone a Git repository in Code using a Personal Access Token (PAT).

1. **Generate a Personal Access Token**
   a. Navigate to your **Settings** in Control to generate a PAT.
   b. To generate a personal access token, click the **Access Tokens** tab in Settings.
   c. Add the Token Name, and set all permissions to Read and Write.
2. **Construct the clone URL for repository owned by username or organization ID**
   a. The URL for cloning is structured with your username and the PAT. For example, assume your username is code@example.com, DevOps Loop is deployed at mydomain.com and your Control repository has the name repo-name, then the cloning URL will look like this:

      https://code-example.com:PAT@mydomain.com/control/code-example.com/repo-name

   b. Note that the @ in the username is replaced with a hyphen (-) in the URL.
   c. Replace PAT with the personal access token you generated in Control.

      Note: When creating a repository in Control, the **Owner** tab gives you two options: username or teamspace/organization ID. This choice dictates the correct structure for the clone URL.

      For a teamspace-owned repository, the teamspace ID must be used as the organization_identifier (the second-to-last part of the URL path) for the clone operation to succeed.

      https://code-example.com:a1b39ac1e546af4dc664ba36f4b12e77f8dad2da@mydomain.com/control/teamspace ID/repo-name

3. **Clone the Repository**
   You can clone the repository either via the terminal or UI:
   Using Terminal:
   a. Run the full git clone command with the constructed URL

      git clone https://code-example.com:<PAT>@mydomain.com/control/code-example.com/repo-name

   Using UI:

a. Go to the Source Control page in the IDE.
b. Click the Clone Repository button in the UI.
c. Paste the constructed clone URL into the input box.
d. Choose the target folder (e.g., /usr/code/repos).
e. Click Clone to start cloning.

Results

The Git repository is successfully cloned to your target folder. You can now begin working with the cloned files in your dev container.

Authenticating Git with device code

You can set up a GPG key and password store within your dev container to perform Git operations securely and establish a robust authentication layer to clone, commit, and push changes to your repository.

Before you begin

You must have performed the following task:

- Read File system in the dev container on page 184.

About this task

The process involves creating a GPG key, initializing a password store, and then using a device code or passphrase to perform Git operations. https://docs.github.com/en/authentication/managing-commit-signature-verification/generating-a-new-gpg-key

1. **Launch the dev container**
   a. From the launcher in DevOps Loop, click the **Code** button.
   b. Run the dev container to start the Code IDE instance.
   c. After the container is running, open a new terminal by clicking the **Explorer** button in the right vertical toolbar and selecting Terminal.

   All subsequent steps must be run as commands from this terminal.
2. **Configure a GPG Key**
   a. In the terminal, run the following command to create a GPG key with a passphrase

      ```
      gpg --full-generate-key
      ```

   b. When prompted, select "RSA and RSA (default)", which is the first option, as the key type.
   c. Specify the desired key size and how long the key should be valid.
   d. Once the key longevity is provided, you will get a prompt showing the key's expiration date. You need to confirm if this date is correct.
   e. The key identification process will then ask for a User ID, which includes your real name, email address, and an optional comment. During this step, you may be instructed to perform actions like moving your mouse or typing on the keyboard to generate enough "entropy".
   f. To protect your new key, you will be prompted to enter a passphrase.

g. After the key is generated, you will see a line that says

   gpg: key <GPG Key> marked as ultimately trusted

   This confirms the key's creation.

h. If the key is not printed properly, use this command:

   gpg --list-secret-keys --keyid-format LONG

3. **Initialize the Password Store**
   - Use the following command to initialize the password store with your key.

     pass init <GPG Key>

     A message similar to the following confirms that the password store has been initialized and a directory (e.g., /usr/code/starter-ibm-devops-automation-code-minimal-1-0-300/.password-store/) has been created:

     mkdir: created directory '/usr/code/starter-ibm-devops-automation-code-minimal-1-0-300/.password-store/'

     Password store initialized for <GPG Key ID>

4. **Export an environment variable**
   You have to export an environment variable each time you open a new terminal.
   export GPG_TTY=$(tty)
5. **Perform Git Operations via Terminal**
   After the setup is complete, you can use a device code to perform Git operations.The device code is only valid as long as the GPG key is valid. If the key expires (for example, in one day), you will need to repeat the entire setup process the next day. When a session expires, you can use the passphrase to perform further Git operations.
   Example: Cloning, adding, committing, and pushing changes to the Control repository
   a. Copy the repository link from Control Repository, and run the following command to clone it:

      git clone <control-repo-link>

      Note: During the clone operation, you are prompted to authenticate by visiting a link provided in the terminal, entering the provided device code, and then granting access to the Git credential manager by clicking Yes.

   b. After cloning, you can add a file, and then commit and push the changes to the repository. This process is similar to working with a standard GitHub repository.

      When you run git push, you are prompted to provide your passphrase to complete the operation.

6. **Alternatively, using the Git UI**
   a. From the left toolbar, click File > Open folder and select the root directory.
   b. Click the Clone Repository button.
   c. Paste the Control repository link when prompted.

d. Authenticate by visiting the provided link and entering the device code, then approve the Git credential manager prompt.
e. Once cloned, use the UI to add, commit, and push changes.
f. When pushing, enter your passphrase when prompted to complete the operation.

Fixing Git clone in air-gapped environment

In air-gapped environments, URLs that start with `service-`, such as the default Control SSH URL, are not accessible from the dev container terminal. You can replace this URL with the internal cluster-local service address to clone a repository.

Before you begin

You must have the following information:

- Access to a dev container terminal running in an air-gapped environment.

About this task

In air-gapped environments, URLs that start with `service-`, for example `git@service-loop.loopairgapvpc1.us-east.containers.appdomain.cloud:30328`, point to an external endpoint that air-gapped virtual private clouds (VPCs) cannot reach. As a result, you cannot use the default Control SSH URL to clone a repository directly from the dev container terminal.

To work around this restriction, replace the external Control SSH hostname with the internal cluster-local service address before you run git clone.

1. **Identify the failing Git command**
   a. Locate the git clone command, or any other Git SSH operation, that references the external Control SSH URL.
   b. An example of a URL that fails in an air-gapped environment is shown below:

      git clone ssh://git@service-loop.loopairgapvpc1.us-east.containers.appdomain.cloud:30328/test_ts/.devopsconfig.git

2. **Replace the Control SSH hostname**
   a. Replace the hostname portion of the URL with the internal cluster-local service address, using the following format, where *platform_namespace* is typically `devops-loop`:

      git@devops-loop-control-ssh.<platform_namespace>.svc.cluster.local:22

   b. Change the port number to (`22`) and keep the repository path unchanged. Only the hostname and port may be modified.

      Note: Do not modify any other part of the URL. The repository path and all other URL components must remain exactly as they are.

3. **Run the updated clone command**

a. In the dev container terminal, run the updated git clone command. For example:

   git clone ssh://git@devops-loop-control-ssh.devops-loop.svc.cluster.local:22/test_ts/.devopsconfig.git

b. The Control repository clones successfully because the dev container resolves the internal cluster-local address instead of attempting to reach the inaccessible external `service-` URL.

Code Genie

You can use **Code Genie** to automate tasks on the repository contents of DevOps Control.

Code Genie automates a wide range of tasks on the contents of a Control repository. You can trigger Code Genie either automatically through webhooks on page 212, or manually through the **Code Genie** button in the Plan user interface on page 158.

When a you create or update a PR in a repository, **Code Genie** launches a development container, clones the repository from the PR source branch, runs one or many commands, collects JavaScript Object Notation (JSON) results according to a standardized schema, maps them to PR comments, and can approve or reject the PR.

When you act on a work item in Plan, Code Genie launches a development container in the background, generates code based on the work item description, and creates a branch and pull request with the implementation.

Code Genie is a general-purpose feature for any PR automation task. Trivy Security Scanning on page 228, AI Code Review on page 224 and Automated JUnit Testing are some examples that uses Code Genie.

Default Capabilities

The following capabilities are available by default through the configuration file `.devops-loop/code-config.jsonc`, which is discussed in the **Configuration File** section.

- **Plan work item implementation**: When you act on a work item in Plan, Code Genie reads the work item coding instructions, generates code and creates a pull request implementing the requested changes. To use this feature, you must configure a coding CLI token for either GitHub Copilot or IBM Bob.
- **Trivy scanning and AI code review**: When you create or update a pull request, Code Genie automatically runs a Trivy security scan followed by an AI-powered code review using GitHub Copilot. The security scan runs independently of the coding CLI token. However, to run the code review, you must have a GitHub Copilot or IBM Bob token configured(based on what is configured is for code review)
- **Interact with Code Genie through PR comments**: When you add a comment to a pull request, you can ask Code Genie to explain specific code sections, suggest fixes, or answer questions about the implementation. Code Genie responds directly within the pull request comment thread.

You can use Code Genie for other use cases that include, but are not limited to the following tasks:

- Run unit tests on the PR source branch and reject the PR if any test fails.
- Let a large language model perform a code review for the PR and reject the PR if severe problems are found.

- Perform language-specific static code analysis, such as clang-tidy for C++ or ESLint for TypeScript, and reject the PR if critical problems are found. For more information, refer to Clang Tools 23.0.0 git documentation and ESLint.
- Automatically approve small PRs that only involve certain low-risk files, such as documentation files, possibly after performing sanity checks such as spell checking.

Code Genie uses JSON

JSON is the core format used by Code Genie to connect automated tools with pull request (PR) outcomes.

It defines a structured contract between:

- what runs inside the development container (tools, scripts, analyzers).
- what Code Genie displays or enforces in the PR (comments and approval decisions)

Code Genie uses JSON in two key areas: configuration and execution results, which is elaborated in the following sections:

Configuration File

When creating a Loop, a Control repo autoconfigures Code Genie via `.devops-loop/code-config.jsonc`.

This default configuration defines how Code Genie implements Plan work items, performs pull request security scanning and AI-powered code reviews, and responds to pull request comments.

```
{
  "code-genie": {
    "workitem": [
      {
        "dev-container": "Copilot",
        "coding-instructions": [/*URL to markdown file, for example
https://github.com/WDI-SEA/code-review/blob/master/code-guide.md*/],
        "coding-command": "export GH_TOKEN=${loop_property:copilotclitoken} &&
cp /opt/run-copilot.ts /usr/code/ && tsx /usr/code/run-copilot.ts --prompt-file=${promptFile}
--llm_args=\"--allow-all-tools --model claude-sonnet-4.5\""
      },
      {
        "dev-container": "Bob",
        "coding-instructions": [/*URL to markdown file, for example
https://github.com/WDI-SEA/code-review/blob/master/code-guide.md*/],
        "coding-command": "export BOBSHELL_API_KEY=${loop_property:bobtoken} &&
cp /opt/run-bob.ts /usr/code/ && tsx /usr/code/run-bob.ts --prompt-file=${promptFile}
--bob_args=\"--yolo --accept-license --auth-method api-key\""
      }
    ],
    "pull-request": [
      {
        "dev-container": "TrivyScan",
        "interactive": false,
        "custom-commands": [
          {
            "run-trivy": "cp /opt/run-trivy.sh /usr/code/ && chmod +x /usr/code/run-trivy.sh &&
REPO_URL=https://${platform-fqdm}/control/${repo-owner}/${repo}/src/branch/${pr-branch}/ /
```

```
usr/code/run-trivy.sh ${code-folder} ${result-json} --reject=high --trivyArgs=\"--scanners
 vuln,misconfig,secret,license --license-full --severity UNKNOWN,LOW,MEDIUM,HIGH,CRITICAL\""
          }
        ]
      },
      {
        "dev-container": "Copilot",
        "interactive": true,
        "custom-commands": [
          {
            "code-review-command": "export GH_TOKEN=${loop_property:copilotclitoken} &&
 cp /opt/run-copilot.ts /usr/code/ && tsx /usr/code/run-copilot.ts --prompt-file=${promptFile}
 --llm_args=\"--allow-all-tools --model claude-sonnet-4.5\""
          }
        ]
      }/* Uncomment this block to use IBM Bob Shell for code reviews
      ,{
        "dev-container": "Bob",
        "interactive": true,
        "custom-commands": [
          {
            "code-review-command": "export BOBSHELL_API_KEY=${loop_property:bobtoken} &&
 cp /opt/run-bob.ts /usr/code/ && tsx /usr/code/run-bob.ts --prompt-file=${promptFile}
 --bob_args=\"--yolo --accept-license --auth-method api-key\""
          }
        ]
      }*/
    ]
  }
}
```

In the above example, the configuration splits into two sections: `"workitem"` , which defines how Code Genie implements Plan work items by selecting either the GitHub Copilot or IBM Bob entry based on the configured token, and `"pull-request"`, which defines what runs automatically on PR creation or update. Three entries run sequentially, TrivyScan (always active), GitHub Copilot code review (active by default), and IBM Bob code review (commented out). Setting `"interactive"` to false on TrivyScan runs it entirely in the background, while setting it to true on the AI code review containers allows developers to interact with Code Genie directly through PR comments.

The JSON file provides the following key properties:

`@workitem`

: This property specifies how Code Genie implements a work item from plan UI by defining the dev containers and the coding commands/instructions.

`@dev-container`

: This property specifies the name of the dev container to open. The dev container image should be accessible from Code Genie so that it can open the devcontainer. You must use a non-IDE dev container since such a dev container opens faster and occupies fewer resources than a dev container that contains an IDE. Since a Code

Genie dev container runs in the background, without user interaction, including an IDE would be unnecessary overhead. For more information, refer to the non-IDE dev container on page 209.

`@coding-instructions`

This property specifies an array of URLs pointing to markdown files that contain the coding guidelines Code Genie passes to the AI as context. Replace the placeholder comment with one or more URLs to your own coding standards documents.

`@coding-command`

This property specifies how Code Genie invokes the AI coding assistant to implement a work item. It sets the required authentication token, copies the assistant's runner script into the working directory, and executes the script with a prompt file containing the work item details. Additional arguments can also be provided to configure the model and tool permissions used during code generation.

`@pull-request`

This property specifies how Code Genie is triggered. Code genie is triggered on PR creation and when more commits are added to the PR.

`@custom-commands`

This is an array of commands to run in the dev container. They run sequentially in the order specified in the JSON file. The current working directory for each command invocation is the folder in the dev container file system where the Control repository was cloned. Each command is represented by a JSON object in the array, with a single property describing what the command does (for example, "run-trivy"). The value of the property is the actual Unix command-line to invoke in the dev container. It can use any tool or script that is present in the dev container.

`@interactive`

This property if set to true allows users to interact with Code Genie through PR comments for AI dev containers.

By default, Trivy scanning and code review run on every pull request. To turn off these checks, see Disabling Trivy Scanning and Code Review on Pull Requests on page 206.

If you use Code Genie in an air-gapped environment, you must disable Copilot code review. See Disabling AI Code Review in an Air-Gapped Environment on page 207.

Variables

Before Code Genie runs a command, it replaces certain variables with actual values:

`${platform-fqdn}`

Fully qualified domain name of the Loop installation.

`${repo-owner}`

Owner of the cloned repository (typically a teamspace).

`${repo}`

Name of the cloned repository.

`${pr-branch}`

Name of the PR source branch (currently checked out).

`${code-folder}`

Folder in the dev container where the Control repo is cloned.

`${result-json}`

Path to JSON results file (unique name like cg-result-10-1.json). An invoked command might choose to generate this file, and its contents then must comply with the standardized schema for PR comment translation.

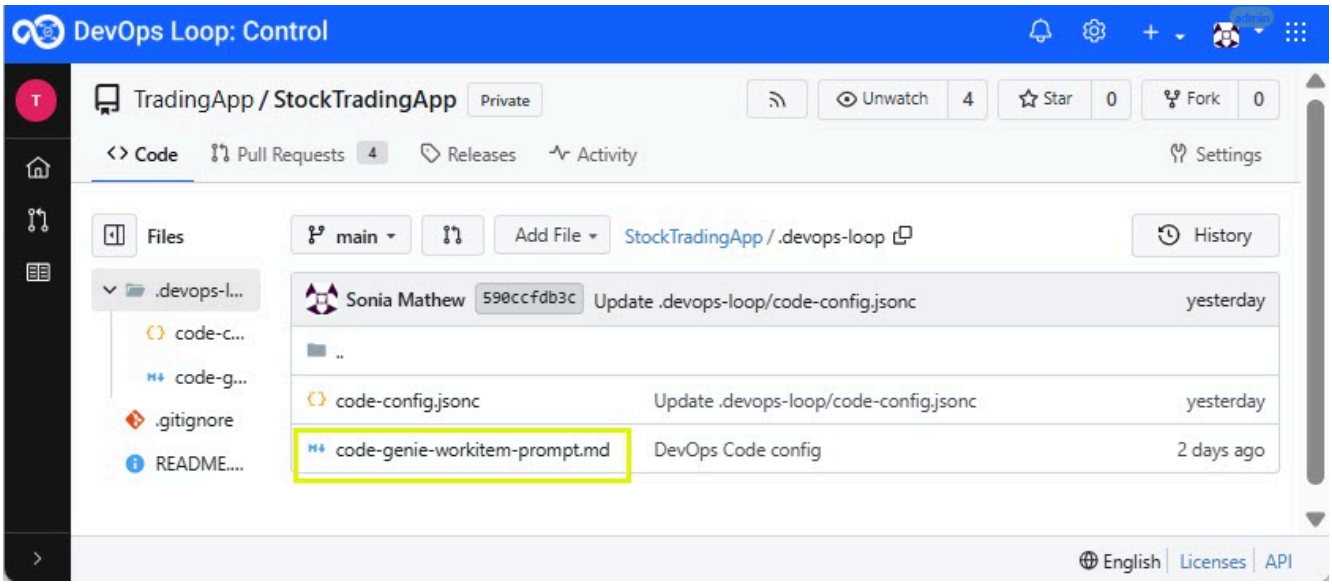
`${promptFile}`

Reserved runtime placeholder used by the Code Genie backend. It is not a real file path and must not be modified or interpreted in the configuration. During execution, the backend replaces it with the actual generated prompt file that contains the work item context. This ensures the coding command receives the correct input without requiring any manual handling.

Note: You can use comments (both line comments (//) and block comments (/* */)) in the configuration file.

Prompt file

When a loop is created, a new prompt file also gets automatically created in the Control repo: `.devops-loop/code-genie-workitem-prompt.md`, that is, at the same location where `code-config.jsonc`. is created.



This prompt is helpful when you use the code genie feature in a Plan work item to implement a work item. You can customize it, if needed.

Note: You must not modify placeholders such as ${targetDir} in the `code-genie-workitem-prompt.md`, as doing so may lead to unexpected behavior or results.

Using webhooks and runner scripts

Each command-related property like `"custom-commands"` or `"coding-command"` in the configuration file invokes runner scripts that are executed inside a dev container by Code Genie to automate tasks such as implementing Plan work items, handling pull request workflows and supporting other customized usecases. For more information, see Runner Scripts on page 210.

In addition to the configuration file, Code Genie requires a webhook to be present on the Control repository. For a repository that is created as part of loop creation, the webhook is automatically created. If you create a repository manually, you must create the webhook. See Creating webhooks on page 212.

Coding CLI token configuration

For Plan work item implementation and AI code review to function, a coding CLI token must be configured. For more information, see Configuring Coding CLI token on page 215.

Execution Result File

The result of running a command can be stored in a JSON result file. The variable `${result-json}` expands to the full path of that JSON file. The file name is unique for each command invocation and includes the Control PR number and index within the custom-commands array. For example, the file name can be **cg-result-10-1.json** if the Control PR number is 10 and the command is the first command in the custom-commands array.

After running the command, Code Genie checks whether a JSON result file is available. If present, it must comply with a standardized JSON schema. The JSON properties are as follows:

`@results`

This is an array of objects that specify code locations, typically locations within files of the Control repository. Each such object is mapped to a PR comment that is associated with a specific file ("path" property) and a line within that file ("new_position" property). The PR comment text is specified by the "body" property and might use markdown for formatting.

`@pr-comments`

This is an array of strings, each of which is mapped to a PR comment that is not associated with any file. The strings might use markdown for formatting.

`@review`

This object can be present to specify whether Code Genie should make a review of the PR as either approved (property "approved" set to true) or rejected (property "approved" set to false). In either case, you can set the "comment" property to a comment explaining the PR approval or rejection.

The following example shows the results JSON file generated by Code Genie when it specifically runs a Trivy scan.

Note: The format is the same when Code Genie runs a Copilot AI code review, but the contents can be different and the "review" property is not used.

```
{
  "results": [
    {
      "path": "package-lock.json",

Create a Loop on page 140

Disabling Trivy Scanning and Code Review on Pull Requests on page 206

Disabling Code Review in an Air-Gapped Environment on page 207

Disabling both Trivy Scanning and AI Code review

You can disable the Trivy security scan and AI-powered code review that Code Genie runs automatically on pull request creation or update.

About this task

By default, Code Genie runs a Trivy security scan and an AI-powered code review every time a pull request is created or updated. To turn off these checks, comment out the corresponding entries in the `"pull-request"` array of `.devops-loop/code-config.jsonc`.

1. Open `.devops-loop/code-config.jsonc` in the Control repository.
2. Locate the `"pull-request"` array.
3. Enclose the `TrivyScan` entry and the `Copilot` entry in block comments (`/* */`).
4. Save the file.

Results

With no active entries in the `"pull-request"` array, Code Genie does not run a security scan or a code review when a pull request is created or updated.

Note: Disabling Trivy scanning and code review affects only the `"pull-request"` array. It does not affect the Plan work item implementation (`"workitem"` array).

Example

The following example shows the `"pull-request"` array with Trivy scanning and code review disabled:

```
"pull-request": [
    /*{
      "dev-container": "TrivyScan",
      "interactive": false,
      "custom-commands": [
        {
          "run-trivy": "cp /opt/run-trivy.sh /usr/code/ && chmod +x /usr/code/run-trivy.sh &&
 REPO_URL=https://${platform-fqdm}/control/${repo-owner}/${repo}/src/branch/${pr-branch}/ /
usr/code/run-trivy.sh ${code-folder} ${result-json} --reject=high --trivyArgs=\"--scanners
 vuln,misconfig,secret,license --license-full --severity UNKNOWN,LOW,MEDIUM,HIGH,CRITICAL\""
```

```
        }
      ]
    },
    {
      "dev-container": "Copilot",
      "interactive": true,
      "custom-commands": [
        {
          "code-review-command": "export GH_TOKEN=${loop_property:copilotclitoken} &&
cp /opt/run-copilot.ts /usr/code/ && tsx /usr/code/run-copilot.ts --prompt-file=${promptFile}
--llm_args=\"--allow-all-tools --model claude-sonnet-4.5\""
        }
      ]
    }*/
    /* Uncomment this block to use IBM Bob Shell for code reviews
    ,{
      "dev-container": "Bob",
      "interactive": true,
      "custom-commands": [
        {
          "code-review-command": "export BOBSHELL_API_KEY=${loop_property:bobtoken} &&
cp /opt/run-bob.ts /usr/code/ && tsx /usr/code/run-bob.ts --prompt-file=${promptFile}
--bob_args=\"--yolo --accept-license --auth-method api-key\""
        }
      ]
    }*/
  ]
```

Code Genie on page 199

Disabling AI Code review in Air-gapped environment

In an air-gapped environment, you must disable the AI-powered code review that Code Genie runs on pull request creation or update.

About this task

An air-gapped environment is a deployment that is physically or logically isolated from the public internet, with no outbound network access to external services.

The `Copilot` code review script requires internet access to communicate with the GitHub Copilot service. In an air-gapped environment, this communication is not possible. You must comment out the `Copilot` entry in the `"pull-request"` array of `.devops-loop/code-config.jsonc` before you use Code Genie in an air-gapped environment.

1. Open `.devops-loop/code-config.jsonc` in the Control repository.
2. Locate the `"pull-request"` array.
3. Enclose the `Copilot` entry in block comments (`/* */`).

Leave the `TrivyScan` entry active as it does not require internet access and can continue to run on pull request creation and update.

4. Save the file.

Results

With the `Copilot` entry disabled, Code Genie continues to run the Trivy security scan on pull request creation and update, but no longer attempts to run AI-powered code review.

Attention: Disabling `Copilot` code review is required in air-gapped environments, not optional. If the `Copilot` entry is left active, the code review dev container fails because it cannot reach the GitHub Copilot service.

Example

The following example shows the `"pull-request"` array configured for an air-gapped environment, with `TrivyScan` active and `Copilot` code review disabled:

```
"pull-request": [
    {
      "dev-container": "TrivyScan",
      "interactive": false,
      "custom-commands": [
        {
          "run-trivy": "cp /opt/run-trivy.sh /usr/code/ && chmod +x /usr/code/run-trivy.sh &&
 REPO_URL=https://${platform-fqdm}/control/${repo-owner}/${repo}/src/branch/${pr-branch}/ /
usr/code/run-trivy.sh ${code-folder} ${result-json} --reject=high --trivyArgs=\"--scanners
 vuln,misconfig,secret,license --license-full --severity UNKNOWN,LOW,MEDIUM,HIGH,CRITICAL\""
        }
      ]
    }
    /*,{
      "dev-container": "Copilot",
      "interactive": true,
      "custom-commands": [
        {
          "code-review-command": "export GH_TOKEN=${loop_property:copilotclitoken} &&
 cp /opt/run-copilot.ts /usr/code/ && tsx /usr/code/run-copilot.ts --prompt-file=${promptFile}
 --llm_args=\"--allow-all-tools --model claude-sonnet-4.5\""
        }
      ]
    }*/
  ]
```

What to do next

Installing extensions in dev containers in an air-gapped environment

When a custom dev container, such as the Java devcontainer, is launched in an air-gapped environment, extensions do not get installed by default, with the exception of the DevOps Code extension itself. This occurs because extension installation

normally requires outbound access to a public extension marketplace, which is not available in an air-gapped environment. In order to make the required extensions available, you can follow the steps below:

1. Identify the extensions required by the custom devcontainer. For example, the Java dev container requires the extensions used for Java development and debugging.
2. Add the required extensions to the extension registry. Refer to extension registry on page 187 documentation.
3. Launch the custom devcontainer, for example the Java dev container.
4. Install the required extensions manually inside the launched dev container, following the same extension registry documentation.

The required extensions are then available inside the devcontainer, in addition to the default DevOps Code extension.

Related information

Code Genie on page 199

Disabling Trivy Scanning and Code Review on Pull Requests on page 206

Non-IDE dev container

You can configure a non-IDE dev container to run background tasks, such as CI/CD pipelines or Code Genie automation, without the overhead of an IDE.

A **non-IDE dev container** runs as a plain container without launching an IDE. It launches faster and occupies less resources than a standard dev container, making it suitable for background tasks that run without user interaction - such as PR automation, CI/CD pipelines, or CLI-only workloads, where including an IDE would be unnecessary overhead.

You can configure one by setting the `"ide": "false"` property in your devcontainer.json file. The following devcontainer.json file on page 172 shows a sample configuration for a non-IDE dev container:

```
{
  "name": "My Dev Container",
  "description": "A plain development container without IDE support.",
  "build": {
    "dockerfile": "Dockerfile"
  },
  "ide": "false",
  "image": "<username>/<container-name>:<tag>"
}
```

You can use a non-IDE dev container with Code Genie on page 199 to improve performance. When a PR is created, Code Genie launches a dev container in the background. Excluding the IDE minimizes startup time and resource consumption, resulting in faster, more lightweight automation.

The following Dockerfile on page 172 shows a sample configuration for a non-IDE dev container with the IDE installation removed:

```
FROM ubuntu:20.04
ENV DEBIAN_FRONTEND=noninteractive
RUN apt-get update && \
    apt-get install -y \
        sudo \
        curl \
        git \
        ca-certificates \
        build-essential && \
    apt-get clean

RUN chmod -R ug+w /etc/pki/ca-trust/source /etc/pki/ca-trust/extracted || true

RUN useradd -m -u 1001 devuser
USER 1001
WORKDIR /home/1001
CMD ["tail", "-f", "/dev/null"]
```

Configuring the timeout for non-IDE dev containers

DevOps Loop automatically terminates idle non-IDE dev containers if not in use after a configurable timeout period.

The timeout value is specified in seconds and can be configured during installation.

For example, to set the timeout to 86,400 seconds (24 hours), add the following to the Loop installation script on page 69:

```
NON_IDE_CONTAINER_TIMEOUT=86400

if [ -n "${NON_IDE_CONTAINER_TIMEOUT}" ]; then
 HELM_OPTIONS="${HELM_OPTIONS} --set global.nonIdeContainerTimeout=${NON_IDE_CONTAINER_TIMEOUT}"
fi
```

Runner Scripts

You can use runner scripts to define the core execution logic that Code Genie runs inside a dev container when a pull request is created or updated.

When **Code Genie on page 199** triggers a container, it runs a command string defined in `code-config.jsonc` via the `custom-commands` or `coding-command` properties. The command string invokes the runner script, which executes the task, processes the results, and generates the structured JSON output that Code Genie reads to post PR comments and decide on approval or rejection.

The default Code Genie configuration includes built-in runner scripts that you cannot access or modify. You can use the information in this topic to create your own runner script for custom use cases, such as running unit tests or performing static code analysis.

The following table lists the built-in runner scripts used in the default Code Genie configuration:

Script	Type	Purpose
`run-trivy.sh`	Shell script	Runs Trivy security scanning on the PR source branch and outputs findings to the result JSON file.
`run-copilot.ts`	TypeScript script	Invokes GitHub Copilot to implement work items or perform AI code reviews on PRs.
`run-bob.ts`	TypeScript script	Invokes IBM Bob to implement work items or perform AI code reviews on PRs.

You can write your own runner script in any language that the dev container supports. For a step-by-step walkthrough of creating a custom runner script, see DevOps Loop: Automated JUnit Testing with Code Genie.

What a Runner Script Does

Regardless of the use case, a runner script performs the following functions:

- Executes the core task, such as performing a security scan, invoking an AI code review, or running tests.
- Generates a structured JSON result file that Code Genie reads to post PR comments and determine approval or rejection.

Creating a Custom Runner Script

To create a custom runner script, you must embed the script into the dev container image and ensure that the command in `code-config.jsonc` passes the inputs that the script expects.

Embedding the script in the dev container: You can embed a runner script into the dev container image at build time by using the `COPY` instruction in the Dockerfile, followed by `chmod +x` to make it executable. The following Dockerfile shows a minimal example that embeds a JUnit runner script into the dev container image:

```
FROM registry.access.redhat.com/ubi9
# Install Java, Maven, Git, and JQ in a single layer
RUN dnf install -y --allowerasing --setopt=install_weak_deps=False \
    git java-17-openjdk java-17-openjdk-devel maven jq && dnf clean all
ENV JAVA_HOME=/usr/lib/jvm/java-17-openjdk
ENV PATH="${JAVA_HOME}/bin:${PATH}"
# Configure non-root user and directories
RUN useradd -u 1001 -m codeuser && \
    mkdir -p /opt /tmp/junit-results && \
    chown -R 1001:1001 /opt /tmp/junit-results /home/codeuser
COPY run-junit.sh /opt/run-junit.sh
RUN chmod +x /opt/run-junit.sh
USER 1001
WORKDIR /home/codeuser
CMD ["/bin/bash"]
```

The script is then available inside the container at a known path. The command in `code-config.jsonc` copies it to the working directory before executing it. Because the Dockerfile bakes the script into the image, the container image and the

command string are tightly coupled, the image determines what scripts are available, and the configuration determines how it invokes them. Any mismatch between the two causes the automation to fail. For more information, see Creating Dev Containers using a Dockerfile on page 172.

Mapping commands to script expectations: The commands in `code-config.jsonc` must map directly to what the runner script expects. Common inputs include:

- `${code-folder}`: The working directory inside the container where Code Genie clones the repository and executes commands.
- `${result-json}`: The target path where the script writes its execution summary in JSON format for Code Genie to parse.
- Use-case specific flags: Such as rejection thresholds or tool-specific arguments that control how the script evaluates results and determines PR approval or rejection.

The following code-config.jsonc shows how the Trivy runner script is invoked, with the required inputs passed as part of the command string:

```
{
  "code-genie": {
    "pull-request": {
      "dev-container": "TrivyScan",
      "custom-commands": [
        {
          "run-trivy": "cp /opt/run-trivy.sh /usr/code/ && \
                        chmod +x /usr/code/run-trivy.sh && \

 REPO_URL=https://${platform-fqdm}/control/${repo-owner}/${repo}/src/branch/${pr-branch}/ \
                        /usr/code/run-trivy.sh ${code-folder} ${result-json} \
                        --reject=high \
                        --trivyArgs=\"--scanners vuln,misconfig,secret,license --license-full
 --severity UNKNOWN,LOW,MEDIUM,HIGH,CRITICAL\""
        }
      ]
    }
  }
}
```

Creating webhooks

For manually-created Control repositories, you must create a webhook so that Code Genie can detect pull request activity and trigger automated scans and reviews

Before you begin

Before you begin, ensure that you have:

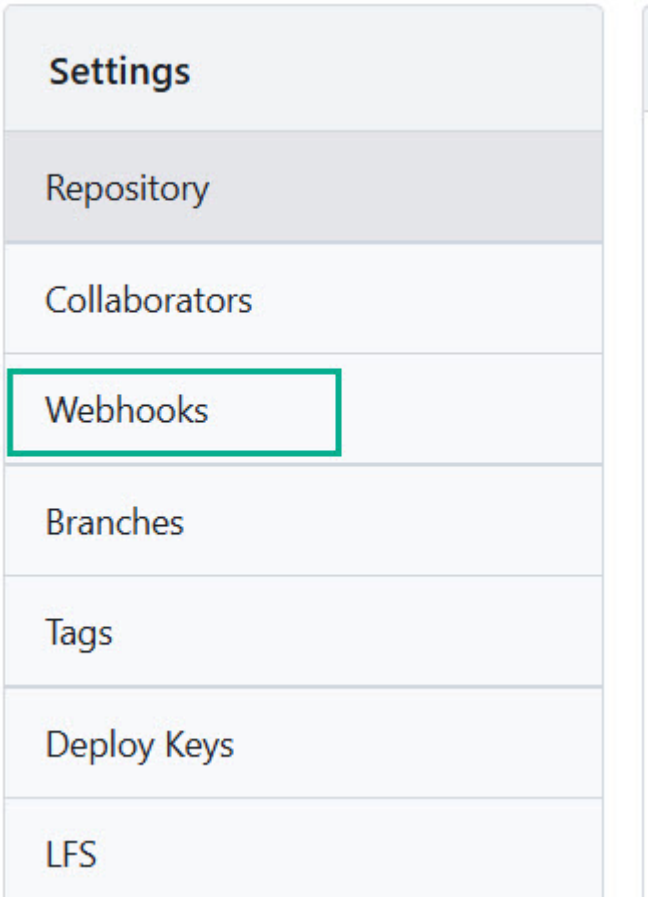
- Administrator access to the **Control** repository
- Created a Control repository manually.
- Read Code Genie on page 199 documentation.

About this task

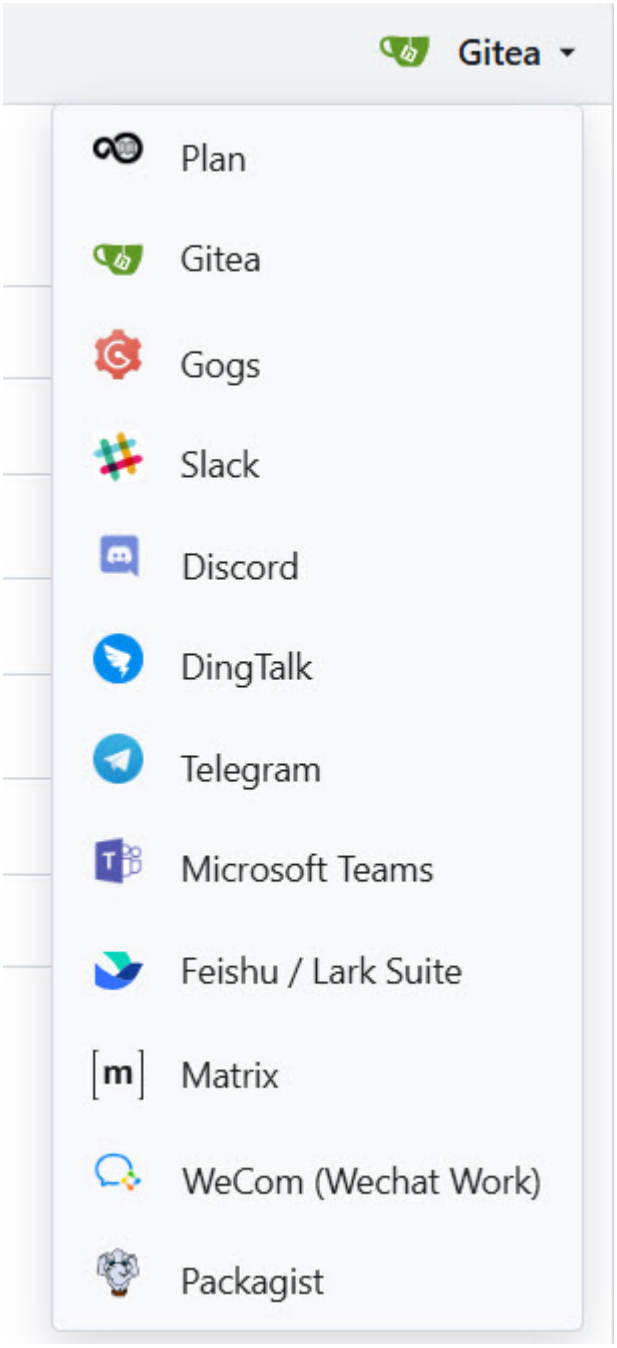
A webhook is an HTTP callback that Gitea triggers automatically when repository events occur. When an event matches your configured trigger, Gitea sends a POST request with a JSON payload to the **Code Genie** target URL. You can filter triggers by event type and branch pattern, giving you precise control over which pull request activities notify Code Genie.

Important: Automatic configuration of the webhook only applies to Control repositories created through the Loop creation process. If you create a Control repository manually, you must create the webhook yourself, as described in this procedure. You must also configure branch protection rules and create the `.devops-loop/code-config.jsonc` file for Code Genie to work correctly.

1. Navigate to your Control repository in Gitea and click **Settings**.



2. In the left navigation panel, click **Webhooks** under **Settings**.
3. Click **Add Webhook** and select **Gitea** from the drop-down list.



4. Configure the webhook with the following values.
    - Target URL: `http://devops-code-container-mgr:3005/api/pull-request`
    - HTTP Method: **POST**
    - POST Content Type: `application/json`
5. Under **Trigger On**, select **Custom Events**.
6. In the **Pull Request Events** section, select the following check boxes.
    - **Pull Request** — fires when a pull request is opened, closed, reopened, or edited.
    - **Pull Request Synchronized** — fires when new commits are pushed to an open pull request.

7. In the **Branch Filter** field, enter `*` to apply the webhook to all branches.
   To restrict to specific branches, use a glob pattern such as `master` or `{master,release*}`.
8. Click **Add Webhook** to save the configuration.
9. Confirm that the webhook appears in the **Webhooks** list with a green status indicator.

Results

You have created a webhook on the Control repository. Gitea will now send a POST request to Code Genie each time a pull request is opened or synchronized on the repository.

What to do next

After creating the webhook, you must complete the remaining manual configuration steps before Code Genie can scan pull requests:

- Configure branch protection rules for the main branch.
- Create the `.devops-loop/code-config.jsonc` file in the Control repository to enable Trivy scanning and AI code review with CoPilot.

Configuring Coding CLI token

Configure a coding CLI token for IBM Bob or GitHub Copilot to enable Code Genie automated work item implementation and AI-powered code reviews.

About this task

For work item implementation and AI code review to function, **Code Genie** requires a Coding CLI token. By default, Code Genie supports two AI providers: GitHub Copilot (using built-in dev container) and IBM Bob (dev container using IBM Bob Shell is available on DockerHub).

The following steps guide you through creating a Coding CLI token:

1. Generate a token or API key from your preferred AI provider:
   Choose from:
   - **GitHub Copilot:** You can obtain a GitHub personal access token with the appropriate Copilot permissions. To create your token, navigate directly to your GitHub Personal Access Tokens Settings. For detailed documentation on managing these personal access tokens to configure Code Genie capabilities, refer to Managing your personal access tokens. If access is denied, contact your IT team to request configuration and enablement of valid GitHub Copilot subscription and username.
   - **IBM Bob:** You can generate an API key from the IBM Bob admin page. Refer to the IBM Bob API Keys Documentation.
2. Navigate to the **Manage Coding CLI** menu in the **Coding CLI** tab from **Installed Integrations** in the **DevOps Loop** settings.

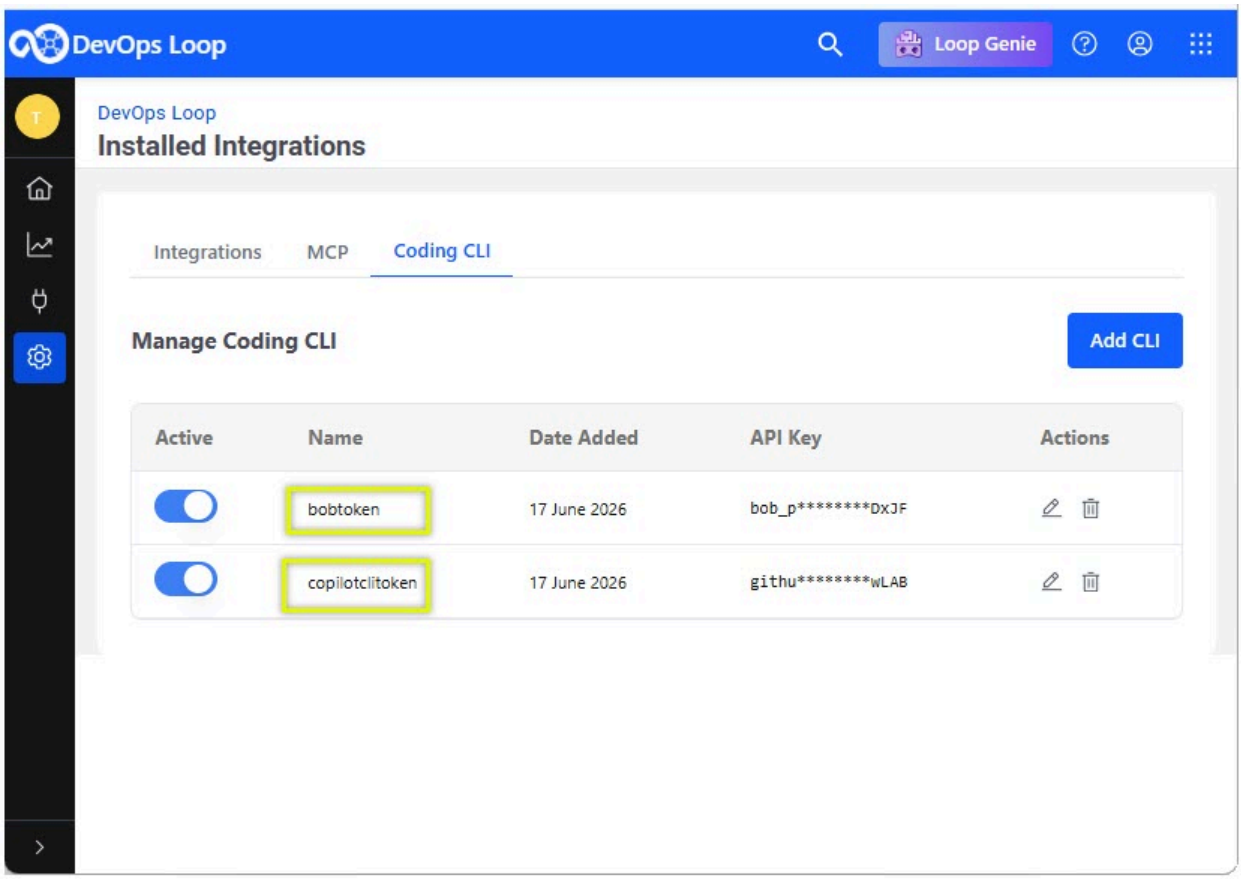
3. Add the generated key or token to the coding CLI configuration section and save the entry.



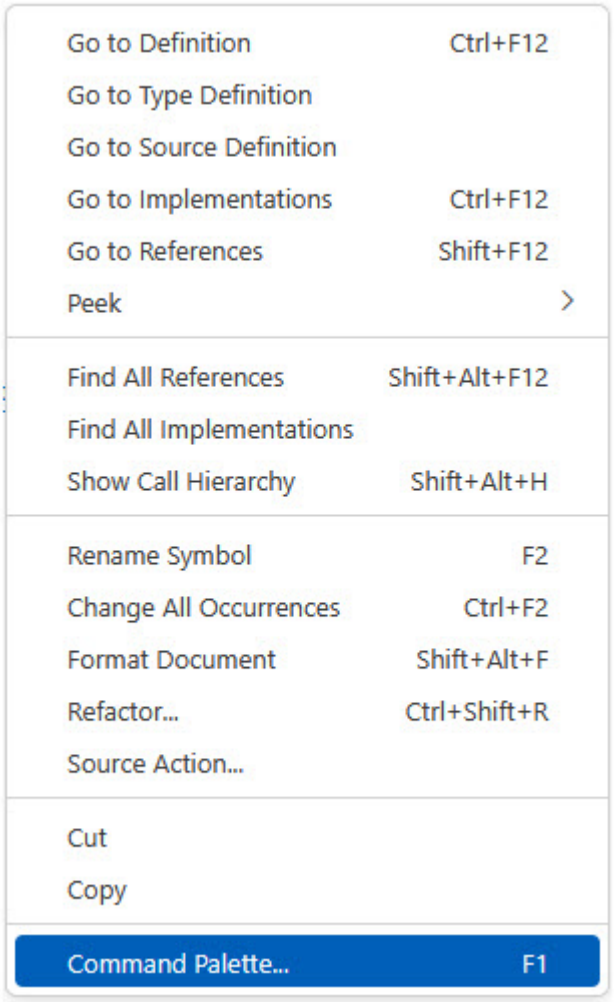
Creating Plan work items from Code

The DevOps Code extension allows integration with HCL DevOps Plan (Plan), enabling you to create and manage work items directly from your development environment in the browser IDE.

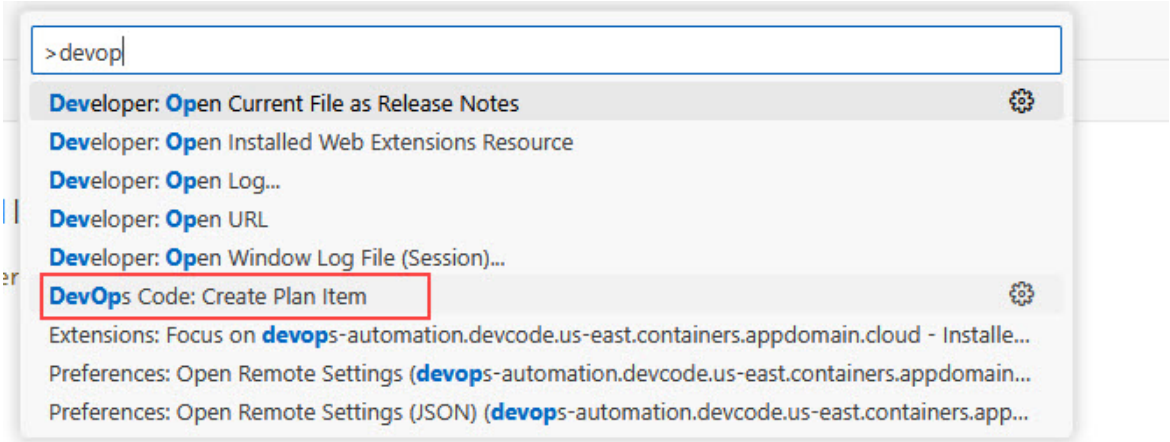
About this task

You can follow these steps to configure DevOps Code extension in the Code browser IDE, and create work items in HCL DevOps Plan (Plan).

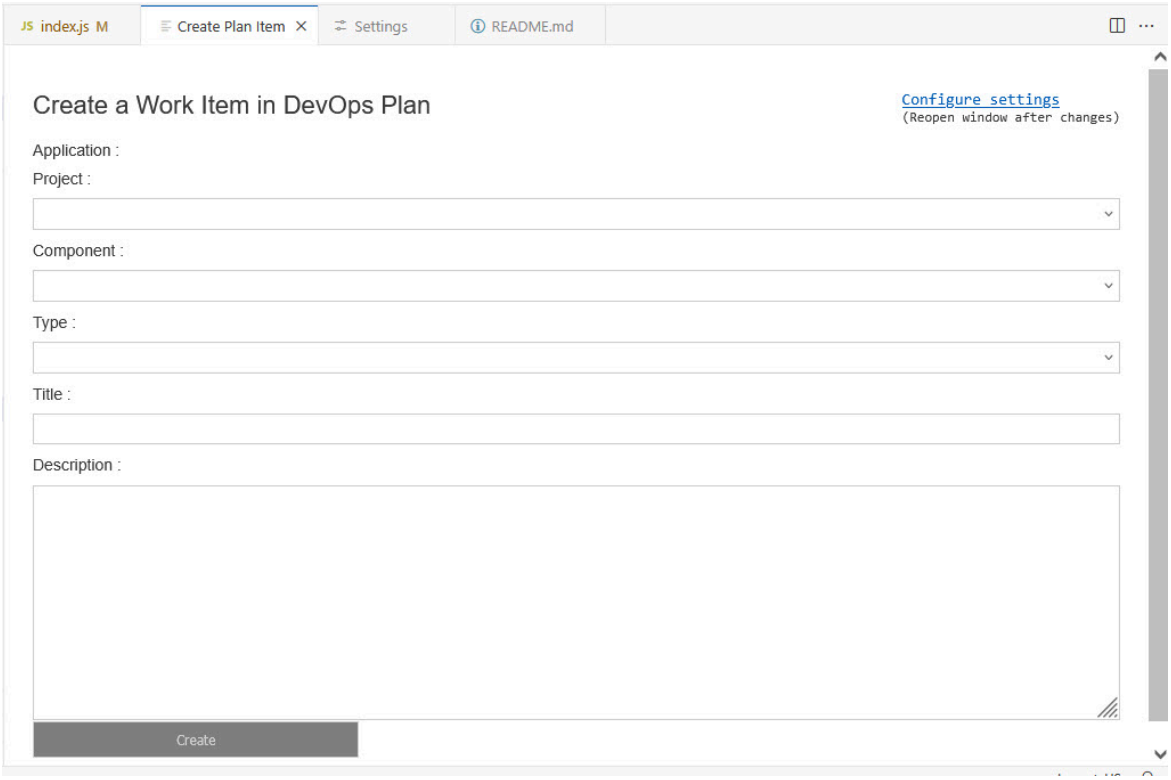
1. Open the Command Palette.
   Right-click to open the context menu and select **Command Palette** in the editor.



2. Access the DevOps Code Command.
    a. Choose the Code command from the list of available commands.



The **Create Plan Item** window is displayed.



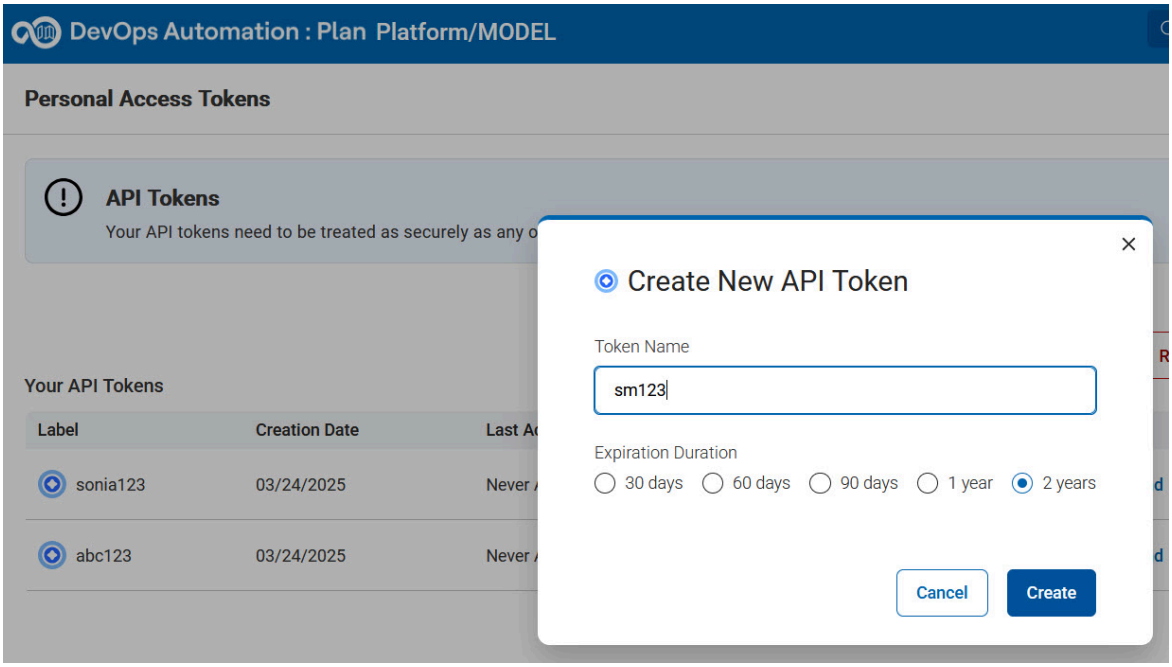
b. Click the **Configure settings** button to integrate DevOps Code with Plan for the first time.

   The **Settings** window is displayed to add the Personal Access Token, Plan Server URL, and Team Space ID.

   You can add these fields by navigating to the Plan platform, which is detailed in the next step.

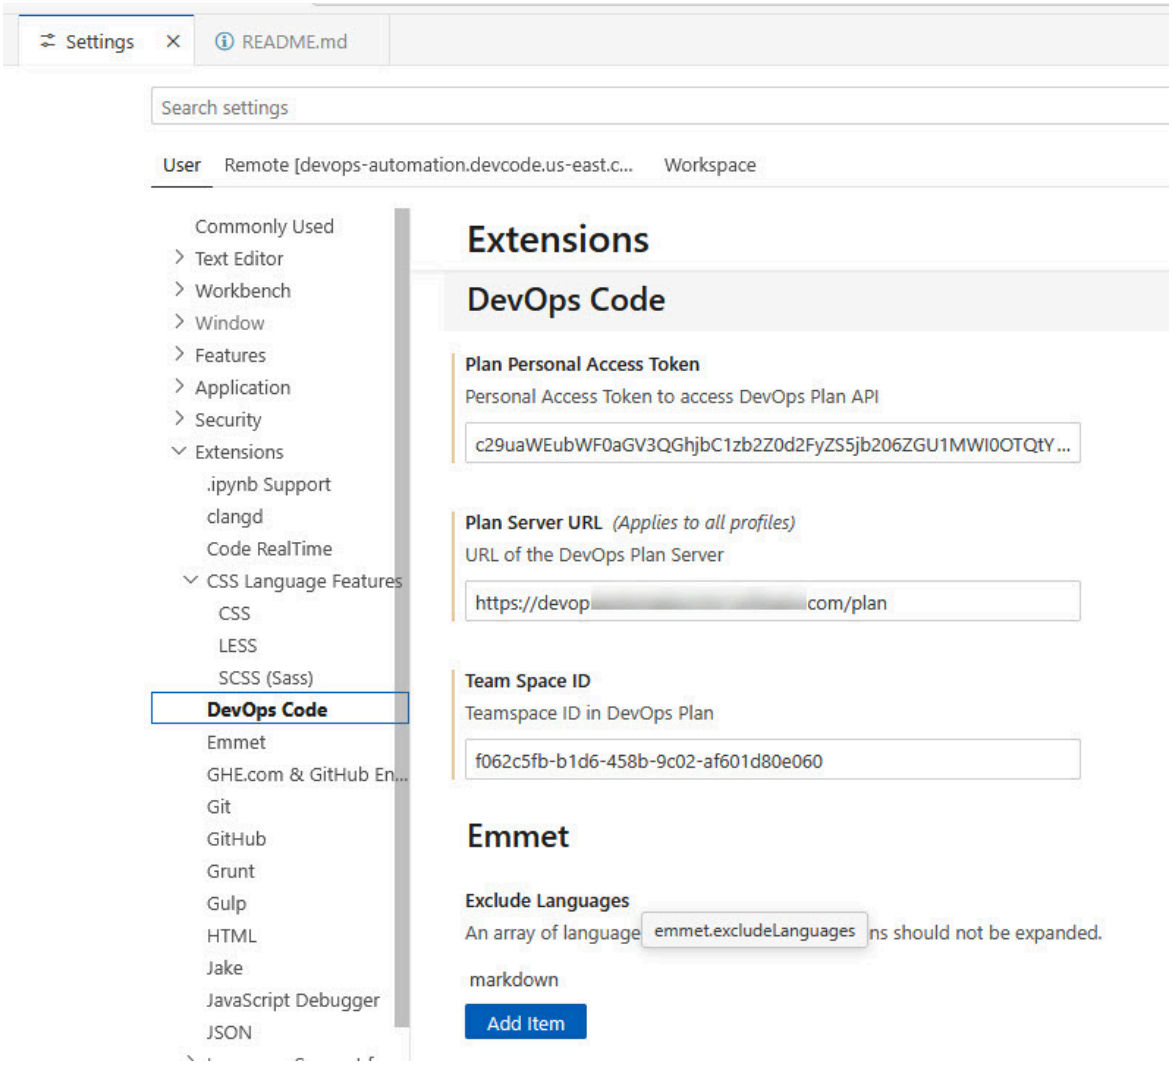
3. Perform the following steps to get configuration details from Plan:

a. Click the **Plan** button in the HCL DevOps Loop switcher to navigate to the Plan page.
b. Go to the **Settings** section of Plan, and enter the **Personal Access Token** (or API tokens) in the **Create New API Token** dialog.



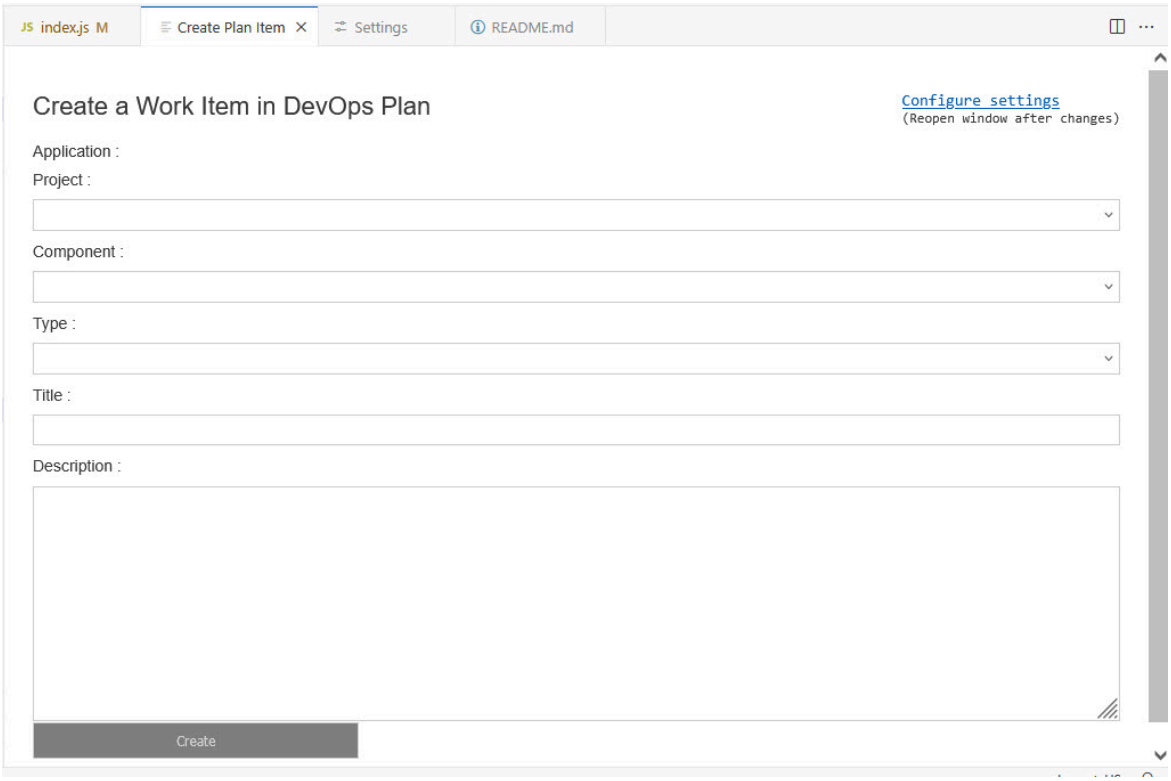
4. Perform the following steps to enter the configuration details:
   a. Navigate back to the Code application window from the switcher.
   b. Update the configuration details in the **Settings** window of Code.

Note: To find the team space ID to use, open a work item in Plan and look in the browser address bar for the text between the words "repos" and "databases". For example, 'f062c5fb-b1d6-458b-9c02-af601d80e060' in https://<DevOpsLoopURL>/plan/#/ccmweb/view/repos/f062c5fb-b1d6-458b-9c02-af601d80e060/databases/MODEL/records/WorkItem/MODEL00000179

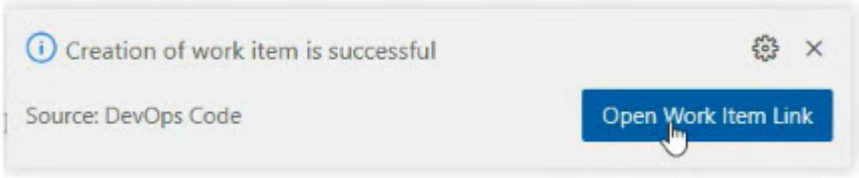


5. Create a work item:
    a. Select the **DevOps Code** command from **Command Palette**.

    The **Create Plan Item** window is displayed again.

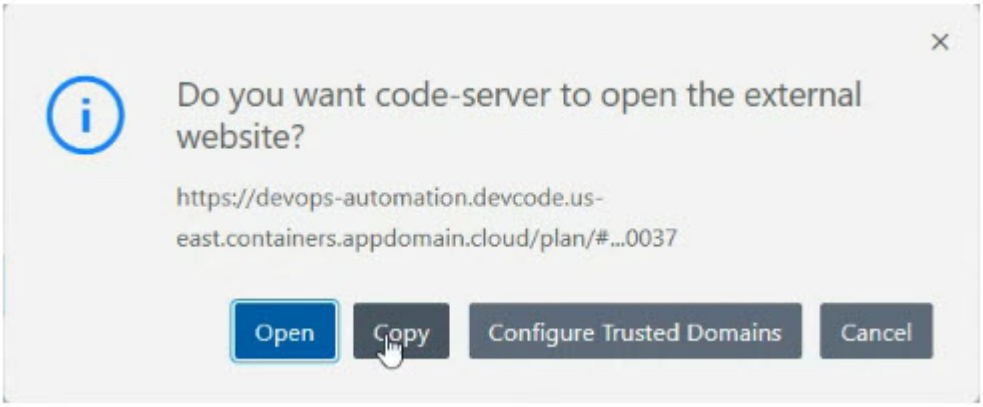


b. Fill in the required fields such as Application Project, Component, Type, Title, and Description.
c. Click the **Create** button to create your work item in Plan.



A prompt is displayed at the end of the IDE to indicate that the work item has been created successfully.

6. Click **Open Work Item Link** to view the work item on the Plan page.
   A dialog is displayed to open the Plan web page.



7. Click **Open** to navigate to the work item page on the Plan web page.

Results

By following these steps, you can easily configure the Code extension and begin creating and managing work items directly within your development environment. This integration eliminates the need to switch between your Code IDE and Plan.

Note: Currently, the DevOps Code extension has the following limitations:

- At most one Plan application can be used. If you have multiple applications, the first one will be used.
- The Plan application must use the Agile business flow. Other flows are currently not supported.
- Your Plan project(s) must have at least one component.

Installing GitHub Copilot in dev containers

As an admin, you can install the GitHub Copilot extension to enable AI-powered code suggestions, and chat assistance within your dev container.

Before you begin

You must have performed the following tasks:

- Gained access to edit the .devopsconfig control repository.
- Have a valid GitHub account with an active GitHub Copilot subscription.

About this task

This task describes how you can configure a dev container to support GitHub Copilot, and install and activate the extension within the running environment.

1. Configure the dev container image:
    a. Navigate to the .devopsconfig Control repository.
    b. Edit the existing devcontainer.json file (for example, within the Java dev container configuration), and update the image property to define the specific container version:

```
"image": "baravich/devcontainer-java-copilot:2.0.000"
```

c. Commit and push the changes to the repository.

2. Launch the dev container:
   a. In Code, locate the appropriate tile for the dev container configured in Step 1.
   b. Click the tile to launch the dev container.
3. Install the Copilot Extensions:
   a. You must run a script to install the necessary binaries once the environment is running. Open a new Terminal in the dev container environment.
   b. Copy and paste the following command to download and run the installation script:

```
curl -fsSL
 https://raw.githubusercontent.com/sunpix/howto-install-copilot-in-
code-server/refs/heads/main/install-copilot.sh
```

   This script automatically installs both the GitHub Copilot and Copilot Chat extensions.
4. Authenticate and access the Copilot:
   a. Locate the GitHub Copilot icon in the activity bar or status bar, once the installation is complete.
   b. Select the icon and follow the prompts to sign in to your GitHub account.
   c. Authorize the extension to access your subscription.

Results

The GitHub Copilot and Chat extensions are now installed and active. You can now use AI assistance for code generation and technical questions directly within your development environment.

Control

Control manages source code within the DevOps Loop using GitHub compatible APIs that integrate with existing developer tools, workflows, and automation. It supports version management, collaboration, and code governance as development progresses.

For more details refer to the Control Documentation.

AI code reviewing with Code Genie

A Control repository that is created as part of creating a Loop will be automatically configured to enable AI-assisted code review using **Code Genie** with the Copilot dev container. Use this procedure when you want to enable interactive, AI-powered code suggestions on pull requests across your team.

Before you begin

Before you begin, ensure that you have:

- Administrator access to your team space.
- Created a teamspace. See Creating a teamspace on page 132.

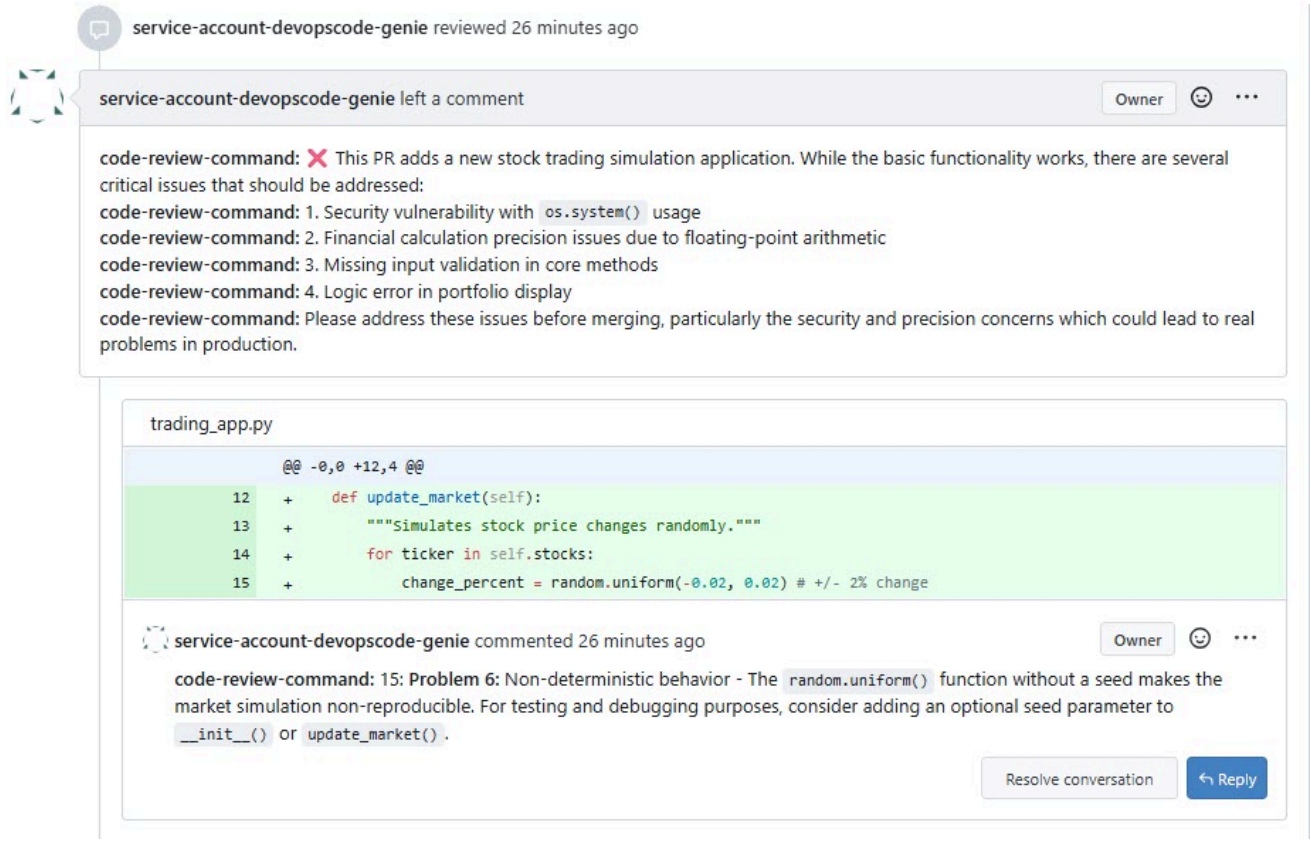
- Created a **DevOps Loop** so that the Control repository, webhook, branch protection, and default `.devops-loop/code-config.jsonc` are provisioned automatically. See Creating a loop on page 140.
- Read the Code Genie on page 199 topic to understand how Code Genie works with AI-integrated features.
- Obtained GitHub Copilot or an IBM Bob AI agent token and save it under Manage Coding CLI on page 215 section. This token is required for the Copilot or Bob dev container to authenticate with the AI service.
- Ensured your team follows a branching strategy on page 233 with a protected main branch.

Attention: If you are deploying in an air-gapped environment, disable the Copilot code review. The Copilot script requires internet access to communicate with the GitHub Copilot service, which is not available in an air-gapped environment. See Disabling Code Review in an Air-Gapped Environment on page 207.

About this task

Code Genie runs the `Copilot` dev container on each pull request to perform AI-assisted code reviews. When a pull request is opened, Code Genie (`service-account-devopscode-genie`) launches an AI agent using the configured model, such as `claude-sonnet-4.5`, and analyzes the pull request diff in the context of the repository.

During the review process, the AI agent reads the pull request diff, examines modified files, checks for repository-specific guidance in `.github` or `.agents` folders, and evaluates the changes for potential security vulnerabilities, logic defects, input validation issues, edge cases, maintainability concerns, and overall code quality. Review findings are posted directly to the pull request as both summary comments and line-level annotations.



Code Genie also provides a detailed CLI execution log that records the review workflow, including prompt generation, repository inspection, file reads, tool usage, code analysis steps, output generation, and validation. These logs provide transparency into how the AI agent arrived at its review findings and can be used for troubleshooting and audit purposes.

../videos/cli-output.mp4

Important: When a pull request is closed, the `Copilot` dev container associated with it is automatically terminated. Any other open pull requests waiting for Code Genie results at that point may not receive their comments because the container is no longer running. This is a temporary limitation in the current release.

1. Open `.devops-loop/code-config.jsonc` in the **Control** repository.
2. Replace the existing configuration with the following, which enables the Copilot AI code generation container:

```
{
  "code-genie": {
    "pull-request": [
      {
        "dev-container": "Copilot",
        "interactive": true,
        "custom-commands": [
          {
```

```
            "code-review-command": "export GH_TOKEN=${loop_property:copilotclitoken} &&
cp /opt/run-copilot.ts /usr/code/ && tsx /usr/code/run-copilot.ts --prompt-file=${promptFile}
--llm_args=\"--allow-all-tools --model claude-sonnet-4.5\""
          }
        ]
      }

      /* Uncomment this block to use IBM Bob Shell for code reviews
      ,
      {
        "dev-container": "Bob",
        "interactive": true,
        "custom-commands": [
          {
            "code-review-command": "export BOBSHELL_API_KEY=${loop_property:bobtoken} &&
cp /opt/run-bob.ts /usr/code/ && tsx /usr/code/run-bob.ts --prompt-file=${promptFile}
--bob_args=\"--yolo --accept-license --auth-method api-key\""
          }
        ]
      }
      */
    ]
  }
}
```

You can adjust the following parameters for the `Copilot` container:

`interactive`

Set to `true` to enable communication of code-genie with user using Pull Request comments.

`loop_property:copilotclitoken`

The Loop property key that holds your Copilot CLI authentication token. Ensure this property is set on the Loop before enabling this container.

`--prompt-file`

Path to the prompt file that instructs the AI model what to generate or review. The `${promptFile}` variable is resolved at runtime by Code Genie.

`--model`

The AI model to use for code generation. Defaults to `claude-sonnet-4.5`. You can substitute another supported model as required by your organization's policy.

`--allow-all-tools`

Grants the AI model access to all available Copilot CLI tools during code generation. Remove this flag to restrict tool access.

Note: This topic focuses on configuring AI-assisted pull request reviews with Code Genie. For a complete overview of Code Genie capabilities, see Code Genie on page 199.

3. Commit and push the updated `code-config.jsonc` to the main branch.
4. Validate the end-to-end **Code Genie** workflow by creating a test branch and opening a pull request to the main branch.

../videos/code-genie-ai-review.mp4

a. Create a test branch in the Control repository, make a minor change, commit and push the changes, and open a pull request targeting main.
b. Confirm that Code Genie shows a yellow dot next to its name, indicating the `Copilot` container is starting.
c. Confirm that Code Genie adds it comments to the pull request after the Copilot review completes and that the merge button becomes active.

5. Verify the webhook on page 212 that was automatically configured during **Loop** creation.
6. Verify branch protection rules on page 233 and Code Genie reviewer settings that were auto-configured during Loop creation.

Results

You have configured AI-integrated Code Genie on your Control repository. Every pull request to the main branch now triggers an interactive Copilot AI code review session. Code Genie posts AI-generated code suggestions as pull request comments for developer review.

What to do next

After completing this configuration, you can:

- Switch to a different AI model by updating the `--model` argument in the Copilot container command in Code Genie's `code-config.jsonc`.
- Enable the IBM Bob Shell container as an alternative AI reviewer by uncommenting the `Bob` dev container block in `code-config.jsonc`.
- Add further dev container blocks to run additional capabilities such as unit testing or static code analysis alongside Copilot. See Code Genie on page 199.

Trivy scanning with Code Genie

A Control repository that is created as part of creating a HCL DevOps Loop will be automatically configured to perform security scanning with **Trivy**. This ensures that every pull request is automatically scanned for problems such as vulnerabilities, security breaches, misconfigurations, etc. before code reaches the main branch. Use this procedure when you want to enforce severity-based merge protection across your team.

Before you begin

Before you begin, ensure that you have:

- Administrator access to your team space.
- Created a teamspace. See Creating a teamspace on page 132.
- Created a **DevOps Loop** so that the Control repository, webhook, branch protection, and default `.devops-loop/code-config.jsonc` are provisioned automatically. See Creating a loop on page 140.
- Read the Code genie on page 199 topic to understand how Code genie works with features like Trivy.
- Familiarized yourself with the Trivy CLI reference for available scan parameters.
- Ensured your team follows a branching strategy on page 233with a protected main branch.

Note: If your security policy doesn't require running Trivy scans on every pull request, you can disable them. For more information, see Disabling Trivy Scanning and Code Review on Pull Requests on page 206.

About this task

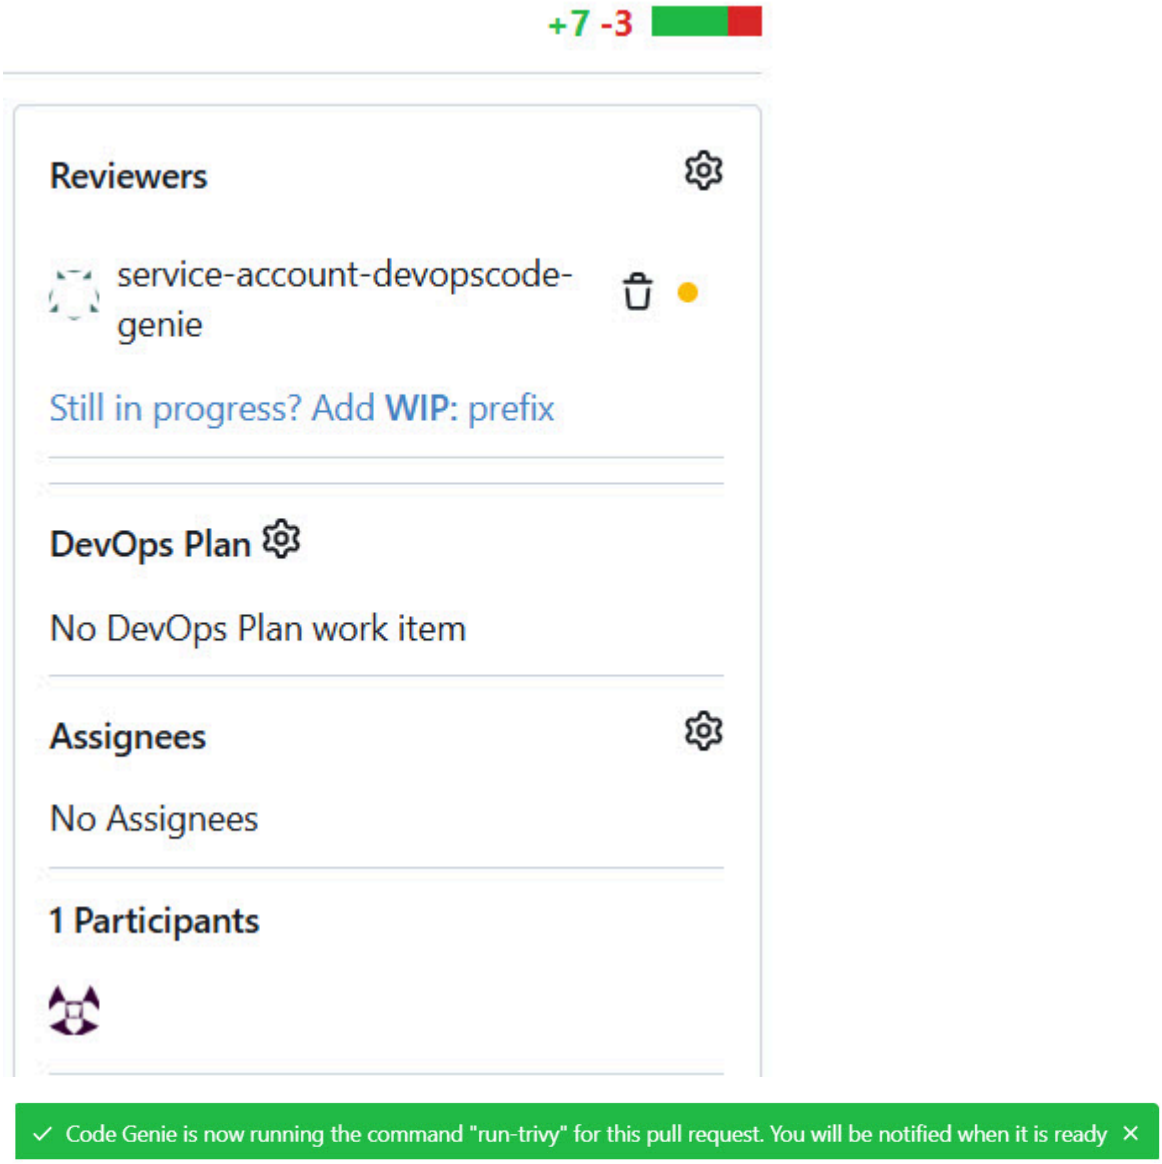
Trivy scans every pull request for vulnerabilities (CVEs), IaC misconfigurations, leaked secrets, and license violations. Code Genie (`service-account-devopscode-genie`) posts the scan results as pull request comments and blocks merges when findings equal or exceed the configured rejection threshold. You can customize the scan behavior in `.devops-loop/code-config.jsonc` by setting the rejection threshold (`--reject`), the scanner types (`--scanners`), and types of severity issues to scan for.

Important: Automatic configuration of the webhook, branch protection rules, and `.devops-loop/code-config.jsonc` only applies to Control repositories created through the Loop creation process. If you create a Control repository manually at a later stage, you must manually add the webhook, configure branch protection rules, and create the `.devops-loop/code-config.jsonc` file for Trivy scanning to work.

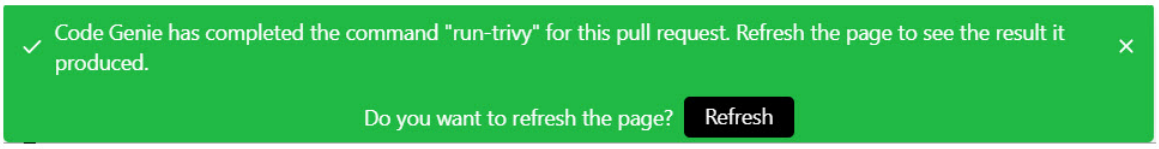
Important: When a pull request is closed, the `TrivyScan` dev container associated with it is automatically terminated. Any other open pull requests waiting for Code Genie scan results at that point may not receive their comments because the container is no longer running.

These are temporary limitations in the current release.

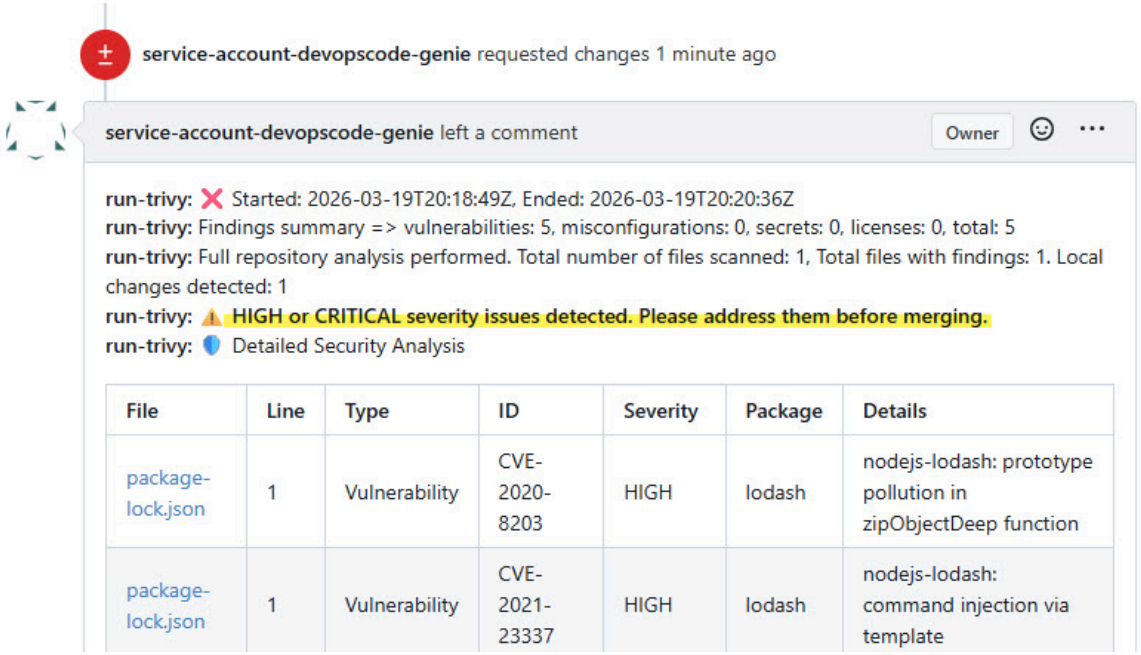
1. Validate the end-to-end **Trivy** workflow by creating a test branch with a vulnerable dependency and opening a pull request to the main branch.
    a. Create a test branch in the DevOps Control repository, add a dependency with a known vulnerability, commit and push the changes, and open a pull request targeting main.
    b. Confirm that Code Genie shows a yellow dot next to its name, indicating the scan is running, and that the merge button is disabled.



c. Wait until a pop-up appears that tells Trivy scanning is completed. It usually takes around 20 seconds, but it depends on the size of the Control repository.



d. Review the Code Genie pull request comments and confirm that HIGH or CRITICAL findings are blocking the merge, if the `--reject` is set to high.



service-account-devopscode-genie requested changes 1 minute ago

Write Preview

2. Verify the webhook that was automatically configured during **Loop** creation.

a. Go to **Settings > Webhooks** in the repository.

b. Confirm that the webhook shows the following values.

- Target URL: `http://devops-code-container-mgr:3005/api/pull-request`
- HTTP method: POST

- Content type: `application/json`
- Trigger events: Pull Request as well as PR Synchronized
- Status: Active

Warning: Do not delete or modify the auto-generated webhook. Doing so breaks Trivy scanning.

3. Open `.devops-loop/code-config.jsonc` in the **Control** repository and customize the Trivy scan parameters to match your security policy.

   The default configuration is as follows:

```
{
  "code-genie": {
    "pull-request": [
      {
        "dev-container": "TrivyScan",
        "interactive": false,
        "custom-commands": [
          {
            "run-trivy": "cp /opt/run-trivy.sh /usr/code/ && chmod +x /usr/code/run-trivy.sh &&
 REPO_URL=https://${platform-fqdm}/control/${repo-owner}/${repo}/src/branch/${pr-branch}/ /
usr/code/run-trivy.sh ${code-folder} ${result-json} --reject=high --trivyArgs=\"--scanners
 vuln,misconfig,secret,license --license-full --severity UNKNOWN,LOW,MEDIUM,HIGH,CRITICAL\""
          }
        ]
      }
    ]
  }
}
```

   You can adjust the following parameters:

   - `--reject` — sets the minimum severity level that blocks a pull request merge. Accepted values are `never`, `low`, `medium`, `high`, and `critical`. Also, `never` means that the PR will never be rejected, and that only Trivy scan results will be provided as PR comments.
   - `--scanners` — sets the scanner types to run.
   - `--severity` — sets the severity levels that Trivy reports on.

4. Verify branch protection rules on page 233 and Code Genie reviewer (auto-configured during Loop creation).
5. Commit and push the updated `code-config.jsonc` to the main branch.

Results

You have configured Trivy security scanning on your Control repository. Every pull request to the main branch now triggers an automatic Trivy scan. Code Genie approves or blocks the merge based on the `--reject` threshold you defined in `code-config.jsonc`.

What to do next

After completing this configuration, you can:

- Adjust the `--reject` threshold or `--scanners` list in `code-config.jsonc` as your security policy evolves.
- Add further dev container blocks to run additional capabilities such as unit testing or static code analysis alongside Trivy. See Code Genie on page 199.
- Review the Trivy CLI reference for the full list of available scan arguments.

Branching strategy with a protected main branch

Verify that branch protection rules and Code Genie are correctly configured on your Control repository to enforce a pull request-based workflow on the main branch.

1. Navigate to **Settings > Branches > Branch Protection** in the **Control** repository.
   ../videos/branch-protection.mp4
2. Verify branch protection rules and Code Genie on page 199 reviewer (auto-configured during Loop creation).

    a. Confirm that the **main** branch protection shows the following:
        - Direct pushes to main are blocked.
        - Require pull request reviews before merging: ENABLED. At least one PR approval is needed.
        - Required reviewers list contains: `service-account-devopscode-genie`.
        - Block merge on rejected reviews: ENABLED.

Managing Git authentication for developers

In this topic, you will learn how to manage authentication when using Git on your system to access Control repositories within DevOps Loop deployment.

There are three types of credentials you can use with Control in a Loop deployment:

- **SSH keys**: For information, see the Using an SSH key (for Desktop) section in the Control Documentation.
- **Personal access token via HTTPS**: For information, see the Using HTTPS (not with OAuth2 support) section in the Control Documentation.
- **OAuth credentials with Git Credential Manager via HTTPS**: To configure your Git client in the development environment for HTTPS communications with Control in a DevOps Loop deployment, add settings similar to the following example using the Git command line. Replace *`yourhost.example.com`* with your Loop server's hostname:

```
git config --global credential.https://yourhost.example.com.provider generic
git config --global credential.https://yourhost.example.com.oauthClientId git-credential-manager
git config --global credential.https://yourhost.example.com.oauthTokenEndpoint /auth/realms/devops-
automation/protocol/openid-connect/token
git config --global credential.https://yourhost.example.com.oauthDeviceEndpoint /auth/realms/devops-
automation/protocol/openid-connect/auth/device
git config --global credential.https://yourhost.example.com.oauthAuthorizeEndpoint /auth/realms/devops-
automation/protocol/openid-connect/auth
git config --global credential.https://yourhost.example.com.oauthAuthModes DeviceCode
git config --global credential.https://yourhost.example.com.oauthScopes api:control:all
```

This configuration ensures secure and efficient access to your repositories.

Note: After any Loop upgrade, you should remove cached credentials from the previous use of Git Credential Manager. Refer to the documentation for your Git Credential Manager to find instructions on how to clear the cached credentials.

Build

Build offers the capability to build applications, manage continuous integration workflows, and store build artifacts.

Build uses a template-driven approach, enabling the creation of projects based on predefined templates that can be extended with additional process and workflow templates. These templates help standardize build procedures, enforce source control policies, integrate testing practices, and manage reporting workflows.

System requirements

Build runs on Windows and Unix-based systems. While the minimum requirements provided below are sufficient for an evaluation, use server-class machines for production deployments.

For more requirement details, you can dynamically generate a system requirements report using the Software Product Compatibility Reports (SPCR) tool.

Server installation for best results

- **Two server-class computers**

  Use two computers for the server: a primary server and a standby for fail-over. In addition, host the database on a separate computer in a fail-over configuration.

- **Database servers:** Separate computers.
- **Processor:** 2 processors and at least 2 cores for each.
- **Memory:** 8 GB
- **Java:** 32-bit or 64-bit JDK.
- **Disk Space:** Individual requirements depend on usage, retention policies, and application types. In general, the larger the number of retained artifacts in the Build artifact repository CodeStation, the more storage is required.

  Note:

  CodeStation is installed when the Build server is installed.

  For production environments, use the following guidelines to determine storage requirements:

- 10-20 GB of database storage is typically sufficient for most environments.
- Use this format to calculate CodeStation storage requirements:

```
Average artifact size x Number of versions imported per day x Average number of days before cleanup
```

- Approximately 1MB of database storage per build. This value varies according to the build process.

For further assistance in determining storage requirements, contact IBM Software Support.

- **Network:** Gigabit (1000) Ethernet with low-latency to the database.

Minimum agent requirements

Designed to be minimally intrusive (typically, an idle agent uses 5MHz of processor power), agents require 64-256 MB of memory and 100 MB of disk space. Agents can run with a 32-bit or 64-bit JDK. Additional requirements are determined by the processes that the agent runs. In production environments, install agents on separate computers.

Minimum server installation requirements

- **Operating System:** Windows 2000 Server (SP4) or later, Linux (any distribution). Ask IBM Software Support about other operating systems.
- **Processor:** Single core, 1.5 GHz or faster.
- **Memory:** 2 GB, with 512 MB available to Build.
- **Java:**

DevOps Build version	Java version
7.1.0.2	JRE 17
7.1.0.1	JRE 11
7.1.0.0	JRE 11 or JRE 8

- **Disk Space:** 300 MB minimum. More is required when you start publishing build artifacts and using the embedded database.

Agent Minimum Requirements

Agents require 64-256 MB of memory and 100 MB of disk space. Agents can run with a 32-bit or 64-bit JDK. Additional requirements are determined by the processes that the agent runs. In production environments, install agents on separate computers. For requirement information, generated a report using the Software Product Compatibility Reports (SPCR) tool.

Overview of Build

Build is a continuous integration and build-management system.

Build is a distributed, multi-platform, enterprise-scale build management tool. Build uses a template-driven system to configure and run builds. Projects are created from project templates and are configured by assigning other templates to them, such as process and workflow templates. The templates can define standard build processes, source control rules, and testing and reporting processes.

With the flexible role- and team-based security system, you can create an environment that conforms to your organization. For example, you might maintain a design team that creates templates for other teams. Development teams can create projects quickly by configuring the preset templates. Values for template properties can be supplied at design time or at run time.

Every time that you build a project, build artifacts are added to an embedded artifact and dependency management system, CodeStation. CodeStation helps manage complex projects that can depend on numerous sub projects and libraries. Because CodeStation is part of Build, third-party management systems are not necessary. Builds are repeatable, standardized, and traceable.

Distributed agents do the actual work of build processing. An agent is a lightweight process that runs on a host computer and communicates with the server. By handling the build activities, agents distribute the load of concurrently running builds and provide enterprise-level scalability.

The management tools in Build provide project status at any point in the build cycle, and simplify capturing project data. Enterprise-level metrics are available for these areas:

- Compliance
- Governance
- Data aggregation and reporting
- Auditing and logging
- Version and change control

Concepts

To better understand Build, familiarize yourself with these concepts.

Projects

Projects in Build represent the components and applications that your company develops. Each project has its own pipeline for release or distribution. Projects often correspond to how development is organized in your source control management system. Projects might also be composites of other projects that use a dependency management system. If components are developed independently and then composed into applications, the components themselves can become projects that support other projects that represent applications or products. Projects are created with project templates.

Build processes

A build process is a configuration that you run to conduct a build on some source material.

The build processes define:

- Everything that happens during builds and everything that is required by them.
- Where to get source code and dependencies.
- What tools are required to build.
- What tests need to run.

The build processes are created with process templates which typically produce artifacts and are attached to projects, which can have any number of build processes attached to them.

Source configurations

A source configuration identifies the source material for a build. They can define the branch or label to pull source material from, or use other criteria. Source configurations are attached to build processes. A build process can have multiple source configurations assigned to it if it pulls source code from multiple locations. Source code locations can be in multiple repositories and from any type of source control system. Source configurations are created with source configuration templates.

Source repositories

A source repository configuration supplies the information that is required to connect to an external source repository. Because source repository configurations do not define the details of any particular source, they are highly reusable.

Dependencies

Dependencies are configured to provide artifacts and build triggers between projects and third-party artifacts, such as open source libraries. When you create a dependency for a build process, you identify the artifacts that your build requires to run or build. Dependencies are highly configurable; you can specify criteria for version, or status, or other characteristics. Dependencies can trigger builds, which can work bi-directionally by pushing or pulling. Pull dependencies retrieve material from other sources, and push dependencies send material to other targets. If you have a common component project, you might trigger builds when the common project changes.

Templates

Templates are reusable configurations that define projects and processes. Each template encapsulates a type of project, such as a source configuration, workflow, job, or process. You can create templates properties and define their values at design time or run time. For instance, a template might always call a particular type of build script, but the name or location of the script might vary by project. Templates provide a high level of reuse because you decide the number of properties and when their values are defined.

Processes

A process defines the jobs and steps that go into a build. Processes are created with process definition templates, and like all templates, they are reusable. A number of built-in steps are available, but most of steps come from plug-ins. Steps are collected into jobs and jobs are composed into processes. When you place a job in a process, you specify several options, including the agent pool, the working directory, and others. With processes, you can run jobs in parallel and then join them

later. Jobs can also be iterated to run a number of times. Each job run can have its own properties, which are useful for multi-platform, parallel builds.

Build lives

A build life is record of a build. It records the inputs, the build activities, the produced artifacts, and activities that are done after the build. A build life tracks the source, the dependencies, the computer that is used, and the deployment or release of the produced artifacts. All completed steps and their output are recorded. Tests can be recorded, along with defects, features, and stories. Each build has a unique build life.

Secondary processes

A build process produces a new build; a secondary process runs on a build life. Secondary processes can be run only on an existing build life with at least one completed build process. Typically, secondary processes are used for tests or analytic tools. If one of your test suites takes an unusually long time, you might want to schedule it to run nightly in a secondary process.

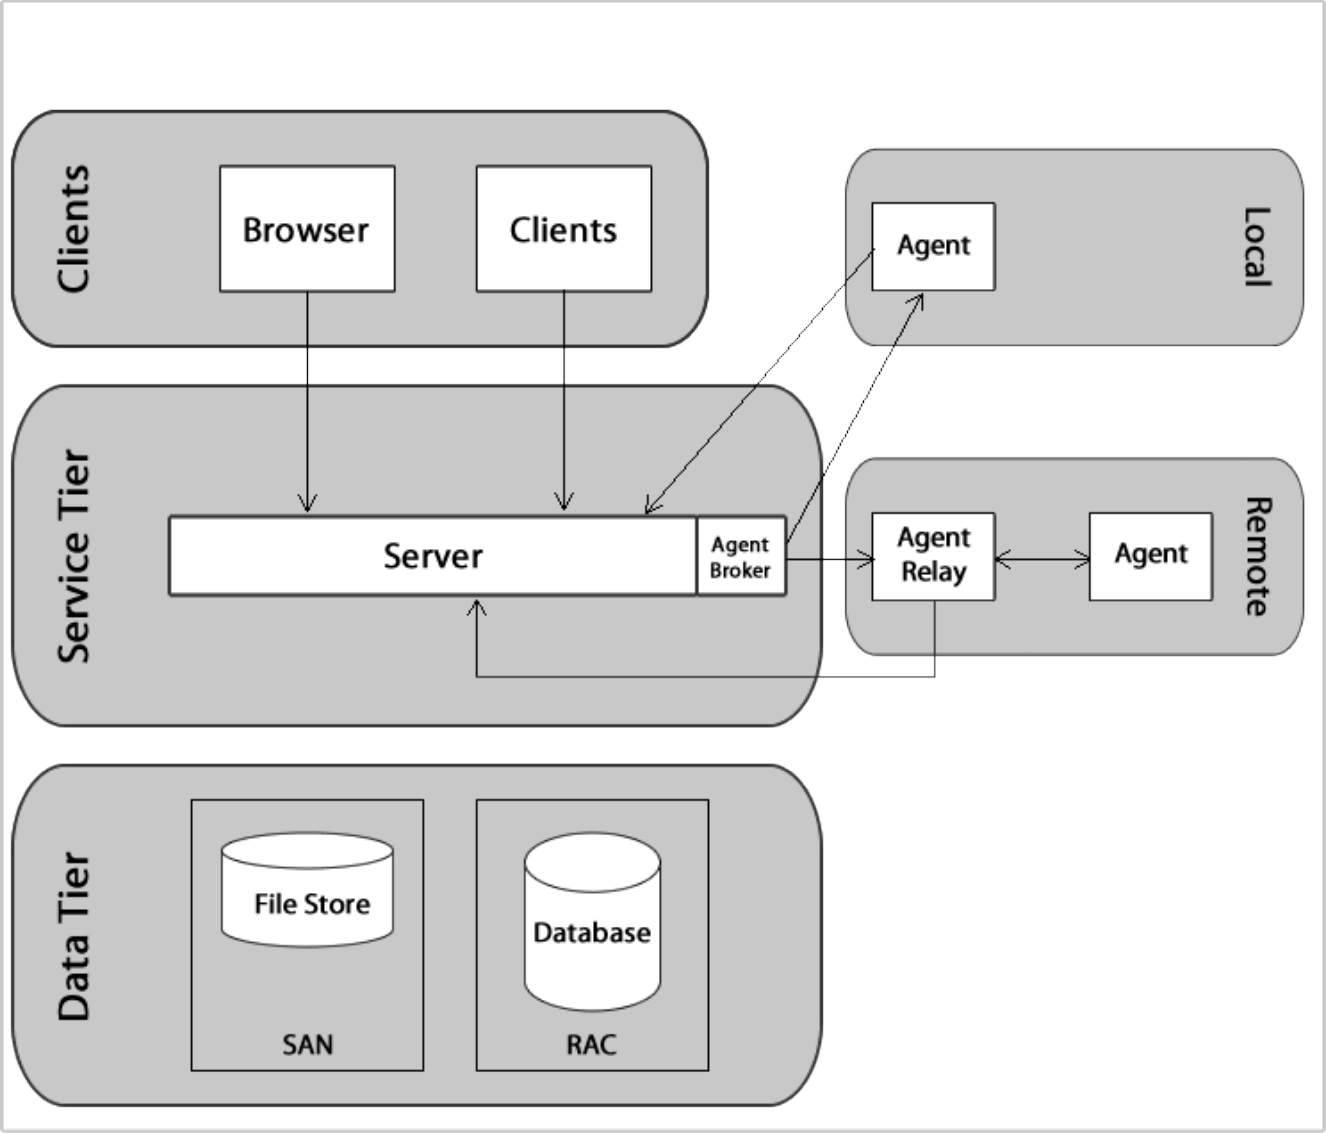
Architecture

Overview of the Architecture

The Build architecture consists of a centralized server and distributed agents. The server provides a data store, user interface, and coordinates agents among other things. All build activities occur on agents, and agents act only when the server tells them to.

The Build server consists of a service tier and a data tier. The service tier consists of a central server that provides a web server front-end and core services, such as workflow, agent management, security, and others. A service can be thought of as a self-contained mechanism for hosting a piece of processing logic. The server orchestrates builds with agents that are distributed throughout the network. The server exposes several interfaces. The first is a web user interface that is exposed through HTTP or HTTPS and is primarily used by users with browsers. Web services use HTTP or HTTPS and are primarily used by agents for some types of communications, and for integrations with external tools. The last interface is used for server-agent communication and is done with JMS (discussed later) and uses TCP/IP.

Architectural overview



JMS server-agent communication and associated web services are stateless forms of communication. "Stateless," as used here, means that the server retains little session information between requests and each request contains all the information that is required to handle it. With this setup, the communication system performs well without a lot of resource overhead.

Server-agent communication is used to send work to agents and the results back to the server. Because JMS connections are persistent and are not based on a request-response protocol, Build does not have to continually open and close connections. With persistent connections, the server can communicate with agents at any time while it remains secure and scalable. The server listens on a port for agents to connect to it. For added security, agents do not listen on ports and make connections to the server only to provide two-way communication. This arrangement simplifies firewall configuration because all connections are initiated in one direction, from the agent to the server.

Many services in Build are exposed as REST-type (representational state transfer) web services. These services are used to send and receive information over HTTP or HTTPS. The information can be formatted in XML or JavaScript Object Notation (JSON). The REST-style services are stateless and ensure that requests include all the data that the server requires to respond coherently.

The data tier stores information in a relational database and on the file system. The data tier's relational database stores configuration and run time data. The data tier's file store contains log files and build artifacts. Artifacts are stored in a system that is called CodeStation, which is also a dependency management system. CodeStation stores the build artifacts in a content-addressable storage format that minimizes storage requirement by not storing the same files multiple times. By default, file storage is contained in the `var` directory of the server installation. The location of this storage can be changed with the server configuration, or you can map the directory to a network addressable storage location.

Service tier

The Build server provides various services, such as: the user interface, process engine, and security services, among others. The REST-based user interface provides the web-based front end that you use to create projects and define workflows; request processes, and manage security and resources, among other things.

When a workflow is requested, many services are used to fulfill the request. Workflow requests are initiated with the user interface or a REST service.

Table 6. Services

Service	Description
User Interface	Used to manage the configuration of all items and see the current and historical runtime information of the system.
Process Engine	Does processing for builds and secondary processes. This service also uses the agent manager service to acquire agents for jobs and run steps on agents. This service also sends events about job starts and completions that are used by notification and dependency services for sending notification and triggering other jobs.
CodeStation	Is a dependency management system and artifact repository. CodeStation can store and process dependency configurations, with which builds can retrieve the artifacts that they require at build-time. This resolution is also stored with the build life as a permanent history of what was used. CodeStation also provides an interface as a Maven repository.
Agent manager	Tracks agents and their offline and online status. This service also controls access to agents if a workflow must run a step on an agent. Agent manager also stores the properties of an agent and can be used to upgrade or restart an agent remotely.
Plug-in manager	Build can interact with virtually any system through its extensible plug-in system. Plug-ins provide functions by breaking-down tool features into automated steps. Plug-ins can be configured at design- and run time. When a plug-in step runs, the controlling agent calls its runtime process to run the step.

Table 6. Services (continued)

Service	Description
Event service	A message bus with publishers and subscribers that provides messaging between services in an asynchronous method.
Notification manager	Notifies users about events by using notification schemes, which consist of the when, who, what, and how of notifications. When is the event that triggers a notification. The who is to whom the notification is sent. What is the content that is sent which, is generated from templates. How is the notification channel and can be email or instant message.
Security	Includes authentication and authorization functions. The authentication is configuration for determining who a user is and might use an internal database, LDAP, Active Directory, or a Single Sign-On service. The authorization is configuration for what a user can do. The security service includes tools for assigning users to groups, and for assigning users and groups to roles.

Data tier

The Build data tier contains a relational database and a file storage system.

Relational databases

Build supports Oracle, Microsoft™ SQL Server, and MySQL relational databases. The provided Derby database, though sufficient for proof-of-concept work, is insufficient for the enterprise. Ideally, the database you use is configured for high-performance and is backed up regularly.

Database storage of 10-20 GB is typically sufficient for most environments. The following configurations are sufficient in most cases:

- Oracle RAC
- Microsoft™ SQL Server, clustered
- MySQL, cluster

File storage: CodeStation

The data tier also provides log file and CodeStation artifact storage.

Artifacts represent items such as files, images, databases, configuration materials, or anything else that is associated with a software project. By default, these artifacts are stored in the `var` subdirectory in the Build server installation directory. In an enterprise environment, the default installation might not be ideal. See CodeStation relocation on page 242 for enterprise options.

The artifact repository uses content addressable storage to maximize efficiency while it minimizes disk use. The repository tracks file versions and maintains a complete history for all artifacts. Maximizing efficiency is important because the repository stores files that are much larger than source files.

The artifact repository comes with a client application that provides remote access to the repository. Using the client application, you can add or modify files, create packages, retrieve files, and view the history of changes. The client application provides a file transfer capability that can be used to deliver files to target servers during deployments. This built-in transfer mechanism verifies the integrity of all transferred files against their expected cryptographic signatures. This verification ensures that files were not corrupted during transmission or tampered with during storage. In addition to the client application, the artifact repository provides REST-based web services.

CodeStation relocation

By default, log files and CodeStation artifacts are stored in the `var` subdirectory within the Build server installation. You can store this data in another location. Ideally, the new location is on a network storage system that is regularly synchronized with an off-site disaster recovery facility. In addition, make sure that the Build server has a fast network connection to the storage. Agents do not need access to the storage location. In UNIX environments, you can use symbolic links from within the `var` subdirectory to network storage. On Windows platforms, there are several options for redirecting logs and artifacts, including mklink, which is supported in Windows 7 and later.

You can also move file storage to a location other than the `var` directory by setting a `server/var.dir` property for the Build server. To set the property, edit the server's `set_env` file in the server's `bin` subdirectory. Edit the definition of `JAVA_OPTS` to include the redirection property, as shown in this example:

```
-Dserver/var.dir=/alternate/var/path
```

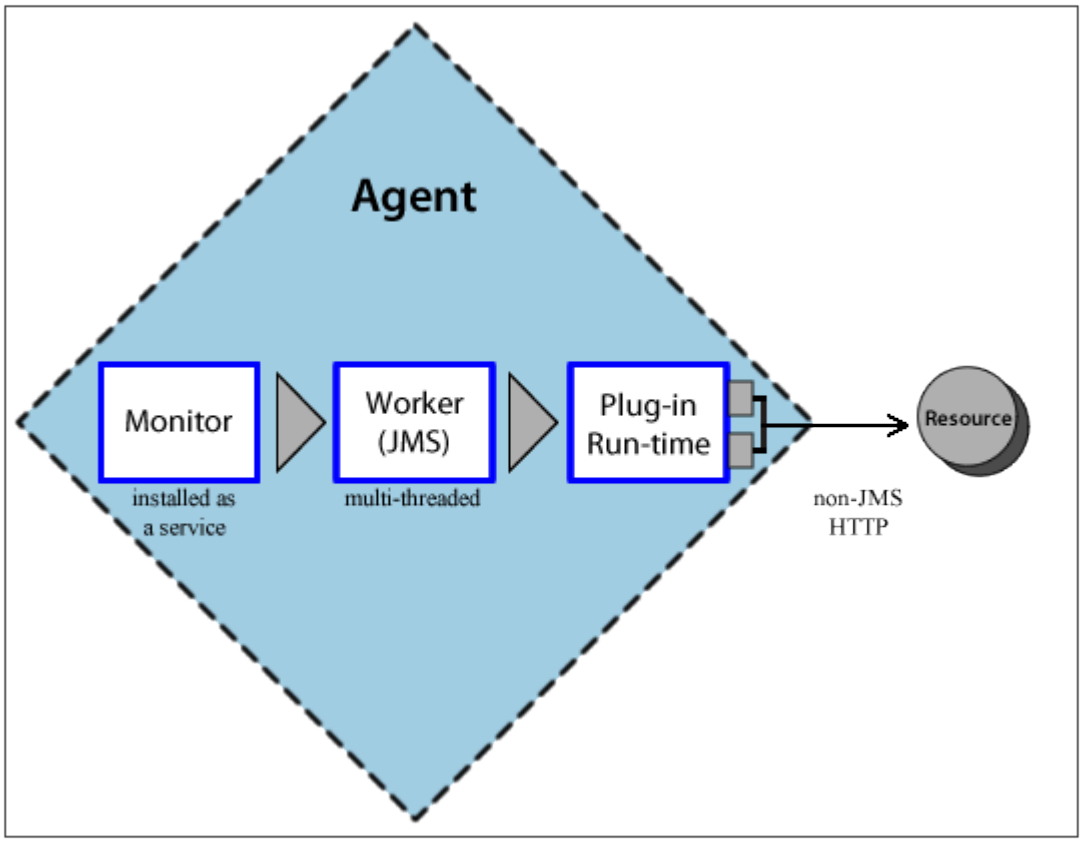
Distributed teams can also take advantage of Build location-specific CodeStation proxies to improve performance and lower WAN use.

Agents

An agent is a lightweight process that runs on a host computer and communicates with the Build server. Agents are the workers of the Build architecture. Agents complete the actual build activity, which distributes the load of concurrently running builds and provide scalability. After an agent is started, the agent opens a connection to the Build server. Communication between server and agents uses a JMS-based (Java Message Service) protocol and SSL, which can optionally enforce mutual authentication. This communication protocol is stateless and resilient to network outages.

Although an agent is characterized as a single process, technically an agent consists of a monitor process and a worker process. The monitor is a service that manages the worker process. It is responsible for starting and stopping the worker, handling restarts, and completing upgrades. If the worker fails for an unexpected reason, the monitor restarts it. The worker is a multi-threaded process that connects to the server and completes any work that the server sends to it. Agents do not have to be upgraded every time that the server is upgraded. The server maintains a minimum agent version property, which is the minimum version that is required to work with the server. When agents are updated, it is to take advantage of new features or fix bugs. Agents can be upgraded with the installation process on the host computer or remotely through the server web user interface. After an agent is installed and connected to the server, it is displayed in the web user interface where it can be activated and placed into agent pools. A newly installed agent does not receive work until you activate it.

Agent processes



Agents are an important part of Build scalability. By adding more agents, the throughput and capacity of the system increases and can scale to serve even the largest enterprise.

Server-agent communication

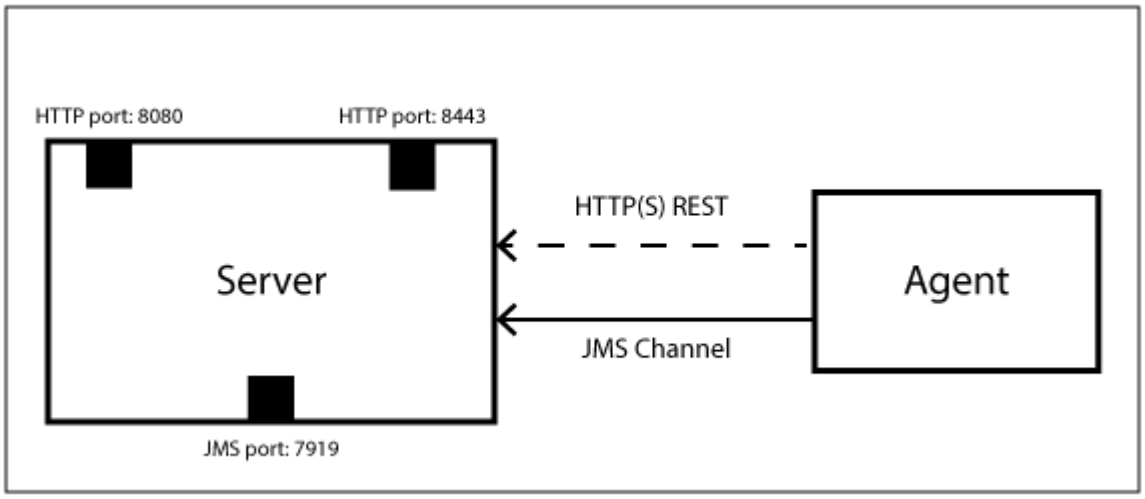
Most server-agent communication is done with JMS, but some agent activities such as uploading logs, test results, or artifact files to CodeStation use HTTP or HTTPS as needed. The JMS channel is the primary control channel for Build. It is the channel that the server uses to send agent commands. By default, the server listens on port 7919 for JMS, port 8080 for HTTP, and port 8443 for HTTPS. These ports are configured during the server installation. The agent needs to know only the server's host and JMS port. The web interface URL is sent to the agent when it is needed.

The server's agent manager service uses JMS for all server communications and for sending commands, such as "run step," to the worker process. The worker process uses JMS for system communications, and HTTP REST services when it processes plug-in steps or retrieves information from the server.

Stateless server-agent communication provides significant benefits to performance, security, availability, and disaster recovery. Because each agent request is self-contained, a transaction consists of independent message, which can be synchronized to auxiliary storage as it occurs. The server or agent can be taken down and brought back up without repercussion (other than lost time). If communications fail mid-transaction, no messages are lost. When reconnected, the server and agent automatically determine which messages got through and what work was completed. After a connection

outage, the system synchronizes the endpoints and recovers affected processes. The results of any work that an agent completes during the outage are communicated to the server.

Agent-server communication



In the accompanying figure, the arrow represents the direction in which communications was established, but the flow can be in both directions with JMS.

Mutual authentication

With Secure Socket Layer (SSL) technology, clients and servers can communicate securely by encrypting all communications. Data is encrypted before it is sent and decrypted by the recipient. Communications cannot be deciphered or modified by third-parties. SSL can be used in two modes:

In unauthenticated mode, communication is encrypted and decrypted but endpoints do not have to verify the other's credentials. By default Build uses this mode for its JMS-based server-agent communication.

In mutual authentication mode, communications are encrypted and decrypted, but endpoints are also required to authenticate themselves by providing certificates. A *certificate* is a cryptographically signed document that is intended to assure to others the identity of the endpoint that uses the certificate. Mutual authentication is enabled on a per-endpoint basis.

When mutual authentication mode is enabled on an endpoint, the endpoint requires that the other endpoint that it is communicating with has a trusted certificate. A certificate is trusted if that certificate is signed by another trusted certificate such as a certificate authority or is a trusted certificate itself. A certificate is trusted if it is imported into the endpoint's keystore as a trusted certificate.

When the server has mutual authentication enabled, the agent certificates that are used must be signed by a trusted certificate authority or be imported into the server's keystore. The same applies for the agent. The server and the agent are not required to have mutual authentication enabled together. The setting applies only to the endpoint and how it accepts certificates of endpoints it communicates with.

Tutorials

This section contains tutorials for users of all experience levels. If you are new to Build, this tutorials introduces the most-used product features in an easy-to-follow way. You do not need additional resources to complete the tutorial.

Create a Maven build project

In this tutorial, you create a project that builds the open source product JUnit. The source code is downloaded from GitHub (an open source code repository) and built with Maven.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a Git repository from which your project downloads the source for JUnit.
- Create a build process and associate an agent pool to it.
- Create a job that checks-out the JUnit source from GitHub and uses Maven to build JUnit, and run tests and generate test reports.
- Create templates that define properties. You supply values for these properties when you create the project.
- Create a project that is based on the templates you created.
- Run a build and monitor its progress.
- Examine build details and troubleshoot problems.

Time required

2 hours

Introduction

In this tutorial, you create a project that builds the open source product JUnit. The source code is downloaded from GitHub (an open source code repository) and built with Maven.

The project that you create in this tutorial introduces you to the most-used product features. The workflow that you create contains the job types you use everyday.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a Git repository from which your project downloads the source for JUnit.
- Create a build process and associate an agent pool to it.
- Create a job that checks-out the JUnit source from GitHub and uses Maven to build JUnit, and run tests and generate test reports.
- Create templates that define properties. You supply values for these properties when you create the project.
- Create a project that is based on the templates you created.
- Run a build and monitor its progress.
- Examine build details and troubleshoot problems.

Time required

This tutorial takes approximately 2 hours to finish. If you explore other concepts that are related to this tutorial, it might take longer to complete.

System requirements

To run this tutorial, you need the following resources:

- An installation of Build, version 6.1 or later.
- An Build agent installed.
- An installation of Maven on the computer where the agent is installed.

Prerequisites

To complete this tutorial, you must have an account on the server with permissions to create and edit projects, jobs, and repositories, and to create and run processes.

Configure the tutorial system

To run the tutorial project, you must configure an *agent*, install the required plug-ins, and create an artifact set.

Before you begin

Before you begin the tutorial, make sure that you completed the Prerequisites on page 246.

About this task

To complete the tutorial, you must have an agent that is running on a target computer. An agent is a lightweight process that runs on a target computer and does the actual work of building the project. This target computer can be a virtual image, or a physical computer, including the one where the server is installed. You must have access to this computer and be able to install the agent on it.

To prepare the tutorial system:

1. Prepare a computer for use as the target system.
2. Install the plug-ins used in the tutorial.
   The tutorial uses the following plug-ins: Git, Maven, and JUnit. The Maven plug-in is installed with the product. Download and install the Git and JUnit plug-ins. Plug-ins can be downloaded from the Build plug-in site: Build plug-ins website. For information about installing plug-ins, see Installing plug-ins on page 351.
3. For performance reasons, agents are generally not installed on the same computer where the Build server is located. For the tutorial, installing the agent on the computer where the server is located is fine.
4. Configure the agent on page 342.
   Your agent must be included in the list of configured agents on the **Agents** page with a status of `Online`.
5. Create an agent pool and add the installed agent to it. on page 345
6. Install the open source tools Git and Maven on the computer where the Build agent is located.
   Add the home directory for each tool to the *PATH* variable on the target system. Add the *MAVEN_HOME* variable to the *PATH* variable.

7. Ensure that the artifact set included with the product, **maven,** is available. If it is not installed, create the artifact set by completing these steps:
    a. From the Build dashboard, click **System**, then click **Artifact Sets**.
    b. In the **Artifact Sets** page, click **Create New Artifact Set**.
    c. In the **New Artifact Set** dialog box, in the **Name** field, type `maven`.
    d. Click **Save**.
8. **Optional:** Configure Java™.
   The agent that runs the tutorial project must be configured to use a Java™ JDK instance, and not a JRE. If the agent is configured to use a JRE (identified by the agent's `java.home` property), reconfigure the agent to point to a JDK. Alternately, you can add the `JDK_HOME` property to the `installed.properties` file, which is in the *`agent_installation`*`/conf/agent` directory. In addition, the tutorial's Maven Build step must reference that property with the `JAVA_HOME` setting.

Results

Your Build environment is ready to being the tutorial.

The tutorial project is also available in a file that you can download and import. To import the tutorial project, follow these steps:

1. Navigate your browser to the file repository URL:http://download.boulder.ibm.com/ibmdl/pub/software/rationalsdp/documentation/product_doc/UrbanCode/uBuild/.
2. Download the file named `DemoProject1.xml`.
3. On the Build **Project** page, click **Import**, and then select the downloaded file.

   Note: Make sure that you install the plug-ins described earlier in this topic before you import the file.

4. In the **Import** window, click **Import**. The server imports the project. The server does not import plug-ins when it imports a project, so you still need to install the plug-ins described earlier in this topic.

Lesson checkpoint

The server and agent are configured for the tutorial, and the files that represent artifacts are ready to use. If you installed the agent on a remote system, you must know the credentials that are required to access the remote system.

Lesson 1: Create a Git repository

Repository integrations enable Build to checkout code, access change logs, and do other project-related activities.

Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the tutorial system on page 246.

About this task

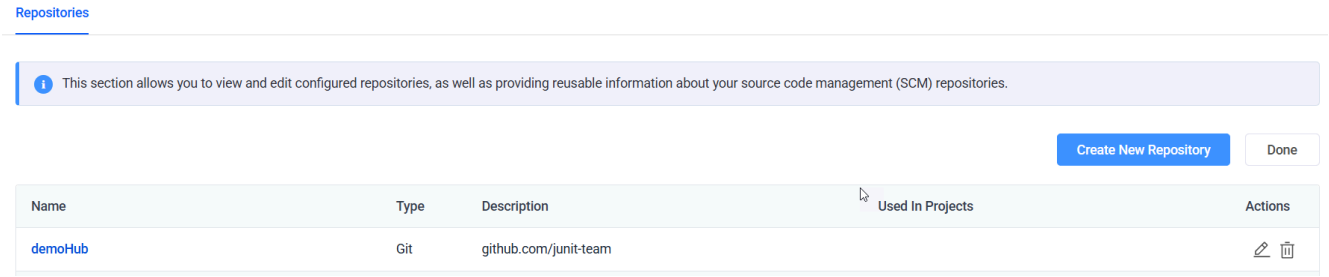
1. On the left navigational panel, click **System > Repositories**.
2. Using the **Repositories** page, click **Create New Repository**.
3. In the **Source Plug-in** list, select **Git** and then click **Set**.
4. In the **Name** field, type `demoHub`.
5. In the **Repository Base URL** field, type `https://github.com/junit-team`.
   This GitHub project contains the JUnit source code.
6. Click **Save**.

Lesson checkpoint

In this lesson, you created a repository based on the Git integration.

About this task

The DemoHub repository is listed on the **Repositories** page.



For more information about repositories, see Repositories on page 330.

Lesson 2: Creating a job and adding steps

A job is a series of steps that, taken together, complete some activity, such as building a project. The steps are run one at a time in the order you specify.

Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the tutorial system on page 246.

About this task

In this lesson, you create a job and add several steps to it.

Creating a job

Most job steps are created from plug-ins. Plug-in steps can be thought of as distinct pieces of automation.

About this task

By combining steps from various plug-ins, you can create fully automated build processes. The number of steps that are provided by a particular plug-in can vary, and each step has a variable number of properties. Property values can be supplied when you define a step or at process run time.

Note: Several plug-ins are included in the product, and you can download other plug-ins as described earlier in the tutorial on page 246. Some steps, such as Assign Status and Create Stamp, are not derived from plug-ins, but you use them in the same way you use plug-in steps.

Create a job by completing the following steps:

1. On the left navigational panel, click **Templates > Jobs**.
2. On the **Jobs** page, click **Create**.
3. In the **Create a Job** window, specify the name to be `Demo Job`.
4. Click **Save**.
   Result
   The **Main** tab for the new job is displayed.

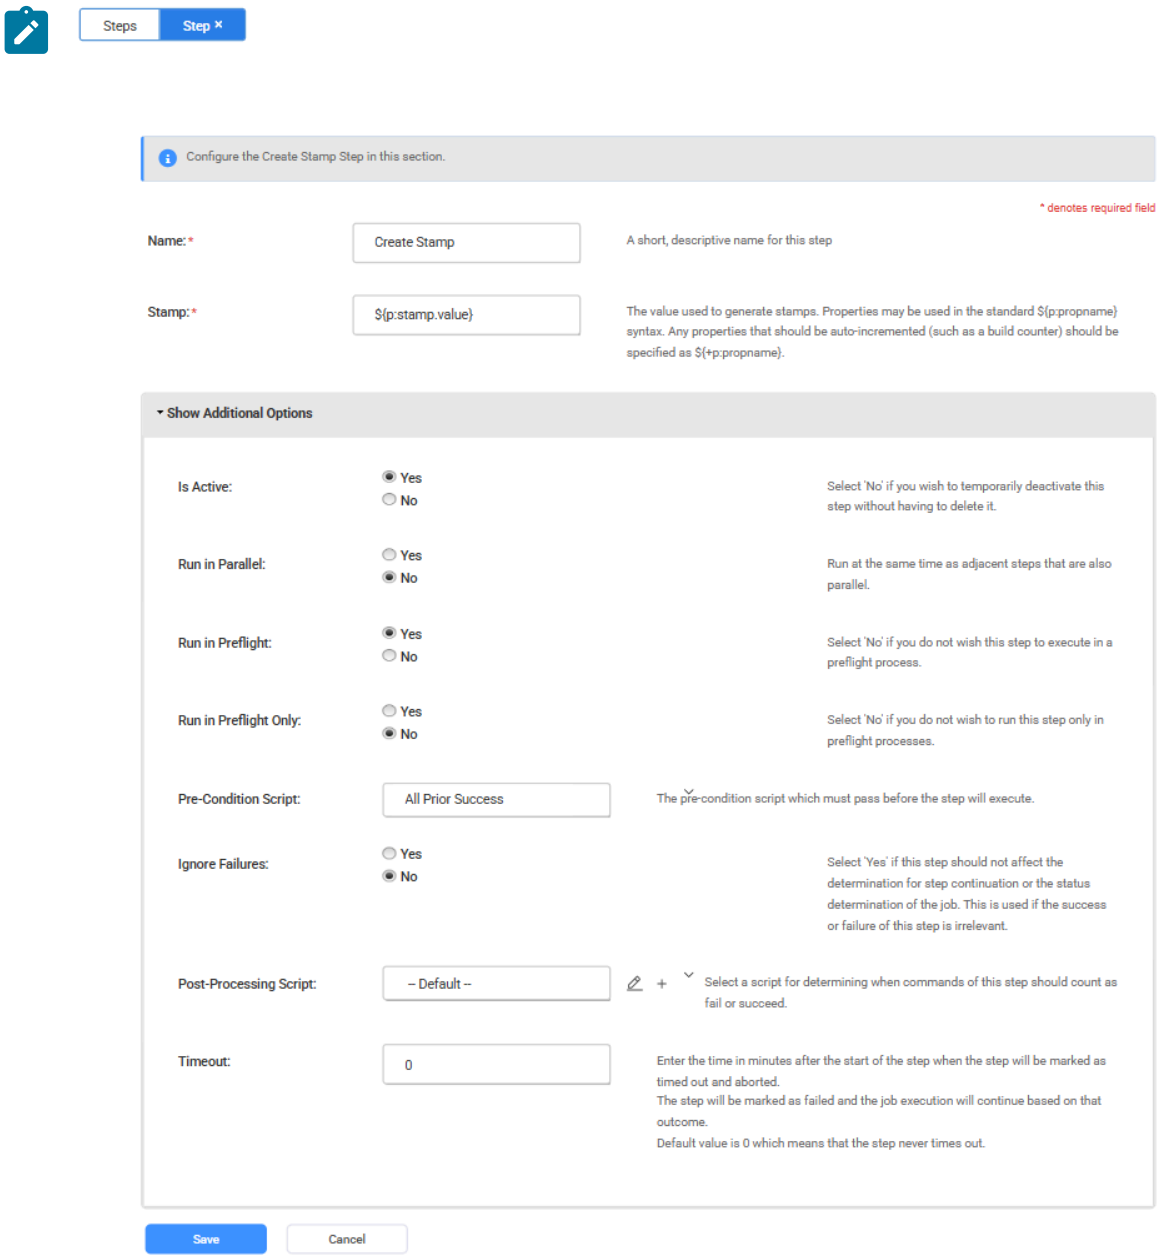
Results
Use the **Main** tab to add steps to the job. Except for the first step, steps can be inserted before or after other steps. When you run the job, the steps are run in the order you specify.

Creating a stamp step

A stamp is a custom identifier that is applied to a build. Stamps are often used in addition to the automatically generated build life identifiers. A stamp step is part of most jobs.

1. If the **Main** tab for the Demo Job is not displayed, then from the Build dashboard, click **Templates > Jobs**, and then click **Demo Job**.
2. Click **Create Step**.
3. Using the **Steps** dialog, click **Build**.
   The **Build** list expands to display the available build-type steps and plug-ins.
4. Click **Create Stamp** step, and then click **Select**.
   Result
   The Stamp dialog is displayed. The dialog that is displayed after selecting a step contains properties for the selected step, and other properties common to all steps.

   Note: Each step dialog has more options available than is initially displayed. To see the other options, click **Show Additional Options**. The additional options are the same for all steps and are set to default values that are acceptable for most jobs. The default value for the **Pre-Condition Script** field is `All Prior Success`, which means the step runs only if the preceding steps are successful. The additional options are show in the following figure. For most of the steps in the tutorial job, the default values are fine.



5. In the **Name** field, type `Create Stamp`.
6. In the **Stamp** field, enter a script to define the stamp: `1.0.0.${p:buildlife/id}`.
   The simplest way to make a unique stamp is to associate it with the build-life number. This short script looks-up the current build-life ID and applies it to the stamp. This script references a property that is part of every build life. Another option might be to reference a property that you can create and define later. For the tutorial, the build life property is fine. For information about the available properties, see the Scripting API Reference *server_url*`/tools/scripting/ibm-ucb-scripting/`.
7. Click **Save**.

Results

The Create Stamp step is listed on the **Main** tab for the job, as shown in the following figure:

After a job has a step, the **Create Step** button is no longer used and actions are used instead to insert steps.

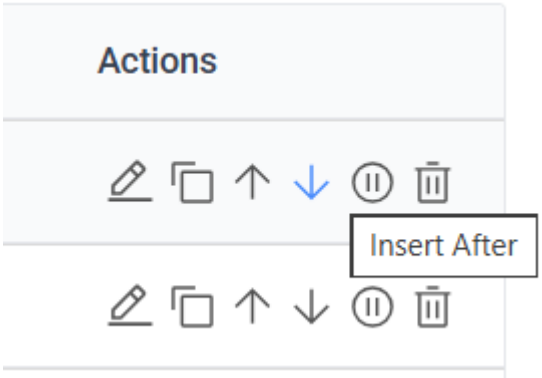
Cleaning the workspace

To ensure that no files from a previous build get incorporated into the new one, add a step to clean the agent's workspace. This step is part of most build jobs.

1. Click the **Insert After** action for the Create stamp step.

   Result

   After a job has its first step, steps are inserted before or after other steps. The **Insert After** action, as the name implies, inserts the new step after the selected step.

2. On the **Steps** dialog, click **Source** and then click **Clean Workspace**.
3. Click **Select**.

   Result

   The Clean Workspace step is selected.
4. In the **Name** field, type `Clean`.
5. Click **Save**.

Results

The Clean step is added to the job after the Create Stamp step, as shown in the following figure:

Steps

	Name	Type	Pre-Condition	Parallel	Actions
::	Creating Stamp	Create Stamp	All Prior Success	false	
::	Clean	Clean Workspace	All Prior Success	false	

Populating the workspace

This step places the checked-out code (defined later in the project's source configuration) in the agent's workspace.

1. Use the **Insert After** action for the Clean step.
2. On the **Steps** dialog, click **Source** and then click **Populate Workspace**.
3. Click **Select**.
4. In the **Name** field, type `Populate`.
5. Click **Save**.

Results

The Populate step is added to the job, as shown in the following figure

Steps

	Name	Type	Pre-Condition	Parallel	Actions
::	Creating Stamp	Create Stamp	All Prior Success	false	
::	Clean	Clean Workspace	All Prior Success	false	
::	Populate	Populate Workspace	All Prior Success	false	

Creating a get changelog step

This step retrieves source changes since the last build. The prior build life is located by using status or stamp parameters.

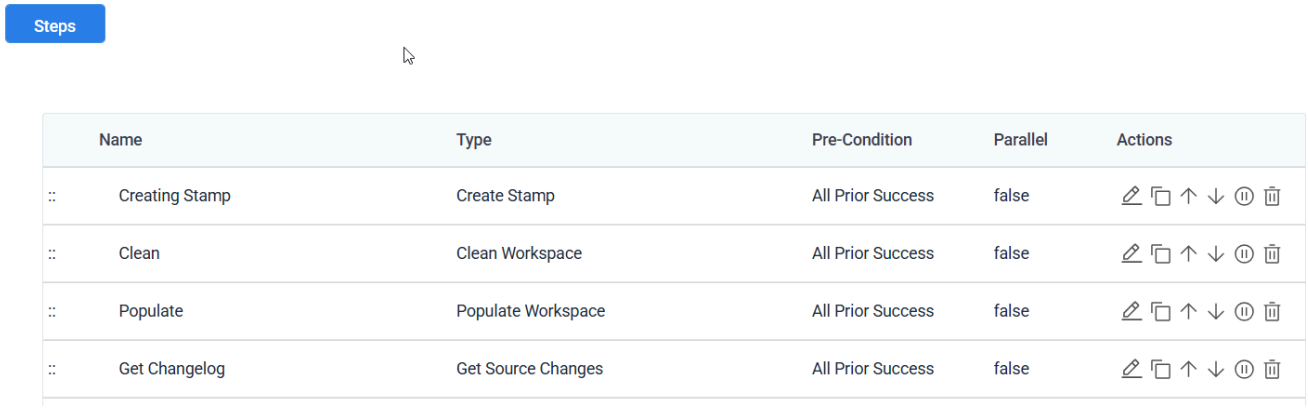
1. Click the **Insert After** action for the Populate step.
2. On the **Steps** dialog, click **Source** and then click **Get Source Changes**.
3. Click **Select**.
4. In the **Name** field, type `Get Changelog`.
5. Select **Success** on the **Start Status** list.
   The value that is selected determines which source items are retrieved. In this case, only items with a value of `Success` are retrieved.
6. Ensure that **Save Changes in Database** is selected (it is by default diabled).

This parameter can be used in build reports.

7. Click **Save**.

Results

The Get Changelog step is inserted into the job after the Populate step, as shown in the following figure:



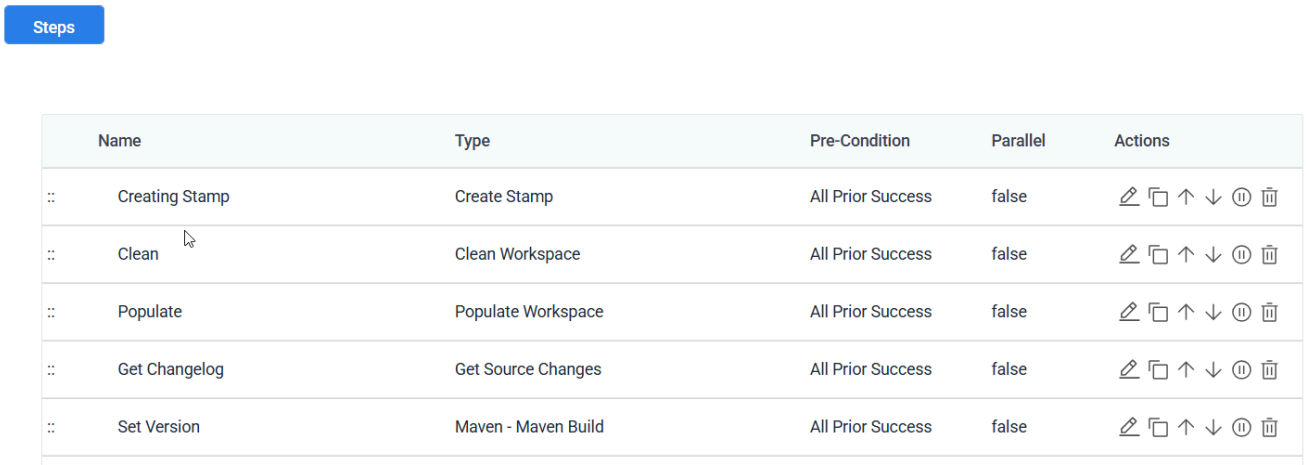
Creating the set version step

Create a version ID that Maven can use.

1. Click the **Insert After** action for the Get Changelog step.
2. On the **Steps** dialog, click **Build > Build Tools > Maven**, and then click **Maven Build**.
3. In the **Name** field, type `Set Version`.
4. Ensure that the default value `pom.xml` is set in the **Maven POM File** field.
   Maven uses the project object model file (POM) to control builds.
5. In the **Goals** field, type `versions:set`.
   Goals are similar to Ant tasks and define the actions that Maven performs.
6. **Optional:** If you did not put the Maven home variable on your system PATH variable, enter it in the **Maven Home** field.
7. In the **Properties** field, type `newVersion=${p:buildlife/latestStamp}`.
8. Click **Save**.

Results

The Set Version step is inserted into the job after the Get Changelog step, as shown in the following figure:



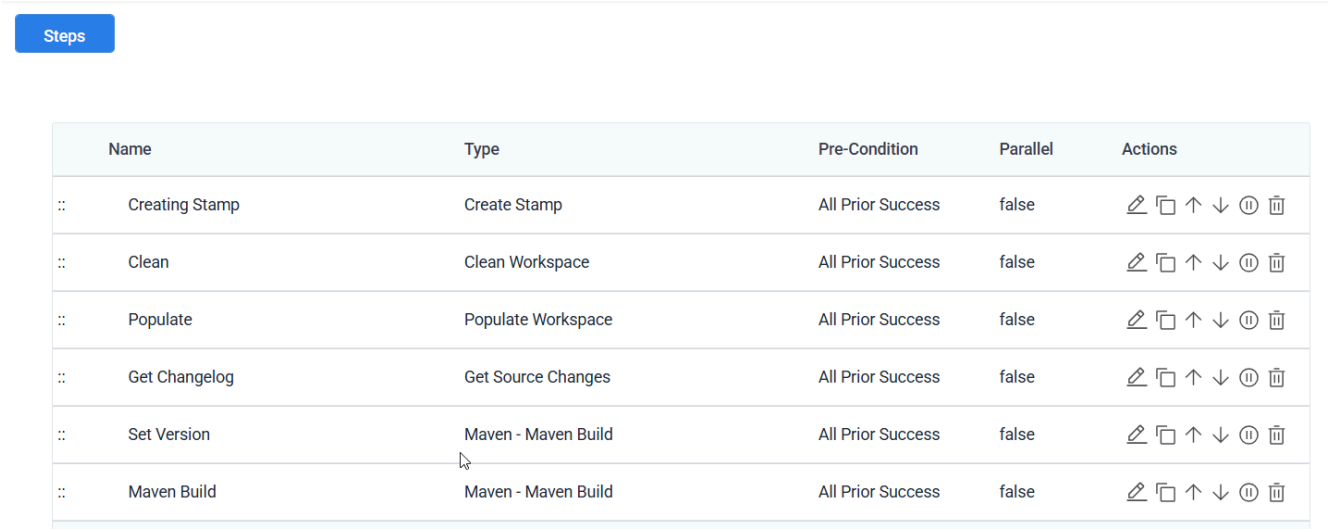
Creating the Maven build step

This step uses Maven to build the project.

1. Click the **Insert After** action for the Set Version step.
2. On the **Steps** dialog, click **Build > Build Tools > Maven**, and then click **Maven Build**.
   This step uses the same plug-in step as the previous step, Set Version.
3. In the **Name** field, type `Maven Build`.
4. Ensure that the default value `pom.xml` is set in the **Maven POM File** field.
5. In the **Goals** field, type `${p:maven.goals}`.
   Unlike the other properties you used in the job, this value references a new property. Later, you create the property and define the value.
6. **Optional:** If you did not put the Maven home variable on your system PATH variable, enter it in the **Maven Home** field.
7. Click **Save**.

Results

The Maven Build step is inserted into the job after the Set Version step, as shown in the following figure:



Creating the publish unit tests step

JUnit is a testing framework for Java™. This step runs tests and reports the results. It is configured to always run.

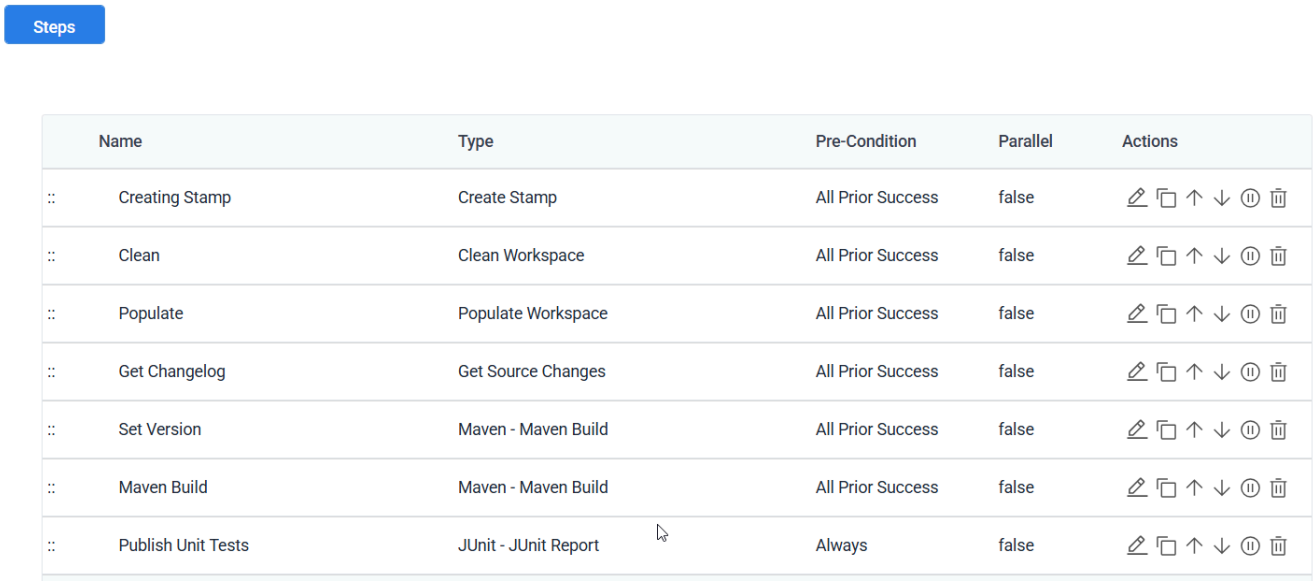
Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the tutorial system on page 246.

1. Click the **Insert After** action for the Maven Build step.
2. On the **Steps** dialog, click **Quality > Unit Testing > JUnit**, and then click **JUnit Report**.
3. In the **Name** field, type `Publish Unit Tests`.
4. In the **Report Name** field, type `JUnit Report`.
5. In the **Source Directory** field, type `target/surefire-reports`.
6. In the **Include Patterns** field, type `TEST*.xml`.
7. Display the **Pre-Condition Script** list by clicking **Show Additional Options**, and then select **Always**.
   Unlike the other steps in this job, this step always runs even if the preceding step fails. Test reports are displayed on the **Tests** tab for a selected build life. Reports are also written to the location you specified with the **Source Directory** field. Test files that match the pattern that is specified in the **Include Patterns** field are written to the same directory.
8. Click **Save**.

Results

The Publish Unit Tests step is inserted into the job after the Maven Build step, as shown in the following figure:



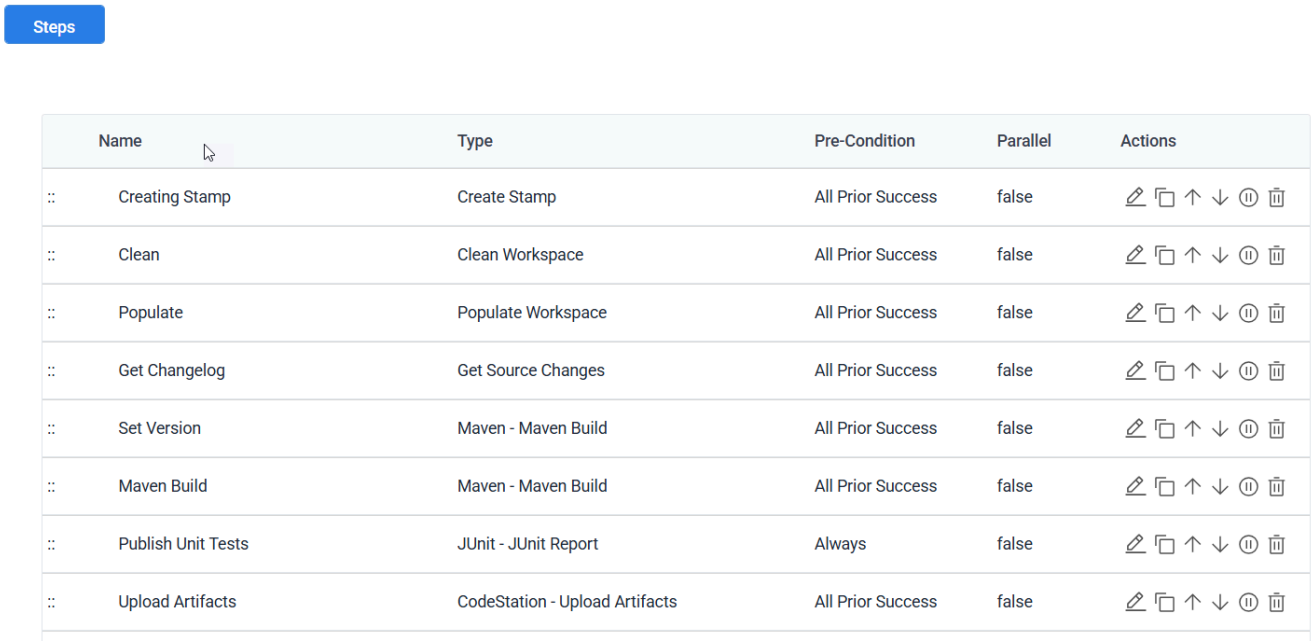
Creating the upload artifacts step

Upload the build artifacts to the CodeStation repository.

1. Click the **Insert After** action for the Publish Unit Tests step.
2. On the **Steps** dialog, click **Build Systems**, and then click **CodeStation**.
3. Click **Upload Artifatcs**, and then click **Select**.
4. In the **CodeStation-Upload Artifacts** window, in the **Name** field, type `Upload Artifacts`.
5. Click **Save**.

Results

The Upload Artifacts step is inserted into the job after the Publish Unit Tests step, as shown in the following figure:



Creating the assign success step

If all previous steps are successful, this step assigns a status of Success to the entire job. If the preceding steps are not successful, this step does not run and the next step runs instead.

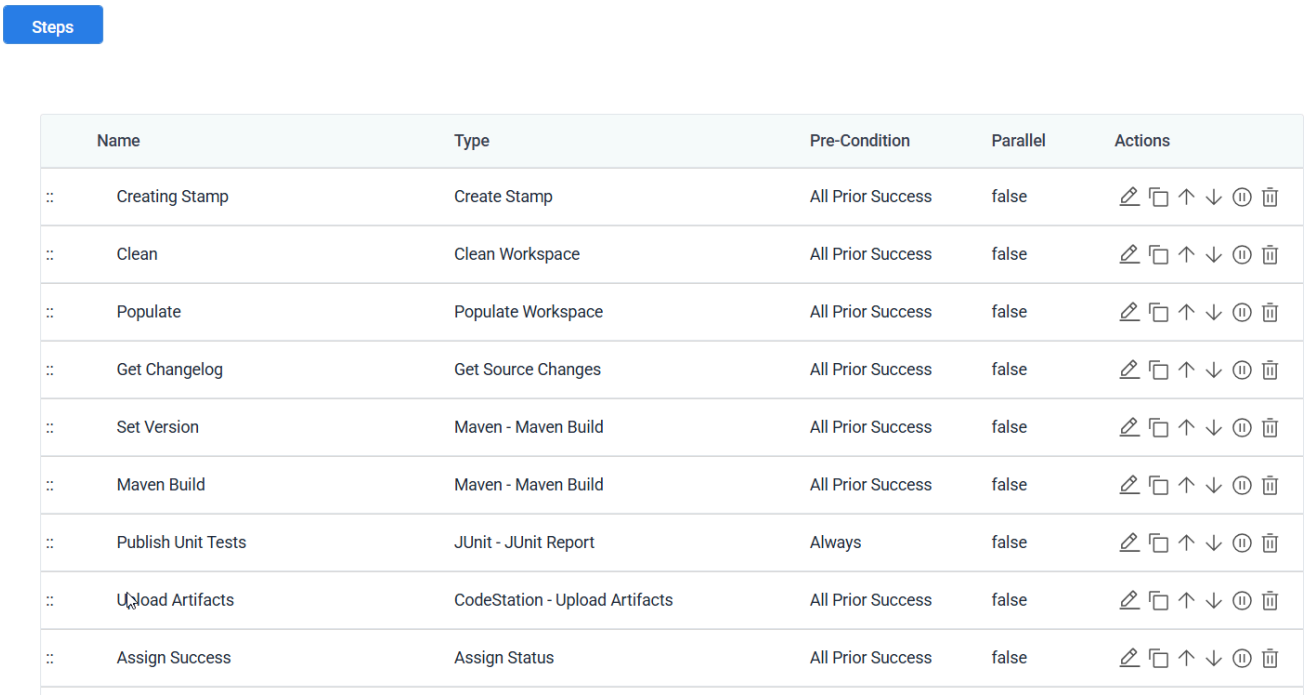
1. Click the **Insert After** action for the Upload Artifacts step.
2. On the **Steps** dialog, click **Build**, and then click **Assign Status**.
3. In the **Name** field, type `Assign Success`.
4. In the **Status** list, select **Success**.
5. Click **Save**.

   Result

   Because the **Pre-Condition Script** field is set to **All Prior Success** by default, you can accept the value.

Results

The Assign Success step is inserted into the job after the Publish Unit Tests step, as shown in the following figure:



Creating the assign failure step

This step assigns a status of Failure to the job. The step runs if any of the preceding steps fail.

1. Click the **Insert After** action for the Assign Success step.
2. On the **Steps** dialog, click **Build**, and then click **Assign Status**.
3. In the **Name** field, type `Assign Failure`.
4. In the **Status** list, select **Failure**.
5. Display the **Pre-Condition Script** list, and select **Any Prior Failure**.
6. Click **Save**.

Results

The Assign Failure step is inserted into the job after the Assign Success step.

Lesson checkpoint

In this lesson, you created job and added the steps required to build JUnit.

About this task

This job builds JUnit and assigns a status to the job. It also runs the JUnit plug-in step to create a report about the job. A job can use steps from any installed plug-in. Steps have preconditions that determine whether they run. Steps are configured individually as you insert them into a job.

The steps for the completed Demo Job are shown in the following figure:

Steps

	Name	Type	Pre-Condition	Parallel	Actions
::	Creating Stamp	Create Stamp	All Prior Success	false	
::	Clean	Clean Workspace	All Prior Success	false	
::	Populate	Populate Workspace	All Prior Success	false	
::	Get Changelog	Get Source Changes	All Prior Success	false	
::	Set Version	Maven - Maven Build	All Prior Success	false	
::	Maven Build	Maven - Maven Build	All Prior Success	false	
::	Publish Unit Tests	JUnit - JUnit Report	Always	false	
::	Upload Artifacts	CodeStation - Upload Artifacts	All Prior Success	false	
::	Assign Success	Assign Status	All Prior Success	false	
::	Assign Failure	Assign Status	All Prior Success	false	

Lesson 3: Creating a project template

Projects manage builds, dependencies, and artifacts. A project template is a reusable blueprint that defines a generic project.

About this task

Because project templates are reusable, you can apply the same standards to similar projects. Properties can be defined and the values supplied later by the projects created from the templates. A project template might always use a particular type of build script, for example, but the name or location of the script can vary by project.

In this lesson, you create a project template that you use later to create the tutorial project.

1. On the left navigational panel, click **Templates**.
   The **Projects** tab is open by default .
2. Click **Create**.
3. In the **Name** field, type `Demo Project Template`.
4. Click **Save**.
   Result
   The **Main** tab for the new project template is displayed.
5. Click **Build Pre-Processing**, and click **Edit.**.
6. Click **Agent Pool Selection**, and then select the agent pool you created when you configured the tutorial system on page 246.
7. Click **Save**.

Lesson checkpoint

In this lesson, you created the project template you use to build the tutorial project.

About this task

For more information about project templates, see Creating project templates on page 384.

Lesson 4: Creating a source template

A source template is a reusable source configuration that can be used by any project that requires the same source type.

Before you begin

Ensure that you installed the Git source-type plug-in before you start this lesson.

About this task

In this lesson, you define a Git configuration that is used by the tutorial project.

1. On the left navigational panel, click **Templates**, click **Source**, and then click **Create**.
2. In the **Source Type** list, select **Git**.
   All installed source-type plug-ins are listed.
3. Click **Select**.
   Result
   Fields that are related to the selected source type are displayed.
4. In the **Name** field, type `GitHub`.
5. In the **Working Directory Script** list, select **Default Workflow Directory**.
6. In the **Remote URL** field, type `${p:git.project}`.
   This refers to a property you create in the next section. You supply the property value when you configure the project.
7. In the **Branch** field, type `${p?:git.branch}`.
8. Click **Save**.

Results

The **GitHub** source template is listed along with the other source templates on the **Source Templates** tab.

Creating properties for the source template

Define the properties you referenced in the previous section.

1. If the **Source** tab is not already displayed, then on the Build dashboard, click **Templates**, click **Source**, and then click the `GitHub` source template that you created earlier in the lesson.
2. Click **Properties**, and then click **Create**.
3. Create the `git.project` property by completing these steps.
   a. In the **Name** field, type `git.project`.
   b. In the **Label** field, type `Git Project`.

The label text identifies the property to users that use the source template.

c. In the **Description** field, type `Path of the GitHub project within the account`.
The description text is displayed to users.

d. In the **Display Type** list, select **Text**.

e. In the **Value** area, accept the default option **Defined**.
The **Value** option determines when and where the value for the property is defined. By selecting **Defined**, you can provide a value in the **Default Value** field, or supply the value on the project configuration before the project runs.

f. Leave the **Default Value** field blank.
You define the property value when you configure the project.

g. Select the **Value Required** check box.

h. Click **Save**.

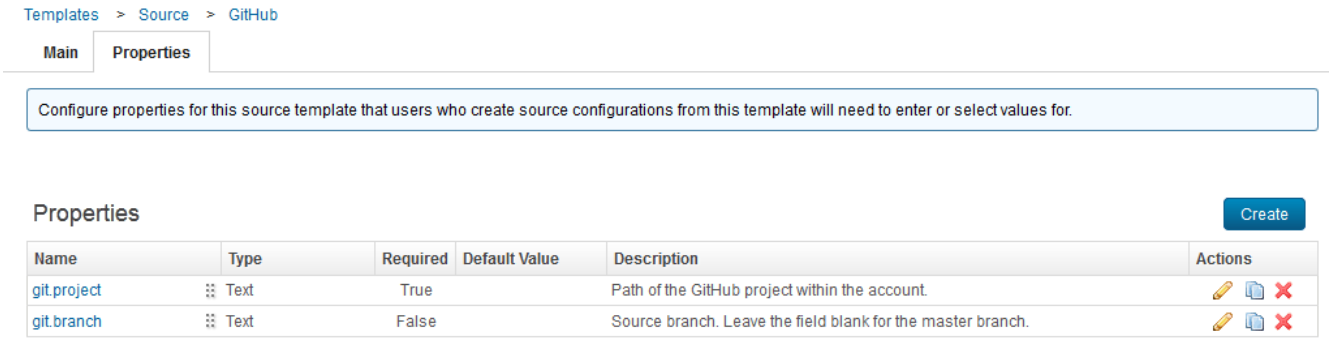
4. Create the `git.branch` property by completing these steps.
   a. On the **Properties** tab, click **Create**.
   b. In the **Name** field, type `git.branch`.
   c. In the **Label** field, type `Git Branch`.
   d. In the **Description** field, type `Source branch. Leave the field blank for the master branch`.
   e. In the **Display Type** list, select **Text**.
   f. Leave the **Default Value** field blank.
   g. Clear the **Required** check box.
   h. Click **Save**.

Lesson checkpoint

In this lesson, you created a source template and defined properties that identify the source material used in the build.

About this task

The GitHub source template properties are shown in the following figure:



Lesson 5: Creating a process template

Build a process template for the tutorial project.

About this task

In this lesson, you create a process template, define a process, create a property, and an artifact set that is used by the project.

1. On the left navigational panel, click **Templates**, click **Process**, and then click **Create**.
2. In the **Name** field, type `Demo Build Process`.
3. Under **Type**, make sure that **Build Process** is selected.
4. Click **Save**.

Results

The **Main** tab for the new process template is displayed.

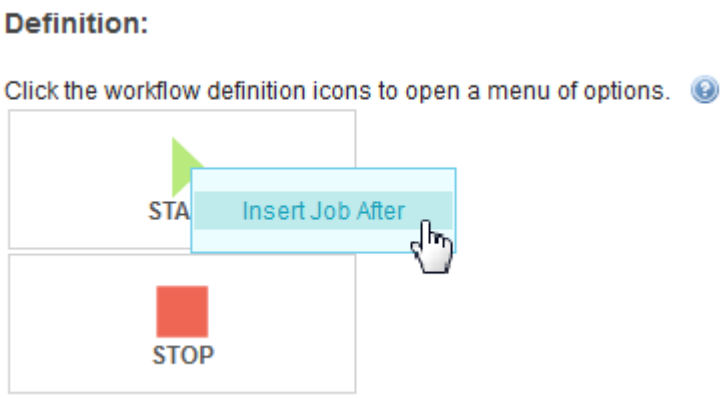
Creating a process definition

Process definitions identify the jobs that comprise a build.

About this task

In order for a job to be used in a project, it must be assigned to the process. A process can have several jobs and their order in the process is determined similarly to the way steps are inserted into jobs. In this lesson, you assign the job you created in the last lesson to a process definition.

1. On the Build dashboard, click **Templates > Process**.
2. In the **Process Templates** page, click **Demo Build Process**, and then click **Definition**.
3. Click **Start**, and then select **Insert Job After**.
   The **Insert Job After** action is displayed after you click **Start**, as show in the following figure:



4. In the **Insert Start Job** window, in the **Job** list, select the job you created in the last lesson, **Demo Job**.
5. In the **Pre-condition** list, select **Always**.

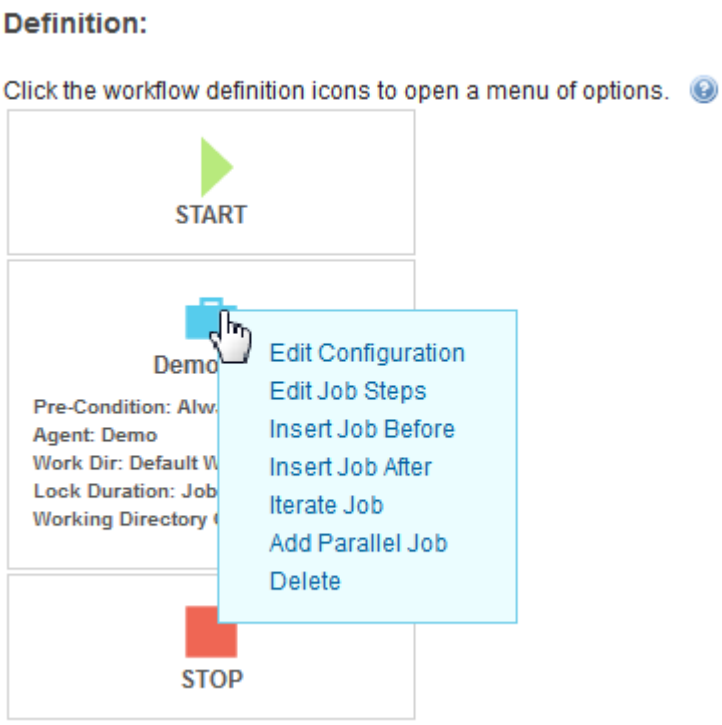
6. In the **Agent Selection** area, select **Agent Pool Selection**, and then select the agent pool you created when you configured your tutorial system on page 246.
   An agent in the agent pool runs the jobs assigned to the workflow.
7. In the **Working Directory** list, select **Default Workflow Directory**.
   An agent's default working directory is:

   ```
   agent_directory/var/work/project/
   ```

8. Click **Insert Job**.

Results

After a job is added to the process definition, the list of available process actions increases. Actions to insert jobs before or after other jobs, or to delete jobs are available, as show in the following figure.



Creating process template properties

Define the property you referenced in Lesson 2.

About this task

In this step, you define the property you referenced in the Maven Build step on page 254, `${p:maven.goals}`, in Lesson 2.

1. Using the Demo Build Process, click **Properties**, and then click **Create**.
2. In the **Name** field, type `maven.goals`.
3. In the **Label** field, type `Maven Goals`.
4. In the **Display Type** list, select **Text**.

5. In the **Default Value** field, type `package`.
   This is a Maven lifecycle build phase.
6. Select the **Value Required** check box.
7. Click **Save**.

Creating process artifact sets

Generated artifacts are assigned to an artifact set. An artifact set is a collection of build artifacts.

Before you begin

Ensure that you configured a Maven artifact set on page 246 before you start this step.

About this task

In this lesson, you configure the artifact set that is used by the project.

1. Ensure that the window for your build process is displayed and click **Artifacts**, and then click **New Artifact Config**.
2. In the **Artifact Set** list, select the artifact set you created earlier, **maven**.
3. In the **Base Directory** field, type `target`.
4. In the **Include Artifacts** field, type `*.jar`.
5. Click **Save**.

Lesson checkpoint

In this lesson, you created a process template and added a property and an artifact set to it.

Lesson 6: Creating a project

You use projects to configure and run builds. After a build runs, projects provide a wealth of information that you can use to manage the project lifecycle and troubleshoot problems.

Before you begin

Ensure that you completed all of the preceding steps before you start this lesson.

About this task

Projects are built from templates. In this lesson, you will use the templates that you made earlier to create the tutorial project. You can run builds automatically on a predetermined schedule, or you can run builds manually, as you do in the tutorial. To define the tutorial project, you select the process that you defined earlier. When you start the build, the workflow begins running the job that you created with the job template. The project determines the source code to use, and manages any dependencies. Each build generates a unique build life ID.

1. On the left navigational panel, click **Projects**, and then click **Create**.
2. Select the project template that you created in Lesson 3 on page 259, **Demo Project Template**.
3. In the **Name** field, type `Demo Project`.
4. Click **Save**.

Configuring the project build process

A project must be associated with a build process. A project might have any number of build processes associated with it.

1. Ensure that the **Configuration** tab for the Demo Project project is displayed, then, under **Build Processes**, click **New**.
2. In the **Template** list, select **Demo Build Process**, and then click **Select**.
   The **Maven Goals** field is derived from the process template that you created in last lesson.
3. In the **Name** field, type `Demo Build`.
4. In the **Maven Goals** field, accept the value, `package`.
   The `package` value is a basic Maven lifecycle build phase. The `package` attribute instructs Maven to put the compiled code into a distributable format, such as a JAR file. You can use the tutorial project to run other Maven builds and change the goals.
5. Click **Save**.

Results

The **Configuration** tab for the new build process is displayed.

Configuring the project source

A project's build source is defined by assigning a source template to a build configuration.

Before you begin

Ensure that the **Configuration** tab for the build process you defined in the previous section is displayed.

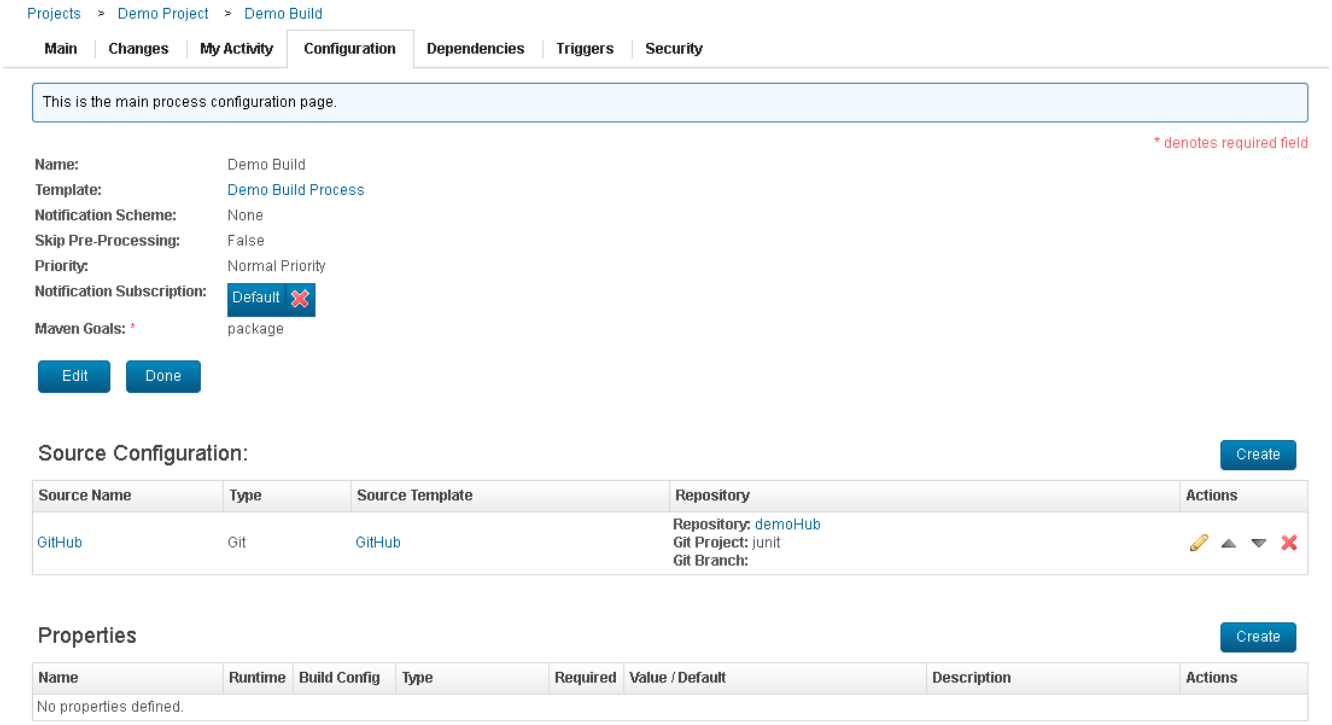
About this task

You define the source configuration by selecting the source template that you created earlier, and by using template properties to identify the source location.

1. Under **Source Configuration**, click **Create**.
2. In the **Source Template** list, select the source template that you created earlier, **GitHub**, and then click **Select**.
3. In the **Name** field, type `GitHub`.
4. In the **Repository** list, select the repository that you created earlier, **demoHub**.
5. In the **Git Project Path** field, type `junit`.
   Because the project uses the `master` branch, you can leave the **Git Branch** field blank.
6. Click **Save**.

Results

With the build process defined and the build source identified, the project is complete. The finished Demo Build process is shown in the following figure:



Lesson checkpoint

In this lesson, you created a project and defined a build process and build source.

About this task

The project is constructed from the templates you made earlier in the tutorial. All projects are built from templates; when you create a project, you identify the templates and provide property values for them. A project can inherit properties from any of the templates used in the project.

Lesson 7: Running the build

Run the project build process to transform the source code into the finished application, JUnit.

Before you begin

Ensure that you completed all previous steps in the tutorial.

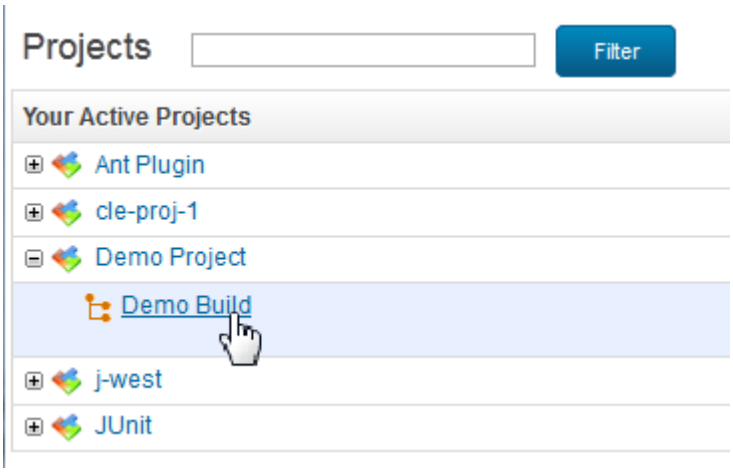
About this task

You run a build by running a build process that is defined for the project. The build process takes the source material and transforms it, using a job that is assigned to the project, into the final output.

1. On the left navigational panel, click **Projects**, and then expand the project that you created in the last lesson, **Demo Project**.

   Result

   Builds configured for the selected project are listed beneath the project, as shown in the following figure:



2. Click **DemoBuild**.

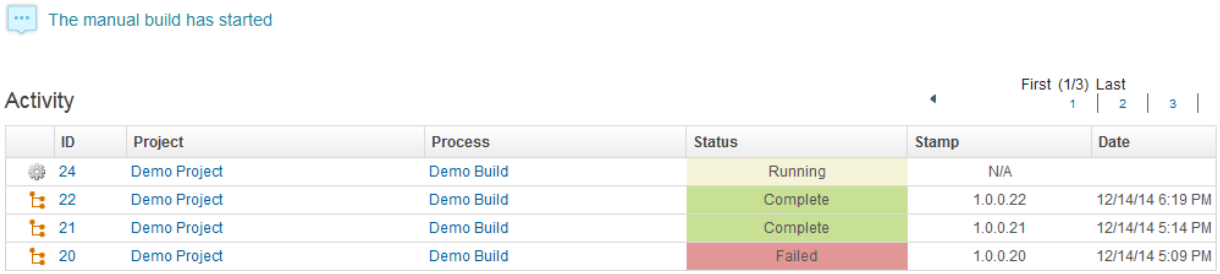
   Result

   The **Main** tab for the DemoBuild project build is displayed.

3. Click **Build**.

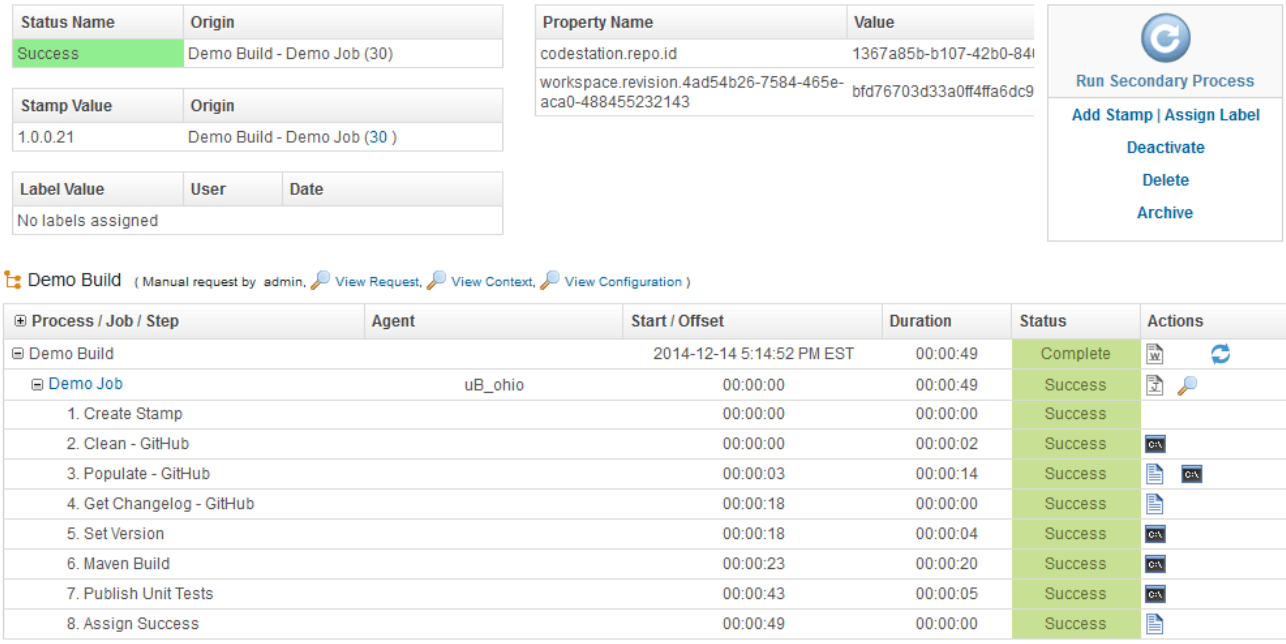
   Result

   The build process starts and the **My Activity** tab for the build is displayed. The build, with a new build life number, is listed with a status of `Running`, as shown in the following figure:



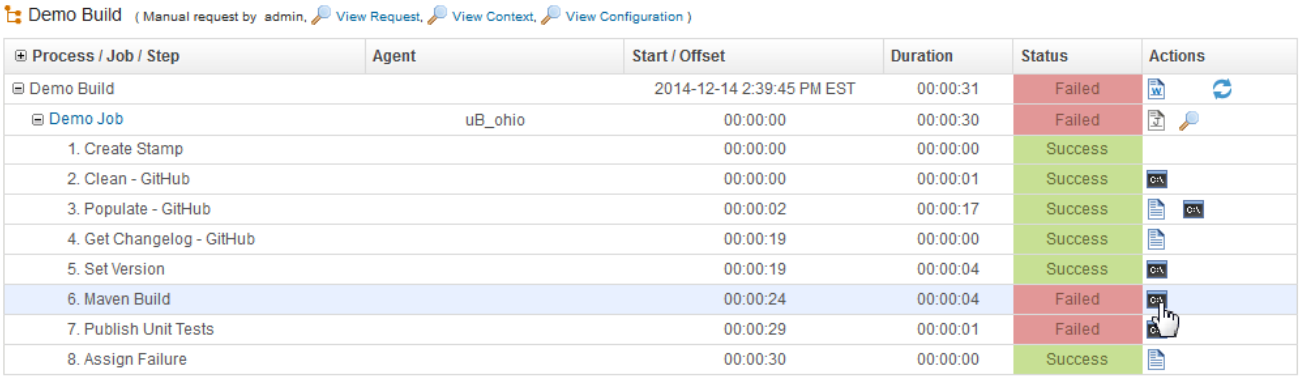
Results

Refresh the **My Activity** page. If the build is successful, the status changes to `Complete`; otherwise, the status changes to `Failed`. A successful run is shown in the following figure:



What to do next

The project's Main tab contains information about the builds generated by the project. To see details about a build, click the build life ID in the **Build** column. To see a step's output, use the **View Output** action, as shown in the following figure. Use the log to identify errors and troubleshoot failed steps.



To see the JUnit test results, display the **Test** tab for the build.

Lesson checkpoint

In this lesson, you ran a build of the tutorial project, Demo Project, and examined its progress, tests, and final output.

About this task

In this lesson, you ran a build for the project you created. The build created the application JUnit. The JUnit application is in the *agent_install*`\var\work\project\Demo_Project\Demo_Build` folder. Project artifacts are stored in the CodeStation repository.

Summary

In this tutorial, you learned to build a project and run a build with Build.

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How to create a repository and use it in a build process
- How to create jobs and add steps to them
- How to create source and process templates
- How to create project templates
- How to create projects and configure their sources, and processes
- How to run a build and examine its tests and output

Create a project that integrates with DevOps Deploy

In this tutorial, you create a project that builds distributable artifacts and loads them into HCL DevOps Deploy (Deploy) components. The source code is downloaded from GitHub and built with Ant.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a Git repository that connects to GitHub.
- Create templates that define properties. You specify values for these properties when you create the project.
- Create a process definition and associate an agent pool with it.
- Create a job that uses Ant to build the project artifacts, run JUnit tests, create an Deploy component version, and assign a status to the component.
- Create a project that is based on the templates that you create.
- Run a build and monitor its progress.
- Examine the results of the build by reviewing the component version that was created by the project in Deploy.

Time required

2 hours

Introduction

In this tutorial, you create a project that builds distributable artifacts and loads them into HCL DevOps Deploy (Deploy) components. The source code is downloaded from GitHub and built with Ant.

The project that you create in this tutorial introduces you to the most-used product features. The workflow that you create contains the job types that you use every day.

Learning objectives

In this tutorial, you learn how to complete these tasks:

- Create a Git repository that connects to GitHub.
- Create templates that define properties. You specify values for these properties when you create the project.
- Create a process definition and associate an agent pool with it.
- Create a job that uses Ant to build the project artifacts, run JUnit tests, create an Deploy component version, and assign a status to the component.
- Create a project that is based on the templates that you create.
- Run a build and monitor its progress.
- Examine the results of the build by reviewing the component version that was created by the project in Deploy.

Time required

This tutorial takes approximately 2 hours to finish. If you explore other concepts that are related to this tutorial, it might take longer to complete.

System requirements

To run this tutorial, you need the following resources:

- An installation of Build, version 6.1 or later.
- An Build agent that is installed and configured. The agent must be able to access the Deploy server you use in the tutorial.
- An installation of Deploy.

Prerequisites

To complete this tutorial, you must have an account on the Build server with permissions to create and edit projects, process definitions, jobs, and repositories, and to create and run processes. In addition, you must have an account an the Deploy server with, at a minimum, permission to view, create, and edit component versions, and access the **Settings** page.

Configure the tutorial system

Before you can run the tutorial project, you must configure your Build and DevOps Deploy environments.

Before you begin

Before you begin the tutorial, make sure that you meet the Prerequisites on page 270.

About this task

To complete the tutorial, you must have an installation of Build and HCL DevOps Deploy (Deploy). Your Build agent must have access to the Deploy server.

To prepare the tutorial system.

1. Prepare a computer for use as the target system.
2. Install the plug-ins that are used in the tutorial.
   The tutorial uses several plug-ins. Most of them are installed when you install the product, but you must install some plug-ins yourself. Download and install these plug-ins:

- Git
- JUnit

You can download plug-ins from the Build plug-in site: Build plug-ins website. For information about installing plug-ins, see Installing plug-ins on page 351.

3. Typically, agents are not installed on the same computer where the Build server is located. For the tutorial, installing the agent on the computer where the server is located is fine.
4. Configure the agent on page 342.
   Your agent must be included in the list of configured agents on the **Agents** page with a status of `Online`.
5. Create an agent pool and add the installed agent to it. on page 345
6. Install the open source tool Git on the computer where the Build agent is located.
   Add the home directory for the tool to the *PATH* variable on the target system.

   Note: The tutorial also requires Ant. Ant is installed with the agent when the agent is installed.

7. Create the artifact set used by the tutorial by completing these steps:
   a. From the Build dashboard, click **System**, and then click **Artifact Sets**.
   b. In the **Artifact Sets** tab, click **Create New Artifact Set**.
   c. In the **New Artifact Set** dialog box, in the **Name** field, type `dist`.
   d. Click **Save**.
8. Install Deploy.
   You must know the version number of the server because the Deploy plug-in works differently for versions before 6.1. The Deploy server must be accessible by the Build agent. When the tutorial project runs, the agent communicates with the Deploy REST API.

   Note: The Deploy server must be running when you run the tutorial project.

9. Configure an integration on page 307 with the Deploy server you installed in the previous step. To complete the configuration, you need the URL of the Deploy server.
10. In your Deploy installation, create a component that is named Ant.
    When you create the component, provide the following property values:
    - **Component Type**: **Standard**
    - **Source Configuration Type**: **none**

    You can accept the default values for the other properties.

    Note: To complete this step, you need an Deploy account with, at a minimum, permission to view, edit, and create components. If you have your own component, you can use that. However, the tutorial uses the name of the component in one of its properties and you will have to substitute the name of your component for the name used in the tutorial. See Prerequisites on page 270.

11. In your Deploy installation, create a version status and name it Success.

The tutorial project assigns this status to the component version that it creates in Deploy. Make sure that you create a version status and not an inventory or snapshot status.

Note: To complete this step, you need an account with access to the Deploy **Settings** page. See Prerequisites on page 270.

Results

Your Build environment is ready to being the tutorial.

The tutorial project is also available in a file that you can download and import. To import the tutorial project, follow these steps:

1. Navigate your browser to the file repository URL:http://download.boulder.ibm.com/ibmdl/pub/software/rationalsdp/documentation/product_doc/UrbanCode/uBuild/.
2. Download the file named `Ant.xml`.
3. On the Build **Project** page, click **Import**, and then select the downloaded file.

   Note: Make sure that you install the plug-ins described earlier in this topic before you import the file.

4. In the **Import** window, click **Import**. The server imports the project. The server does not import plug-ins when it imports a project, so you still need to install the plug-ins described earlier in this topic.

Lesson checkpoint

The servers and agent are configured for the tutorial. If you installed the agent on a remote system, you must know the credentials that are required to access the remote system.

Lesson 1: Creating a Git repository

Repository integrations enable Build to check out code, access change logs, and do other project-related activities.

Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the tutorial system on page 270.

1. On the left navigational panel, click **System > Repositories**.
2. On the **Repositories** page, click **Create New Repository**.
3. In the **Source Plug-in** list, select **Git** and then click **Set**.
4. In the **Name** field, type `GitHub`.
5. In the **Repository Base URL** field, type `https://github.com/IBM-UrbanCode/ant`.
6. Click **Save**.

Lesson checkpoint

In this lesson, you created a repository that is based on the Git plug-in.

About this task

The GitHub repository is listed on the **Repositories** page.

For more information about repositories, see Repositories on page 330.

Lesson 2: Creating a job and adding steps

A job is a series of steps that, together, complete an activity, such as building a project. When a project runs, the steps run one at a time in the order that you specify.

Before you begin

Before you begin this lesson, make sure that you complete the steps that are described in Configure the tutorial system on page 270.

About this task

In this lesson, you create a job and add steps to it that download source code, builds artifacts, runs tests, creates a component versions in HCL DevOps Deploy (Deploy), and assigns a status to the component. The job will be used by the workflow that you create later in the tutorial. As you create the job, you define several properties that will be used later when you create and run the project.

Creating a job

Most job steps are created from plug-ins. Plug-in steps can be thought of as distinct pieces of automation.

About this task

By combining steps from various plug-ins, you can create fully automated build processes. The number of steps that are provided by a particular plug-in can vary, and each step has a variable number of properties. Property values can be supplied when you define a step or at process run time.

Note: Several plug-ins are included in the product, and you can download other plug-ins as described earlier in the tutorial on page 270. Some steps, such as Assign Status and Create Stamp, are not derived from plug-ins, but you use them in the same way that you use plug-in steps.

Create a job by completing these steps:

1. On the left navigational panel, click **Templates > Jobs**.
2. On the **Jobs** page, click **Create**.
3. In the **Create a Job** window, name the job `Ant Build Job`.
4. Click **Save**.

   Result

   The **Main** tab for the new job is displayed.

Results

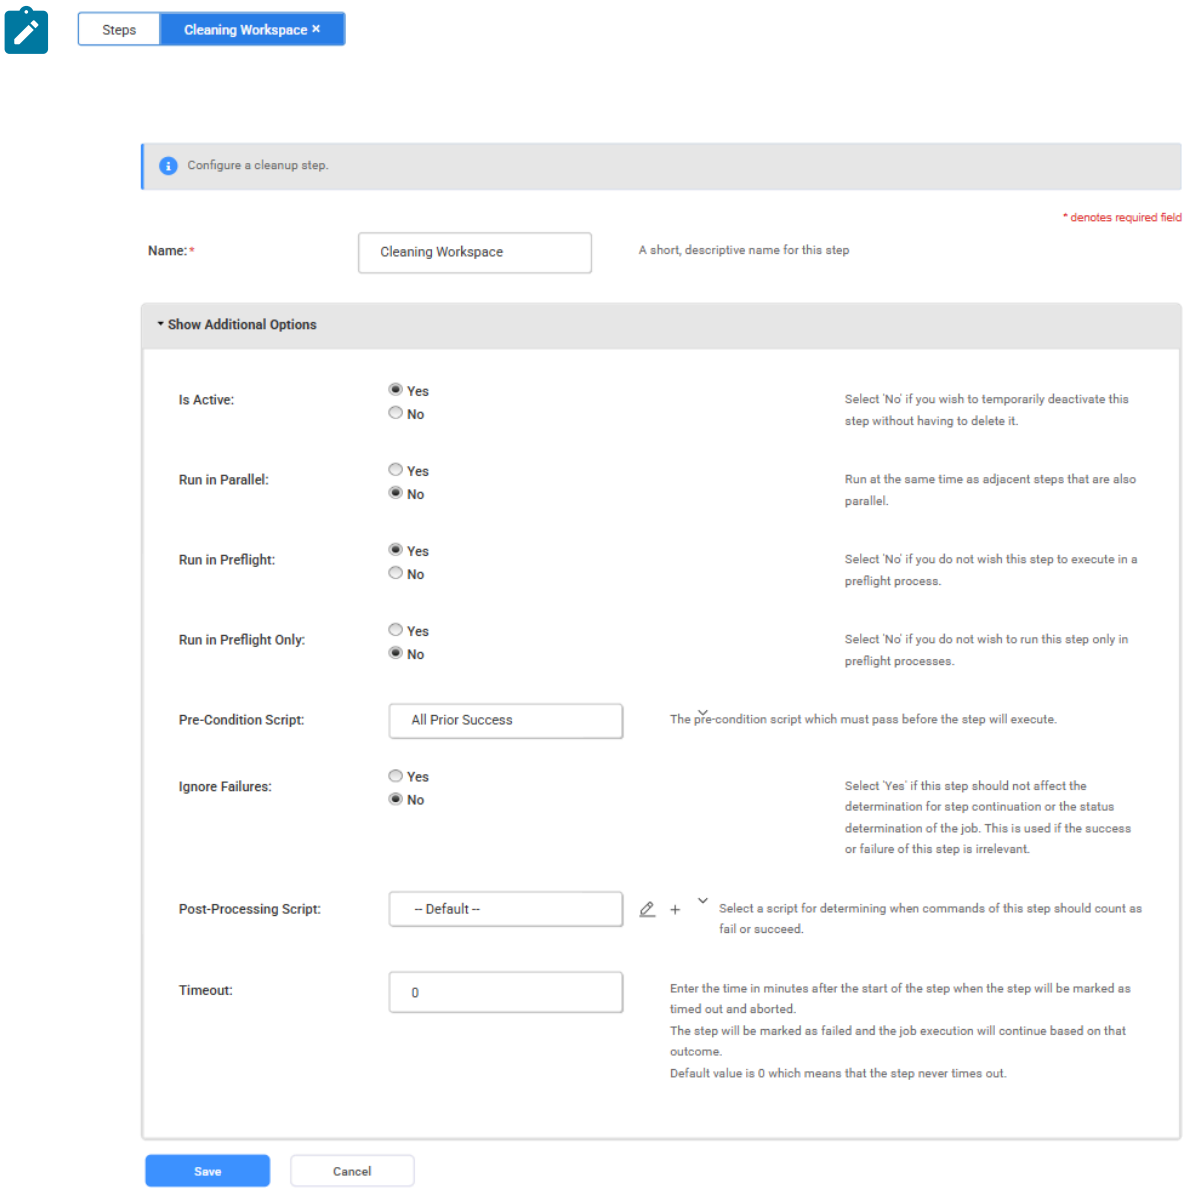
You use the job's **Main** tab to add steps to the job. Except for the first step, steps can be inserted before or after other steps. You can rearrange the steps and change their order. When you run the job, the steps are run in the order that you specify.

Cleaning the workspace

To ensure that no files from a previous build get incorporated into the new one, add a step to clean the agent's workspace. This step is part of most build jobs.

1. If the **Main** tab for the Ant Build Job is not displayed, then from the Build dashboard, click **Templates > Jobs**, and then click **Ant Build Job**.
2. Click **Create Step**.
3. Using the **Steps** dialog box, click **Source**.
   Result
   The **Source** list expands to display the available source-related steps and plug-ins.
4. In the **Steps** dialog box, click **Clean Workspace**, and then click **Select**.
   Result
   The **Change Source** dialog box is displayed. The dialog box that is displayed after you select a step contains options that are related to the selected step. Some of the options are unique to the step, while others are common to all steps.

   Note: Each step dialog box has more options available than are initially displayed. To see the other options, click **Show Additional Options**. The additional options are the same for all steps and are set to default values that are acceptable for most jobs. For example, the default value for the **Pre-Condition Script** field is `All Prior Success`, which means that the step runs only if the preceding steps succeed. The additional options are shown in the following figure. For most of the steps in this tutorial job, the default values are fine.



5. On the **Cleanup Source** dialog box, in the **Name** field, type `Cleanup`.
6. Click **Save**.

Results

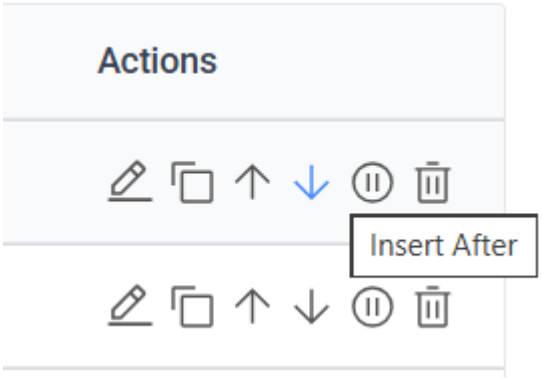
The Cleanup step is listed on the **Main** tab for the job.

After a job has a step, the **Create Step** push button is no longer used and actions are used instead to insert steps.

Populating the workspace

This step places the checked-out code, which is defined later in the project's source configuration, in the agent's workspace.

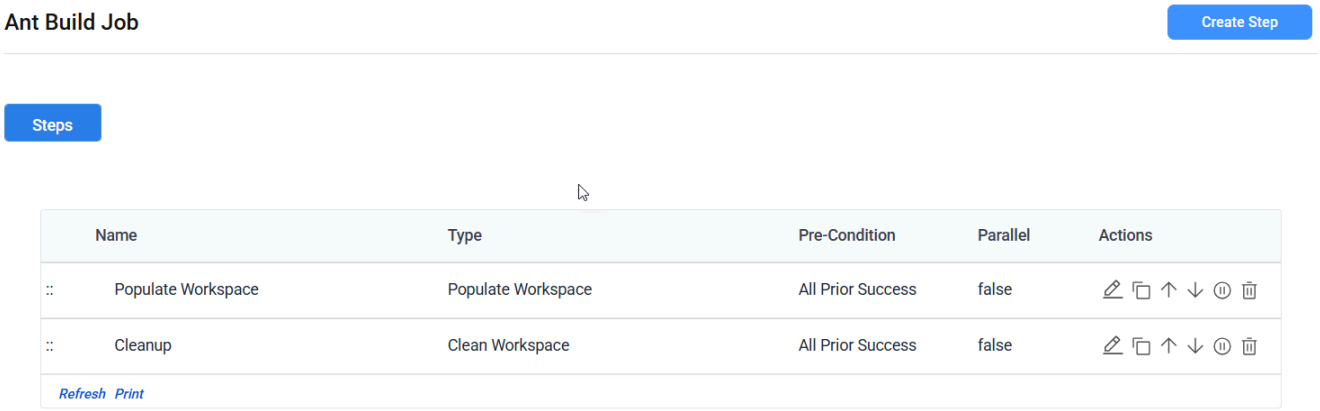
1. Use the **Insert After** action for the Cleanup step.



2. In the **Steps** dialog box, click **Source**, and then click **Populate Workspace**.
3. Click **Select**.
4. Using the **Populate Workspace** dialog box, in the **Name** field, type `Populate Workspace`.
5. In the **Date String** field, type the `${bsh:WorkspaceDate.get()}` BeanShell script line.
   This script sets the date to the date that the source is checked out. The default date is the `workspace.date` property on the job.
6. Click **Save**.

Results

The Populate Workspace step is added to the job, as shown in the following figure



Creating a stamp step

A stamp is an identifier that is applied to a build. Stamps are often used in addition to the automatically generated build life identifiers. A stamp step is part of most jobs.

1. If the **Main** tab for the AntBuild Job is not displayed, then from the Build dashboard, click **Templates > Jobs**, and then click **Ant Build Job**.
2. Use the **Insert After** action for the Populate Workspace step.
3. Using the **Steps** dialog box, click **Build**.

Result

The **Build** list expands to display the available build-type steps and plug-ins.

4. In the **Build** list, click **Create Stamp**, and then click **Select**.

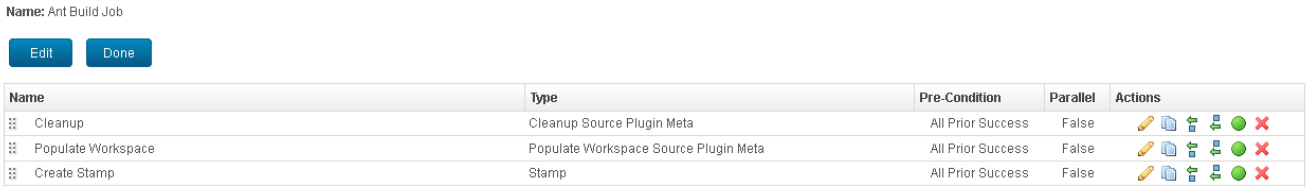
   Result

   The Stamp dialog box is displayed.
5. In the **Name** field, type `Create Stamp`.
6. In the **Stamp** field, enter a script to define the stamp: `${p:product.version}.${gvy:BuildLifeLookup.current.id}`.

   The Groovy script looks up the current build-life ID, which is part of every build life, and appends it to the `product.version` property. You create the `product.version` property later in the tutorial when you create the build process.
7. Click **Save**.

Results

The Create Stamp step is listed on the **Main** tab for the job, as shown in the following figure:



Creating a get changelog step

This step retrieves source changes that were saved since the last build. The prior build life is located by using status or stamp parameters.

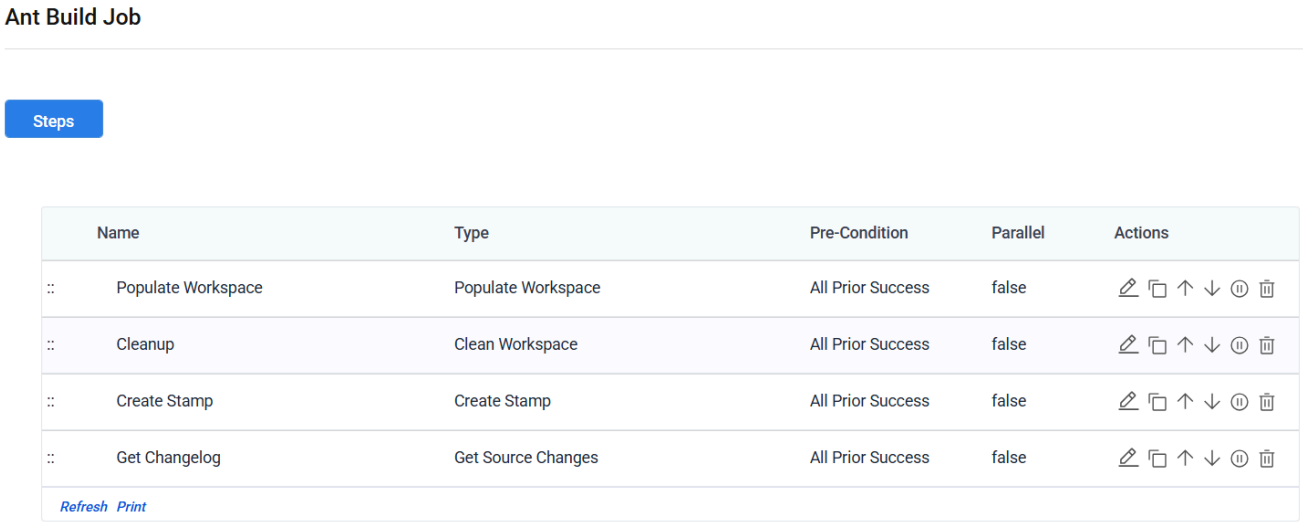
1. Click the **Insert After** action for the Create Stamp step.
2. In the **Steps** dialog box, click **Source**, and then click **Get Source Changes**.
3. Click **Select**.
4. In the **Get Changelog Source Plugin Meta** dialog box, in the **Name** field, type `Get Changelog`.
5. Select **Success** on the **Start Status** list.

   The value that is selected determines which source items are retrieved. In this case, only items with a `Success` value are retrieved.
6. Ensure that **Save Changes in Database** is selected, it is selected by default.

   This parameter makes the data available to the web application's user interface, and for reporting.
7. Click **Save**.

Results

The Get Changelog step is inserted into the job after the Populate step, as shown in this figure:



Creating an Ant build step

Create a step that runs an Ant build process.

About this task

This step runs an Ant build. Like most steps, the Ant build step is defined by the properties that you specify. Many properties that you define for this step are placeholders and their values will be specified by other templates or at run time.

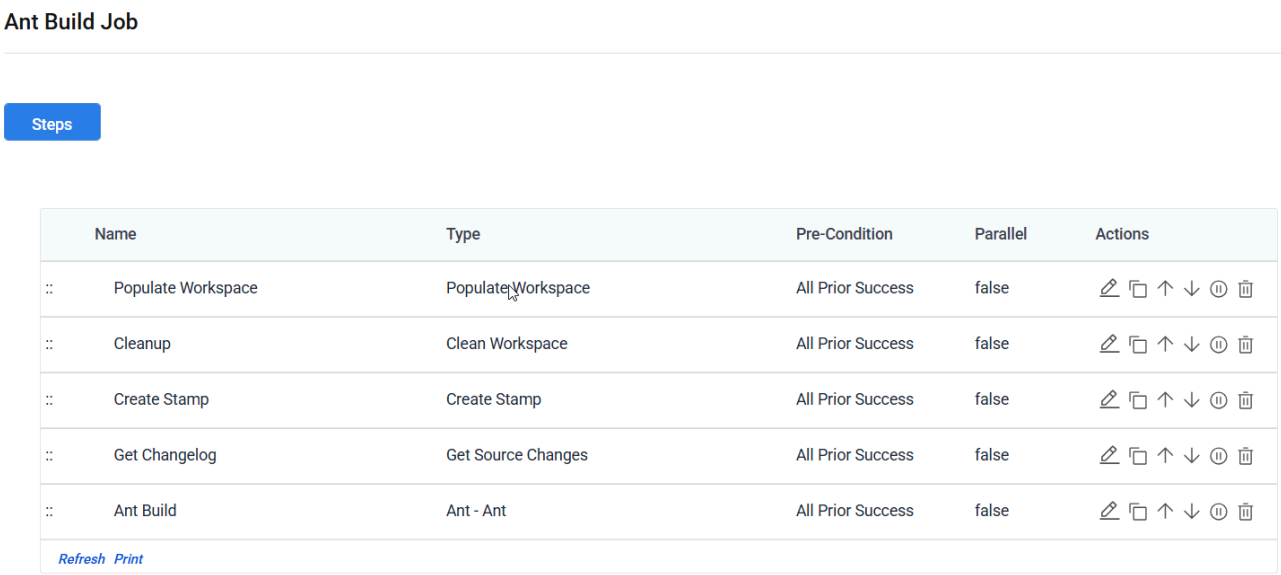
1. Click the **Insert After** action for the Get Changelog step.
2. In the **Steps** dialog box, click **Build > Build Tools > Ant > Ant**, and then click **Select**.
3. In the **Plugin Command** window, in the **Name** field, type `Ant Build`.
4. In the **Working Directory Offset** field, type `${p?:dir.offset}`.
   The question mark character, ?, can be used to reference properties. The format is `${p?:propertyName}`. In this instance, if the user specifies a value for the `dir.offset` property, this script returns the value. Otherwise, it returns an empty string.
5. In the **Ant Script File** field, type `${p:build.script.name}`.
6. In the **Targets** field, type `${p?:ant.targets}`.
7. In the **Properties** box, type `${p?:build.properties}`.
8. In the **Ant Properties** box, type `${p?:ant.properties}`.

   Note: The **ANT_HOME** and **JAVA_HOME** fields are set to default values for the computer where the agent is located.

9. Click **Save**.

Results

The Ant Build step is inserted into the job after the Get Changelog step, as shown in this figure:



Creating the publish JUnit tests step

JUnit is a testing framework for Java™. This step runs tests and reports the results.

Before you begin

Before you begin this lesson, make sure that you install the JUnit plug-in as described in Configure the tutorial system on page 270.

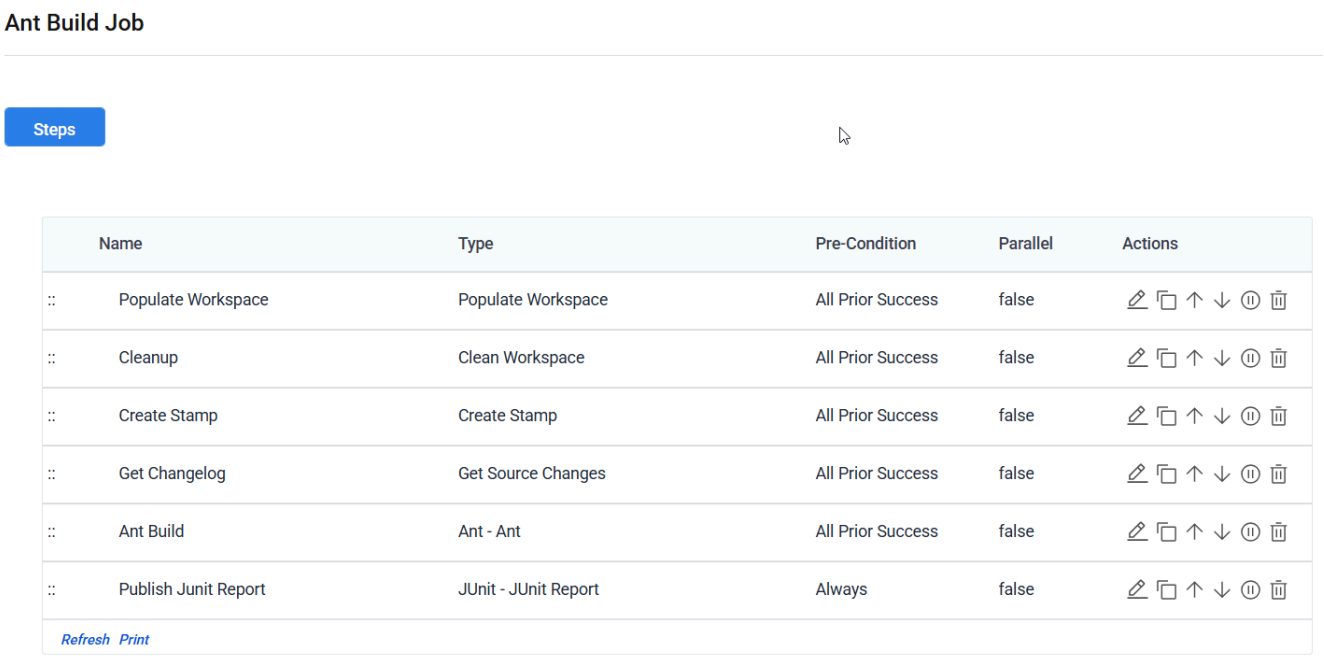
About this task

Unlike most of the other steps in the Ant Build job, this step is configured to always run even if the preceding step fails. Test reports are displayed on the **Tests** tab for build life.

1. Click the **Insert After** action for the Ant Build step.
2. In the **Steps** dialog box, click **Quality > Unit Testing > JUnit**, and then click **JUnit Report**.
3. Click **Select**.
4. In the **Name** field, type `Publish JUnit Report`.
5. In the **Report Name** field, type `JUnit Report`.
6. In the **Source Directory** field, type `${p:junit.report.base.dir}`.
   Reports are written to the specified location.
7. In the **Include Patterns** field, type `TEST*.xml`.
   Test files that match the specified pattern are written to the same directory.
8. Display the **Pre-Condition Script** list by clicking **Show Additional Options**, and then select **Always**.
9. Click **Save**.

Results

The Publish JUnit Report step is inserted into the job after the Ant Build step, as shown in this figure:



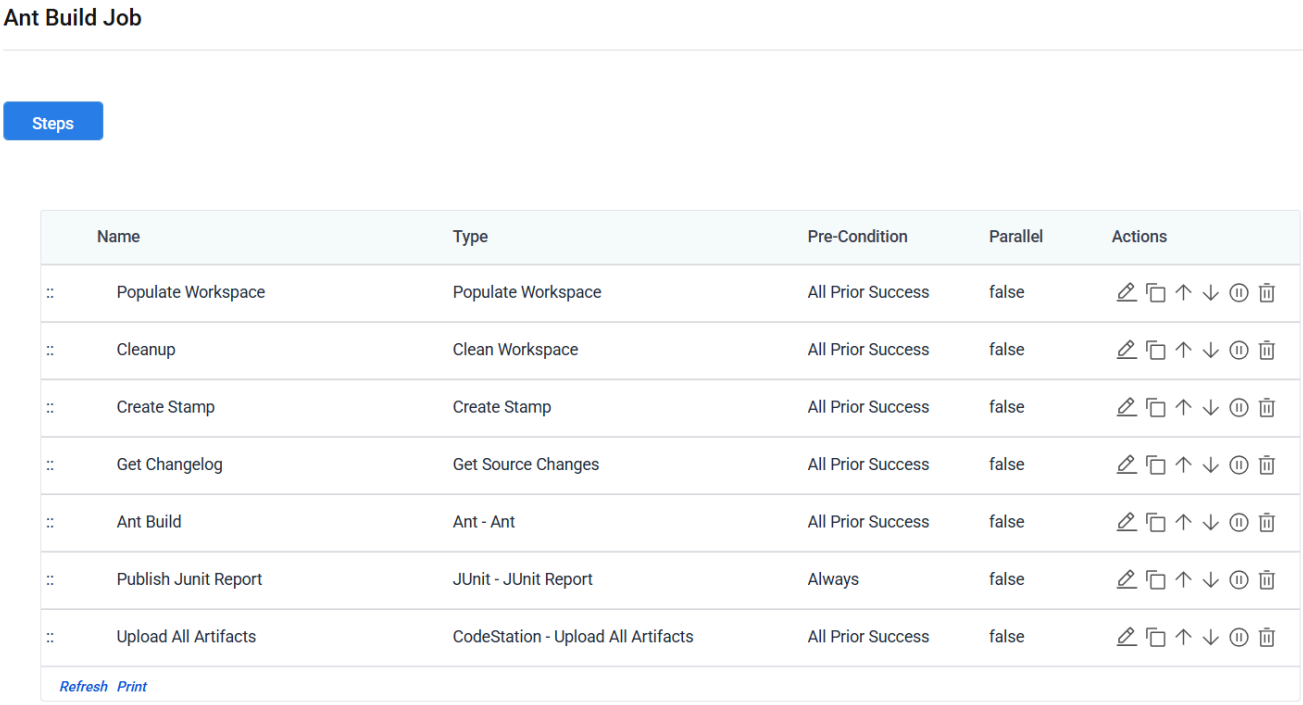
Creating the upload artifacts step

Create a step that uploads the build artifacts into the artifact repository, CodeStation.

1. Click the **Insert After** action for the Publish JUnit Report step.
2. In the **Steps** dialog box, click **Build Systems > CodeStation > >Upload All Artifacts**, and then click **Select**.
3. In the **Name** field, type `Upload All Artifacts`.
4. Accept the default values for the other fields and click **Save**.

Results

The Upload All Artifacts step is inserted into the job after the Publish JUnit Report step, as shown in this figure:



Creating the step to upload artifacts to DevOps Deploy

Create a step to upload the build artifacts to HCL DevOps Deploy (Deploy).

Before you begin

Make sure that you created an integration with Deploy, and created a component that is named Ant as described in Configure the tutorial system on page 270.

About this task

This step creates a component version and loads the build artifacts into the Deploy Ant component that you created when you configured the tutorial system.

1. Click the **Insert After** action for the Upload All Artifacts step.
2. In the **Steps** dialog box, click **Deploy > Tools > DevOps Deploy > Upload All Artifact Sets**, and then click **Select**.
3. In the **Name** field, type `Upload All Artifact Sets to UCD`.
4. In the **Component Name** field, type `${p:project/name}`.

   Note: This property value loads the artifacts into an Deploy component with the same name as the project that runs the build. Later you create a tutorial project that is named Ant. If you name your project something else, make sure that you name a component in Deploy with the name that you use for the project.

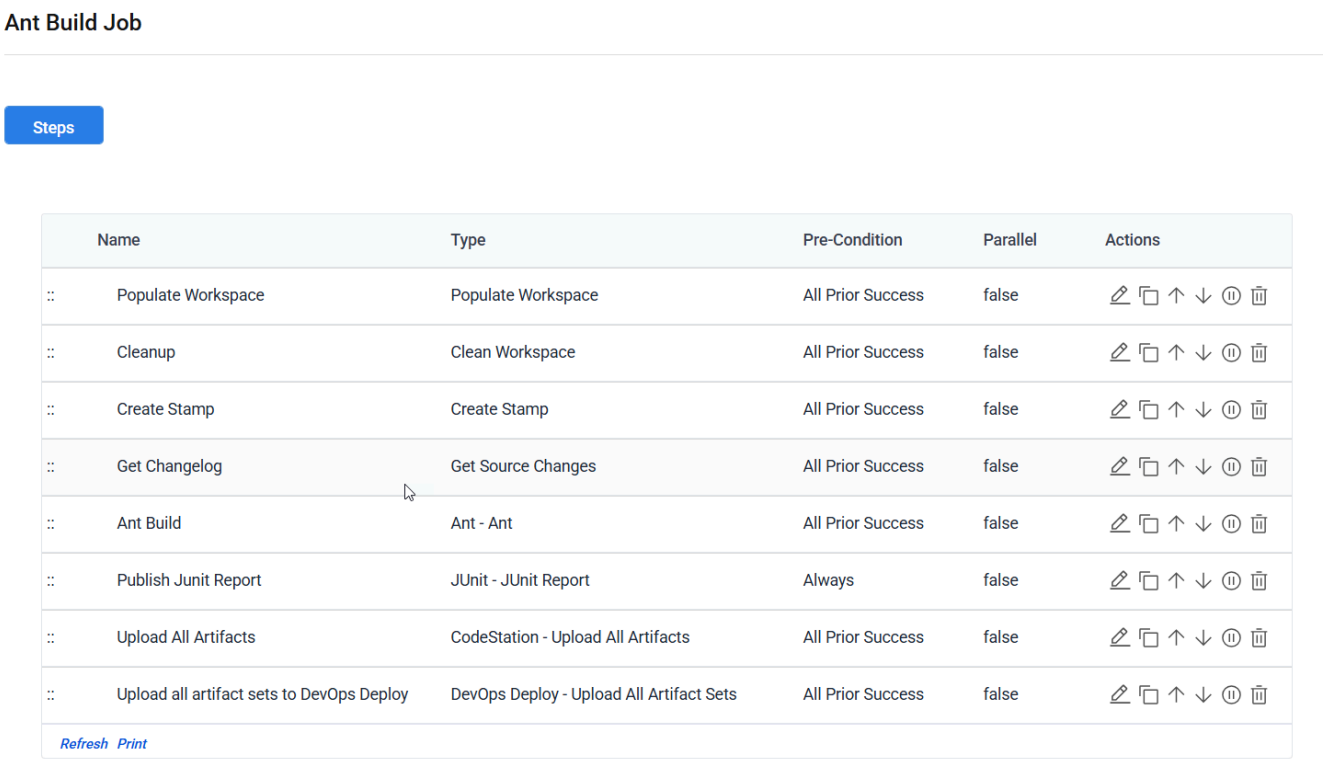
5. In the **Component Version** field, type `${p:buildlife/latestStamp}`.
   This value generates a version number for the Deploy component version. The component version ID that is created in Deploy is equal to the value that the Create Stamp job step creates.

6. In the **DevOps Deploy Server** list, select the server that you integrated with Build.
7. Accept the default values for the other fields and click **Save**.

   Result

Results

The Upload All Artifact Sets to UCD step is inserted into the job after the Upload All Artifacts step, as shown in this figure:



Creating the component version status step

Create a step that sets the component version status in HCL DevOps Deploy (Deploy).

Before you begin

Before you begin this lesson, make sure that you created a component version status with a value of `Success` in Deploy, as described in Configure the tutorial system on page 270.

About this task

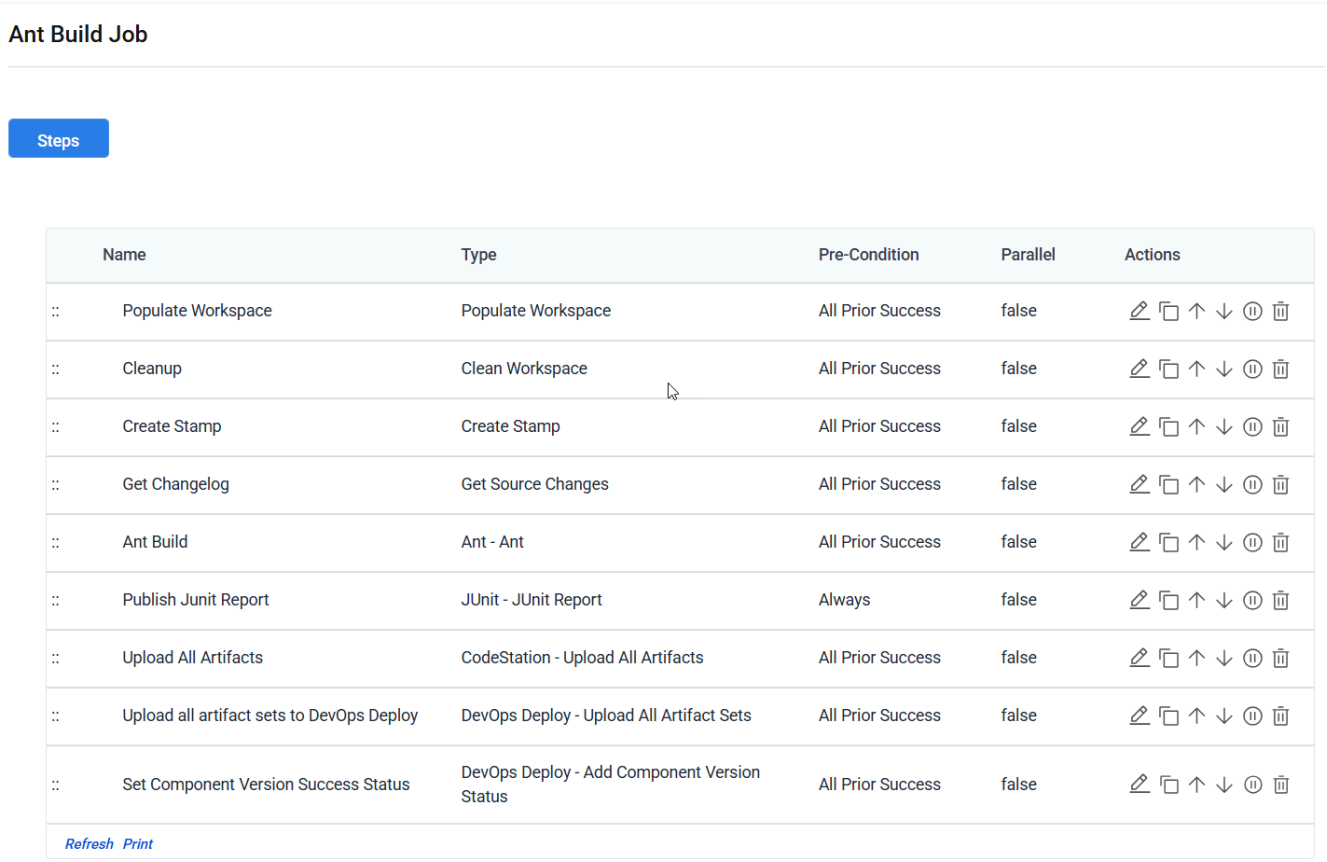
This step adds a status to the component version that was created in Deploy in the previous step.

1. Click the **Insert After** action for the Upload All Artifact Sets to UCD step.
2. On the **Steps** dialog box, click **Deploy > Tools > DevOps Deploy > Add Component Version Status**, and then click **Select**.
3. In the **Name** field, type `Set Component Version Success Status`.
4. In the **Component Name** field, type `${p:project/name}`.
5. In the **Version Name** field, type `${p:buildlife/latestStamp}`.

6. In the **Status Name** field, type `Success`.
   The status value is applied to the component version that was created in the previous step.
7. In the **DevOps Deploy Server** list, select the server that you integrated with Build.
8. Accept the default values for the other fields and click **Save**.

Results

The Set Component Version Success Status step is inserted into the job after the Upload All Artifact Sets to UCD step, as shown in this figure:



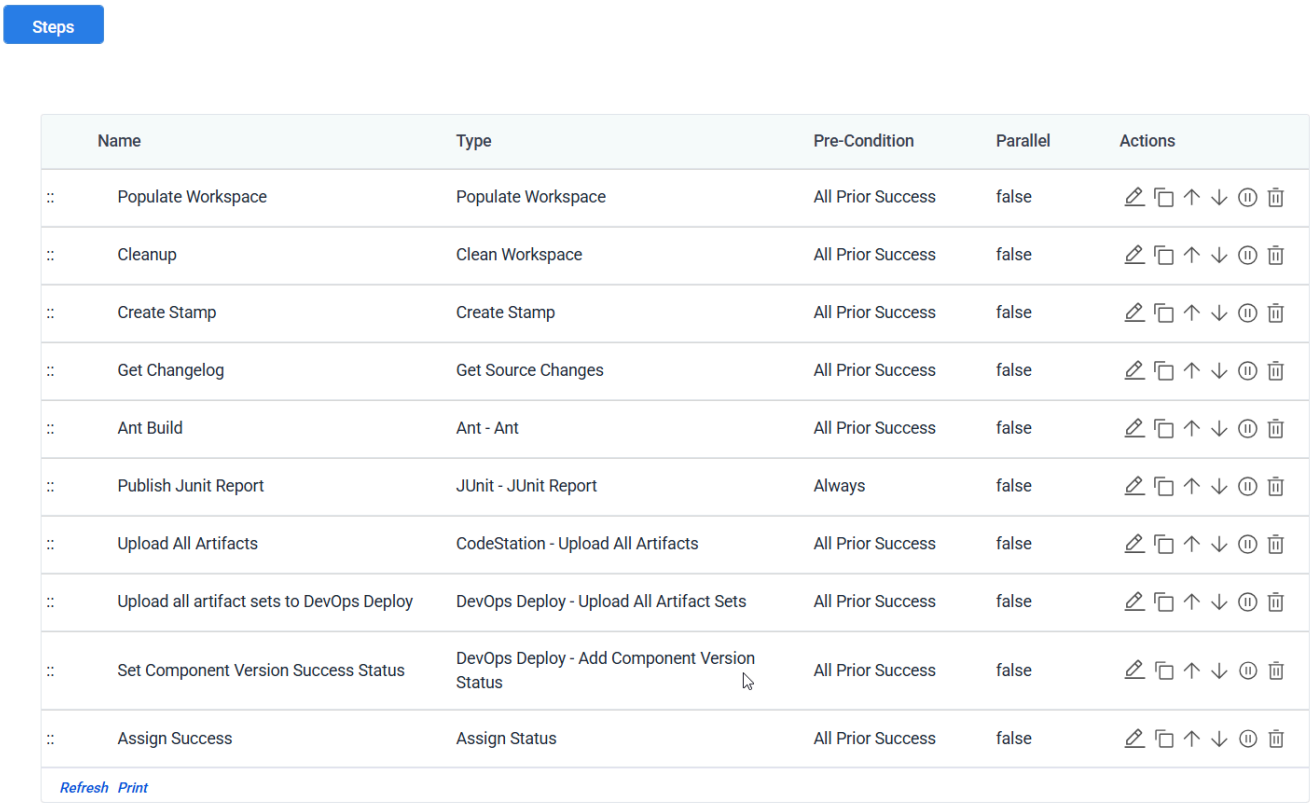
Creating the assign success step

If all previous steps succeed, this step assigns a status of Success to the entire job. If the preceding steps fail, this step does not run, and the next step runs instead.

1. Click the **Insert After** action for the Set Component Version Success Status step.
2. In the **Steps** dialog box, click **Build**, and then click **Assign Status**.
3. In the **Name** field, type `Assign Success`.
4. In the **Status** list, select **Success**.
5. Click **Save**.
   Result
   Because the **Pre-Condition Script** field is set to **All Prior Success** by default, you can accept the value.

Results

The Assign Success step is inserted into the job after the Set Component Version Success Status step, as shown in this figure:



Creating the assign failure step

This step assigns a status of Failure to the job. The step runs if any of the preceding steps fail.

1. Click the **Insert After** action for the Assign Success step.
2. In the **Steps** dialog box, click **Build**, and then click **Assign Status**.
3. In the **Name** field, type `Assign Failure`.
4. In the **Status** list, select **Failure**.
5. Display the **Pre-Condition Script** list, and select **Any Prior Failure**.
6. Click **Save**.

Results

The Assign Failure step is inserted into the job after the Assign Success step.

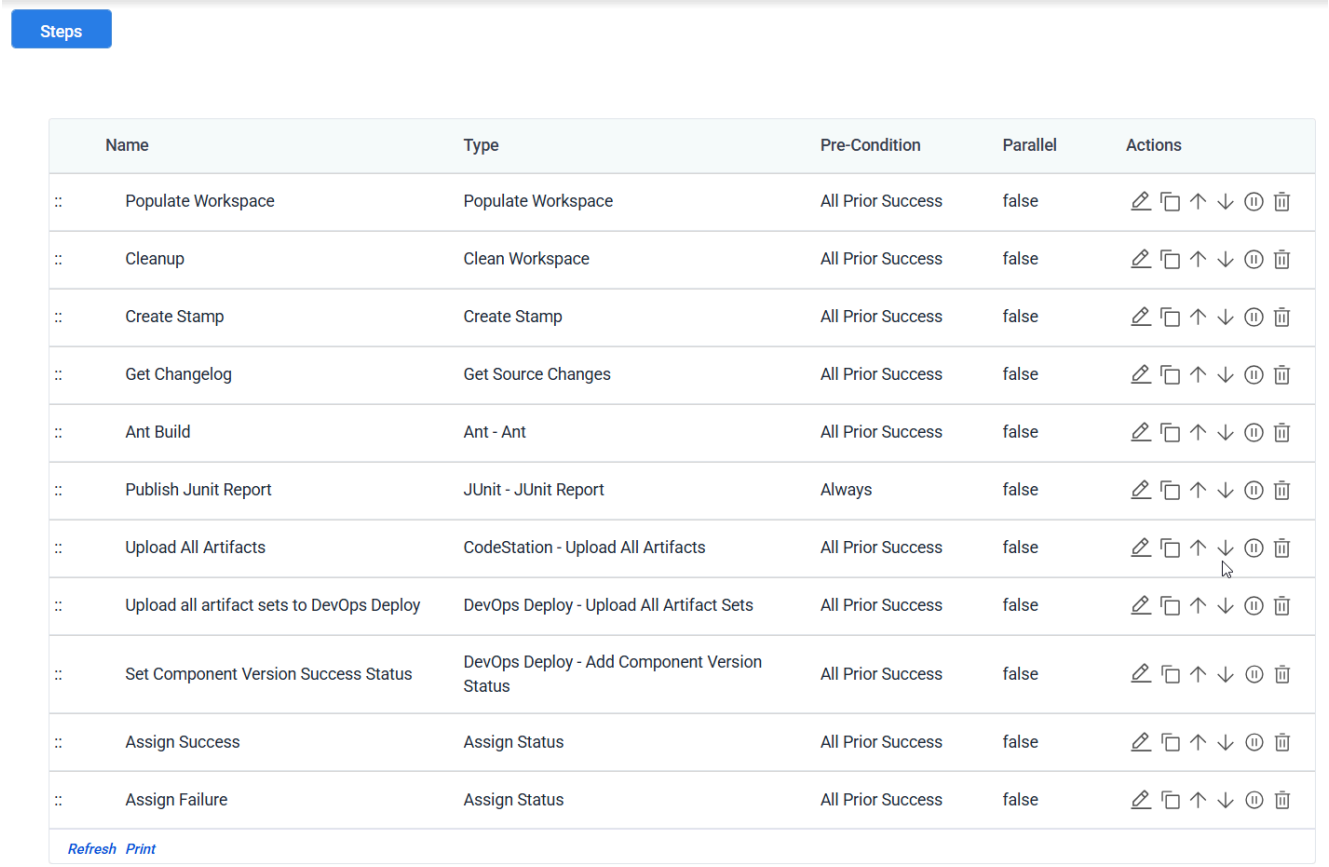
Lesson checkpoint

In this lesson, you created job and added steps to it.

About this task

This job retrieves source from GitHub and runs an Ant build process on it. It uploads the artifacts into HCL DevOps Deploy (Deploy) and generates JUnit test reports. Steps are configured individually as you insert them into a job.

The steps for the completed Ant Build Job are shown in this figure:



Lesson 3: Creating a source template

A source template is a reusable source code configuration that defines a source-code build type. Source templates can be used by any project that requires the same source type.

Before you begin

Ensure that you installed the Git source-type plug-in before you start this lesson.

About this task

In this lesson, you define a Git source configuration that the tutorial project uses.

1. On the left navigational panel, click **Source**, and then click **Create**.
2. In the **New Source Config Template** dialog, in the **Source Type** list, select **Git**.
   All installed source-type plug-ins are listed.
3. Click **Select**.
   Result
   Fields that are related to the selected source type are displayed.

4. In the **Name** field, type `gitHubSource`.
5. In the **Working Directory Script** list, select **Default Workflow Directory**.
6. In the **Remote URL** field, type `${p:remote.url}`.
   This value refers to a property that you create in the next section. You supply the property value when you configure the project.
7. In the **Remote Name** field, type `${p:remote.name}`.
8. In the **Branch** field, type `${p:branch}`.
9. Click **Save**.

Results

The **gitHubSource** source template is listed along with the other source templates on the **Source Templates** tab.

Creating properties for the source template

Define the properties that you referred to in the previous section.

1. If the **Source** tab is not already displayed, then on the Build dashboard, click **Templates**, click **Source**, and then click the **gitHubSource** source template that you created earlier in the lesson.
2. Click **Properties**, and then click **Create**.
3. Create the `remote.url` property by completing these steps.
   a. In the **Name** field, type `remote.url`.
   b. In the **Label** field, type `Remote URL`.
      The label text identifies the property to users who use the source template.
   c. In the **Display Type** list, select **Text**.
   d. In the **Value** area, accept the default option, **Defined**.
      The **Value** option determines when and where the value for the property is defined. By selecting **Defined**, you can provide a value in the **Default Value** field, or supply the value on the project configuration before the project runs.
   e. Select the **Value Required** check box.
   f. Leave the **Default Value** field blank.
      You define the value when you configure the project.
   g. Click **Save**.
4. Create the `remote.name` property by completing these steps.
   a. In the **Properties** tab, click **Create**.
   b. In the **Name** field, type `remote.name`.
   c. In the **Label** field, type `Remote Name`.
   d. In the **Display Type** list, select **Text**.
   e. In the **Value** area, accept the default option **Defined**.

f. Select the **Value Required** check box.
g. In the **Default Value** field, type `origin`.
h. Click **Save**.

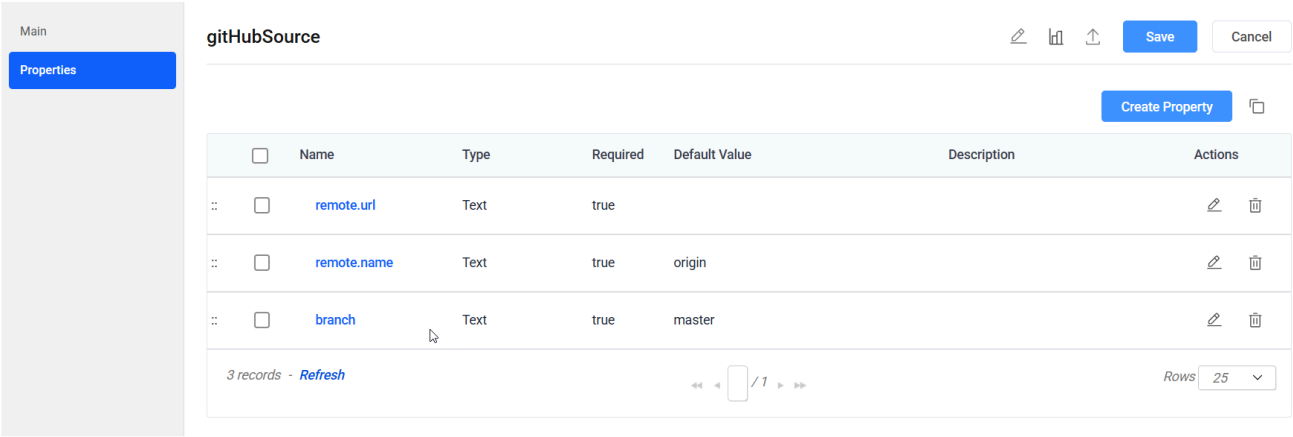
5. Create the `branch` property by completing these steps.
   a. In the **Properties** tab, click **Create**.
   b. In the **Name** field, type `branch`.
   c. In the **Label** field, type `Branch`.
   d. In the **Display Type** list, select **Text**.
   e. In the **Value** area, accept the default option **Defined**.
   f. Select the **Required** check box.
   g. In the **Default Value** field, type `master`.
   h. Click **Save**.

Lesson checkpoint

In this lesson, you created a source template and defined properties that identify the source material that is used in the build.

About this task

The gitHubSource source template properties are shown in this figure:



Lesson 4: Creating a process template

Build process templates associate processes with project templates.

About this task

In this lesson, you create a process template and assign the workflow that you created to it. In addition, you define several project properties and the artifact set that the project uses.

1. On the left navigational panel, click **Templates**, click **Process**, and then click **Create**.
2. In the **New Process Template** dialog box, in the **Name** field, type `Ant Build Process`.
3. Under **Type**, make sure that **Build Process** is selected.
4. Click **Save**.

Results

The **Main** tab for the new process template is displayed.

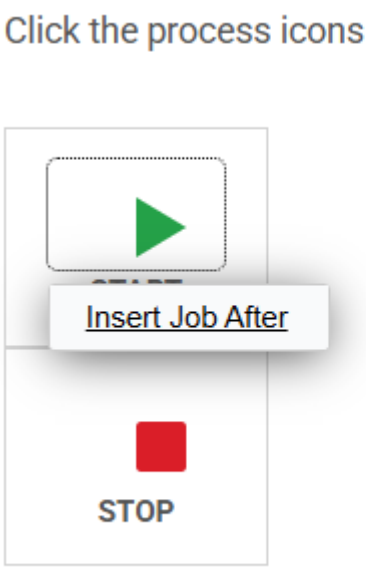
Creating a process definition

Process definitions identify the jobs in a build.

About this task

Process definitions define the jobs and steps in a build. When you place a job in a process definition, you specify several options, such as the agent pool and the working directory. Process definitions can have several jobs attached to them and, like the steps in a job, you control their order. Process definitions are created with reusable templates. In this lesson, you create a process definition and assign the job that you created in the previous lesson to it.

1. On the Build dashboard, click **Templates > Process**.
2. In the **Process Templates** page, click **Ant Build Process**, and then click **Definition**.
3. In the **Definition** area, click **Start**, and then select **Insert Job After**.
   The **Insert Job After** action is displayed after you click **Start**, as shown in this figure:



4. In the **Insert Start Job** window, in the **Job** list, select the job that you created in a previous lesson, **Ant Build Job**.
5. In the **Pre-condition** list, select **Always**.
6. In the **Agent Selection** area, select **Agent Pool Selection**, and then select the agent pool that you created when you configured your tutorial system on page 270.
   An agent in the agent pool runs the jobs that are assigned to the process definition.
7. In the **Working Directory** list, select **Default Workflow Directory**.
   An agent's default working directory is as follows:

   ```
   agent_directory/var/work/project/project_name
   ```

When this option is selected, the agent creates a folder for each project that it runs.

8. Accept the default values for the other fields and click **Insert Job**.
   Result
   The **Ant Build Job** is inserted in the **Ant Build** process definition.

Creating process template properties

Define the property that you referred to in Lesson 2.

About this task

In this step, you define properties that every project that uses the template can use. Because this template is related to Ant builds, most properties are related to Ant builds. Some properties have default values defined for them, while others are left to be defined later.

1. Click **Properties**, and then click **Create**.
   Use the values in the following table to create the properties for the tutorial workflow. You can enter any text for the property labels but remember that the labels are displayed to users who use the template. In addition, if you use the suggested label text, it is easier to follow the tutorial in Lesson 6 on page 292. If a cell is empty in the Default value column, leave the corresponding **Default Value** field blank. Accept the default values for the other fields. The descriptions you enter are displayed on some of the project's dialog boxes. Descriptions for some of the properties are provided in the figure below.

Table 7. Tutorial process template properties

Name	Label	User May Override	Type	Required	Default Value
`dir.offset`	Directory Offset	No	Text	False	
`build.script.name`	Build Script	No	Text	True	`build.xml`
`ant.targets`	Ant Targets	Yes	Text	False	`${p?:default.ant.targets}`
`build.properties`	Build Properties	Yes	Text Area	False	
`ant.properties`	Ant Properties	Yes	Text Area	False	
`product.version`	Product Version	No	Text	True	`1`
`artifacts.base.dir`	Artifacts Base Dir	No	Text	True	`.`
`artifacts.includes`	Include Artifacts	No	Text Area	True	`*`
`artifacts.excludes`	Exclude Artifacts	No	Text Area	False	

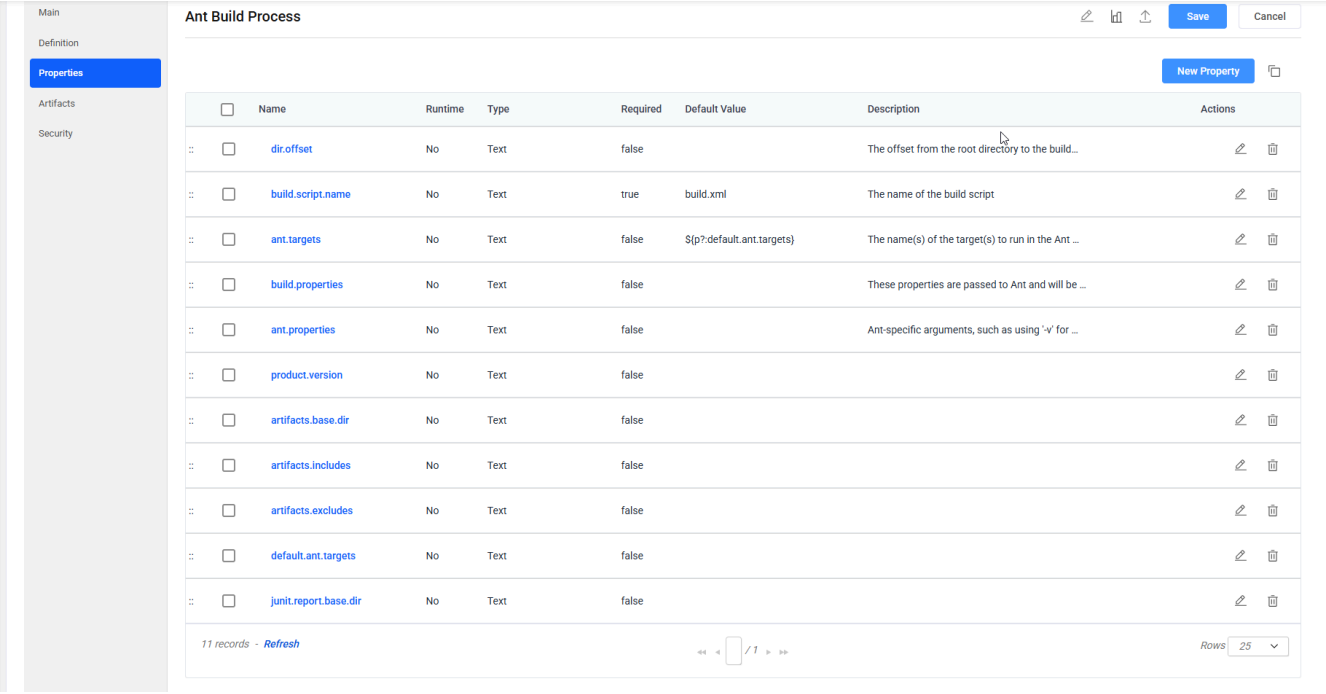
Name	Label	User May Override	Type	Required	Default Value
`default.ant.targets`	Default Ant Targets	No	Text	False	
`junit.report.base.dir`	JUnit Report Base Dir	No	Text	True	

The artifact set you create in the next section uses three properties: `artifacts.base.dir`, `artifacts.includes`, `artifacts.excludes`.

2. Click **Save** after you finish each property.

Results

The properties are listed on the **Properties** tab of the Ant Build Process process template.



Creating process artifact sets

Generated artifacts are assigned to an artifact set. An artifact set is a collection of build artifacts.

Before you begin

Before you begin this lesson, make sure that you created the artifact set as described in Configure the tutorial system on page 270.

About this task

In this lesson, you configure the artifact set the project uses. The items in the artifact set are loaded into HCL DevOps Deploy (Deploy) as a component version.

1. Ensure that the window for your build process is displayed, click **Artifacts**, and then click **New Artifact Config**.
2. In the **Artifact Set** list, select the artifact set you created earlier on page 270, **dist**.
3. In the **Base Directory** field, type `${p:artifacts.base.dir}`.
   This property and the next two properties refer to the properties you created in the last section. The default value,which was defined in the last section, means the process will use the current directory.
4. In the **Include Artifacts** field, type `${p:artifacts.includes}`.
   The default value,which was defined in the last section, means the process will include all artifacts.
5. In the **Exclude Artifacts** field, type `${p?:artifacts.excludes}`.
6. Click **Save**.

Lesson checkpoint

In this lesson, you created a process template and defined a process for it. You created properties and added an artifact set to the template.

Lesson 5: Creating a project template

Projects bring together build processes, source configurations, dependencies, and artifacts. A project template is a reusable blueprint that defines a generic project.

About this task

Because project templates are reusable, you can apply the same specifications to similar projects. Properties can be defined and the values can be supplied later in the projects that are created from the template. A project template might always use a particular type of build script, for example, but the name or location of the script can vary by project.

In this lesson, you create a project template that you use later to create the tutorial project.

1. On the left navigational panel, click **Templates**.
   The **Projects** tab is open by default.
2. Click **Create**.
3. In the **Create a Project Template** dialog box, in the **Name** field, type `Git Project Template`.
4. Click **Save**.
   Result
   The **Build Pre-Processing** tab for the new project template is displayed. You can use this tab to check for source changes or define other things to occur before the build starts.
5. Click **Agent Pool Selection**, and then select the agent pool that you created when you configured the tutorial system on page 270.
   The agent pool that you selected in Lesson 4 on page 287 will run the tutorial process. The agent pool you select here will be available during project quiet periods. A quiet period is a specified period of time during which changes cannot be committed to the source code.
6. Accept the default values for the other fields and click **Save**.

Lesson checkpoint

In this lesson, you created the project template that you use to build the tutorial project.

About this task

For more information about project templates, see Creating project templates on page 384.

Lesson 6: Creating a project

You use projects to configure and run builds. After a build runs, projects provide a wealth of information that you can use to manage the project lifecycle and troubleshoot problems.

Before you begin

Ensure that you completed all the preceding steps before you start this lesson.

About this task

Projects are built from templates. In this lesson, you use the templates that you made earlier to create the tutorial project. To define the project, you select the process and process definition templates and provide values for the properties that are defined by them.

You can run builds automatically on a schedule, or you can run builds manually, as you do in the tutorial. When you start the build, the job that you created with the job template is started. The project determines which source code to use and manages dependencies. Each build generates a unique build life

As the project runs, the build life provides feedback about the build's status and generates logs that you can use to troubleshoot problems. If projects are configured to run tests, as the tutorial project is, test results are available on the **Tests** tab for the build life.

1. On the left navigational panel, click **Projects**, and then click **Create**.
2. Select the project template that you created in Lesson 5 on page 291, **Git Project Template**.
3. In the **Name** field, type `Ant`.

   Note: The build uses the project's name to identify the HCL DevOps Deploy (Deploy) component. If you use another name for your project, make sure there is a component with the same name in Deploy.

4. Click **Save**.
   The **Configuration** tab for the project is displayed. You use this page to configure projects. You can also run project builds on this page. Later, you will use this page to run the tutorial project.

Configuring the project build process

A project must be associated with a build process. A project can be associated with any number of build processes.

1. Ensure that the **Configuration** tab for the Ant project is displayed; then, under **Build Processes**, click **New**.
2. In the **New Process** window, in the **Template** list, select **Ant Build Process**, and then click **Select**.
   The fields that you see depend on the selected template. In this case, several fields are derived from the process template that you created the previous lesson.

Note: If the only template you have is the one you created earlier in the tutorial, the template is automatically selected and this step is skipped.

3. In the **Name** field, type `GitHub Build Process`.
4. In the **Build Script** field, accept the `build.xml` value.
   You defined the default value, `build.xml`, when you created the process template.
5. In the **Product Version** field, accept the `1` value.
   You defined the default value when you created the process template.
6. In the **Artifacts Base Dir** field, type `dist/lib`.
   This overrides the default value you defined earlier.
7. In the **Include Artifacts** field, type `*.jar`.
   This overrides the default value you defined earlier.
8. Leave the **Exclude Artifacts** field blank.
9. In the **Default Ant Targets** field, type `main junit-batch`.
   You can use another target, `main junit-batch-with-failure` to automatically fail the Ant build step and produce a lot of JUnit test results.
10. In the **JUnit Report Base Dir** field, type, `build/testcases/xml`.
11. Click **Save**.

Results

The **Configuration** tab for the new build process is displayed.

Configuring the project source

You define a project's build source by assigning a source template to a build configuration and defining values for its properties.

Before you begin

Ensure that the **Configuration** tab for the build process that you defined in the previous section is displayed.

About this task

You define the source configuration by selecting the source template that you created earlier, and by using template properties to identify the source location.

1. Under **Source Configuration**, click **Create**.
2. In the **New Source from Template** dialog box, in the **Source Template** list, select the source template that you created earlier, **gitHubSource**, and then click **Select**.

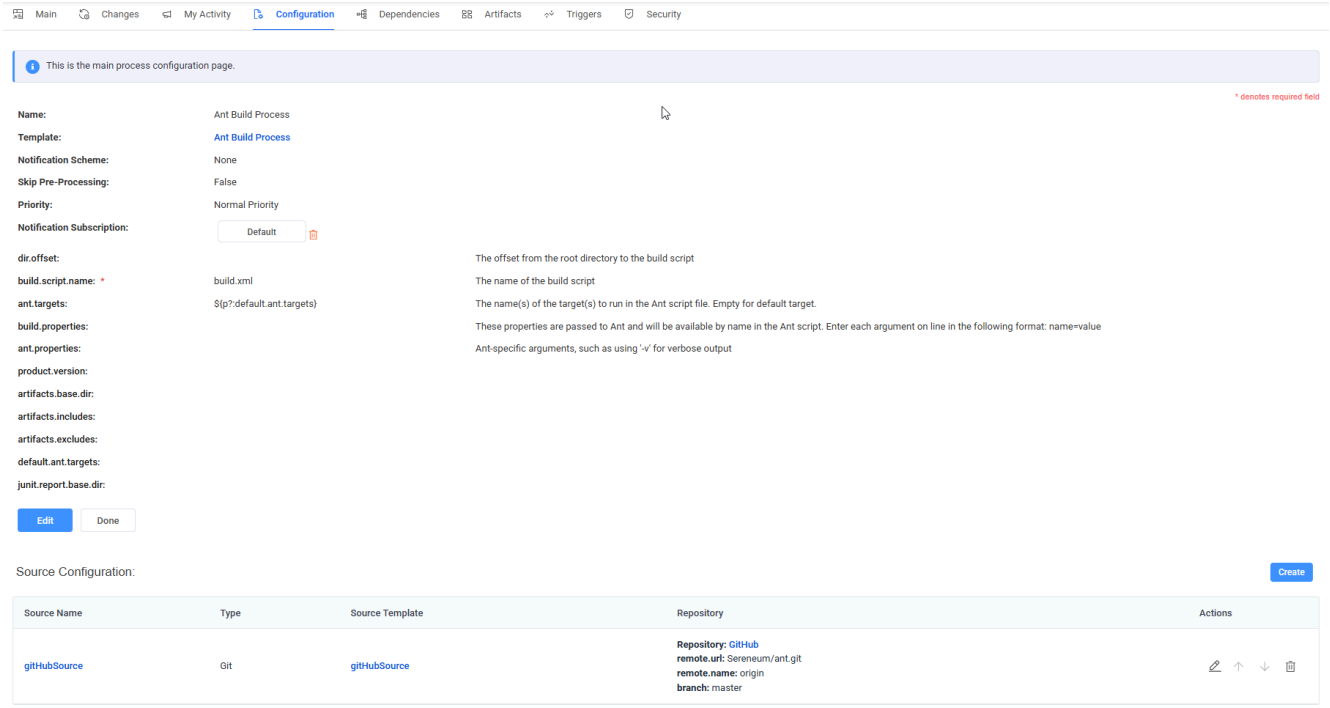
Note: If the only template you have is the one you created earlier in the tutorial, the template is automatically selected and this step is skipped.

3. In the **Name** field, type `gitHubSource`.

4. In the **Repository** list, select the repository that you created earlier, **GitHub**.
5. In the **Remote URL** field, type `Serneum/ant.git`.
   You defined this field and the next two fields when you created the source template.
6. In the **Remote Name** field, accept the default value `origin`.
   You defined the default value for this field when you created the source template.
7. In the **Branch** field, type `ANT_18_BRANCH`.
   This overrides the default value, `master`, you defined earlier.
8. Click **Save**.

Results

With the build process defined and the build source identified, the project is complete. The finished project is shown in this figure:



Lesson checkpoint

In this lesson, you created a project and defined a build process and a build source.

About this task

The project is constructed from the templates that you made earlier in the tutorial. All projects are built from templates. When you create a project, you identify the templates and provide property values for them. With this lesson finished, it's time to run the project.

Lesson 7: Running the build

Run the project build process to transform the source code into a distributable component and load it into HCL DevOps Deploy (Deploy).

Before you begin

To see the finished build objects that are loaded into Deploy, make sure that you complete these tasks before you run the build:

- Configure an instance of Deploy and the Build agent that you use in the tutorial project can access it.
- Create an Deploy integration that identifies the Deploy server that you are using in the tutorial.
- Make sure that your instance of Deploy is running
- Create a component named Ant in Deploy.
- Create a version status in Deploy that is named Success.

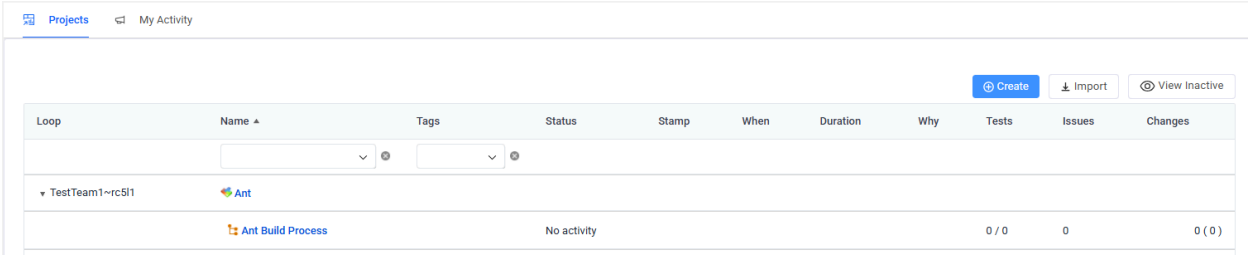
About this task

You run a build by running a build process that is defined for a project. The build process takes the source material and transforms it into the final output by using a job that is assigned to the project. The job in the tutorial project completes these activities:

1. Checks out source material from the GitHub repository.
2. Uses Ant to build the project artifacts.
3. Runs JUnit tests on the build process.
4. Loads the artifacts into an Deploy component.
5. Assigns a status of Success to the component in Deploy.

Typically when you run a build, you can use several run-time properties. The number of properties depends on the template. In the case of the tutorial project, the **Ant Targets** property affects the build's outcome. If you accept the `${p:?default.ant.targets}` default value for the **Ant Targets** property, the build process uses the `main junit-batch` value that you defined in the previous lesson. You can overwrite the default value with one of your own, but for the tutorial accept the default value. Another target is discussed later in this lesson.

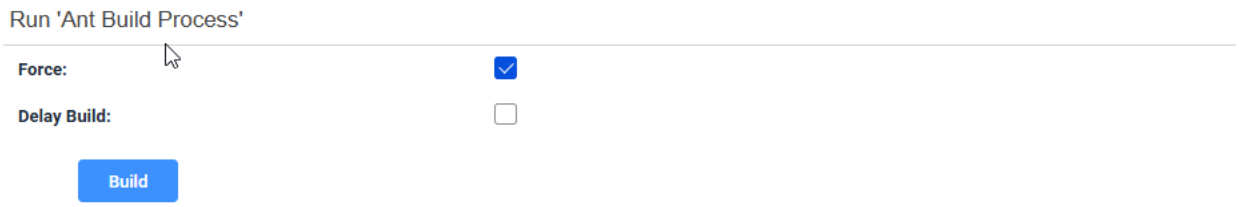
1. On the left navigational panel, click **Projects**, and then expand the project that you created in the previous lesson, **Ant**.
   Result
   Build processes that are configured for the selected project are listed beneath the project, as shown in this figure:



2. Click **Ant Build Process**.

Result

The **Main** tab for the Ant Build Process is displayed.

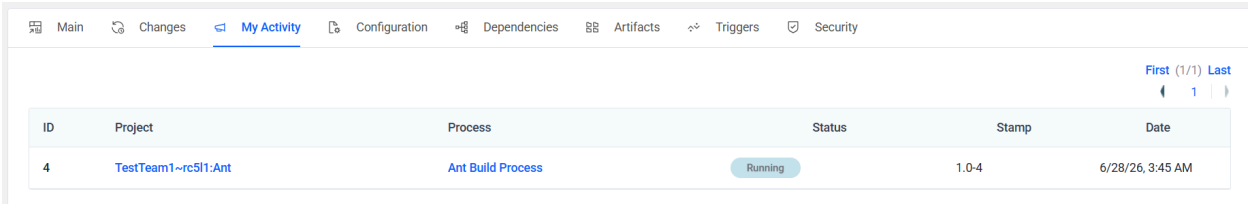


A project build process can have any number of run-time properties. The user who runs the build can enter values that are related to a particular build or override default values.

3. Accept the default value in the **Ant Targets** field.
4. Click **Build**.

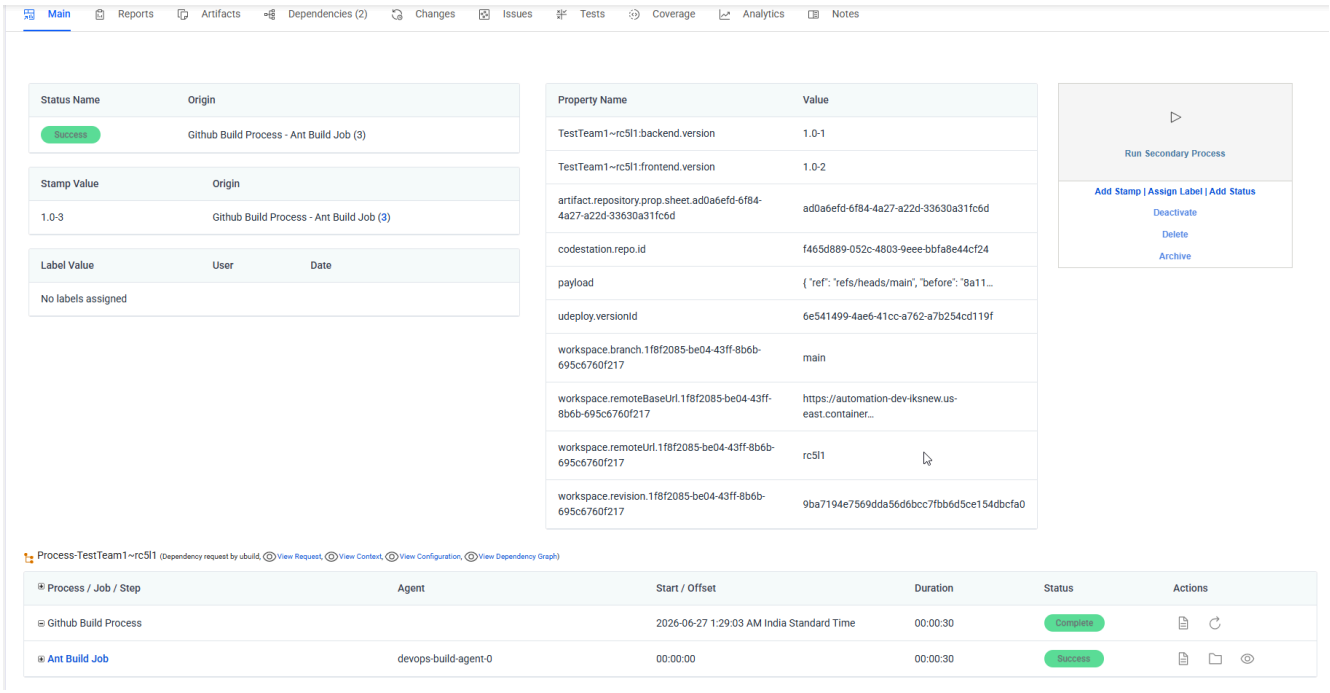
   Result

   The build process starts and the **My Activity** tab for the build is displayed. The build, with a new build life number, is listed with a status of `Running`, as shown in this figure:



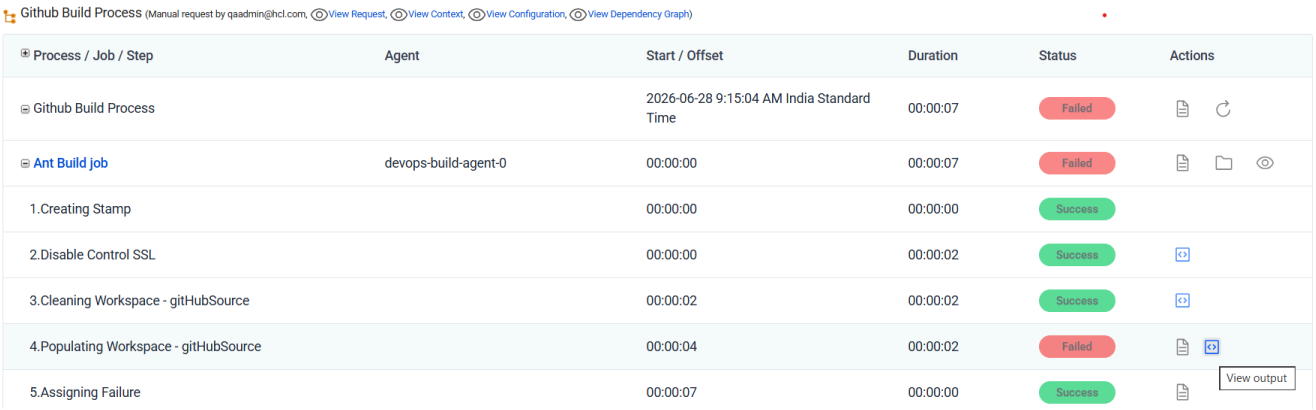
Results

Refresh the **My Activity** page. If the build succeeds, the status changes to `Complete`; otherwise, the status changes to `Failed`. The project's **Main** tab contains information about the builds that the project generated. To see information about a build, click the **ID** for the build life. A completed build of the tutorial project is shown in this figure:



What to do next

If a build fails, you can see information about a failed step. To see a step's output, use the **View Output** action, as shown in the following figure. Use the log to identify errors and troubleshoot failed steps.



The tutorial project is configured to run JUnit tests. To see the types of reports that are created when a build fails, run the build again, but use the `main junit-batch-with-failures` target in the **Ant Targets** field. This target automatically fails on the Ant Build step in the Ant Build Job, and generates numerous JUnit reports.

To see the JUnit test results, open the **Tests** tab for the build.

Lesson checkpoint

In this lesson, you ran a build of the tutorial project and examined its progress, tests, and final output.

About this task

In this lesson, you ran a build for the project that you created in the tutorial. The build created artifacts that were loaded into an Deploy component version and assigned a status of Success. Finally, the build created JUnit reports that are available on the **Tests** tab of the build life.

Lesson 8: Verifying the build results

Check the component version that was created by the tutorial project in HCL DevOps Deploy (Deploy).

Before you begin

Run the project that is described in the previous lesson and ensure the build life status is `Complete`.

About this task

The build that you ran in the previous lesson loaded artifacts into an Deploy component version and assigned a status of success to it. In this lesson, you review the component version in Deploy.

1. Access the instance of Deploy that you configured for the tutorial project.
2. From the Deploy Dashboard, click **Components**, and then click the **Ant** component you created for the tutorial.
3. Click **Versions**.

   Result

   The component version that the tutorial project created is listed on the **Versions** tab. The component version status is listed in the **Statuses** column. The tutorial project assigns `Success` status to the component version.

   The version number corresponds to the stamp that you created in the Ant Build Job.

What to do next

The artifacts that the tutorial project created are loaded in Deploy. To see the actual artifacts, expand the `dist` artifact set that you defined in the project.

Lesson checkpoint

In this lesson, you reviewed the component version that the tutorial project created in Deploy.

Summary

In this tutorial, you learned how to build a project and run a build with Build.

Lessons learned

By completing this tutorial, you learned about the following concepts and tasks:

- How to create a repository and use it in a build process
- How to create jobs and add steps to them
- How to create and use workflow templates
- How to create source and process templates
- How to create project templates
- How to create projects and configure their sources, processes, and workflows
- How to run a build and examine its output

Administering

Users with the correct permissions can configure security, create users, configure integrations, and create notifications and announcements among other things.

Feature flags

Feature flags allow you to enable and disable product functions.

To modify the value of a feature flag, edit the `installed.properties` file and locate the feature flag. If not found, a line with the feature and its value. The format is *`featureflag_name=value`*, where the value is true or false. In the following example, the first line enables the automatic keystore generation feature and the second line disables the Build client download link from the tools menu.

```
automatic.keystore.generation.enabled=true
ucb.client.download.enabled=false
```

The following table contains a description of the available feature flags.

Note: Several feature flags control optional and experimental features.

Feature name	Description	Default Value
ucb.licensing.lazyInit	Initialize licensing in the background to avoid blocking server startup for checking licenses.	false
user.profile.locale.enabled	Allow Build users to select a locale in their profile.	true
user.profile.collation.enabled	Allow Build users to select a collation in their profile.	true
token.licensing.enabled	Allow the use of tokens for fallback licensing.	true
ucb.client.download.enabled	Show the Build client on the **Tools** page.	true
globalization.test.languages.enabled	Allow the use of special pseudo-translations for globalization testing.	false
process.dependency.graph.enabled	Enable the **Visual Dependency Graph View** button on the **Process Configuration** page.	true
oracle.nls.settings.enabled	Configure the national language support (NLS) settings for Oracle	false

Feature name	Description	Default Value
	databases. Enabling this feature might degrade the execution performance of various SQL statements in exchange for correctly sorting result sets for non-English locales.	
automatic.server.upgrade.enabled	Allow the server to run upgrade scripts during startup operations. This feature is useful when you run Build in a container. It is not applicable to non-container installations.	false
automatic.keystore.generation.enabled	Allows the Build server to generate the required keystore files and keys and certificates that are based on information from the `installed.properties` file, if the specified keystore files do not exist.	false
manage.all.roles.enabled property	Allow users with the Team User Management role to add users to all roles within the team, with the exception of the Admin role.	false

Running agents

To start an agent, run the shell script or batch file. An agent can be started before or after Build is started. The agent must be started and configured before it can be used.

1. Go to the script. *`agent_installation`*`\bin` directory.
2. Run the appropriate command.
    - On Windows, run this command:

      ```
      agent start
      ```

    - On Linux or UNIX, , run this command:

      ```
      .\agent start
      ```

3. After the agent starts, go to the Build web application, and open the **Agents** tab.

Results

When the process is complete, the agent is listed with a status of `Online` on the **Agents** page.

Starting agents on z/OS

After an agent is installed on z/OS, it can be started.

About this task

The agent can be started manually or by using Job Control Language (JCL).

Starting agents on z/OS manually

After an agent is installed on z/OS, it can be started.

About this task

The agent can be started manually or by using Job Control Language (JCL).

1. Locate the directory where the agent is installed.
2. From a command line, issue the following command to start the agent.
   bin/agent start.

   The agent process runs in the background.

Using JCL to start the z/OS agent

About this task

The agent can be started manually or by using Job Control Language (JCL).

1. Locate the JCL script in the `ibm-devops-build-agent-install/install/zos/BULAGNT` path.
2. Verify that the agent directory is correct in the JCL script file.
3. Submit the JCL script file.

Viewing z/OS agent logs

The z/OS agent log files are stored in UTF-8 charset. To read agent log files, use an editor that supports the UTF-8 format.

About this task

To view the agent log file, issue the following command.

```
vi -W filecodeset=UTF-8,pgmcodeset=IBM-1047 agent.out
```

Configuring an external agent for Build in DevOps Loop

You can configure an external Build agent to connect with DevOps Loop installed on Kubernetes (K8s), Azure Kubernetes Service (AKS), IBM Kubernetes Service (IKS), or OpenShift Container Platform (OCP).

Before you begin

Before you begin, ensure the following prerequisites are met:

- Installed DevOps Loop on Kubernetes (K8s), Azure Kubernetes Service (AKS), IKS, or OCP.
- Ensured that you have access to the Kubernetes or OpenShift cluster where DevOps Loop is running.

- Installed the DevOps Build agent on a supported external platform.
- Been granted permissions to edit services or create routes in the cluster.

1. Edit the Emissary ingress service to expose the Build agent port for Kubernetes (K8s), Azure Kubernetes Service (AKS), or IKS deployments.

    a. Run the following command:

    ```
    kubectl edit svc emissary-ingress -n emissary
    ```

    b. Under the *spec.ports* section, add the following configuration:

    ```
    - name: build-agent
    nodePort: 31123
    port: 7920
    protocol: TCP
    targetPort: 7920
    ```

2. Update the `installed.properties` file of the agent located at `<agent-install-dir>/conf/agent` with the cluster domain and port.

    a. For Kubernetes (K8s) environments:

    ```
    locked/agent.brokerUrl=failover:(ah3://{{.Values.global.domain}}:7920)
    locked/agent.jms.remote.host={{.Values.global.domain}}
    locked/agent.jms.remote.port=7920
    ```

    `Values.global.domain` is the same URL used to access the DevOps Loop UI.

    b. For IKS environments:

    ```
    locked/agent.brokerUrl=failover:(ah3://<service-domain>:7920)
    locked/agent.jms.remote.host=<service-domain>
    locked/agent.jms.remote.port=7920
    ```

    `<service-domain>` is the domain configured for the IKS cluster in Step 4 on page 302.

3. Start the external Build agent by running the following command:

    ```
    sudo <agent-install-dir>/bin/agent run
    ```

    Result

    The agent is displayed under the **Agents** section in the Build UI.

4. For IKS, configure the cluster service domain, if it is not configured.
    Follow steps in the Installing DevOps Loop on IBM Cloud Kubernetes Service (IKS) on page 46 topic for setting up the service domain.
5. **Optional:** If the above approach does not work, use the following alternate method for a Kubernetes cluster running on a demo RHEL setup.

    a. Patch the service to expose an external IP and port.
    Run the following commands:

    ```
    kubectl patch svc devops-build-server -n devops-loop --type=merge -p
     '{"spec":{"externalIPs":["<machine-ip>"]}}'
    ```

```
kubectl patch svc devops-build-server -n devops-loop --type=json
 -p='[{"op":"replace","path":"/spec/ports/2/port","value":<required-port>}]'
```

Replace `<machine-ip>` and `<required-port>` with appropriate values. Ensure that the specified port allows inbound and outbound traffic from the host machine where the external agent is running.

b. Update the `installed.properties` file of the agent.

```
locked/agent.brokerUrl=failover:(ah3://<machine-ip>.nip.io:<required-port>)
locked/agent.jms.remote.host=<machine-ip>.nip.io
locked/agent.jms.remote.port=<required-port>
```

6. For OpenShift deployments, create a route to expose the Build agent service.

a. Apply the following route definition:

```
cat <<EOF | oc apply -n <namespace> -f -
apiVersion: route.openshift.io/v1
kind: Route
metadata:
name: devops-build-agent
spec:
to:
kind: Service
name: devops-build-server
port:
targetPort: agent
tls:
termination: passthrough
insecureEdgeTerminationPolicy: Redirect
EOF
```

b. Retrieve the route host by running the following command:

```
oc get route devops-build-agent
```

c. Update the `installed.properties` file of the agent located at `<agent-install-dir>/conf/agent` as follows:

```
locked/agent.brokerUrl=failover:(ah3://<route-host>:443)
locked/agent.jms.remote.host=<route-host>
locked/agent.jms.remote.port=443
```

d. Start the external Build agent by running the following command:

```
sudo <agent-install-dir>/bin/agent run
```

Result

The agent is displayed under the **Agents** section in the Build UI.

Results

You have configured the external Build agent and connected it to DevOps Loop.

What to do next

You can now run jobs on this agent.

Integrating Build resources with existing loop and teamspaces

You can integrate the previously created Build resources, including teams, mappings, and agent pools to an existing teamspace and loop after you upgrade from DevOps Loop 1.0.2 to 1.0.3 or later.

Before you begin

You must have completed the following tasks:

- Ensured that you have the administrator privileges in DevOps Loop.
- Ensured that you have a valid bearer token.
- Ensured that you have a loop ID, teamspace ID, and loop name.

1. Create a team in Build by using the following API call:

```
curl -kX PUT "${LOOPDOMAIN}/build/rest2/team/loop/${loopId}" \
-H "Authorization: Bearer ${BEARER_TOKEN}" \
-H "Content-Type: application/json" \
-d '{
"name": "${LoopName}",
"description": "",
"type": "Loop",
"teamspaceId": "${teamspaceId}",
"roleMappings": [
{
"role": "Platform User",
"user": "${UserEmailAddress}",
"authenticationRealm": "Platform_build_OIDC"
}
]
}'
```

   Replace all variables with actual values:

   - **loopId**: Navigate to **Deploy > Settings > Teams**. Select the team created during loop initialization and loop ID can be found at the end of the URL.
   - **teamspaceId**: Navigate to **Deploy > Settings > Teams**. Select the team created during teamspace creation and teamspace ID can be found at the end of the URL
   - **LoopName**: Use the loop's name, without any prefix.
   - **BEARER_TOKEN**: Use a valid bearer token.

   You can assign additional members in the `roleMappings` array. Supported roles include `Platform User` and `Platform Admin`.

2. Perform the following steps to map resources to the newly created team in Build:

   a. Click **Teams** in the left navigation panel.
   The **Teams** tab is displayed with the list of teams.

   b. Select the newly created team.

c. Map the following resources in the **Team Objects Mappings** section:
   - Project
   - Project Process
   - Job
   - Repository
   - Template
   - Agent Pool

d. Select each resource from the drop-down, click **Add**, select the newly created team, and click **OK**.

3. Add the required users to the new team.
4. Configure the agent and assign it to the appropriate agent pool.
5. Click **Retry** for the failed teamspaces after upgrading from DevOps Loop 1.0.2 to DevOps Loop 1.0.3 or later to complete the teamspace creation.

Results

The Build environment is now successfully integrated into the previously created loops and teamspaces after upgrading from DevOps Loop 1.0.2 to DevOps Loop 1.0.3 or later.

Configuring Agents

Assigning users to teams

Integrations

When you configure integrations, you allow Build to use and manage the objects and artifacts that are produced in external tools such as HCL DevOps Deploy (Deploy).

Build provides integrations with many tools. Integrations are implemented at the job and step levels. With these integrations, Build can distribute process execution and access third-party tools.

Integrating with Eclipse

Eclipse projects can be integrated with Build.

Build includes a plug-in for use with Eclipse. Use this plug-in to view the current activity and state of Build projects, to run builds from Eclipse, and to map Eclipse projects to projects in Build.

Installing the Eclipse plug-in

To integrate with Eclipse, install the Eclipse plug-in that comes with Build.

1. In Build, click the **Help** icon, and then click **Tools**.
2. Copy the URL for the Eclipse plug-in.
   The URL format is `http://build_server.example.com/tools/eclipse`.
3. In Eclipse, click **Help > Install New Software**.
4. In the **Add Repository** window, specify a name for the repository, copy the URL for the Eclipse plug-in into the **Location** field, and then click **OK**.
5. Select **Build Plugins** from the list of available software, and then click **Next**.
6. Read and accept the license terms, and then click **Finish**.
7. After the installation is complete, restart Eclipse.

Configuring the Eclipse plug-in

After you install the Eclipse plug-in, you must configure the plug-in. Use the Eclipse plug-in to browse Build projects and processes and to start a build in a process.

1. In Eclipse, click **Window > Preferences > Build Preferences**.
2. Specify values for the Build settings.

Preference	Value
URL	The base URL to the Build server, including the protocol. Specify a port number if the Build server does not use the default port. For example, specify `https://server.example.com:8443`.
User	The Build user name.
Password	The Build password.
Recent Process Activities Displayed	The number of recent build lives to display for each process. The default value is 5. You can specify up to 999 recent build lives to display.

3. Click **Window > Show View > Other**, and then expand **Build**, and select **Build View**.
4. Click **OK**.
   Result
   The Build view opens. Projects are displayed in the Build Projects folder. To start a build, right-click a process, and then click **Run Process**.

Results

The Build view is available in Eclipse.

What to do next

To resolve dependencies in a project, configure CodeStation preferences.

Configuring CodeStation preferences

To resolve dependencies in a project, you must configure CodeStation preferences in the Eclipse plug-in.

Before you begin

Create a Java project in Eclipse. The project dependencies are stored in the Java project.

1. In Eclipse, click **Window > Preferences > CodeStation Preferences**.
2. Specify values for the preferences.

Preference	Value
URL	The base URL to the CodeStation server, including the protocol. Specify a port number if the CodeStation server does not use the default port. For example, enter `https://server.example.com:8443`.
User	The Build user name.
Password	The Build password.

3. In Eclipse, right-click the Java project, and then click **Build Path > Add Libraries**.
4. Select **CodeStation Managed Artifacts** from the list.
    a. Under **Build Project**, select the Build project that corresponds to the Eclipse project.
    b. Under **Build Process**, select the Build process that corresponds to the Eclipse project.
    c. To lock the dependency artifacts to a build life, enter a build life number under **Build Life ID**. If **Build Life ID** is left blank, the latest dependencies are retrieved.
5. Go to the **Console** view, click **Open Console**, and then select **CodeStation Console** from the list.
6. Go to the **Package Explorer** view, right-click the Java project, and then select **CodeStation > Resolve Dependencies**.

   Result

   The plug-in downloads dependencies from Build to the Eclipse project.

Integrating with DevOps Deploy

HCL DevOps Deploy (Deploy) applications and components can be integrated into Build.

Before you begin

You can use a user account or authentication token to connect to Deploy. To use a user account, obtain a user ID and password. To use an authentication token, use Deploy to generate a token. Ensure that the server is available and you have its URL.

1. Click **System > DevOps Deploy**.
2. On the **DevOps Deploy** page, click **Create New Integration**.
3. Specify a name for the integration in the **Name** field.
4. Type the URL for the Deploy server in the **DevOps Deploy URL** field.

   The format is `[HOST]:[PORT]`. For example, type: `http://devops_deploy.domain.com:8080`.

5. Type the user name for the Deploy account in the **Name** field.
6. Type the password for the account in the **Password** field.
7. **Optional:** To use a property to generate the password, enter the script in the **Password Script** field.
8. To use an authentication token instead of user credentials, enter or paste the authentication token Deploy generates in the **Auth Token** field.
   Authentication tokens are created with the **DevOps Deploy Token** page. (**Settings > Tokens**.)

   Note: The token must be generated for the `admin` user.

9. Select the Deploy version number from the **Version** list.
10. Click **Save**.

Results

Build job steps can create and update Deploy component versions, component version statuses, properties, and artifacts.

Integrating with Maven

Build can act as a Maven repository for projects that are built in Build and as a caching proxy for external Maven repositories.

About this task

You can configure Maven repositories and the artifacts from them can be used in CodeStation projects. Downloaded Maven projects are stored as CodeStation projects. See CodeStation projects on page 372.

1. Click **System > Maven**.
2. On the **Maven** page, click **Edit**, and then select a trigger type from the **Dependency Trigger Type** options.

   This option determines the type of build trigger that is created when project dependencies are detected. When a project builds, push triggers initiate builds for dependent parent projects. When a project builds, pull triggers initiate builds for child projects that changed since the last time the parent was built.
3. **Optional:** To configure a Maven repository, see Creating Maven repositories on page 331.
4. Click **Done**.

Managing scripts

The script library provides numerous scripts for you to use and modify.

Javadoc™ documentation on the **Tools** page describes the scripting system. Scripting objects are described and numerous examples are provided.

To access the scripting tools, click **Help > Tools > Scripting API**.

Creating job-precondition scripts

Job-precondition scripts are used to determine whether a job can run.

About this task

A typical precondition is to require that all ancestor jobs are complete before the job runs.

1. On the left navigational panel, click **System > Job Precondition** in the **Script Library** area.
2. Click **Create New Script**.
3. In the **New Job Precondition Script** window, type a name for the script in the **Name** field.
4. Enter the script in the **Script** box.
   The script can be any JavaScript™ code that results in a true or false value.
5. Click **Save**.

What to do next

To review or edit an existing script, select the script. For information about scripting, see the **Build Scripting** page: click **Help > Tools > Scripting API**.

Creating post-processing scripts

Post-processing scripts are used in job steps to determine the success or failure of a step. Success is determined by the exit code and log of the step.

About this task

A typical post-processing script might check for a nonzero exit code, or look for some expected string in the step output.

1. On the left navigational panel, click **System > Post-Processing** in the **Script Library** area.
2. Click **Create New Script**.
3. On the **New Post-Processing Script** window, type a name for the script in the **Name** field.
4. Enter the script in the **Script** box.
   The script must be written in JavaScript.™ The step output properties are in a `java.util.Properties` variable named `properties`. The `exitCode` property contains the exit code of the process. The `Status` property contains the final status. Any `Status` value other than Success results in the step failing. The `scanner` variable can be used to scan the output log of the step. The `scanner` variable has several public methods:
   - `register(String regex, function call)` registers a new function to be called whenever the regular expression is matched.
   - `addLOI(Integer lineNumber)` adds a specific line to the lines of interest list. The lines are displayed in the LogViewer after the process finishes. This is implicitly called anytime `scan()` matches a line.
   - `getLinesOfInterest()` returns a `java.util.List` list that contains the lines of interest. This method can be used to remove lines if necessary.

   After all regular expressions are registered, use `scan.scan()` to scan the log.
5. Click **Save**.

Example

```
commandOut.println("This is a test command output line! This can be used as a means of logging messages!");
var prop1Value = "";
```

```
scanner.register("^prop1=", function(lineNumber, line) {
  commandOut.println("Inside callback for line of interest: " + line);
  prop1Value = line.substr(line.indexOf('=') + 1, line.length - line.indexOf('='));
  properties.put("buildlife/prop1", prop1Value);
});
scanner.scan();
commandOut.println("Exit code is: " + properties.get("exitCode"));
commandOut.println("Value for property 1 is: " + prop1Value);
properties.put("Status", "Success");
```

The example includes a couple of statements with the commandOut command. You can use commandOut command to print messages that can be used for tracing flow and debugging.

In regards to setting Status, while there is nothing wrong with explicitly setting a Failure status, there is no need to. Lack of a Status property with a value of Success is equivalent to Failure. Basically, anything other than Success is considered Failure.

What to do next

To review or edit an existing script, select the script. For information about scripting, see the **Build Scripting** page: click **Help > Tools > Scripting API**.

Creating step-precondition scripts

Step-precondition scripts define the conditions that must be fulfilled before a step can run.

About this task

A typical step precondition might require that all prior steps are complete before the step can run.

1. On the left navigational panel, click **System > Step Precondition** in the **Script Library** area.
2. Click **Create New Script**.
3. On the **New Step Precondition Script** window, type a name for the script in the **Name** field.
4. Enter the script in the **Script** box.
   The script can be any JavaScript™ code that results in a true or false value.
5. Click **Save**.

What to do next

To review or edit an existing script, select the script. For information about scripting, see the **Build Scripting** page: click **Help > Tools > Scripting API**.

Creating working directory scripts

Project source configurations use working directory scripts to determine where checked-out source files are placed.

About this task

Working directory scripts can contain hardcoded paths or literal values. Every plug-in has access to working directory scripts.

1. On the left navigational panel, click **System > Work Dir** in the **Script Library** area.
2. Click **Create New Script**.
3. Type a name for the script in the **Name** field.

4. Enter the path to the working directory in the **Script** box.
   The script can include `$` and `{}` variables, and `${bsh:...}` scriptlets.
5. Click **Save**.

What to do next

To review or edit an existing script, select the script. For information about scripting, see the **Build Scripting** page: click **Help > Tools > Scripting API**.

User notifications

Build can send information about build results to selected users by email, instant messaging, and other methods.

Notifications are managed by notification schemes. A notification scheme defines the rules that determine who receives notices, and the events that trigger notification. Processes are configured with notification schemes, and a single scheme can be shared by other processes.

Notifications can be sent to users in various formats. Most commonly, notifications are configured as email or IM messages. Recipients can be non-users as well as users.

Configuring mail servers

Build uses an external mail server to route messages through SMTP.

Before you begin

Configure a user account on the server so that emails can be sent from an address similar to `build@mycompany.com`. You must have administrative permissions to configure mail servers.

1. On the left navigational panel, click **System > Mail Server** in the **Notifications** area.
2. Click **Edit**.
3. Type a name for the mail server in the **Name** field.
4. Type the host name for the mail server in the **Mail Host** field.
   The IP address or network name that can be resolved from the Build server.
5. Enter the port number for the mail server in the **Mail Port** field.
   The default value is 25.
6. Enter the sender's email address in the **Sender** field.
   This value appears in the email `From` header.
7. Enter the user name in the **User Name** field.
   This name is authenticated by the SMTP server. It is the name that is used to log on to the SMTP server.

   Note: Some email servers and firewalls consider emails with different sender and user names as suspicious. If this problem occurs, use the same name in both fields.

8. Enter the password that is associated with the user name in the **Password** field.
9. **Optional:** To use TLS, select **Use TLS if available**.
10. Click **Done**.

Configuring instant messaging

Build can use XMPP-type messages for user notifications.

Before you begin

Configure an XMPP messaging server to route messages.

About this task

You can configure notifications that send instant messages to users when certain events occur. See Creating notification schemes on page 312.

1. On the left navigational panel, click **System > XMPP IM** in the **Notifications** area.
2. Click **Edit**.
3. Type a name for the IM service in the **Name** field.
4. Type the host name for the XMPP server in the **Server Host** field.
   The IP address or a host name that can be resolved from the Build server.
5. Enter the port number for the server in the **Server Port** field.
   The default value is 5222. Separate multiple ports with commas.
6. Enter the XMPP user domain in the **Domain** field.
7. Enter the user name in the **User Name** field.
   This name is authenticated by the XMPP server.
8. Enter the password that is associated with the user name in the **Password** field.
9. Click **Done**.

What to do next

Click **Test** to test the configuration. The test results are displayed in the **Service Status** field.

Creating notification schemes

Notification schemes define who is notified, when they are notified, and how notifications are sent.

Before you begin

To manage notifications, ensure that the following conditions are met:

- You must have read and write permissions to the **System** page.
- At least one user must be created, see Security on page 316.
- To send emails, an email server must be configured, see Configuring mail servers on page 311.
- To send instant messages, an XMPP service must be configured, see Configuring instant messaging on page 312.

About this task

Notification schemes define rules that determine which user groups are notified about selected events.

Note:

1. On the left navigational panel, click **System > Notification Schemes** in the **Notifications** area.
2. Click **Create Create Notification Scheme**.
3. Using the **New Notification Scheme** page, type a name for the scheme in the **Name** field, and click **Save**.
4. Click **Add Who-When** and complete the following actions.

    a. Select the event that triggers notifications from the **Event Selector** list.
    Build provides several event selectors. For information about creating your own event selector, see Configuring event selectors on page 315.

    b. Select the recipient generator that determines who receives notifications from the **Recipient Generator** list.
    Build provides several recipient generators. For information about creating your own recipient generator, see Creating recipient generators on page 314.

    c. **Optional:** Select the recipient generator that determines who receives CC notifications from the **CC Recipient Generator** list.

    d. **Optional:** Select the recipient generator that determines who receives BCC notifications from the **BCC Recipient Generator** list.

5. Click **Save**.

Creating notification templates

Notification templates determine how users are notified about events.

About this task

Notification templates are Apache Velocity templates that create documents from build results. Templates are paired with events. Different templates are appropriate for different mediums. A template for instant messages, for example, does not have a subject section. Build provides various templates for you to use and customize.

1. On the left navigational panel, click **System > Notification Templates** in the **Notifications** area.
2. Click **Create New Template**.
3. Using the **New Email Template** page, type a name for the template in the **Name** field.
4. Enter the template in the **Template Text** area.
    Templates are written in the Velocity template language. Each template must contain a Subject and Body section.
    Example
    Here is an example template. The Build Request Failed Template is one of the templates that are provided with the product.

```
## BEGIN SECTION Subject

#set($trace = $request.JobTrace)
#set($project = $trace.Project)

Request Failed: $project.Name - $request.Workflow.Name
```

```
## END SECTION Subject

## BEGIN SECTION Body
## PROPERTY Content-Type: text/html
## PROPERTY X-Priority: 3

<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN">

#set($trace = $request.JobTrace)
#set($project = $trace.Project)

<html>

<head>
<title>Process</title>
</head>
<body>

Request Failed: $project.Name - $request.Workflow.Name
<p>

Additional information available here:
<a href="$request.Url">$request.Url</a>

</body>
</html>

## END SECTION Body
```

5. Click **Set**.

Creating recipient generators

Recipient generators determine which users are notified about various events.

About this task

Recipient generators can generate lists where the recipients are fixed and invariable, or lists where recipients vary. The recipient generators provided with the product determine recipients that are based on user roles. For information about user roles, see Roles and permissions on page 319.

1. On the left navigational panel, click **System > Recipient Generators** in the **Notifications** area.
2. Click **Create Recipient Generator**.
3. Using the **New Recipient Generator** page, select the type from the **Type** list, and click **Set**.
   Fixed types expect you to directly enter recipient information, such as email and IM addresses. Group-Based types use security groups to generate recipients. Scripted types use JavaScript scripts to generate recipients.

   Note: To give users the ability to unsubscribe from notification subscriptions, use group-based or scripted types. If a process has a fixed type, users cannot unsubscribe from notification subscriptions.

4. Type a name for the generator in the **Name** field, and click **Save**.

5. Define the generator by completing these actions:

   Choose from:

   - If you selected the **Fixed** type, enter the user's email address in the **Email** field, or XMPP ID in the **XMPP** field, then click **Add**.
   - If you selected the **Group-Based** type, select the groups that you want notified from **Groups** area.
   - If you selected the **Scripted** type, enter the script in the **Script** box. The script can be any JavaScript script that resolves to a user or group. This example script selects all users: `users.getAllUsers()`.

6. Click **Done**.

What to do next

Add the recipient generator to notification schemes, see Creating notification schemes on page 312.

Configuring event selectors

Event selectors are used to select events that trigger user notification.

About this task

Build provides a selection of events that can trigger notification. The provided scripts examine events and return a value of true if a notification is triggered, or false otherwise.

1. On the left navigational panel, click **System > Event Selectors** in the **Notifications** area.
2. Click **Create Event Selector**.
3. Using the **New Event Selector** page, type a name for the template in the **Name** field.
4. Select the event that you want to use as a trigger from the **Event Type** list.

   The following list describes the event types that are provided with the product:

   - **Agent Status Changed** triggers when an agent changes status, such as Online or Offline.
   - **Build Deleted** triggers when a workflow is deleted.
   - **Build Status Applied** triggers when a build status is added or changed.
   - **Build Request Failed or Build Not Needed** triggers when a workflow fails or does not start because of lack of source changes.
   - **Build Not Needed** triggers when a workflow does not start because of lack of source changes.
   - **Build Request Failed** triggers when a workflow does not occur due to an error in the build request.
   - **Workflow End** triggers notifications when the workflow ends regardless of status.

5. Enter the script in the **Scripted** box.

   The script can be any JavaScript script that resolves to a true or false value.

   Example

   The Workflow Status Change script triggers when a workflow ends successfully after the previous invocation failed, or fails after the previous invocation was successful. This script is one of the scripts that are provided with the product.

```
var result = false;
var prevBuildLife = workflow.getBuildLife().getPrevious()
if (prevBuildLife == null) {
    result = true
}
else {
```

```
    var prevWorkflowCase = prevBuildLife.getWorkflow()
    if (prevWorkflowCase == null || !prevWorkflowCase.isComplete() ||
 prevWorkflowCase.statusIsSuccess() != workflow.statusIsSuccess()) {
        result = true
    }
}

result
```

6. Click **Save**.

What to do next

Add the event selector to notification schemes, see Creating notification schemes on page 312.

Security

Build provides a flexible team-based, and role-based security model that maps to your organizational structure.

From a high level, the security system consists of an authentication realm, authorization realm, roles, and teams. The authentication realm verifies the identity of the user or system that is trying to log on to Build. The authorization realm manages user groups. Roles manage permissions. Teams join users with roles and secure product areas.

Overview of permissions and security types

A good starting point for learning about the team-based security system is to understand permissions. Build uses the term *permission* in a way that is familiar to most readers: each permission controls access to a product area or product function. Most permissions refer to typical activities such as creating, reading, updating, and deleting. Permissions define *what* can be done, not *who* can do it

A product area that can have defined permissions is referred to as a *security type* or *security resource*. Each security type has a set of permissions that affects how users interact with it. The project security type, as the name implies, has a set of permissions that affects a user's ability to interact with projects; the permissions that are available for the agent pool security type affect agent pools, and so forth.

Most security types can have additional types defined for them. Each eligible security type comes with a "standard" type that is defined for it, such as "Standard Process". Each additional type within an area shares the same set of permissions. For example, each agent pool type has the same set of permissions: edit and view. See Security types on page 318.

Roles

A *role* is a set of granted permissions. Defining a role consists of granting permissions for all security types that the role affects. The number of roles and their functions are completely up to you. As delivered, Build provides one role, the administrator role, which has all permissions granted for all security types.

Importantly, a role by itself does not impart its granted permissions to any actual user. Like permissions, roles define what can be done, not who can do them. Roles and their associated permissions are applied to users by teams.

Teams

A *team* is a construct that associates users or groups with roles. When a user is added to a team, that person is assigned to a role; users cannot be added to a team without a role assignment. Role members are automatically granted all permissions that are defined for the role. Groups can also be added to roles, in which case all group members are automatically granted the permissions that are defined for the role.

When a team is created, all users and groups are available for assignment, and all roles are available for use. Users can be assigned to more than one role. If a user is assigned to one role that grants a particular permission and another role that does not grant that permission, the user is considered to have the permission.

Teams secure resources. To secure a workflow, for example, a team is associated with it. After being secured, only team members who are assigned a role with an appropriate permission can affect the workflow.

Securing resources

The Build security system enables fine-grained customizations. The way all elements come together might not be clear. A further discussion about permissions might provide more clarity.

Two types of permissions are available: types with specific scope; and types with a more general scope. The Job security type has three permissions: create, edit, and view. Except for create, these permissions affect only a specific resource; they are scoped to a specific job. If a team with the edit permission is attached to Job A, for example, then only team members with that permission can edit Job A. Team members with other roles that do not grant the edit permission cannot edit the job. Members of teams that are not attached to Job A cannot edit it regardless of whether they have the edit permission for other jobs.

The create permission is different from other permission types. The create type is not scoped to a specific resource but is more broadly scoped. Team members with a create-type permission can create resources of the related type without first being attached to a specific resource. To continue the job example, users with the create job permission can create jobs even if their team is not attached to a specific job.

Guidelines for setting up security

Although there is no single best way to set up security, the following steps are sufficient in most cases.

1. Create an authorization realm. Authorization realms are used by authentication realms to associate users with groups and to determine user access. Build includes an internal database for storing security information as well as integration with the Lightweight Directory Access Protocol (LDAP). LDAP is a widely-used protocol for accessing distributed directory information over IP networks. See Authorization realms.
2. Create an authentication realm. The authentication realm is used to determine a user's identity within an authorization realm. See Authentication realms.
3. Create roles and define permissions for them. For most uses, the default security types are adequate. See Roles and permissions on page 319.
4. Create and import users and groups.
5. Create teams and assign users and groups to them. See Security teams on page 320.

Security types

Security types have permissions that define the actions that users can do.

A *security type* or security resource, is a product area that can have permissions defined for it. Each security type has a set of permissions that affects how users interact with it. Most security types can have additional defined types, which are sometimes called *subtypes*. By default, each type has a defined subtype, which is called the Standard type. The following table lists security types and permissions.

Table 8. Security types

Security type	Permissions
Agent pool	• **edit:** Modify and delete agent pools • **view**: Access agent pools in the UI but cannot modify them
CodeStation	• **create**: Create CodeStation projects • **edit**: Modify and delete CodeStation projects • **view**: Access CodeStation projects in the UI but cannot modify them • **download**: Download artifacts from CodeStation
Job	• **create**: Create jobs • **edit**: Modify and delete jobs • **view**: Access jobs in the UI but cannot modify them
Project	• **create**: Create projects • **edit**: Modify and delete projects • **view**: Access projects in the UI but cannot modify them • **artifact download**: Download artifacts from CodeStation or other repositories
Project process	• **add manual stamp**: Apply manual time stamps • **add manual status**: Apply manual statuses • **delete history**: Delete project history • **abort**: Cancel running project processes • **artifact download**: Download project artifacts from CodeStation or other repositories • **prioritize**: Determine run priority when a project has two or more processes • **restart**: Restart project processes • **run**: Run project processes

Table 8. Security types (continued)

Security type	Permissions
Template	• **create**: Create templates • **edit**: Modify and delete templates • **view**: Access templates in the UI but cannot modify them
Report	• **edit**: Modify and delete reports • **run**: Run reports
Repositories	• **create**: Create repositories • **edit**: Modify and delete repositories • **view**: Access repositories in the UI but cannot modify them
Security	• **Agent management**: Create, modify, and delete agents • **Agent view**: Access the Agents page in the UI • **Audit administration**: Run audit reports for resources and users • **Report create**: Create reports • **Scripts administration**: Add, modify, and delete scripts in the Script Library • **Security administration**: Create, modify, and delete authorization and authentication realms • **System administration**: Modify system-related settings, such as license servers, properties, and server settings • **Team resource Management**: Assign security types to teams, such as projects and workflows • **Team user management**: Add and remove users to/from teams • **User Management**: Create, modify, and delete users

Creating security types

Security types can have additional defined types, which are called subtypes.

1. On the left navigational panel, click **System > Resource Types**.
2. From the list of resource types, select the one to which you want to add a subtype.
3. Click **Create New Type** to open the **Create New Type** dialog box.
4. Type a name for this type in the **Name** field.
5. Click **Save**.

Roles and permissions

Roles provide permissions to users.

A *role* is a set of permissions. Typically, the permissions in a role define a particular activity that a user might do. Users can be assigned to more than one role. The number of roles and their permissions is up to you. Build provides one role, the Administrator role, which has all available permissions.

Users are granted permissions by being assigned to roles. When assigned to a role, a user is automatically granted all permissions that are defined for the role. Typical activities include changing or running an item, such as a project process, or modifying security settings.

Note: If a role has the create permission for some security type, such as projects, the role typically grants the edit permission for that type.

Creating roles

Follow these steps to create roles and assign permissions to them.

1. On the left navigational panel, click **System > Roles**.
2. Click **Create New Role**.
3. Type a name for the role in the **Name** field, and then click **Save**.
4. Select the role to display the list of security types and permissions.
5. With the role selected, click the security type to use. The available permissions for the security type are displayed.
6. Grant permissions by selecting the associated check boxes.
7. Click **Done**.

Note: If a role has the create permission for some security type, such as projects, the role also grants the edit permission for that type.

Security teams

Through teams, users are assigned to roles and can secure product resources.

Teams provide two important functions. First, a team provides the mechanism to assign users roles. When a user is assigned a role, all permissions that are granted to the role are automatically granted to the user. Second, teams secure product resources. When a team is attached to a resource, only team members with the appropriate permissions can interact with the affected resource.

Creating teams

Follow these steps to create teams.

1. On the left navigational panel, click **Teams**.
2. Click **Create New Team**.
3. In the **Create New Team** page, type a name for the team in the **Name** field.
4. Click **Save**.

Assigning users to teams

To add users to teams, select the users and assign them to a role.

1. On the left navigational panel, click **Teams**.
2. In the team list, select the team to add users to.

   When a team is selected, all roles that were previously defined are available. All previously defined roles are displayed and users are listed below their assigned roles.
3. To add users to roles, do one of these actions:
   Choose from:
   - Click **Add** button for the target role, and then select the check boxes from the list of users.
   - Click **Add Users and Groups** button, and then drag users onto target roles.

What to do next

Assign teams to resources, such as projects.

Mapping teams to resources

In addition to assigning a team to a resource (such as a workload or job) while you create the resource, you can use the **Teams** page to map teams to resources.

Before you begin

To map a team to an object, you must be a member of the team and have the manage teams permission for that type of object.

About this task

You can assign teams to many items that you create. Teams can be assigned when you create an item in the associated **Create New item** window. Teams can also be mapped to objects with the object mapping security feature as described here. When a team is assigned to an item, such as a project, only team members with the appropriate permissions can interact with the affected item.

Note: All user-created resources are automatically assigned to the System Team. Because the System Team's Administrator role has all permissions that are granted for all Standard security types, System Team users with that role automatically have all permissions for all objects. Initially, only the admin user is assigned to the Administrator role. Neither the System Team nor the admin user can be deleted.

1. On the left navigational panel, click **Teams**.
2. Select a team from the list of teams.
3. Under **Team Object Mappings**, in the **View** list, select the object type, such as **Project**.
   Result
4. From the **Type** list, select the security type.
   Types for the current object type are available. For information about security types, see Table 8: Security types on page 318.

5. Click **Add**.
   A list of user-created objects that are not already assigned is displayed.
6. Select the check boxes for the objects to assign to the team and then click **OK**.

Results

Teams that are mapped to objects are displayed on the associated **Security** page for the object.

Viewing resources that are assigned to teams

You can view the resources that are assigned to a team.

1. Click **Teams**.
2. In the **Teams** pane, select a team from the team list.
3. Under **Team Object Mappings**, select the product area to view from the **View** list.
   Example
   For example, select **Workflow**.
   All objects for the selected product area that are mapped to the team are displayed.

Viewing teams that are assigned to resources

You can view the teams that are assigned to a resource.

1. Select the object to review, such as a project or workflow.
2. On the page for the object, click **Security**.
   Result
   The **Resource Security** window displays the roles and users that are granted permissions. For example, the **Resource Security** window for project templates lists the roles and users that can create, edit, and view the selected template.

Auditing team activity

You can review team activity for many product areas.

About this task

You can review activity for the entire team or for a single team member.

1. On the left navigational panel, click **Teams > Auditing**.
2. Select a team from the **Team** list.
3. Select a user from the **User** list.
   To see activity for all users, select **All Users**.
4. In the **Start Time** field, enter the first date to review activity for.
   The format is `yyyy-mm-dd`.
5. In the **End Time** field, enter the last date to review activity for.
6. Click **Search**.

Users and groups

Users and user groups can be created manually or imported from external systems, such as LDAP.

For information about importing users, see Creating authentication realms.

For information about importing groups, see Authorization realms.

Manually creating groups

Groups are logical containers that serve as a mechanism to grant permissions to multiple users; members automatically share a group's permissions.

About this task

You can create groups manually for internal storage type authorization realms. Groups must be imported for others types, such as LDAP.

1. On the left navigational panel, click **System > Groups**.
2. Click **Create Group**.
3. Type a name for the group in the **Group Name** field.
4. Select an authorization realm from the **Authorization Realm** list.
   Groups are only valid for the selected realm.
5. Click **Save**.

What to do next

Add users to the group. See Manually adding users to groups.

Creating users manually

You can add users manually to internal-type authentication realms.

1. On the left navigational panel, click **Teams > Users > Create User**.
2. If you have more than two authentication realms, select a realm from the **Authentication Realm** list.
3. Type a user name to be used to log into the user interface for the user in the **Name** field.
4. Type a password for the user in the **New Password** field, and then reenter the password in the **Confirm Password** field.
5. From the **Groups** area, select the groups to add the user.
6. Type the user's name in the **Actual Name** field.
7. Type the user's email address in the **Email Address** field.
8. Type the user's instant messaging ID in the **IM ID** field.
9. Select time and date format to be used for the user:
   a. Select the user's preferred date and time format from the **Date and Time Format** list.
   b. Select whether the time format is based on the 24-hour clock or 12-hour clock.
10. Select the user's time zone from the **Time Zone** list.
11. Specify the number of items that are displayed on the user's dashboard in the **Number of Dashboard Rows** field.

12. **Receive Notifications**
13. Click **Save**

Deleting users manually

Users can be permanently removed. To remove a user, you must be assigned either the **User Management** or **Security Administration** permission. Before removing a user, you should verify that the user is no longer needed or created in error. A user will not be deleted if there is any history associated with the user.

1. On the left navigational panel, click **Teams > Users**.
2. Click the delete icon ( ) to the right of the user to be deleted.
3. A confirmation message displays. Click **OK** to delete the specified user.
   An error message is displayed if history is associated with the user.

User profiles

Information about users is maintained in a *user profile* for each user. The information can be viewed and modified from the dashboard.

The user profile contains the following information:

- User name and password
- Name of the user
- Authentication realm of the user
- Groups the user is associated with
- User email address
- Date and time format preference of the user
- Time zone the user is located in
- Geographical location of the user
- Amount of information to show on the dashboard
- Notification preference for receiving information from the server

The information that is defined in the user profile can be modified by an administrator. Some of the values can also be modified by the user.

Updating your user profile and password

You can change your user profile information and password .

1. At the upper-right corner of the server window, click your user name, and then click **Edit Profile**.
   The **User Profile** displays.
2. Click **Profile**, and then click **Edit**.
3. You can modify the following fields.

User Name

The user name to be used to log into the user interface for the user in the **Name** field.

Name

The full name of the user.

Email Address

The email address of the user.

Instant Messaging ID

Time and Date Format

The time and date format used by the user and whether the time format is based on the 24-hour clock or 12-hour clock.

Locale

The geographical location of the user.

Number of Dashboard Rows

The number of items that are displayed on the user's dashboard.

Receive Notifications

Enable to receive notifications from the server.

4. Click **Save**.

Changing your password

1. At the upper-right corner of the server window, click your user name, and then click **Edit Profile**.
   The **User Profile** displays.
2. On the **General** page, click the **Update Password**.
3. Type your current password in the **Old Password** field.
4. Type a new password in the **Password** field, and then type it again in the **Confirm Password** field.
5. Click **Update** to save the new password.

Managing user profiles

The administrator can modify user profiles and reset passwords for internal authentication realm-based user accounts.

Before you begin

You must have administrator access to update another user's profile or reset a user's password.

1. On the left navigational panel, click **Teams > Users** and then select a user from the **User Name** list.
   The **Access** page displays the teams that the user belongs to, and the resources that those teams manage.
2. Click the **Profile** tab, and then click **Edit**.
3. Select the user that the profile is being updated.

4. From the **Groups** area, select the groups to add the user.
5. Type the user's name in the **Actual Name** field.
6. Type the user's email address in the **Email Address** field.
7. Select time and date format to be used for the user:
    a. Select the user's preferred date and time format from the **Date and Time Format** list.
    b. Select whether the time format is based on the 24-hour clock or 12-hour clock.
8. Select the user's time zone from the **Time Zone** list.
9. Specify the number of items that are displayed on the user's dashboard in the **Number of Dashboard Rows** field.
10. Click **Save**.

Resetting user passwords

1. From the Build dashboard, click **Teams**, click **Users**, and then select a user from the **User Name** list.
2. Click the **Profile** tab, and then click **Reset Password**.
3. Type a password for the user in the **New Password** field, and then reenter the password in the **Confirm Password** field.

Creating tokens

Tokens provide authorization for agents, users, and external systems or applications. Agents use tokens when they run process steps and communicate with the Build server and external services.

You can create tokens in addition to the tokens that the product provides.

1. On the left navigational panel, click **System > Auth Tokens > Create New Token**.
2. Type a user name in the **User** field.

    Note:

    If you are using the token to integrate with HCL DevOps Deploy (Deploy), you must have the necessary permissions. The Build user account must have permission to create component versions, set statuses on versions, and upload artifacts to component versions.

3. Specify the expiration date and time.

Tokens can be used immediately after they are created.

Auditing user activity

You can review user activity for many product areas.

About this task

You can review activity for one user or all users. You can review activity for all object types or a single type, such as workflows and projects.

1. On the left navigational panel, click **System > Auditing**.
2. Select the product area to review from the **Object Type** list.
   To see activity for all types, select **All Object Types**.
3. Select a user from the **User** list.
   To see activity for all users, select **All Users**.
4. Enter the first date to review activity in the **Start Time** field.
   The format is `yyyy-mm-dd`.
5. Enter the last date to review activity in the **End Time** field.
6. Click **Search**.

Project support

Projects represent items that can be built individually for release or distribution.

Projects often correspond to how development is structured in your source control management system. For example, projects can be composites of many other projects using a dependency management system. Projects are built from templates.

Creating artifact sets

Artifact sets are groups of artifacts that are produced by a build.

Before you begin

Typically, there is an artifact set for each type of artifact. Run-time-dependent artifacts, such as `jar` or `dll` type files, might be contained in an artifact set called lib. Source code artifacts might be contained in an artifact set called source.

1. On the left navigational panel, click **System > Artifact Sets**.
2. Using the **Artifact Sets** page, click **Create New**.
3. Using the **New Artifact Set** dialog box, type a name for the workflow in the **Name** field.
4. Optionally, enter a description of the artifact set in the **Description** area.
5. Click **Save**.

What to do next

Artifact sets can be configured when you create build process templates. See Creating build process templates on page 388.

Managing cleanups

Cleanups are scheduled based on the cleanup policy. The cleanup policy contains settings that determine when build lives, build requests, and miscellaneous jobs are cleaned up.

About this task

Build life cleanup is determined by cleanup type and retention policy. Each build life is evaluated by its status. A build without a status is evaluated with the **All Builds** status. If the **All Builds** type has the **Keep Days** property or **Keep Latest** property set

to `Forever`, no builds with this type are be cleaned up. A build life is not cleaned up if either the **Keep Days** or **Keep Latest** properties are met.

Complete the following steps to schedule a cleanup.

1. On the left navigational panel, click **System > Cleanup**.
2. Click **Edit**.
3. Select a schedule from the **Schedule** list.
   Schedules are defined on the **Schedules** page, see Creating schedules on page 332.
4. Specify a number of days to keep lockable resources in the **Days to Keep Lockable Resources** field.
   This option applies to resources such as working directories. The default value is 30 days. Enter `-1` to never clean up lockable resources.
5. Specify the number of days to keep preflight builds in the **Days to Keep Preflight Builds** field.
   The default value is 30 days. Enter `-1` to never clean up lockable resources.
6. Click **Save**.
7. **Optional:** Create additional cleanup policies.
   Click **New** to create a cleanup policy. See Adding and editing cleanup policy settings on page 328 for details on cleanup policy settings.
8. Click **Done** after you finish.

Related information

Adding and editing cleanup policy settings on page 328

Adding and editing cleanup policy settings

Use the cleanup settings to determine when build lives, build requests, and miscellaneous jobs are cleaned up.

About this task

You can define multiple cleanup policies and modify the default policy. The list of policies is displayed on the **Cleanup** window. Policies that you create can be deleted using the delete icon. The default policy can be disabled.

1. On the left navigational panel, click **System > Cleanup**.
2. Click **New** to add a policy. To modify a cleanup policy, click the policy name.
   If you are creating a new policy, complete the **Name** and policy settings are displayed.
3. To modify a build cleanup settings, click the edit icon in the **Cleanup Build** area.

   a. Specify the number of days to keep build lives in the **Keep Days** field.
      Leave the field blank to keep builds forever.

   b. Specify the number build lives to keep regardless of other cleanup settings in the **Keep Latest** field.
      The number of build lives that are kept indefinitely is equal to the number you specify.

c. Select the cleanup type from the **Cleanup Type** list.
   The cleanup type determines what happens to build lives with a certain status when a cleanup is scheduled:
   - **Delete** deletes the build life, artifacts, and logs from the server.
   - **Deactivate and Delete Logs** deletes the build artifacts and logs and sets the build to inactive status. This option prevents running processes on the build life and prevents the use to satisfy dependencies.
   - **Deactivate** deletes the build life artifacts and sets the build life to inactive status. This option prevents process runs and prevents the use of the build life to satisfy dependencies.
   - **Archive** deletes the build life artifacts and sets the build life to archived status. The build life can be unarchived and its artifacts rebuilt with an unarchive process. No secondary processes can run on this build and it cannot be used to satisfy dependencies.

d. Click **Save**.

4. To modify a build request cleanup settings, click the edit icon in the **Cleanup Build Requests** area.

   a. Specify the number of days to keep miscellaneous jobs in the **Misc Jobs** field.
      Miscellaneous jobs refer to cleanups and notifications among others. These jobs and their logs can be deleted from the server by specifying a number to keep. Leave the field blank to keep them forever.

   b. Specify the number of days to keep build requests without builds in the **Build Requests Without Build** field.
      These build requests did not produce builds. Leave the field blank to keep requests forever.

   c. Click **Save**.

5. Click the **Dependencies** tab, and then specify projects that depend on the policy.
6. Click the **Main** tab and then click **Done**.

Managing Labels

Labels are assigned to build lives. Using the **Label** page, you can create, modify, and delete labels. Deleting a label removes the label from the server.

1. On the left navigational panel, click **System**, then click **Labels** located under **Project Support**.
2. To create a label, click **Create New Label**.
   a. Type a name in the **Name** field.
   b. Optionally, type a description in the **Description** field.
   c. Click **Save**.
3. To modify an existing label, click the label name in the table.

   a. Change the existing name in the **Name** field. You can also update the text in the **Description** field.

   b. Click **Save**.
      The new label name is displayed in the table.

4. To delete a label, click the delete icon ( ) for the label to be deleted.

a. Click **OK** to confirm the deletion.
   The deleted label no longer exists on the server causing it to be removed from all associated build lives.

Creating lockable resources

Lockable resources are resources that can be reserved by other objects, such as agents, when a process runs.

About this task

Locked resources cannot be accessed by other objects after the lock is acquired. Other requests for the resource are queued until the lock is released.

1. On the left navigational panel, click **System > Lockable Resources**.
2. Click **Create New**.
3. Using the **Edit Lock** dialog box, type a name for the resource in the **Name** field.
4. Specify the maximum number of simultaneous lock holders in the **Maximum Number of Lock Holders** field.

   The default value is 1, which means that only one process can obtain a lock on the resource. If you specify 2, for example, a maximum of two different processes can concurrently use the resource. This value can be overridden on individual processes.
5. Click **Save**.

What to do next

Lockable resources must be added to processes. Resources can be configured when you create build process templates.
See Creating build process templates on page 388

Repositories

Repositories contain the source materials that are used in build processes.

Repositories are configured from source plug-ins. Initially, the File System and Maven plug-ins are available. If you want to create other types of repositories, install the corresponding source plug-ins. For information about installing plug-ins, see Installing plug-ins on page 351.

Note: File System and Maven are not derived from source plug-ins, and cannot be configured like other repositories derived from source plug-ins.

Creating file system repositories

File system repositories manage files that are stored in file systems.

1. On the left navigational panel, click **System > Repositories**.
2. Click **Create New**.
3. Using the **Create Repository** page, select a plug-in from the **Source Plug-in** list, then click **Set**.
4. Type a name for the repository in the **Name** field.

5. Enter a description the repository in the **Description** area.
6. Select a team to manage the repository from the **Teams** list.
7. Click **Save**.

What to do next

Source integrations are implemented as steps for build jobs. After you configure a repository, you can add steps from the associated source plug-in to jobs.

Creating Maven repositories

Build can act as a Maven repository for projects that are built in Build, and can serve as a caching proxy for external Maven repositories.

Before you begin

Before you start the integration, ensure that these preconditions are met:

- The build agent must be in the same location as Maven (or Maven must be downloaded with the project).
- You must have administrative permissions to configure projects and have access to the Build **System** page.
- You must be able to edit the Maven `settings.xml` file, which is usually located in the */user.home/*`.m2/` directory. By default, this file does not exist and Maven uses default values for configuration properties. If you create the file and place it in the location specified, Maven usees it instead of the default values. Maven provides an sample `settings.xml` for you to use and modify, which is found in the *maven_install_dir*`/conf` directory.
- You must be able to edit the Maven POM file, which is usually located in the Maven application's root directory.

Note: The File System and Maven source configurations are not derived from source plug-ins, and cannot be configured like other repositories derived from source plug-ins.

Modify the Maven POM file to reference the repository that is used by Build. The POM file should look similar to this example:

```
<project>
 <distributionManagement>
    <repository>
      <id>DevOps_Build</id>
      <name>DevOps Build Repo</name>
      <url>${env.DEVOPS_BUILD_WEB_URL}rest/maven2dist/${env.DEVOPS_BUILD_BUILD_LIFE_ID}</url>
    </repository>
    <snapshotRepository>
      <uniqueVersion>false</uniqueVersion>
      <id>DevOps_Build</id>
      <name>DevOps_Build Repo</name>
      <url>${env.DEVOPS_BUILD_WEB_URL}rest/maven2dist/${env.DEVOPS_BUILD_BUILD_LIFE_ID}</url>
    </snapshotRepository>
  </distributionManagement>
</project>
```

Modify the `settings.xml` file in the location where the agent that is accessing Maven is located. The file must provide a user name and password for Maven authentication, similar to the example in the following code fragment:

```
<settings>
  <servers>
    <server>
      <id>DevOps_Build</id>
      <username>username</username>
      <password>password</password>
    </server>
  </servers>
</settings>
```

About this task

With this integration, you can retrieve artifacts from CodeStation or directly from your Maven repositories. The integration provides visibility into the project dependencies you manage using Maven 2.

1. On the left navigational panel, click **System**, then click **Maven** under **Integrations**.
2. In the **New Maven Repository** dialog, type a name for the repository in the **Name** field.
3. Enter a description the repository in the **Description** area.
4. Type the URL for the Maven repository in the **URL** field.
   The format is `[HOST]:[PORT]`; for example, `http://maven.domain.com:8080`.
5. Type the Maven user name fin the **User Name** field.
6. Type the password for the account in the **Password** field.
7. **Optional:** To configure a proxy server, see Creating proxy servers on page 336.
8. To verify transferred Maven files, select **Verify Hashes**.
9. Click **Save**.

Creating schedules

You can use schedules to determine when certain events, such as builds and backups, occur.

Before you begin

To create a schedule, you must have administrative permissions.

About this task

A schedule can be used in many product areas. For example, you can create a schedule that triggers nightly builds and add it to a project trigger. Schedules are used with cleanup options, see Managing cleanups on page 327. You can create two types of schedules:

- Interval-based schedules use a fixed time interval to determine when events occur.
- Cron-based schedules can use complex criteria to define when events occur.

1. On the left navigational panel, click **System > Schedules**.
2. Click **Create Schedule** then define the schedule type:
   Choose from:
   - To create a cron-based schedule, select **cron expression**.

   Choose from:
   - To create an interval-based schedule, select **interval schedule**.

3. **Optional:** If you selected **cron expression**, complete the following steps.

    a. Type a name for the schedule in the **Name** field

    b. Enter the cron expression in the **Cron Expression** field.

    A cron expression is a string of six mandatory properties and one optional properties. Properties must be defined in the order they are presented in the table. Separate properties with white spaces. Use the following table to complete the expression:

    Table 9. Cron expression properties

Name	Expected values
Seconds	0-59
Minutes	0-59
Hours	0-23
Day of Month	1-31
Month	1-12 or JAN-DEC
Day of Week	1-7 or SUN-SAT
Year (optional)	empty, 1970-2099

    The following special characters can be used in expression properties:

    Table 10. Special characters

Character	Description
*	All values. For example, "*" in the minute field means every minute.
?	Used in the day-of-month and day-of-week fields and means no specific value. Use this character when you need to specify something in one field but not another.
-	Specifies a range of values. For example `10-12` in the hour field means the hours 10, 11 and 12.
,	Specifies additional values. For example `MON,WED,FRI` in the day-of-week field means the days Monday, Wednesday, and Friday.
/	Specifies increments. For example `0/15` in the seconds field means the seconds 0, 15, 30, and 45.
L	Used in the day-of-month and day-of-week fields. Short-hand for last, but it has a different meaning in the 2 fields. For example, the value `L` in the day-of-month field means the last day of the month. Used in the day-of-week field by itself, it means 7 or SAT. Used in the day-of-week field after another value, it

Character	Description
	means the last x day of the month. For example, `6L` means the last Friday of the month. When you use this character, do not specify lists, or ranges of values.
W	Used in the day-of-month field. Specifies the weekday (Monday-Friday) nearest the day. For example, `15W` means the nearest weekday to the 15th of the month. If the 15th is a Saturday, the trigger is on Friday the 14th. If the 15th is a Sunday, the trigger is on Monday the 16th. If you specify `1W` and the first is a Saturday, the trigger is on Monday the third because it does not cross the month boundary. Cannot be used for a range or list of days. `L` and `W` can be combined. For example, `LW` means the last weekday of the month.
#	Used in the day-of-week field. Specifies the nth day of the month. For example, `6#3` means the third Friday of the month (day 6 = Friday and `#3` = the third one in the month). If you specify `#5` and there is not 5 of the specified days-of-week in the month, the trigger does not occur that month.
C	Used in the day-of-month and day-of-week fields. Short-hand for calendar, which means values are calculated against the associated calendar. If no calendar is associated, it represents an all-inclusive calendar. For example, `5C` in the day-of-month field means that the first day included by the calendar on or after the fifth.

Example

`0 0 * ? * MON-FRI` means run every hour every Monday, Tuesday, Wednesday, Thursday, and Friday.

c. Click **Save**.

Result

The builds that match your search criteria are displayed.

4. **Optional:** If you selected **interval schedule**, complete the following steps.
   a. Type a name for the schedule in the **Name** field
   b. Enter the number of minutes between event triggers in the **Build Interval (minutes)** field.
   c. Enter the time when the schedule starts in the **Interval Start Tim (hh:mm)** field.
   d. Click **Save**.

Creating statuses

Statuses represent build conditions, such as success or failure.

About this task

Statuses can be used for reporting, such as finding all source changes since a status was applied. They can also be used in dependency relationships.

1. On the left navigational panel, click **System > Statuses**.
2. Click **Create New**.
3. Using the **New Status** dialog box, type a name for the status in the **Name** field.
4. Enter a description the status in the **Description** area.
5. Select a color for the status from the **Color** list.
6. Enter the number of days the status is kept in the **Keep Days** field.
   Leave the field blank to keep the status indefinitely.
7. To prevent a number of builds from being cleaned up, enter the number in the **Keep Latest** field.
   The value prevents the number of builds with this status from being cleaned up. Leave the field blank to keep all builds with this status from being cleaned up.
8. Select a clean-up type from the **Cleanup Type** list.
   For information about clean-up types, see Managing cleanups on page 327
9. Click **Save**.

Server management

Use server settings to manage your server other system-related settings.

These settings are used to configure the following features:

Creating announcements

Announcements are messages that are displayed on the Build dashboard for all users.

About this task

Announcements can be created by an Build administrator. Users can hide any announcement by clicking the **Hide** link within the announcement.

1. On the left navigational panel, click **System > Announcements**.
2. Using the **Announcements** page, click **New**.
3. Type or paste the body of the message in the **Message** area.
   The message can be up to 4,000 characters.
4. Select a priority level from the **Priorty** list.
   Priority levels affect the color of the background color of the message: **Low**=Blue, **Normal**=Green, **High**=Red
5. Click **Save**.

Creating system properties

System properties can set system-wide values for processes and projects.

About this task

The syntax for property references is `${p:property_name}`.

1. On the left navigational panel, click **System > Properties**.
2. Using the **Properties** page, click **Add Property**.
3. Type a name for the workflow in the **Property Name** field.

4. Type a value for the property in the **Value** field.

   Empty-value properties allow a template to be reused across a large number of projects, even if different projects require different values. Empty-value properties can also be used to create standardized project templates.

5. **Optional:** To secure the value, select **Secure** then type the value.
   Because secured values are obfuscated, you must also type the value in the **Confirm** field.
6. Type a description for the property in the **Description** field.
7. Click **Save**.

Creating proxy servers

Use a proxy server if you need to access servers or repositories, such as Maven, that are on external networks.

Before you begin

You must have administrative permissions to configure proxies.

1. On the left navigational panel, click **System**, then click **Proxy Settings** in the **Server** area, then click **Create Proxy**.
2. Using the **New Proxy** page, in the **Proxy Name** field, type a name.
3. Enter a description the proxy server in the **Description** area.
4. Type the host name for in the **Host** field.
5. Type the port number that Build uses to communicate with the proxy server in the **Port**.
6. Type the user name fin the **User Name** field.

   The name Build uses to connect to the proxy server.

7. Type the password for the account in the **Password** field.
8. Click **Save**.

Server settings

Use server settings to configure server-related features, such as displaying graphs on users' dashboards.

Server settings are used to configure the following features:

Configuring network settings

The properties on **Network** tab define the server's external URLs, and configure the Rational Common Licensing Server.

Before you begin
These values for the External URL and Agent External URL properties are initially defined when you install the product. The value for the Rational Common Licensing Server property can be set during installation or at any other time.

1. On the left navigational panel, click **System > Server Settings**.
2. Using the **Network** tab, click **Edit**.
3. Type the URL used by the server in the **External URL** field.
   This is the URL users use to connect to Build. Include `http(s)://` and any ports.

Example

For example, `http(s)://myserver:8080`.

4. Type the URL used by agents to access the web application in the **Agent External URL** field.
   Agents use this URL to connect to the web service to upload logs and reports. Include `http(s)://` and any ports.
   Example
   For example, `http(s)://myserver:8080`.
5. Type the location of the license server that manages your licenses in the **Rational Common Licensing Server** field.
   You can specify the port and host name or IP address for the license server, such as `27000@RCLServer.example.com`.
   To avoid problems when a license server is not available, you can specify multiple license servers. In this case, separate each address with colons on Linux™ and UNIX™ or semicolons on Windows™, as in the following example: `27000@RCLServer.example.com;27000@backupRCLServer.example.com`.
6. Click **Done**.

What to do next

The **External URL** and **Agent External URL** properties are stored in the `installed.properties` file in the `/server_install/conf/server/` directory.

Setting system-level security

Use system-level security settings to determine access to the Build server

1. On the left navigational panel, click **System > Server Settings**.
2. Click **Security**, then click **Edit**.
3. Using the following table, enable options by selecting the associated check box.

Table 11. System-level security settings

Option	Description
Audit User Transactions	When selected, the server stores security and configuration changes. The log can be accessed on the **Audit** page. The default value is unselected. See, Auditing user activity on page 326.
Allow Multiple Sessions per User	Enables users to concurrently log on from multiple computers and browsers. If cleared, the current session automatically expires if the user logs on from a second computer. The default value is selected.
Allow Use of Login Cookie	Allows users to log on with a cookie based on prior log-ins with the same computer and browser. The default value is selected.
Allow Auto-Complete Feature in Web Browsers	Allows web browsers to use auto-complete features. The default value is unselected.

Option	Description
Allow Anonymous Guest Access	Allows anonymous logon as guest user. The default value is unselected.
Show Error Trace in UI	Displays server errors in the UI. The default value is selected.
Unique Names Across All Authentication Realms	Forces all user names to be unique regardless of the authentication realm used. The default value is unselected.

4. **Optional:** Enter IP addresses and host names that can serve as repository triggers for builds in the **Allowed Addresses for Repository Triggers** area.
   Place each item on a separate line. Each item must be a regular expression. In IP addresses or host names, escape periods with the backslash character '\'. For example, `127\.0\.0\.1`. Initially, no addresses are listed.
5. Click **Save**.

Configuring miscellaneous system settings

Use miscellaneous system-level settings to manage the repository cache, dependencies, and server logging.

1. On the left navigational panel, click **Server Settings > Misc**.
2. Click **Edit** then enter the number of minutes between repository event triggers in the **Repository Trigger Cache Time** field.
   The number should equal the longest quiet period plus the longest time that is required to obtain a revision log. If the number is too small, changes might not be accurately detected when building dependent projects. The time that it takes to get the revision logs can vary significantly, depending on server load and the complexity of the dependency relationships. The default value is 30 minutes.
3. Select **Build if No Prior Successful Builds Found** if you want to build requests to produce builds even if there are no previous successful builds for the workflow.
4. Select an algorithm from the **Digest Algorithm** list.
   This option is the algorithm that is used to calculate digests when uploading artifacts to CodeStation project builds. SHA-256 is used by default. The selected algorithm is used in addition to it.
5. Select the option that is used to determine dependency conflicts from the **Dependency Conflicts** options:
   Choose from:
   - **DETECT ALL** detect all dependency conflicts even if the dependencies are not resolved.
   - **DETECT RESOLVED** only detect dependency conflicts that are resolved.
6. Select **Cascade Properties to Dependencies** if you want properties to cascade from a request to a created dependency request.
   This option applies to requests from pull and push dependencies. By default, Build does not cascade properties to requests made due to dependency relationships.
7. Select the default type from the **Default Dependency Type** list.
   This option determines the default dependency relationship for new dependencies. Users can override this setting.

8. Select the file trigger type from the **File Dependency Trigger Type** options:
   This option determines the type of dependency trigger when resolving build artifacts by using a file that defines the dependencies. If a process uses trigger-only dependencies, dependencies on the resolved projects are created with this trigger type.
9. Select **Merge Manual Builds** list to merge related manual builds.
   Requests that depend on existing requests wait for them to complete, and other requests for waiting requests are merged.
10. Select a level from the **Logging Level** options.
    The **System Properties** page lists the agent's system properties. System properties cannot be edited.
    Choose from:
    - **Info** provides basic information about server activity.
    - **Warn** logs all server warnings. The default option.
    - **Error** logs all server errors.

Placing an administrative lock on the server

Administrators can place an administrative lock on the server.

About this task

An administrative lock blocks new build requests. Blocked requests are saved and start when the lock is released. Processes that are processing when the server is locked continue normal processing. When the server is unlocked, the server status is `Normal`; when the server is locked, the status is `Administrative Lock`. Administrative locks are typically used in preparation for server maintenance.

1. On the left navigational panel, click **System > Server Settings**.
2. **Maintenance**
3. Click
4. Change the lock status with one of the following actions.
   Choose from:
   - To lock the server, click **Lock Server**.
   - To unlock the server, click **Release Lock**.

   Releasing the lock starts a recovery process that begins 1 minute after the lock is released.
5. Click **Done**.

Viewing the server log

You can view and download the server log file.

About this task

The **Log** page displays the content of the `server.out` file. The default location for this file is here: `/server_install/var/log/`.

1. On the left navigational panel, click **System > Server Settings**.
2. Click **Log**.
3. To download the log file, click **Download Log** and specify a location for the file.

Viewing the server error log

You can view and download the server error log file.

About this task

The **Log** page displays the content of the `server.err` file. The default location for this file is here: `/server_install/var/log/`.

1. On the left navigational panel, click **System > Server Settings**.
2. Click **Error**.
3. To download the log file, click **Download Log** and specify a location for the file.

Displaying graphs on the dashboard

You can display graphs on the Build user interface.

About this task

By default, graphs appear on the main dashboard and the project and process dashboards. Administrators can disable any or all of them.

1. On the left navigational panel, click **System > Server Settings**.
2. Click **Views**, then click **Edit**.
3. To disable or enable a dashboard graph, select the associated **Yes** or **No** option.
   An enabled graph displays total source activity, build activity, and average test success.
4. Click **Done**.

Running system diagnostics

You can use the diagnostics options to troubleshoot and debug various features. You can view information about active request contexts, thread CPU use, and system properties among others.

1. On the left navigational panel, click **System > Server Settings > Diagnostics**.
2. Select the options that you want to review.
   Multiple can be selected.
3. Click **View**.
   Result
   Information for the selected options is displayed.

Adding a cold standby server

Adding a *standby server* provides a backup server for disaster recovery in case the main server for Build is lost. A cold standby server is not turned on until needed. The environment must be configured to route network traffic to the standby server after a failure of the primary server.

Before you begin

- Make sure that the server is connected to a license server with available licenses.
- Ensure that you have the required security rules to get from your various endpoints to both the primary server and to the standby server.

About this task

At any given time, only one of the servers is active and connected to agents, the database, and network file systems. If the primary server encounters any issues and becomes nonoperational, then the standby server can be brought online and incoming network traffic can be directed to it instead of the primary server.

Both the primary and standby server must use the same database. The following directories and files must be moved to a network storage location that is accessible by both servers:

```
server/var
server/plugin
server/patches
server/opt/tomcat/webapps
server/opt/tomcat/work
server/conf/server.keystore
server/conf/server/base.xml
server/conf/server/ehcache.xml
server/conf/server/java.security
server/conf/server/hibernate.properties
server/conf/server/log4j.properties
server/conf/server/spy.properties
server/conf/server/rsa_api.properties
server/conf/server/upgrade.properties
```

All files and directories in the `server/opt/tomcat/work` directory should be deleted whenever a new patch is applied to the server.

1. Install the standby server in a separate location and connect it to the same database as the primary server.

   Specify the database that the production server is using when prompted for database information.

   Note: Do not start the server.

2. Set up the environment to stop the primary server, start the standby server, and direct traffic to it in the case of a failure with the primary server.
   If a load balancer is used to switch to the standby sever, set the **install.server.external.web.url** property for both server instances to the URL of the load balancer.

Agents

Agents are light-weight processes that are installed on hosts and communicate with the Build server.

Agents run commands on the host, move files to and from it, and work with other tools installed on the host. Agents are responsible for running builds and driving third-party tools. After an agent is installed, it opens a socket connection to the server for server-agent communication. Agents can also use the Build web services. After agent communication is established, agent information is displayed in the web-based UI, where it can be configured and modified.

Configuring agents

After an agent is installed, it must be configured before it can be used.

Before you begin

Install at least one agent and ensure that it is online. Once configured, access to the agent can be restricted using the security features, see Security on page 316.

1. On the left navigational panel, click **Agent > Available**.
   Agents with the status of **Available** are connected to the Build server but not yet configured.
2. Select the agents that you want to configure then use the **Configure** action .
   Result
   If configuration is successful, the agents are no longer displayed in the **Available** list.
3. Click **Configured**.
   Result
   The configured agents are displayed in the **Configured** list with the status of **Online**.

What to do next

After an agent is configured, you can modify its settings.

Modifying agent settings

After an agent is installed, you can modify its settings.

Before you begin

You must have administrative privileges to modify agent settings

About this task

Most settings are configured during installation but you can edit them any time after installation. From the **Agents List** window you can manage installed agents. The table filters at the beginning of the agent table allows you to locate a specific agent or narrow the list displayed. You can filter by agent name, host name, status, time frame the agent was used, and available, configured or ignored agents.

1. Click **Agents** and the **Agent List** window displays.
2. Click the name of the agent to view and modify agent properties.

3. On the **Main** tab, settings that define the agent and connection are displayed. You can modify the following settings. Click **Save** when finished.

   Name

   The current name of the agent was given during the installation process. The agent is automatically updated if the name is changed.

   Configured

   Enable to indicate that the agent is configured.

   Throughput Metric

   The throughput metric is an arbitrary integer that indicates the ability of an agent relative to other agents to handle extra work. An agent with a metric of 10, for example, usually gets more work before an agent with a metric of 1. A weight is applied to the agent by using a formula based on throughput and the number of active jobs. The formula is `Weight = Throughput / (Number of Active Jobs + 1)`.

   Maximum Number of Jobs

   The maximum number of concurrent jobs the agent runs. If an agent reaches the maximum number of jobs, extra requests are queued until a job finishes.

   Agents Pools

   The agent pools to which the agent is assigned.

4. Click the **Properties** tab, to view, edit, remove, and add properties to the agent.
   Agent properties are used to configure builds or other process to use values that depend on the agent that is doing the work. For example, an agent property can use an agent's local settings during a build. Agent properties are resolved at run time on the agent. Secure property values are obfuscated in logs.
   Choose from:
   - To remove a property, click the delete icon ( ) under the **Actions** column to the right of the desired property name.
   - To edit the property, click the edit icon (or). You can modify the property name and value in the **Edit Property** window. Click **Save** when finished.
   - Click **Add Property**. The **New Property** windows displays. Click **Save** when finished.

   Property Name

   Type a name for the property.

   Secure

   Click the check box to make the property secure.

   Property Value

   Type a value for the property. If you create a secure property, the typed value is obfuscated and must be retyped in the **Confirm Value** field

5. To view, edit, and create an agent environment variable, click the **Environment** tab.

Agent environment variables are set during agent installation and stored on the server.

Choose from:

- To remove an environment variable, click the delete icon ( ) under the **Actions** column to the right of the desired environment. Secure environments variables cannot be deleted.
- To edit an environment variable, click the edit icon ( ). You can modify the environments value in the **Edit Environments Variables** window.
- Click **Add Environment Variable** and the **Add Environment Variable** windows displays.

Variable Name

Type a name for the variable.

Secure

Click the check box to make the variable secure. If you create a secure variable, the typed value is obfuscated and must be retyped in the **Confirm Value** field.

Variable Value

Type a value for the property.

6. To view locked properties, click **Locked Properties**.
   The **Locked Properties** page lists the agent's locked properties. Locked properties cannot be edited.
7. To view system properties, click **System Properties**.
   The **System Properties** page lists the agent's system properties. System properties cannot be edited.
8. To set the cache location for the CodeStation repository used by the agent, click the **CodeStation** tab.
   Type the location of the cache in the **Cache Location** field. The default value is *agent_installation_directory*`/.codestation/cache`. Click **Save**.
9. Click **Done** when finished.

Related information

Configuring agents on page 342

Creating agent pools

Agent pools represent collections of agents. An agent pool can consist of one or more agents.

Before you begin

Install and configure at least one agent.

About this task

You manage agent pools on the **Agent Pool** window. A list of defined agent pools is displayed and clicking on the agent pool name details are displayed.

There are two types of agent pools: Fixed and Dynamic. You manually add agents to fixed pools. Dynamic agent pools automatically determine which agents are members of the pool.

1. On the left navigational panel, click **Agents > Agent Pools**.
2. To create a pool, click **Create Fixed Agent Pool** or **Create Dynamic Agent Pool**.
    a. Type a name for the pool in **Name** field.
    b. Enter a description in the **Description** field.
    c. Select a team to manage the pool from the **Team** list.
    d. Click **Save**.
3. To add or remove agents from a fixed agent pool, click the agent pool **Name**.
    a. Click **Add/Remove Agents**.
    b. Using the **Add/Remove Agents** window, select the agents that you want to add or remove.
    c. To add agents to the pool, select them from the **Potential Agents** list, then click the add icon .

    To remove an agent from the pool, select the agent and the remove icon ( ).
    Result
    The agents are added to the team.
    d. Click **Save**.
4. **Optional:** To review security assignments for an agent pool, select a pool then click **Security**.
   The **Resource Security** window displays the teams and users that can view and edit the pool.

Managing agent pools

Agent pools represent collections of agents. When an agent pool is assigned to a project, any pool member can do the work.

Before you begin
Install and configure at least one agent.

About this task

Agent pools help you organize and manage agents. A pool can consist of one or more agents. There is no limit on the number of agents that can be assigned to a pool. You manage agent pools on the **Agent Pool** window. In the window is a table of defined agent pools.

From the table you can view agent pool details or remove an agent pool. To remove an agent click the delete icon ( ) in the **Actions** column next to the agent pool name. To view or modify an agent pool, following the procedure below.

1. On the left navigational panel, click **Agent > Agent Pools**.
2. Click the name of the agent to view or modify.
   On the **Main** tab is a list of agents in the pool and a list of projects using the agent pool. Agent pool information is also displayed on the build life details page. From the build life you can see which agent was used by a process.
3. To modify the name of the agent or description, click **Edit**. When finished click **Save**.
4. If the agent is a fixed type pool, you can add and remove agents. Click **Add/Remove Agents**.

a. Using the **Add/Remove Agents** window, select the agents that you want to add or remove.

b. To add agents to the pool, select them from the **Potential Agents** list, then click the add icon .

c. To remove agents from the pool, select them from the **Agents in *agent_name*** list, then click the remove icon ( ).
The agents are moved to the potential agent list.

d. Click **Save**.

5. To review security assignments for an agent pool, select a pool then click **Security**.
The **Resource Security** window displays the teams and users that can view and edit the pool.

Modifying agent settings

After an agent is installed, you can modify its settings.

Before you begin

You must have administrative privileges to modify agent settings

About this task

Most settings are configured during installation but you can edit them any time after installation. From the **Agents List** window you can manage installed agents. The table filters at the beginning of the agent table allows you to locate a specific agent or narrow the list displayed. You can filter by agent name, host name, status, time frame the agent was used, and available, configured or ignored agents.

1. Click **Agents** and the **Agent List** window displays.
2. Click the name of the agent to view and modify agent properties.
3. On the **Main** tab, settings that define the agent and connection are displayed. You can modify the following settings. Click **Save** when finished.

Name

The current name of the agent was given during the installation process. The agent is automatically updated if the name is changed.

Configured

Enable to indicate that the agent is configured.

Throughput Metric

The throughput metric is an arbitrary integer that indicates the ability of an agent relative to other agents to handle extra work. An agent with a metric of 10, for example, usually gets more work before an agent with a metric of 1. A weight is applied to the agent by using a formula based on throughput and the number of active jobs. The formula is `Weight = Throughput / (Number of Active Jobs + 1)`.

Maximum Number of Jobs

The maximum number of concurrent jobs the agent runs. If an agent reaches the maximum number of jobs, extra requests are queued until a job finishes.

Agents Pools

The agent pools to which the agent is assigned.

4. Click the **Properties** tab, to view, edit, remove, and add properties to the agent.
   Agent properties are used to configure builds or other process to use values that depend on the agent that is doing the work. For example, an agent property can use an agent's local settings during a build. Agent properties are resolved at run time on the agent. Secure property values are obfuscated in logs.
   Choose from:
   - To remove a property, click the delete icon ( ) under the **Actions** column to the right of the desired property name.
   - To edit the property, click the edit icon (or). You can modify the property name and value in the **Edit Property** window. Click **Save** when finished.
   - Click **Add Property**. The **New Property** windows displays. Click **Save** when finished.

   Property Name

   Type a name for the property.

   Secure

   Click the check box to make the property secure.

   Property Value

   Type a value for the property. If you create a secure property, the typed value is obfuscated and must be retyped in the **Confirm Value** field

5. To view, edit, and create an agent environment variable, click the **Environment** tab.
   Agent environment variables are set during agent installation and stored on the server.
   Choose from:
   - To remove an environment variable, click the delete icon ( ) under the **Actions** column to the right of the desired environment. Secure environments variables cannot be deleted.
   - To edit an environment variable, click the edit icon ( ). You can modify the environments value in the **Edit Environments Variables** window.
   - Click **Add Environment Variable** and the **Add Environment Variable** windows displays.

   Variable Name

   Type a name for the variable.

   Secure

   Click the check box to make the variable secure. If you create a secure variable, the typed value is obfuscated and must be retyped in the **Confirm Value** field.

Variable Value

Type a value for the property.

6. To view locked properties, click **Locked Properties**.
   The **Locked Properties** page lists the agent's locked properties. Locked properties cannot be edited.
7. To view system properties, click **System Properties**.
   The **System Properties** page lists the agent's system properties. System properties cannot be edited.
8. To set the cache location for the CodeStation repository used by the agent, click the **CodeStation** tab.
   Type the location of the cache in the **Cache Location** field. The default value is *agent_installation_directory*`/.codestation/cache`. Click **Save**.
9. Click **Done** when finished.

Related information

Configuring agents on page 342

Restarting agent brokers

The JMS broker manages server-agent communication.

About this task

Restart brokers to resolve communication errors between agents and the server. Users with administrative permissions can restart agent brokers.

1. On the left navigational panel, click **Agent > Broker**.
2. Click **Restart Broker**.
   Result
   All existing connections between agents and the server are dropped when the broker restarts. Agents reconnect automatically after the broker starts.

Managing untrusted agent certificates

If you are using mutual authentication, the server must have a certificate in its keyStore for each agent.

About this task

Agents that do not have certificates in the server's keystore are listed on the **Agent Certificate Management** page with a status of **Untrusted**. You can override this setting.

1. On the left navigational panel, click **Agent > Agent Certificate Management**.
2. Select the agents with untrusted certificates, then click **Trust**.
   Result
   Information about the agent is displayed.
3. Click **Done**.

Viewing agent workspace data

Use the view workspace feature to view the contents of an agent's workspace related to a job for a build. The workspace viewer displays real-time content of an agent directory structure and files. You can expand directory structures and view individual file contents. There is no need to use another tool such as Remote Connect to view files on the agent.

About this task

The agent workspace viewer requires a plug-in that is included with the product. If you remove this plug-in the function becomes unavailable.

You can use the view agent workspace to troubleshoot issues and to verify that expected files were created. Log files that the agent creates might contain data that is not passed to the Build logs. This information provides additional details that are related to a failure and the build process. Output from the intermediate working files that the build job uses temporarily can be viewed on the agent. You can verify whether the files were created or corrupted while you debug issues.

It is important to understand that the viewer shows real-time data. If the workspace was cleaned as part of the build process or reused, the data that is viewed is not the job run data. If the directory is empty when you request to view it, it is empty or the agent is not online.

Access to the view workspace feature is available on several user interface pages that contain job information that is related to a build, such as the main page of a build or **Job Execution** page for a specific job.

To view agent workspace data:

1. Click the **View Workspace** icon to open the Workspace Viewer.

   The **Properties** tables contains the directory structure displayed in the Workspace Viewer window.
2. To view a specific file, navigate to the file and click **Click here to view file contents** in the right pane.
   Use the **View As** field to display the text in ASCII or EBCDIC character encoding. Binary file types are not readable.
3. To download the file, click **Download**.

Creating scripts to automate administrative tasks

The Build Client facilitates writing scripts that interact with various REST endpoints in Build to automate tasks such as creating templates, assembling projects, running builds, and various other administrative tasks.

Use the **Tools** menu to downloaded the `devops-build-client.zip` file which contains the following files:

- `devops-build-client.jar`
- API documentation
- Sample Groovy script

See Accessing development tools on page 350 for information on downloading the Build Client.

Accessing development tools

Use the **Tools** window to access the Build development tools.

About this task

There are several Build development tools that you can include in your environment.

Agent Installer

Installs build agents.

Build Client

Write scripts to create objects within the system, such as projects, project templates, and other administrative task.

CodeStation Client

Download project dependencies and build artifacts from a CodeStation repository.

Preflight Client

Initiate pre-flight builds in Build to test code before committing changes to the source code repository.

Scripting API

Javadoc that describes the scripting system and types of scripts that can be written.

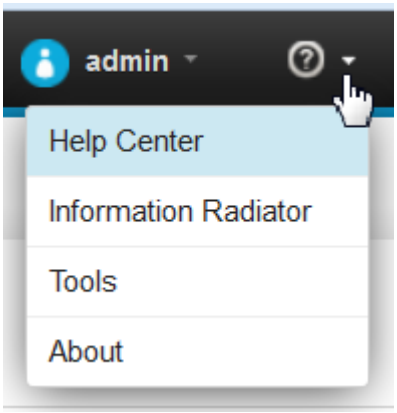
REST API

Documentation describing the REST API and how different endpoints can be used.

Build Plug-in Update Site

Run builds and download project dependencies from within an Eclipse IDE.

1. From the Build dashboard, click Help icon.



2. Click the **Help > Tools**.
3. From the Tools window, select the desired Build development tool.

Installing plug-ins

You install plug-ins by downloading the installation files and loading them into Build.

About this task

Plug-ins can be installed at any time. You do not have to restart the server after you install a plug-in. You can upgrade a plug-in by installing the new version over the old version.

1. Download the installation files for one or more plug-ins from Buildprovides plug-ins website.

   Documentation for plug-ins and the steps in the plug-ins is available on that site.

2. Load the plug-ins:
   a. On the left navigational panel, click **System > Plug-ins**.

   a. On the **Plug-ins** page, click **Browse** and select the downloaded plug-in file.
   You do not have to extract the compressed file.

   b. Click **Load**.

   c. Click **Done**.

Results

The plug-in is listed in **Loaded Plug-ins** list. After the plug-in is installed, it is available immediately.

Creating and Managing Projects

Projects run builds, manage dependencies with third-party tools, and can be used for administrative, operational, and system maintenance.

Projects often correspond to how the development process is structured in your source control management system. By using the dependency management system, projects can be composites of other projects.

Projects provide a wealth of information about the build and release cycle. Build projects create build lives every time builds run and that information is always available to you. Templates are provided for managing the dependencies and artifacts that are associated with projects. Because templates are reusable, you can reapply the same standards to similar projects.

Creating projects

You create projects by combining process and source definitions into complete build processes.

Before you begin

Before you create a project:

- Ensure that at least one agent is installed and running. .
- Configure a repository and make sure Build has access to it. See Repositories on page 330.
- Create a project template. See Creating project templates on page 384.

- Create a workflow. See Creating process definitions on page 390.
- Create a job and add it to the workflow. See Creating jobs on page 376.

1. On the left navigational panel, click **Projects > Create**.
2. In the **New Project** dialog box, type a name for the project in **Name** field.
3. Enter a description in the **Description** field.
4. Select a template from the **Template** list.
5. To add tags to the project, complete one of these actions:

   Choose from:

   - Select an tag from the **Tags** list.
   - Create a tag: type a name for the tag in the **Tags** field, and click **Add**.

   The tag is displayed in the **New Project** dialog box. Any number of tags can be assigned to the project.
6. From the **Team** list, select a team to manage the project
7. Click **Save**.

What to do next

To further define the project, see these topics for more information:

- Configuring projects: Configuring projects on page 352.
- Reviewing projects: Monitoring projects on page 369.
- Running projects: Running projects on page 370.
- Managing subscription notifications: Managing notification subscriptions on page 365.

Configuring projects

You configure a project by adding build and secondary processes to it, and manage tags and notification subscriptions

1. On the left navigational panel, click **Projects**, select a project, and then click **Configuration**.
2. **Optional:** To export the project, click **Export**, and identify the location to save the project file.

   Result

   The project is saved to an an XML file with the same name as project.
3. **Optional:** To copy the project, click **Copy**, and then name the project and click **Save**.

   Result

   The copied project is available on the **Projects** page.
4. To create a build process, click **New** in the **Build Processes** area.

   For information about build processes, see Managing build processes on page 353.
5. To create a secondary process, click **New**.

   For information about secondary processes, see Managing secondary processes on page 367.
6. To manage notification subscriptions, see Managing notification subscriptions on page 365.
7. **Optional:** To manage tags, click **Edit** and complete the following steps.
   a. Select a tag from the **Tags** list to add an existing tag to the project.
   b. Type a new tag in the **Tags** box to add a new tag to the project.

c. Click the Delete action associated with a tag to remove it from the project.
d. Click **Save**.

What to do next

To review and monitor projects, see Monitoring projects on page 369.

Managing build processes

Build processes define the input, transformational processes, and the expected output of projects

Before you begin

Before you create a build process, complete these actions:

- Create a process. See Creating process definitions on page 390.
- Create at least one job and add it to the process. See Creating jobs on page 376.

About this task

Build process input is source code that is stored in a source code manager (SCM). The actions that transform source code into the expected output are defined by processes and jobs. The results are called build artifacts.

1. On the left navigational panel, click **Projects**, and then select a project.
2. Click **Configuration**.
3. On the **Configuration** page, click **New** in the **Build Processes** area.
4. Define the process by completing these steps:

    a. Select a process template from the **Template** list.
    For information about build process templates, see Creating build process templates on page 388.

    b. Type a name for the process in the **Name** field.

    c. Select a team to manage the process from the **Team** list.

    d. Select a scheme from the **Notification Scheme** list.
    For information about notification schemes, see User notifications on page 311.

    Note: If a notification scheme is not selected for the process, notification subscriptions will not work. For information about managing notification subscriptions, see Managing notification subscriptions on page 365.

    e. Select a priority option from the **Priority** list.
    Priority options determine when processes run. Processes with a **High** priority run before processes with **Normal** or **Low** priorities. Processes with **Normal** priority run before processes with **Low** priority. When a process begins, it is not suspended or stopped when a higher-priority process is requested. **Normal** is the default option.

f. Select an option from the **Skip Pre-Processing** options.
If you select **Yes**, build preprocessing, such as checking for source changes, is skipped. The default selection is **No**. For information about preprocessing, see User notifications on page 311.

g. Click **Save**.

5. Define a source configuration by completing these steps:

a. Click **Create** in the **Source Configuration** area.

b. Using **New Source from Template** window, select a template from the **Source Template** list.
For information about creating source templates, see Creating source templates on page 387.

c. Type a name for the source configuration in the **Name** field.

d. Select a repository from the **Repository** list.

6. **Optional:** Add process properties by completing these steps:

a. Click **Create Property** in the **Properties** area.

b. Type a name for the property in the **Name** field.

c. Specify whether users can override the default value by selecting the **User May Override** option.
If selected, users are prompted to specify a value when they run the process.

d. Enter a value for the property in the **Value** field.

7. **Optional:** Define a build configuration by completing these steps:

a. Click **Create** in the **Build Configurations** area.

b. Type a name for the build configuration in the **Name** field.

c. **Optional:** Specify values for the available properties.
The properties are derived from the project templates and vary depending on the project.

d. Click **Save**.

8. Define dependencies for the build process by completing these steps:

a. Click **Dependencies**.

b. Select an option from the **Conflict Strategy** list.
This option determines what happens when a dependency conflict occurs. **Fail** means do not continue until conflicts are resolved. **Favor Old** means that the oldest build's artifacts are used. **Favor New** means that the newest build's artifacts are used. **Fail** is the default option.

c. Select **Trigger Only Dependencies** if you want dependencies to trigger only builds.
If cleared, dependencies trigger builds and set additional dependencies. Select this option when dependencies are determined by external dependency management tools, but you want to use dependencies as triggers. The default option is cleared.

9. Define a trigger by completing these steps:

a. Click **Triggers**, and then click **New Trigger**.

b. Select a trigger type from the **Type** list, and click **Select**.
The trigger types are described in the following table.

Table 12. Trigger types

Trigger type	Description
Scheduled Trigger	Scheduled triggers run on their own timers that poll the SCM tools for changes. When changes are detected, the build starts at the scheduled time. Scheduled triggers can be configured to force builds regardless of whether source changes occurred.
Repository Trigger	Repository triggers initiate builds whenever source code changes occur in the repository.
Post-Process Trigger	Post-processing triggers listen for post-processing events. When an event is detected, it can trigger other events. See Creating post-processing scripts on page 309.

c. Type a name for the trigger in the **Name** list.

d. **Optional:** If you selected **Scheduled Trigger**, select a schedule from the **Schedule** list.
For information about schedules, see Creating schedules on page 332.

e. Select **Force** to force builds when triggers occur.
If **Force** is selected, builds are triggered even if source changes are not detected.

f. Select a priority option from the **Priority** list.
Priority options determine when queued build requests run. Requests with a **High** priority run before requests with **Normal** or **Low** priorities. Requests with **Normal** priority run before requests with **Low** priority. **Normal** is the default option.

g. Selected **Enabled** to make the trigger active.

h. **Optional:** If you selected **Post-Processing Trigger**, select a process from the **Secondary Process** list.

For information about schedules, see Creating schedules on page 332.

i. Click **Save**.

What to do next

To see information about the teams that are assigned to the process and their permissions, click **Security**.

Defining source configurations

A source configuration defines a project's source type and the type of build artifacts that the project generates.

Before you begin

Before you create a build configuration, create at least one source template, see Creating source templates on page 387.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process, and click **Configuration**.
3. Define a source configuration by completing these steps:

    a. Click **Create** in the **Source Configuration** area.

    b. Using **New Source from Template** window, select a template from the **Source Template** list.
    For information about creating source templates, see Creating source templates on page 387.

    c. Type a name for the source configuration in the **Name** field.

    d. Select a repository from the **Repository** list.

4. Click **Save**.

Defining build configurations

Build configurations are collections of properties that are used to configure runtime project properties.

Before you begin

Before you create a build configuration, create the build process to which you want to attach it, see Managing build processes on page 353.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process, and click **Configuration**.
3. Define a build configuration by completing these steps:

    a. Click **Create** in the **Build Configurations** area.

    b. Type a name for the build configuration in the **Name** field.

c. **Optional:** Specify values for the available properties.
The properties are derived from the project templates and vary depending on the project.

d. Click **Save**.

Defining build properties

Build properties can be used by builds that are associated with the build process.

Before you begin

Before you create a build configuration, create the build process to which you want to attach it, see Managing build processes on page 353.

About this task

Build properties typically hold variable data for builds, such as compiler versions, or are used for an audit trail.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process, and click **Configuration**.
3. Add process properties by completing these steps:

   a. Click **Create Property** in the **Properties** area.

   b. Type a name for the property in the **Name** field.

   c. Specify whether users can override the default value by selecting the **User May Override** option.
   If selected, users are prompted to specify a value when they run the process.

   d. Enter a value for the property in the **Value** field.

4. Click **Save**.

Moving build processes

Defined processes can be moved from one project to another.

1. On the left navigational panel, click **Projects**, and then select the project that contains the process to move.
2. Click **Configuration**.
   On the **Configuration** window, under the **Build Processes** area the processes are listed.
3. Under **Actions** for the process to move, click the move icon ( ).
4. In the **Select Project** window, select the project to move the process to.
5. Click **Select**.
   On the **Projects**, the process is now under the selected project.

Defining project dependencies

Dependency configurations are used to trigger builds in related projects.

Before you begin

Before you create a build configuration, create the build process to which you want to attach it, see Managing build processes on page 353.

About this task

Projects often require outside libraries or files. The dependent project can use artifacts that child projects produce. Dependency configurations can also trigger related builds. A dependency can determine whether its dependencies must be built before it can build or whether the dependencies can trigger builds that depend on this build.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process.
3. Define dependencies for the build process by completing these steps:
    a. Click **Dependencies**.
    b. Select an option from the **Conflict Strategy** list.
    This option determines what happens when a dependency conflict occurs. **Fail** means do not continue until conflicts are resolved. **Favor Old** means that the oldest build's artifacts are used. **Favor New** means that the newest build's artifacts are used. **Fail** is the default option.
    c. Select **Trigger Only Dependencies** if you want dependencies to trigger only builds.
    If cleared, dependencies trigger builds and set additional dependencies. Select this option when dependencies are determined by external dependency management tools, but you want to use dependencies as triggers. The default option is cleared.
4. Click **Save**.

Configuring build artifacts

Build artifacts can be configured within the build template or on a build process based on the created artifact sets.

Before you begin

The artifact sets must be created before you can configure them. See, Creating artifact sets on page 327.

About this task

Configuring artifacts for a build process on templates provides for standardization among build processes. However, sometimes you require a more specific configuration for a build. By configuring artifacts on the build process you can create this specialization. The artifacts that are configured at the build level are concatenated with those that are defined at the template level and apply to the build process they are configured on. For information about creating templates, see Creating build process templates on page 388.

1. On the left navigational panel, click **Projects**.
2. Expand the project to configure by clicking the expand icon to display the project's build processes and select a build process.
3. Click the **Artifacts** tab.
   The **Artifacts** page displays the currently configured artifacts and their properties.
4. To add a new artifact configuration, click **New Artifact Config**.
   a. Select the artifact set from the associated menu. Remember, only configured artifact sets are listed.
   b. Specify the base directory in the **Base Directory** field. The directory is relative to the working directory when the Publish Artifacts step runs. To use the working directory, enter a period (.). You can use process and project properties to define the location, such as ${property: value}.
   c. Specify the artifacts to retrieve in the **Include Artifacts** field. You can use the * and ** wildcards to define the pattern. The ** wildcard indicates every directory and the* wildcard indicates every file. For example, the `dist/**/*` pattern retrieves every folder and file beneath the `dist` directory. You can also use process and project properties to define the pattern.
   d. To exclude artifacts that would otherwise be included, specify them in the **Exclude Artifacts** field. You can use process and project properties to define the pattern.
   e. Click **Save**.

Defining build triggers

Triggers can determine when builds occur. There are several types of triggers.

Before you begin

Create a build process to which you want to add a trigger.

About this task

Builds can be triggered by repository events, such as source code changes; triggered on a schedule; or triggered by post-processing events, such as completing builds in related projects.

1. On the left navigational panel, click **Projects**, and then use the expand icon associated with a project to display the project's build processes.
2. Select a build process.
3. Define a trigger by completing these steps:
   a. Click **Triggers**, and then click **New Trigger**.
   b. Select a trigger type from the **Type** list, and click **Select**.
      The trigger types are described in the following table.

Table 13. Trigger types

Trigger type	Description
Scheduled Trigger	Scheduled triggers run on their own timers that poll the SCM tools for changes. When changes are detected, the build starts at the scheduled time. Scheduled triggers can be configured to force builds regardless of whether source changes occurred.
Repository Trigger	Repository triggers initiate builds whenever source code changes occur in the repository.
Post-Process Trigger	Post-processing triggers listen for post-processing events. When an event is detected, it can trigger other events. See Creating post-processing scripts on page 309.

c. Type a name for the trigger in the **Name** list.

d. **Optional:** If you selected **Scheduled Trigger**, select a schedule from the **Schedule** list.
For information about schedules, see Creating schedules on page 332.

e. Select **Force** to force builds when triggers occur.
If **Force** is selected, builds are triggered even if source changes are not detected.

f. Select a priority option from the **Priority** list.
Priority options determine when queued build requests run. Requests with a **High** priority run before requests with **Normal** or **Low** priorities. Requests with **Normal** priority run before requests with **Low** priority. **Normal** is the default option.

g. Selected **Enabled** to make the trigger active.

h. **Optional:** If you selected **Post-Processing Trigger**, select a process from the **Secondary Process** list.
For information about schedules, see Creating schedules on page 332.

i. Click **Save**.

Monitoring build processes

You can review activities that are related to build processes, historical information that is related to the build process, and review information about individual build lives.

Before you begin

Create a build process and run one or more builds.

About this task

The **Main** tab for a build process displays information about recent build statuses and recent build lives that are generated from the build process. Graphs of related information, such as the percent of completed builds, can be displayed. Controls are available to run builds with this build process. See Running projects on page 370 for information about running builds.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process.
3. **Optional:** To see information that is related to changes that are made to the build process, click **Changes**.
   Result
   You can order the list of changes by build or by user.
4. To see information about the build lives that are created from this build process, click **My Activity**.
   Result
   Builds that are generated by your ID that use this build process are displayed.

What to do next

For information about running builds, see Running projects on page 370. For information about particular build lives, see Managing build lives on page 361.

Managing build lives

You can review current and historical information that is related to a build life.

Before you begin

Create a build process and run one or more builds.

About this task

Several tools are provided to help you manage build lives and diagnose problems.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process, and then select a build life.
   Result
   The **Main** tab for a build life displays information about the build and provides access to reports and artifacts that are generated by the build. Additionally, the agent used by the build processes is displayed.
3. **Optional:** To complete actions that are related to the build life, complete these steps.

   a. To see information that is related to the build request that generated the build life, click **View Request**.
      Result
      The **Request** page displays information about the user who requested the build and the project that is associated with it. You can access the build log and the request's context.

   b. To see information about the build's context, click **View Context**.
      Result

The **Request Context** page displays information about related process requests. If a request triggers another request by dependencies, the requests are in the same context. All requests that are created by a schedule are in the same context. For additional information about the features on the **Request Context** page, see View build context on page 363.

c. To see information about the build process's configuration, click **View Configuration**.
See Managing build processes on page 353.

d. To see information about a job, click the job in the **Process/Job/Step** list.
Result
The **Job Execution** page displays information about the processed job. You can access the output log for the job and the job template.

e. To restart the build, use the Restart icon .

f. To run a secondary process, use the Run Secondary Process icon , and select a secondary process.

g. To add a stamp the build, click **Add Stamp**, and specify the stamp.

h. To add a label to the build, click **Assign Label**, and specify the label.

i. To deactivate the build life, click **Deactivate**.
When you deactivate a build life, it is permanently disabled and its artifacts removed. A deactivated build life can never be enabled nor used in dependency relationships. A build life cannot be deactivated until all the dependency relationships are resolved.

j. To delete the build life, click **Delete**.
Deleting a build life permanently removes all traces of the build life. This action cannot be reversed.

k. To archive a build life, click **Archive**.
This action stores the build properties, such as time of build, labels, and build number, and removes artifacts from CodeStation. Dependencies are locked. Archived build lives can be unarchived.

4. **Optional:** To review information that is related to the build life, complete these actions:

a. To see reports about the build life, click **Reports**.
Result
The **Reports** page displays information about published reports and links.

b. To see the artifacts that are generated by the build life, click **Artifacts**.
Result
The **Artifacts** page displays information about the generated artifacts. You can also download and review them.

c. To see the build life's dependent relationships, click **Dependencies**.
Result
The **Dependencies** page displays information about projects the build depends on, and other projects that depend on this build.

d. To see information about source and dependency changes, click the job in the **Dependencies**.

e. To see information about errors that are related to the build, click **Issues**.
Result
The **Issues** page displays information from issue trackers and represents defects or work items that are listed in source changes.

f. To see information about tests that were done on the build, click **Tests**.
Result
The **Tests** page displays test results that are related to the build.

g. To see information about test coverage for the build, click **Coverage**.
Coverage integrations collect information on coverage tests that were run on the build.

h. To see analytic reports, click **Analytics**.
Result
The **Analytics** page displays the results of source code analysis reports.

i. To add a note to the build life, click **Notes**, and then **Add Note**, and type the note.

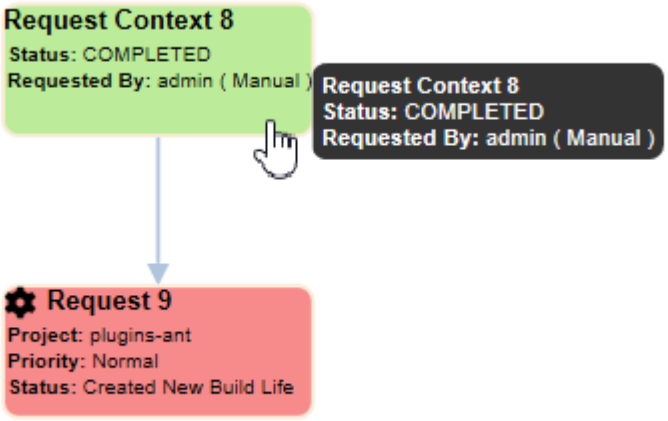
View build context

The **Request** page displays information about a build and the projects that are associated with it.

The **Request Context** page displays information about related process requests. A tree view of the build dependencies is displayed, which provides a hierarchical graphic of the dependencies. All requests that are created by a schedule are in the shown in the tree view.

Child nodes can be hidden, by clicking on the parent node. When nodes are hidden, a black border is shown on the parent node. Click the parent node to expand its child nodes.

The color of the tree nodes indicate the status of the project in the node. Additional information such as project name and date can be obtained by hovering over the node.



The following table lists the colors used to describe the status of a node.

Table 14. Status details

Color	Status
Green	Completed
Yellow	Running
Grey	The project is queued, waiting for an agent or dependency
Red	Failed
Blue	Suspended

Searching for build lives

Use the **Search** window to locate build lives or miscellaneous jobs using a set of specific criteria.

About this task

You can search using a build, request, process, status, or label criterion to search for build lives. To search for a job, use the **Misc Job** tab.

1. On the left navigational panel, click **Search**.
2. Select the tab for the type of criteria that you want to use for your search.
   Choose from:

- To search by build lives, click **Build**. Filter the search based on project name, build ID, latest status, or latest stamp. The latest stamp filter supports using the asterisk wildcard (*) character to match any sequence of characters.
- To search by build request status, click **Request**. Filter the search based on request status and project name. The project name filter supports using the asterisk wildcard (*) character to match any sequence of characters.
- To search by process status, click **Process**. Filter the search based on process status and project name. The project name filter supports using the asterisk wildcard (*) character to match any sequence of characters.
- To search by status, click **Status**. Filter the search based on build life status and project name. The project name filter supports using the asterisk wildcard (*) character to match any sequence of characters.
- To search by label, click **Label**. Filter the search based on a build life label name and project name.

  In addition to searching, you can also create a label, and assign and remove a label from build lives.
  - To assign a label, select the desired builds by using the check boxes on the left side of the table. Select a label from the menu and click **Assign**.
  - To remove a label, select the desired builds using the check boxes on the left side of the table. Select a label from the menu and click **Remove Label**. The label is removed from the selected build lives; it is not removed from the server. To remove a label from the server, see Managing Labels on page 329.
  - To create a label, click **Add Additional Label** and type in the new label name. After the label is created, it can be assigned to a build life by clicking **Assign**.
- To search for jobs using a project name, click **Misc Jobs** and limit the data using the filters on the **Project** field. Type a number in the **Results Per Page** field to limit the number of displayed results. The default value is 40.

Managing notification subscriptions

You can receive email notifications whenever one of your projects run a build.

Before you begin

Make sure that you configure a notification scheme before you manage subscription notifications. For information about notification schemes, see Creating notification schemes on page 312.

About this task

Notifications are triggered based on build statuses that you specify. Notification might be sent whenever a build fails, for example. The notification scheme that is associated with the process determines who receives email notifications. If a notification scheme is not associated with a process, then no notifications are sent regardless of the notification subscription settings

You can use the notification subscription feature to unsubscribe to notifications that you would otherwise receive. You can elect to unsubscribe from all notifications for a project or unsubscribe from specific processes. You can also configure your user account to receive no notifications. If you unsubscribe from notifications, you will not receive any regardless of the notification subscription settings.

1. On the left navigational panel, click **Projects**, and then click the name of the project.
2. In the **Main** page of the project, click **Configuration**.
3. In the **Notification Subscription** field, click the name of the currently selected option. Click **None** if no option is selected.

   For example, if the currently selected option is **Default**, click .

   Result

   The **Notification Subscription** dialog box is displayed. The **Notification Subscription** dialog box displays lists of options for the project itself and each process that is associated with the project. You can also manage subscriptions on the individual process **Configuration** pages. The procedure is the same regardless of where you access the feature.
4. Select a trigger option from the list that is associated with the project or process.
   You can change options independently of each other. The options are.

Table 15. Notification subscription options

Option	Description
Default	Receive notifications based on the settings of the scheme that is associated with the process.
Failure	Receive notifications only when the process fails.
None	Do not receive notifications.
Status Change	Receive notification only when the build status of the process changes.
Success	Receive notifications only when the process succeeds.
Success and Failure	Receive notifications whenever the process succeeds or fails.

Result

Notifications are sent to the users specified by the notification scheme whenever the triggering condition is met. Use this table to determine when notifications are sent when the project setting is different from the setting for individual processes. If you configure your user account to unsubscribe from notifications, you will not receive any notifications regardless of the subscription settings. It bears repeating that if a notification scheme is not configured for a process, no notifications are sent regardless of the notification subscription settings.

Table 16. Notification subscription settings

Project setting	Process setting	When notifications are sent
Success	Default	Success
Success	None	Not sent

Project setting	Process setting	When notifications are sent
None	Success	Not sent
Default	Success	Success
Default	Default	Default
Failure	Success	Success
Default	Success/Failure	Success or failure
None	Default	Not sent

5. **Optional:** Click the **Delete**, , action that is associated with the currently selected option to delete the subscription setting that is associated with the project or process.

Managing secondary processes

Secondary processes manipulate or operate on the artifacts that build processes generate.

Before you begin

Before you create a secondary process, complete these actions:

- Create a secondary process. See Creating process definitions on page 390.
- Create at least one job, and add it to the process. See Creating jobs on page 376.

About this task

The artifacts that build processes generate are stored in CodeStation and are available for more processing, which is called secondary processing. Most secondary processes run tests on build artifacts.

1. On the left navigational panel, click **Projects**, and then use the expand icon that is associated with a project to display the project's build processes.
2. Select a build process, and click **Configuration**.
3. Click **New** in the **Secondary Process** area.
4. Define the process by completing these steps.
    a. Select a process template from the **Template** list.
    For information about build process templates, see Creating build process templates on page 388.
    b. Type a name for the process in the **Name** field.
    c. Select a team to manage the process from the **Team** list.
    d. Select a scheme from the **Notification Scheme** list.
    For information about notification schemes, see User notifications on page 311.

e. Select a priority option from the **Priority** list.
Priority options determine when processes run. Processes with a **High** priority run before processes with **Normal** or **Low** priorities. Processes with **Normal** priority run before processes with **Low** priority. After a process begins, it is not suspended or stopped when a higher-priority process is requested. **Normal** is the default option.

f. Click **Save**.

5. Add process properties by completing these steps:

a. Click **Create Property** in the **Properties** area.

b. Type a name for the property in the **Name** field.

c. Specify whether users can override the default value by selecting the **User May Override** option.
If selected, users are prompted to specify a value when they run the process.

d. Enter a value for the property in the **Value** field.

6. Define a trigger by completing these steps:

a. Click **Triggers**, and then click **New Trigger**.

b. Select a trigger type from the **Type** list, and click **Select**.
The trigger types are described in the following table.

Table 17. Trigger types

Trigger type	Description
Scheduled Trigger	Scheduled triggers run on their own timers that poll the SCM tools for changes. When changes are detected, the build starts at the scheduled time. Scheduled triggers can be configured to force builds regardless of whether source changes occurred.
Repository Trigger	Repository triggers initiate builds whenever source code changes occur in the repository.
Post-Process Trigger	Post-processing triggers listen for post-processing events. When an event is detected, it can trigger other events. See Creating post-processing scripts on page 309.

c. Type a name for the trigger in the **Name** list.

d. **Optional:** If you selected **Scheduled Trigger**, select a schedule from the **Schedule** list.
For information about schedules, see Creating schedules on page 332.

e. Select **Force** to force builds when triggers occur.
   If **Force** is selected, builds are triggered even if source changes are not detected.

f. Select a priority option from the **Priority** list.
   Priority options determine when queued build requests run. Requests with a **High** priority run before requests with **Normal** or **Low** priorities. Requests with **Normal** priority run before requests with **Low** priority. **Normal** is the default option.

g. Selected **Enabled** to make the trigger active.

h. **Optional:** If you selected **Post-Processing Trigger**, select a process from the **Secondary Process** list.
   For information about schedules, see Creating schedules on page 332.

i. Click **Save**.

What to do next

To see information about the teams that are assigned to the process and their permissions, click **Security**.

Monitoring projects

You can review activities that are related to projects and project build processes, and create and import projects.

About this task

The **Projects** tab displays information about projects, recent build lives that are generated from the projects. Graphs of related information, such as the daily success rate, can be displayed. Controls are available to create and import projects.

1. On the left navigational panel, click **Projects**.
   Result
   The **Projects** tab lists all projects and their status.
2. To filter the list of projects, enter search criteria in the **Project** field and click **Filter**.
3. To see the build processes that are associated with a project, click the expand icon that is associated with the project.
4. **Optional:** To see information about a build, click the View Build icon that is associated with the build.
   For information about build lives, see Managing build lives on page 361.
5. To create a project, click **Create**.
   For information about creating projects, see Creating projects on page 351.
6. To import a project, click **Import**, and complete these steps:
   Choose from:
   - To import a project file, click **Browse** and select the file; then, click **Import**.
   - Paste the project definition in the text box, and then click **Import**. The pasted file must be an XML file that was previously exported from Build.
7. To view inactive projects, click **View Inactive**.
   Result

Inactive projects are displayed.

8. To see information about the build lives that were created from the listed projects, click **My Activity**.
   Result
   Builds that were generated by your user ID are displayed. For information about build lives, see Managing build lives on page 361.

What to do next

For information about running builds, see Running projects on page 370. For information about particular build lives, see Managing build lives on page 361.

Creating and Managing Projects

Projects run builds, manage dependencies with third-party tools, and can be used for administrative, operational, and system maintenance.

Projects often correspond to how the development process is structured in your source control management system. By using the dependency management system, projects can be composites of other projects.

Projects provide a wealth of information about the build and release cycle. Build projects create build lives every time builds run and that information is always available to you. Templates are provided for managing the dependencies and artifacts that are associated with projects. Because templates are reusable, you can reapply the same standards to similar projects.

Running projects

When you run a project, you select and run a particular build process that is associated with the project.

1. On the left navigational panel, click **Projects**.
2. Click the expand icon that is associated with a project, and then select the build process to run.
3. On the build process page, select **Force** if you want to force the build.
4. Select **Delay Build** if you want to delay the build.
5. **Optional:** Select a configuration from the **Build Configuration** list.
   For information about build configurations, see Defining build configurations on page 356. The default selection is **None**.
6. Click **Build**.
   Result
   Information about the build is displayed on the **My Activity** page for the build life. Initially, the status is `Running`. A successful build has the status of **Complete**. An unsuccessful build has the status of **Failed**.

What to do next

For information about build lives, see Managing build lives on page 361.

Running preflight builds

You can run test builds in your production build environment without impacting your production environment, using a preflight build. Preflight builds allow you to build code that has not been merged into your production code to determine if the build completes correctly.

About this task

A preflight build is like a regular build life, allowing you to test a build before committing code changes to the source control. The preflight build includes a clean-up service that deletes preflight build older than thirty days. This prevents the accumulation of test builds using server storage.

A preflight build cannot be specified as a dependency for either a regular or another preflight build. Because it can never be a dependency for any other build, it is always safe to delete.

To use this feature, you must download the Preflight client on any computer that can communicate with the Build server.

1. In the Build user interface, click **Help > Tools** on the taskbar and select the Preflight package to download the preflight client.
2. Go to the location of the package that you downloaded and decompress the package. The build executable is in the `/bin` directory.
3. Start a preflight build using a command line interface as shown in the example below. In the example, a preflight build is started for the project with an ID of 1423 and build process number 52. The user ID and password are included in the command to authentication with the build server.

```
preflight build --url http://localhost:8080 --local-server-host localhost -p 1423 -bp 52
-D workspace.revision.6df88f60-0ed2-4da2-8fcc-12fd779d8bfa=cf5cf4a6a185b523fa2d80cf3356981a759a441c
--user PasswordIsAuthToken --password 31e3dcc9-96d5-4640-98f6-0583a6928355
```

--url

Fully-qualified URL of the Build server

--local-server-host

Local name of the Build server. The value is usually `localhost`.

-p

The ID of the project.

-bp

The ID of the build process.

-D

Properties to include with the build. Specify the **workspace.revision.uniqueID** property for the build to use a specific code commit. This property contains information from the **Populate Workspace** step to identify the correct code to use. If a value for the property has not been set, the latest commit is used and the property is set to the latest commit unique ID value.

--user

The user ID to log into the Build server.

--password

The password associated with the user ID.

What to do next

After the build completes, view the output information to verify that the build completed successfully. Below is sample of a Preflight build output.

```
Request URL:
        http://localhost:8080/tasks/project/BuildRequestTasks/viewBuildRequest?buildRequestId=463Request
 Status:
        SubmittedRequest Status:
        BUILD_LIFE_CREATED
        Buildlife URL: http://localhost:8080/tasks/project/BuildLifeTasks/viewBuildLife?buildLif eId=386
        Build Status:  RUNNING
        Build Status: FAILED
```

Notice that the **Build Status** field indicates that the preflight build failed. The error should be investigated and fixed before merging into the production code. The link in the **Buildlife URL** field provides additional information about the failure.

You can continue using the preflight build testing iterations of the code until a successful build occurs.

CodeStation projects

CodeStation projects model external tools or libraries as Build projects.

With CodeStation projects, you can use third-party tools as dependencies, and test and track their status within an application. For example, if your application requires Java 5, you can create a CodeStation project and create an artifact set that contains the Java 5 files. Projects that require Java 5 can use the artifact set as a dependency. CodeStation projects can support multiple versions of the libraries in an artifact set. When the dependency is called during a build, your settings determine which version to use. For example, one process of your project can depend on library version 1 and another component can depend on version 2 of the same CodeStation project.

It is important to note that CodeStation projects cannot depend on other projects.

Creating CodeStation projects

CodeStation projects model external tools or libraries as Build projects.

1. On the left navigational panel, click **CodeStation > Create CodeStation Project**.
2. Type a name for the CodeStation project in the **Name** field.
3. Click **Save**.
4. **Optional:** Add properties to the project by completing the following steps:

a. Click **Properties** and click **New Property**.

b. Type a name for the property in the **Name** field.

c. Enter a value for the property in the **Value** field.
Property values are referenced by using this syntax: `${p:name}`.

5. Click **Save**.

What to do next

Create artifact sets by loading files into the project. See, Creating CodeStation project artifact set versions on page 373. To see the teams assigned to the project and their permissions, click **Security**.

Creating CodeStation project artifact set versions

A CodeStation artifact set is a collection of files that were not created by Build. CodeStation artifact sets are used as dependencies for other projects.

Before you begin

Create the CodeStation project for which you want to create an artifact set version.

About this task

Each time that you load files into a CodeStation artifact set, an artifact set version is created. A CodeStation artifact set can have any number of versions.

1. On the left navigational panel, click **CodeStation**, then select a CodeStation project.
2. Click **New** in the **Versions** area.
3. Type an identifier in the **Stamp** field.
A stamp typically uses an algorithm with an incremental property such as `${+property:propname}`. A stamp can also use constant, such as `myStamp`.
4. Click **Save**.
5. Load files into the version by completing the following steps.

a. Click **Artifacts**.

b. Click **Upload File**, or **Upload Many Files**.
To upload several files, first create a compressed file that contains the files.

c. Select an option from the **Artifact Set** list.
This option assigns a name to the artifact set.

d. Specify the directory where the files are in the **Directory** field.

e. Use **Browse** and select the file.
If you selected **Upload Many Files**, the file must be a compressed-type file.

f. Click **Upload Files**.

6. **Optional:** Define a property for the artifact set version by completing the following steps.
    a. Click **Properties** and click **New Property**.
    b. Type a name for the property in the **Name** field.
    c. Enter a value for the property in the **Value** field.
    Property values are referenced by using this syntax: `${p:name}`. These properties cannot have empty values.
    d. Click **Save**.
7. Add statuses to the artifact set version by completing the following steps.
    a. Click **Status** and click **Add Status**.
    b. Select a status from the **Status** list.
    For information about creating statuses, see Creating statuses on page 334.
    c. Click **Add**.

What to do next

To see projects that depend on the CodeStation project version, click **Dependencies**.

Build pipelines

A build pipeline defines the automated process that transforms source code into deployable artifacts. It specifies the steps required to compile, test, validate, scan, and package the code.

In Build, you can define a pipeline as a **Process** and map each stage of the pipeline to a **Job**.

Pipeline stages as Jobs

A pipeline includes multiple stages. In Build, you can implement each stage as a Job.

A typical build pipeline consists of the following stages:

Table 18. Typical pipeline stages

Stages	Tasks
Build	Compile source code and generate binaries.
Test	Run automated unit and integration tests.
Scan	Perform security, compliance, or quality scans.
Package	Create deployable artifacts.
Publish	Upload artifacts to a repository.

You can create reusable Job templates for the above stages and add them in a Process to standardize execution across pipelines.

Multistage pipeline

Build supports multistage pipeline so that you can define multiple Job templates and combine them in a Process.

To configure a multistage pipeline, complete the following steps:

1. Create Job templates for each required stage.
2. Add the Jobs to a Process definition in the required execution order.
3. Configure dependencies between Jobs to control execution flow.

The system runs the Jobs sequentially according to the defined order. Each Job represents a distinct stage. Downstream Jobs can consume artifacts produced by upstream Jobs. If a Job fails, the system stops or controls subsequent execution based on your configuration.

This multistage pipeline design enforces quality gates and ensures controlled progression.

Parallel pipeline

You can configure Jobs within a Process to run in parallel when no dependency exists between them.

To configure parallel execution, complete the following steps:

1. Add multiple Jobs to the same Process stage.
2. Do not define dependency relationships between those Jobs.
3. Ensure sufficient system resources to support concurrent execution.

The system executes the Jobs simultaneously. Parallel execution reduces overall build time and optimizes resource usage.

Typical parallel execution scenarios are as follows:

- Running multiple test suites simultaneously.
- Running security scans and code quality analysis concurrently with testing.

For detailed procedures on creating Job templates and Process definitions, refer to Creating Jobs and Processes on page 375.

Creating Jobs and Processes

Jobs are the core building blocks of Build. Process definitions assemble jobs into the basic unit of automation. A process definition determines how, when, and where jobs run.

Creating jobs

A job is a series of steps that constitute a process, usually a build. Job steps are processed one at a time in the order you specify.

About this task

The steps that are used to create a job are taken from plug-ins. You can think of a plug-in step as distinct pieces of automation. By combining steps from various plug-ins, you can create fully automated processes. The number of steps that are provided by a particular plug-in can vary, and each step has a variable number of properties. Property values can be supplied when defining a job or enter values at run time.

1. On the left navigational panel, click **Template > Jobs**.
2. Click **Create**.
3. In the **Create a Job** dialog box, type a name for the job in the **Name** field.
4. From the **Teams** list, select a team to manage the workflow.
5. Click **Save**.
   The job is created.
6. Click the **Steps** tab to add steps to the job on the **Jobs** details page.

    a. Click **Create Step**.
    The **Step Types** tab and a list of available steps displays. Installed plug-ins provide the available steps.

    b. Select a step.
    Expand the plug-in name to see individual steps.

    c. Click the step name.
    Result
    A tab opens with the properties associated with the step. Both properties that are specific to the selected step and general properties that are available for every step are displayed.

    d. Enter the property values.
    To see the properties that are available for every step, click **Show Additional Options**. For information about the properties common to all steps, see Configuring properties common to all steps on page 377.
    Result
    The step is added to the list of steps. For environmental properties, click **Show Environmental Variables**.

   Job steps are run in list order from the top of the list.
7. Click **Save**.

What to do next

You can insert steps before or after other steps. To insert a step before another step, click the Insert Before icon for the step before which you want to insert a step. To insert a step after another step, use the associated Insert After icon . You can use the Reorder icon to drag steps to rearrange their order.

Related information

Adding, copying, and arranging job steps on page 378

Disabling and deleting job steps on page 383

Configuring properties common to all steps

A number of properties are common to all steps.

About this task

You can specify common property values when you create the step or edit them after the step is saved. The default values for these common properties are sufficient for most situations.

1. On the left navigational panel, click **Template > Jobs**.
2. Select the job with the step that you want to edit.
3. Use the Edit icon associated with the step.
4. You can edit the displayed values of the step.
5. Click **Show Additional Options**.
   Use the following table to specify step property values.

Table 19. Step common properties

Property	Description
Is Active	Select **No** to temporarily deactivate this step without having to delete it. The default value is **Yes**.
Run in Parallel	The step runs at the same time as adjacent steps that are also parallel. The default value is **No**.
Run in Preflight	Select **No** if you do not want this step to run in preflight builds. The default value is **Yes**.
Run in Preflight Only	Select **Yes** if you want to run this step only in preflight builds. The default value is **No**.
Pre-Condition Script	Select the precondition script that must be successful before the step can run. The default value is **All Prior Success**.

Property	Description
Ignore Failures	Select **Yes** if the step status does not affect job continuation or status. Selecting **Yes** means the success or failure of this step is irrelevant. The default value is **No**.
Post-Processing Script	Specify the script that is used to determine whether the step commands fail or succeeds. To create a script, click **New Script**. For information about post-processing scripts, see The post-processing element on page 416.
Timeout	Enter the number of minutes after the step starts when the step is considered timed out and aborted. When a step times out, it is marked as failed and job execution continues based on that outcome. The default value is 0, which means that the step never times out.

6. Click **Save**.

Adding, copying, and arranging job steps

The list of steps associated with a job are listed in the **Steps** window of the job. There add steps several ways.

About this task

After you add an initial step by clicking **Create Step**, you can add additional steps using one of these methods:

- To add a step, click **Create Step**
- To insert a step before another step, click the Insert Before icon ( ) for the step before which you want to insert a step. The **Step Types** window opens for you to select from the available steps. Installed plug-ins provide the available steps. Click the a step name and complete the properties that are associated with the step.
- To insert a step after another step, use the associated Insert After icon ( ). The **Step Types** window opens for you to select from the available steps. Installed plug-ins provide the available steps. Click a step name and complete the properties that are associated with the step.
- To copy a task, click the copy icon ( ). The **Copy Step** window opens.

Creating Job templates using the Job as Code plugin

Use the Job as Code (JAC) plugin to create build job templates by defining build workflows in JSON or YAML configuration files stored in your source code repository.

Before you begin

Note: This topic applies to Build version 7.2.0.4 or above, for lower versions see Creating Job templates using the Job as Code plugin on page 380.

You must have completed the following tasks:

- Install the latest Job as Code plugin from the plugin portal.
- Ensure that a JSON or YAML configuration file, such as `builder.json`, exists in the source code repository.
- Verify that the source code repository is configured and accessible from the DevOps Build environment.

About this task

The Job as Code (JAC) plugin enables you to create and maintain build job templates as configuration files instead of manually configuring build steps through the DevOps Build user interface. By storing workflow definitions alongside source code in Git, JAC provides a single source of truth for build automation.

JAC supports configuration files stored anywhere within a source code repository. During build execution, the plugin retrieves the configuration file from the branch that triggered the build and dynamically generates the workflow defined in the file.

A configuration file can define steps such as:

- Create stamp
- Populate workspace
- Change log
- Shell script
- Status assignment
- Cleanup

Using JAC provides the following benefits:

- **Version control:** Build workflow definitions are stored with the source code and tracked through Git.
- **Self-service configuration:** Developers can modify build pipelines by updating configuration files without requiring administrative access to the CI tool.
- **Branch-specific workflows:** Different branches can use their own JSON or YAML configuration files, allowing build steps to be customized or skipped for specific branches.
- **Consistency:** Build processes are defined once and executed consistently across environments.

1. On the left navigational panel, click **Template > Jobs**.
2. Click **Create**.
3. In the **Create a Job** dialog box, type a name for the job in the **Name** field.
4. From the **Teams** list, select a team to manage the workflow.
5. Click **Save**.
6. Click the **Steps** tab to add steps to the job.

a. Click **Create Step**.
   The **Step Types** tab and a list of available steps displays. Installed plug-ins provide the available steps.

b. Select **Job as Code**.

c. Click **Configure Job as Code**.

d. In the **Name** field, enter a name for the job template.

e. In the **Config File Path** field, specify the relative path to the JSON or YAML configuration file in the repository.
   Example: `ecologic-payments/builder.json`

f. Optional: Specify `${p:triggered_branch}` to automatically retrieve the configuration file from the branch that triggered the build.
   Ensure that the configuration file name and relative path remain the same across branches.

7. Click **Save**.

Results

The job template is created and uses the workflow defined in the specified JSON or YAML configuration file. When a push or pull request triggers a build, the system dynamically generates and executes the configured workflow.

Creating Job templates using the Job as Code plugin

By using the Job as Code plug-in, you can configure a job step as a JSON or YAML file.

Before you begin

Note: This topic applies to Build version 7.2.0.3 or below, for higher versions see Creating Job templates using the Job as Code plugin on page 378.

Ensure that the Job as Code plugin is installed.

1. Select the job to add the step to, and then add a step.
   See Adding, copying, and arranging job steps on page 378 for information about adding a step.
2. In the **Step Type** window, expand **Job as Code** and click **Configure Job as Code**.
3. Enter the properties for the step.
   The following are required properties.

   Name

   The name of the JSON or YAML file.

   Job as Code File Path

   The location of the JSON or YAML file.

4. Click **Save**.

Layout of Job as Code configuration file

Using the Job-as-Code plug-in, you can configure a job step as a JSON or YAML file.

With this approach you are able to track the changes done to the job steps by maintaining the configuration file by version in an SCM repository. The configuration file must be saved on the same workstation that the Build server is installed on.

Layout of the configuration file

The configuration can be file either in JSON or YAML format. The file can contain more or more steps. Nested steps are not supported.

- If using a JSON file, identify the beginning of the steps with `"steps";`. Each step is separated by a comma. The following example, shows the layout of the JSON file.

```
{
  "steps";
  [
   {step 1},
   {step 2},
    ....
   {step n}
  ]
}
```

- If using a YAML file, identify the beginning of the steps with `steps:`. Each step begins with a dash. The following example shows the layout of the YAML file.

```
  steps:
   -step 1
   -step 2
    ....
  - step n
```

Each step contains properties that define the task.

name

The name of the step. This property is required.

stepType

The type of step. This property is required.

description

A description of the file.

workDirOffset

The working directory to use when this command runs. Specify the directory relative to current working directory.

envVars

Environment variables in format: *variable_name=value* pair.

active

Specify to temporarily deactivate the step. The default value is for the step to be active.

runInParallel

Specify to run this step at the same time as other steps marked as parallel. The default value is do not run in parallel.

runInPreflight

Specify to run this process only in preflight processes. The default is to run in preflight processes.

runInPreflightOnly

Specify to run this step only in preflight processes.

preCondition

The pre-condition script which must pass before the step is run.

ignoreFailures

Specify for this step to not affect other steps to run or determine the status of the job. The default value is the step does not affect the job or other steps.

Post-processing script

A script for determining when commands of this step should count as fail or succeed.

timeout

The number of minutes after the step starts, before it is marked as timed out and aborted. The default value is 0 meaning the step does not timeout.

properties

A list of properties that are based on the configured step type. Specify the properties as a property name value pair.

The following example shows the JSON file layout with properties:

```
[
{
  "name":"step_name",
  "stepType":"step_type",
  "description":null,
  "workDirOffset":"",
  "envVars":"",
  "active":"true",
  "runInParallel": false,
  "runInPreflight":true,
  "runInPreflightOnly":false,
  "preCondition":"",
  "ignoreFailures":"false",
```

```
  "postProcessScript":"",
  "timeout":"0",
  "properties":
  [
    {"key":"", "value":""}
```

The following example shows the YAML file with properties:

```
steps:
  -name: step_name
  stepType: step_type
  description: null
  workDirOffset: ""
  envVars: null
  active: true
  runInParallel: false
  runInPreflight: true
  runInPreflightOnly: false
  preCondition: null
  ignoreFailures:false
  postProcessScript:null
  timeout":0
  properties:
    -key: ""
     value: ""
```

Disabling and deleting job steps

You can remove a step from a job process by either disabling or deleting the step.

1. On the left navigational panel, click **Template > Jobs**.
2. Click the job to work with.
3. Click **Steps.**
4. To the right of the step to remove, complete one of these actions.
   Choose from:
   - Click the disable icon ( ). The job step is removed only from the process. To add it back click the Active icon ( ) .
   - Click the delete icon ( ) to delete the job step.

Managing Templates

Project templates are reusable plans that map build processes.

A template defines a generic configuration by defining properties that are given values by the objects created from them. For instance, a template might always invoke a particular type of build script but the name or location of the script can vary by project.

Creating project templates

When you create project template, you identify the agent pool that it uses, and configure pre-processing options. You can add project-level properties to a project.

1. On the left navigational panel, click **Templates > Create**.
2. Using the **Create a Project Template** dialog, type a name for the template in the **Name** field.
3. Select a team to manage the template from the **Team** list.
   Until you create your own teams, the System Team is available. For information about creating teams, see Security teams on page 320
4. Click **Save**.
   Result
   The **Build Pre-Processing** tab is displayed. To complete the template, you must define the required fields on this page.
5. Type a number of seconds to wait between builds in the **Time Period** field.

   The quiet period determines the amount of time that must pass after changes are made to the source before another build can begin. The value represents seconds.
6. Type a number of seconds to wait between merge triggers in the **Merge Period** field.
   The merge period is the amount of time to wait after a file is added to the source repository before another build can begin. The value represents seconds.
7. Specify criteria that are used to search for source and dependency changes.

   To use a label, type a property or a property value. To specify a property, use the property syntax, such as `${p:my.property}`. To specify a property value, type the value, such as `my property value`.

   To use a stamp, enter the stamp value or a pattern. Patterns can contain '?' for a single character, and '*' any sequence of characters. For example, `1.?` matches 1.2 but not 1.2.0; `1.*` matches both 1.2 and 1.2.0.

   Use the plus icon to enter additional values. Use the drag-and-drop icon to reorder values. If multiple values are specified, they are searched in order, top to bottom.
8. Specify an agent pool:

   a. To pick a specific pool, click **Agent Pool Selection**, then select the pool from the list.
      The job runs on the first available agent in the selected pool.

   b. To select the pool by property, click **Agent Pool Property**, then type the property, such as `${p:my.property}`.
9. To clean the working directory before processing begins, select **Yes** for the **Should Cleanup** option; otherwise, select **No**.
10. To use a precondition script for steps using this template, select the script from the **Step Pre-Condition Script** list.
    For information about step precondition scripts, see Creating step-precondition scripts on page 310
11. Click **Save**.

What to do next

After creating the project template, use the **Properties** tab to define template properties. For information, see Creating project template properties on page 386.

Configuring project template build pre-processing properties

The build pre-processing options define agent pools, and repository triggers among other things.

1. On the left navigational panel, click **Templates**, then click a project template.
2. Click **Build Pre-Processing**.
3. Click the Edit icon .
4. Type a number of seconds to wait between builds in the **Time Period** field.

   The quiet period determines the amount of time that must pass after changes are made to the source before another build can begin. The value represents seconds.
5. Type a number of seconds to wait between merge triggers in the **Merge Period** field.
   The merge period is the amount of time to wait after a file is added to the source repository before another build can begin. The value represents seconds.
6. Specify criteria that are used to search for source and dependency changes.

   To use a label, type a property or a property value. To specify a property, use the property syntax, such as `${p:my.property}`. To specify a property value, type the value, such as `my property value`.

   To use a stamp, enter the stamp value or a pattern. Patterns can contain '?' for a single character, and '*' any sequence of characters. For example, `1.?` matches 1.2 but not 1.2.0; `1.*` matches both 1.2 and 1.2.0.

   Use the plus icon to enter additional values. Use the drag-and-drop icon to reorder values. If multiple values are specified, they are searched in order, top to bottom.
7. Specify an agent pool:

   a. To pick a specific pool, click **Agent Pool Selection**, then select the pool from the list.
      The job runs on the first available agent in the selected pool.

   b. To select the pool by property, click **Agent Pool Property**, then type the property, such as `${p:my.property}`.
8. To clean the working directory before processing begins, select **Yes** for the **Should Cleanup** option; otherwise, select **No**.
9. To use a precondition script for steps using this template, select the script from the **Step Pre-Condition Script** list.
   For information about step precondition scripts, see Creating step-precondition scripts on page 310
10. Click **Save**.

Creating project template properties

Properties can be used to manage variables passed into commands, agent filters, and custom stamping algorithm templates.

About this task

Properties use the syntax `${property:[property_name]}` to pass property values. You can nest properties to create more specific output. Create a nested property by combining multiple properties. For example, if you want to pass the project name using properties: `project_name=project_1.0.0_appA` and the version number is passed in the `$version` property. If the nested property is defined as follows:

```
${p:project_${p:version\}_name}
```

and the value for the version property is 1.0.0, the property first resolves to

```
${p:project_1.0.0_name}
```

which resolves to the value: `project_1.0.0_appA`. There is no limitation on the number of nested properties. Wildcards are not supported. A "\" is required before closing each nested property.

From the **Properties** window, you can edit defined properties using the edit icon ( ) and move their position using the drag and drop icon ( ).

1. From the Build dashboard, click **Templates**, then click a project template.
2. Click the **Properties** tab.
3. Click **Create Property**.
4. In the **Create New Property** window, type a name for the property in the **Name** field.
   The property can be referenced by using the property syntax: `${p:property_name}`.
5. Select a display type from the **Display Type** list.
   The display type determines how the property is presented to users in the user interface. Based on the type you select and the **Values** field value selected, additional configuration fields are displayed. For most types, the **Default Value** field is displayed where you can specify a default value.
   Select one of the following types:
   - **Agent Pool** provides a list of agent pools. If selected, the **Agent Pool** field is displayed, where you can specify a default agent pool.
   - **Checkbox** provides a check box. If the box is checked, the value is true; otherwise, the value is false.
   - **Integration Plug-in** provides a list of integration plug-ins. Select the type of plug-in from the **Plug-in type** field.
   - **Multi-select** provides a list of values from which users can select multiple values.
   - **Select** provides a list of values from which users can select a single value.
   - **Text** provides a text-input field.
   - **Text (secure)** provides a text-input field in which user input is replaced by generic symbols.
   - **Text Area** provides a text-input field in which users can enter a large amount of text.
6. Specify the rules for the selected display type in the **Value** field.
   Depending on the selected display type, some value-related fields might not be displayed.
   Choose from:

- If you want to specify the property rules now during design time, click **Defined** and configure the following fields.
  - If you want users to specify a value for the property, click **Value Required**.
  - Enter all possible values for this property in the **Allowed Values** text area. Put each value on a separate line.
  - Optionally, enter a default value for the property in the **Default Value** field.
- If you want the property values to be generated by a preprocessing script, click **Scripted** and configure the following fields.
  - If you want users to specify a value for the property, click **Value Required**.
  - Enter a BeanShell script that generates property values in the **Allowed Values Script** text area. The script is passed the following implicit variables: `project`, `workflow`, `buildLife`. Put each value on a separate line. The script should return:
    - String value for text, text area, text (secure), and select types.
    - Boolean for the check box type.
    - String array or collection for the multi-select type.
    - The agent pool name for the agent pools type.
    - Null if the field is hidden for all property types.
  - Optionally, enter a BeanShell script that generates a default value in the **Default Value Script** text area.
- If you want the property values to be generated by a job step, click **Job Execution** and configure the following fields.
  - If you want users to specify a value for the property, click **Value Required**.
  - Select an agent pool to run the job from the **Agent Pool** list.
  - Select the job that sets the property value from the **Job** list.

7. Complete the configuration fields based on the type selected.
8. Click **Save**.

Creating source templates

Source templates define the locations of the source materials that are managed by project templates.

Before you begin

Before you create a source templates, create the project template to which you want to attach the source template. Additionally, install the source plug-in that you require if it is not already installed. For information about installing plug-ins, see Installing plug-ins on page 351.

About this task

Source templates define the location of the source material for project templates.

1. On the left navigational panel, click **Templates**, then select the project template to which you want to attach the template.
2. In the **Source** area, click **Create**.
3. Using the **New Source Configuration Template** page, select the source plug-in from the **Source Type** list, then click **Select**.

Initially, the File System source plug-in is available.

Note: The fields that are used to configure a source template can vary depending on the source type selected. The following steps describe configuring a source template with the File System source plug-in. See the documentation for your specific source plug-in.

4. Type a name for the source template in the **Name** field.
5. Select a script from the **Working Directory Script** list.

   The selected script defines the path to the working directory for the source template. Initially, there are two scripts available: **Default Workflow Directory**, and **Unique Job Directory**. The Default Workflow Directory script uses the default directory of the agent that does the work, which is `{agent}/var/work/project/{project}/{workflow}`. The Unique Job Directory script uses a separate directory for each job: `{agent}/var/work/job/{job_id}`.
6. Optional. Create your own working directory script:

   a. Click **New Script**, then select the pool from the list.
      The job runs on the first available agent in the selected pool.

   b. Type a name for the script in the **Name**, then type the property, such as `${variable}.`

   c. Enter the script in the **Script** area.
      The script can include variables that use the property syntax: `${variable}`, and BeanShell scriptlets `${bsh:...}`.

   d. Click **Save**.
      User-created scripts become available the next time the list is accessed.
7. To use an offset from the directory that is specified by the working directory script, enter it in the **Directory Offset** field.
   To specify the current working directory, use the period character '.'.
8. Optional. Specify a filter to limit the source files that are used in the **File Filters** area. To use a precondition script for steps that use this template, select the script from the **Step Pre-Condition Script** list.
   Put each filter condition on a separate line. To include specific files, start the line with the plus character '+'. To exclude files, start the line with the minus character '-'. You can use the following wildcards in the files names: *, **, ?.
9. Click **Save**.

What to do next

To add properties to the template, see Creating project template properties on page 386.

Creating build process templates

Build process templates provide properties, resources, and artifact sets to processes managed by the parent project.

Before you begin

Before you create a build process templates, create a job that you want to attach to the template. For information about creating jobs, see Creating jobs on page 376. If you want to configure resources for the template, create them before you start to work on the template. See, Creating lockable resources on page 330. If you want to configure artifact sets for the template, create them before you start to work on the template. See, Creating artifact sets on page 327.

1. On the left navigational panel, click **Templates > Process**.
2. Click **Create**.
3. Using the **New Process Template** dialog, type a name for the source template in the **Name** field.
4. Select **Build Process** from the **Type** list.
5. Select **Team** from the drop-down list.
6. Click **Save**.
   After you save the template, you can add properties, artifacts, and resources to it.
7. Define a process for the template. on page 390
8. Add a resource to the template.
   Resources can be added during design time, or added dynamically by a script. Resources are created on the **Lockable Resources** page. For more information, see, Creating lockable resources on page 330.

   a. Using the page for the process template, click **Add Resource**.

   b. Using the **Add Resource to Lock** dialog, determine whether you want to add the resource now, at design time, or add the resource at run time with a script.
      To add a resource at design time, select it from the **Explicit Resource** list. Otherwise, enter a BeanShell script in the **Scripted resource** area. The script must return the name of the resource, or a LockableResource object. To use a property, you use this syntax `return PropertyLookup.get("property_name")`. If the property returns null or an empty string, no lock is used during the build. If the name resource does not exist, it is created.

   c. To obtain an exclusive lock on the resource, select **Yes** for the **Exclusive** option.

   d. Click **Save**.

9. Optional. Add a property to the template.
   For information about creating properties, see Creating project template properties on page 386.
10. Optional. Configure artifact sets.
    Artifact sets are created with the **Artifact Sets** page. See, Creating artifact sets on page 327.

    a. Using the page for the process template, click **Artifacts**, then click **Add Artifact Config**.

    b. Using the **Artifact Configurations** pane, select an artifact set from the **Artifact Set** list.

    c. Specify the base directory in the **Base Directory** field.
       The directory is relative to the working directory when the Publish Artifacts step runs. To use the working directory, enter the period character '.'. You can use process and project properties to define the location, such as `${property: value}`.

    d. Specify the artifacts to retrieve in the **Include Artifacts** area.

You can use the * and ** wildcards to define the pattern. The ** wildcard indicates every directory; the* wildcard indicates every file. For example, the pattern `dist/**/*` retrieve every folder and file beneath the `dist`directory. You can also use process and project properties to define the pattern.

e. To exclude artifacts that would otherwise be included, specify them in the **Exclude Artifacts** area.
You can use process and project properties to define the pattern.

f. Click **Save**.

11. Click **Save**.

Creating process definitions

Process definitions define the jobs and steps in a build processes.

Before you begin

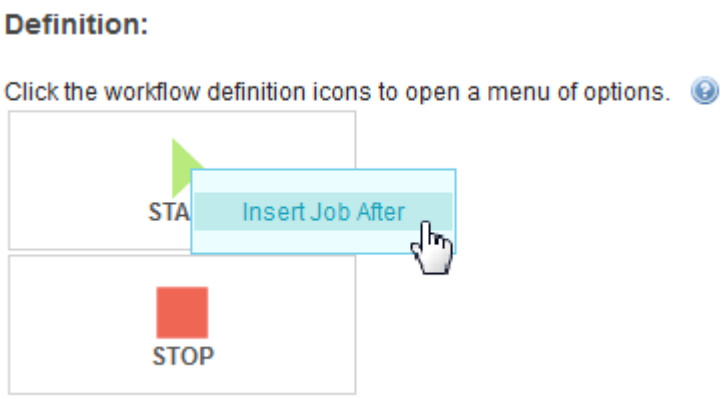
Process definitions are attached to process templates, so before you can define a process, you must create a process template.

About this task

You define processes by inserting jobs into the process and configuring properties that are related to the jobs. Steps are collected into jobs that are composed into processes. When you place a job in a process, you choose options such as the agent pool to run it, and the working directory, among other settings.

1. On the left navigational panel, click **Templates > Process**.
2. In the Process Templates page, select a process template, and then click **Definition**.
3. Using the **Definition** page's design area, define the process by completing these steps:

a. Click the **Start** icon in the **Definition** area, and select **Insert Job After**.
When you click a definition icon, a menu of related actions is displayed. If you click **Stop**, for example, the **Insert Job Before** action is available.



The following table describes all definition menu actions.

Table 20. Workflow action menu

Action	Description
Edit Configuration	Change the precondition script, agent filter, or working directory script on the job.
Edit Job Steps	Edit the individual job steps.
Insert Job After	Insert a job into the process. The selected job is the inserted job's parent and all of the selected job's children become the inserted job's children.
Insert Job Before	Insert a job into the process. The selected job is the child of the inserted job and the selected job's parents are the parents of the inserted job.
Add Parallel Job	Add a job to run in parallel to the selected job.
Iterate Job	Iterate the job a specified number of times.
Iteration Properties	Edit the properties specific to each job iteration.
Delete	Remove the job from the process definition.

4. Complete the following steps to define the properties that are related to the inserted job.

    a. Select the job that you want to insert into the process from the **Jobs** list.

    b. Select the job precondition from the **Pre-Condition** list.
    The job pre-condition script determines whether the job runs. For information about the job pre-condition scripts, see Creating step-precondition scripts on page 310. The precondition script runs before the agent filter runs.

    c. Use the **Agent Selection** options to specify an agent pool. To pick a specific pool, click **Agent Pool Selection** and select the pool from the list. The job runs on the first available agent in the selected pool. To select the pool by agent pool property, click **Agent Pool Property** and type the property, such as `${p:my.property}`. . If you do not want to use an agent or working directory for the job, select **No Agent**. This option requires that the job runs steps on the server, such as stamping or server-side scripts.

    d. Select a script from the **Working Directory** list.
    The selected script defines the path to the working directory for the job. The **Default Workflow Directory** script uses the agent's default directory, which is `{agent}/var/work/project/{project}/{workflow}`. The **Unique Job Directory** script uses a separate directory for each job: `{agent}/var/work/job/{job_id}`. The **Source Config's Working Directory** script uses the directory that is defined for the source configuration.

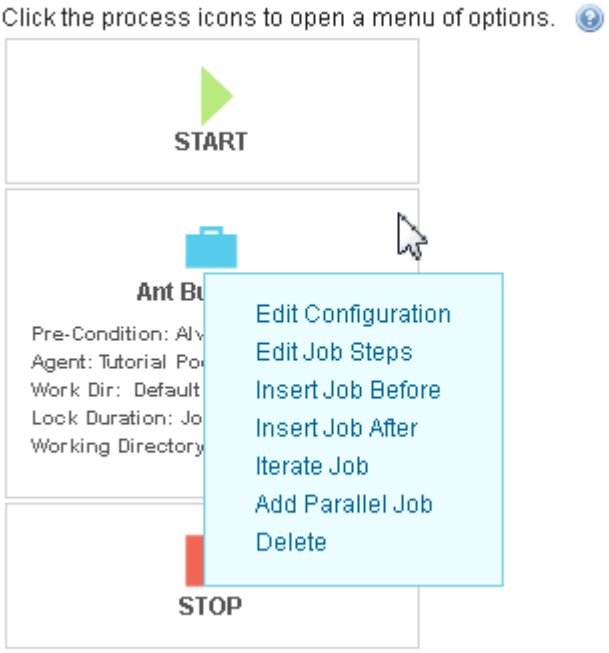
    e. Specify when you want the working directory cleaned by selecting an option from the **Working Directory Cleanup** list.

f. **Lock for Workflow**
Agents and their working directories are always locked when they process jobs. The **No** option locks the agent and working directory only during the current job. The **Yes** option locks the agent and working directory for the entire workflow and prevents other workflows from using the working directory.

5. Click **Save**.

Results

The job is inserted into the process, as shown in the following figure:



What to do next

Add more jobs to the process. Jobs can be inserted before or after other jobs. A process can have any number of jobs.

Creating secondary process templates

Secondary processes are processes that are run after a successful build, and build artifacts are generated and stored.

Before you begin

Before you create a secondary process template, create the project template to which you want to attach it. Create the workflow that you want to assign to the template. See, Creating process definitions on page 390. If you want to configure resources for the template, create them before you start to work on the template. See, Creating lockable resources on page 330.

About this task

Secondary processes inherit most of their configuration properties from the build workflow. After a secondary process is complete, the data is presented on the dashboard, under the same build life number as the parent build. Typically, secondary processes are used for testing.

1. On the left navigational panel, click **Templates > Process**.
2. Click **Create**.
3. Using the **New Process Template** dialog, type a name for the source template in the **Name** field.
4. Select **Secondary Process** from the **Type** list.
5. Select the **Team** from the drop-down list, and click **Save**.
6. Define a process for the template. on page 390
7. Add a resource to the template.
   Resources can be added during design time, or added dynamically by a script. Resources are created on the **Lockable Resources** page. For more information, see, Creating lockable resources on page 330.

   a. Using the page for the process template, click **Add Resource**.

   b. Using the **Add Resource to Lock** dialog, determine whether you want to add the resource now, at design time, or add the resource at run time with a script.
   To add a resource at design time, select it from the **Explicit Resource** list. Otherwise, enter a BeanShell script in the **Scripted resource** area. The script must return the name of the resource, or a LockableResource object. To use a property, you use this syntax `return PropertyLookup.get("property_name")`. If the property returns null or an empty string, no lock is used during the build. If the name resource does not exist, it is created.

   c. To obtain an exclusive lock on the resource, select **Yes** for the **Exclusive** option.

   d. Click **Save**.

8. Add properties to the template. See, Creating project template properties on page 386.
9. Click **Done**.

Monitoring and Reporting

With the monitoring tools you can review current and historical activity and save your filter conditions for future use. You can create charts and reports from most database tables.

Monitoring current activity

You can monitor current processes, agent activity, resource usage, builds, and schedules.

1. On the left navigational panel, click **Current Activity**.
   Result
   The Activity tab displays information about currently running processes, and processes queued to start.
2. If you want to filter the displayed information with a previously saved filter, select the filter from the **Saved Filters** area, then click **Filter**.
3. If you want to create a new search filter, complete the following steps.

a. **Optional:** Type a name for the filter in the **Current Filter** field.

b. **Optional:** Select an option from the **Group By** list, then use the set in current filter icon to add the grouping to the search filter.
Result
The group by option is added to the current filter. The **Context** option refers to related builds. A related build might be a build triggered by a dependency with another build. The **Project** option displays results by project. The **Stamp** displays results by build life stamp.

c. **Optional:** Select an option from the **Filter By** list.

d. **Optional:** Type the search criteria in the field below the **Filter By** list, and use the set in current filter icon associated with the **Filter By** list to add the criteria to the filter.
Result
The criteria is added to the current filter.

e. Click **Filter**.
Result
The results are displayed.

f. **Optional:** To save the filter for future use, click **Save**.
Result
The saved filter is displayed in the **Saved Filters** area.

4. **Optional:** To review current agent activity, click **Agents**.
Result
The **Agents** page displays activity for configured agents, and current directory locks. For information about agents, see Configuring agents on page 342.
5. **Optional:** To review the status of lockable resources, click **Lockable Resources**.
Result
The **Lockable Resources** page displays information about lockable resources and the projects that are using them. For information about lockable resources, see Creating lockable resources on page 330.
6. **Optional:** To review information about defined schedules, click **Schedules**.
Result
The **Schedules** page displays schedules and their next scheduled activities. For information about schedules, see Creating schedules on page 332.

What to do next

You can also monitor builds by using the **Information Radiator** dashboard. For information about the **Information Radiator** dashboard, see Information Radiator dashboard on page 395

Information Radiator dashboard

The **Information Radiator** dashboard provides real-time information about project builds.

The build processes are color-coded by build status, so that you can see at a glance the status of a build. When a build process runs, the status color changes to indicate the build's progress.

Each build process has a separate entry in the dashboard. If a project has several processes that are defined for it, each one has an entry. Build information is updated approximately every 5 seconds. The dashboard displays the following information for each build process:

- Project name and build process.
- Build time. The time is an average of previous builds. If the build process is running, the current build time is also displayed.
- A link to the **Main** tab for the build process.
- A link to the last or current build ID or stamp.
- A link that you can use to claim failed or aborted builds.
- The name of the failed build step for failed builds.
- A list of users who contributed source changes to a failed build.
- The name of the currently running build step for running builds.

The background color of a build entry indicates the build's final status. The dashboard uses the following color coding for build processes:

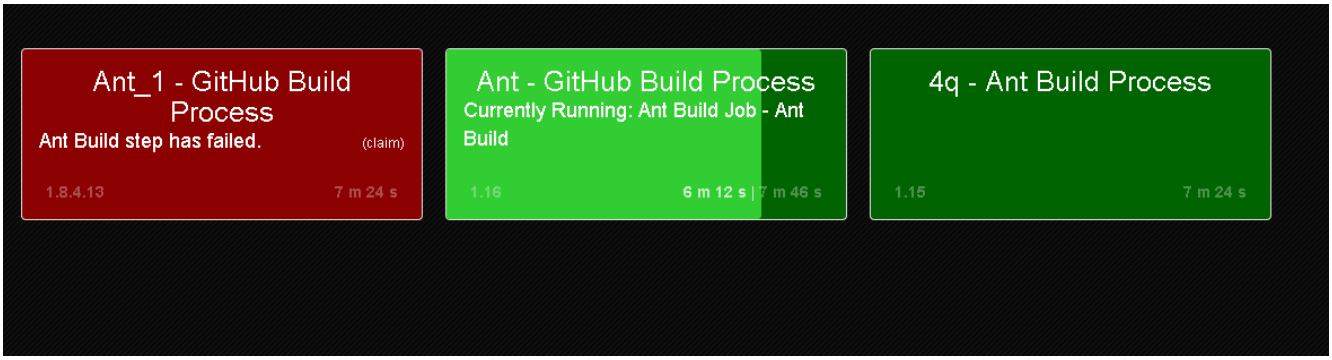
- Succeeded: dark green
- Failed: dark red
- Aborted: dark gray

You can customize the information that is displayed on the dashboard, and filter the information too. For information about customizing the **Information Radiator** dashboard, see Monitoring builds with the Information Radiator dashboard on page 396

Real-time build information

The background color of a build process changes when a build runs. The lighter-colored progress bar indicates the build's progress. Progress is calculated by comparing the current build time to the average time of previous builds. The name of the build's currently running job step is also displayed.

In the following figure, the Ant build process for the project that is named 4q succeeded, which is shown by the dark-green color of the entry, `4q - Ant Build Process`. You can see that the GitHub build process for the Ant project, `Ant - GitHub Build Process`, is running. The build's progress is shown by the lighter-colored progress bar. The name of the currently running step, `Ant Build Job - Ant Build`, is also displayed. The `Ant_1 - GitHub Build Process` build process failed, which is indicated by the dark-red color of the entry. The **claim** link is available for the failed build. If source changes were committed, the users who committed changes to the failed build are also listed. For information about claiming builds, see Monitoring builds with the Information Radiator dashboard on page 396.

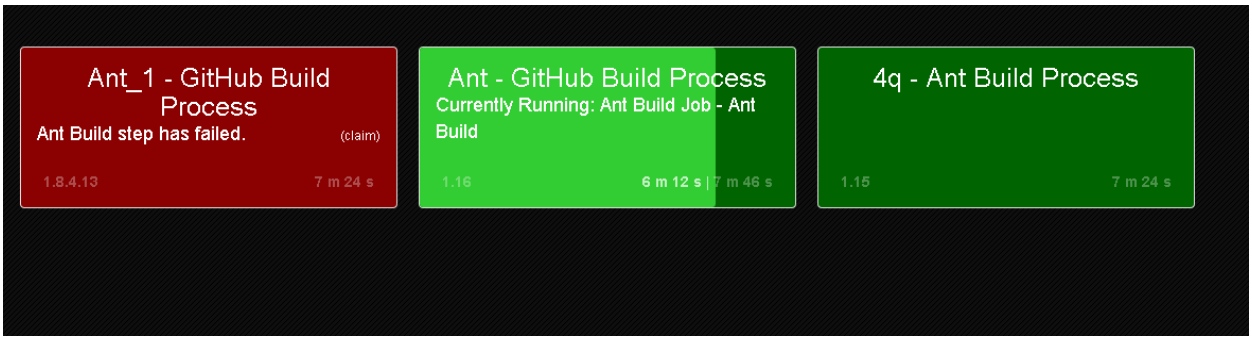


Monitoring builds with the Information Radiator dashboard

Use the **Information Radiator** dashboard to monitor builds.

About this task

You use the **Information Radiator** dashboard to monitor builds and claim failed builds. Anyone can access the dashboard. The build processes for which you have project permissions are available. Initially, each build process that ran at least once is displayed. You can filter the information and customize how the information is displayed. After customizing the dashboard, bookmark it to save your settings.

1. On the left navigational panel, click **Help >** **> Information Radiator**.
   Result
   The **Information Radiator** dashboard is displayed, as shown in the following figure.
   


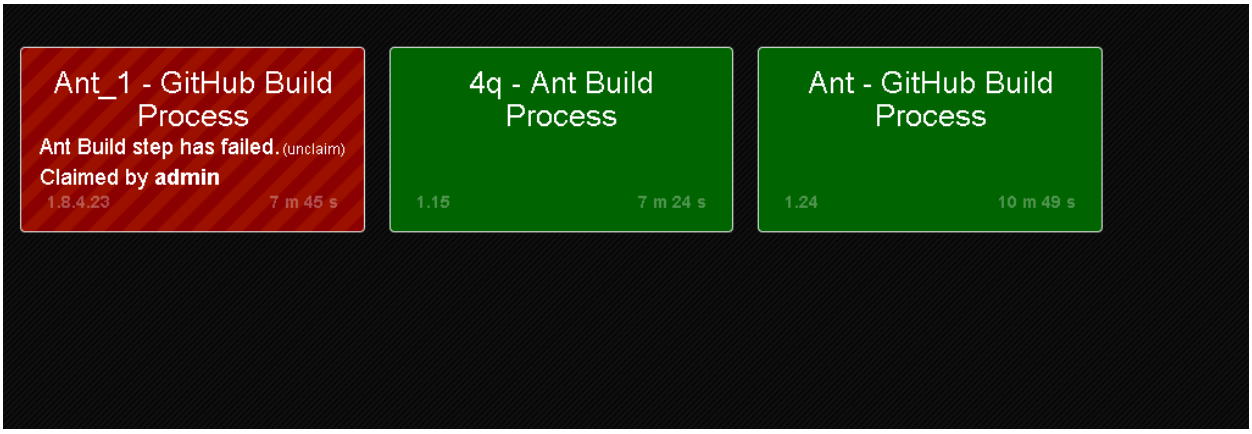
2. **Optional:** Click the name of a build process to display the **Main** tab for the process.
   The **Main** tab for a process provides historical information about the process, and you can use it to run the process.
3. **Optional:** Click the build ID or stamp to display the **Main** tab for the build life.
   The **Main** tab for a build life provides information about the build, and logs that you can use to troubleshoot the build.
4. **Optional:** To claim a failed or canceled build, complete these steps.
   a. Click **claim** for the failed or canceled build process.
   b. In the **Claim** dialog box, in the **User** field, enter the user ID of the user who is claiming the build process. By default, your user ID is entered.

c. In the **Reason** text box, enter your reason for claiming the build process.

d. Click **Done**.

Result

The background color of a claimed process becomes stripped when someone claims a build, as shown in the following figure. If a reason is entered, it is displayed as the entry in the dashboard. The user ID of the user who claimed the process is also displayed.



Note: Claim information is reset when the server is restarted.

5. **Optional:** Click **unclaim** to relinquish a claimed build.
   Any user can relinquish a build, not just the user who claimed it.
6. **Optional:** To customize the size of the build entries, complete thse steps.

   a. **Optional:** On the **Information Radiator** dashboard, click the **Settings** tool, .
   Result
   The **Settings** dialog box is displayed. The **Information Radiator** dashboard is divided into 12 columns. By default, all build entries are the same size, 4. The size refers to the number of entries per row. A setting of 4 means that each row displays 4 entries of 3 columns each (12/4=3). You can emphasize various build statuses by changing the size of build entries with that status.

   b. **Optional:** To change the size of build entries that have the failure status, in the **Failure Size Selector** list, select a column size.
   Build entriess with the failure status are adjusted to the selected column width.

   c. **Optional:** To change the size of entries for builds that are running, in the **Running Size Selector** list, select a column size.
   Entires for builds that are running are adjusted to the selected column width.

d. **Optional:** To change the size of build entries with the status of success, in the **Success Size Selector** list, select a column size.
Builds with the status of success are adjusted to the selected column width.

e. **Optional:** To change the size of builds with the status of aborted, in the **Aborted Size Selector** list, select a column size.
Entries for builds with the status of aborted are adjusted to the selected column width.

7. **Optional:** Click **Show Time Since Build** to display the amount of time that transpired since the last time the build ran.
8. **Optional:** To add or remove processes that are displayed on the dashboard, complete these steps.

a. Click **Add/Remove Processes**.
Result
The **Add/Remove Processes** dialog box is displayed. This dialog box displays all processes for which you have project permissions. By default, all processes are displayed.

b. Click **Select All** or **Select None** to display all processes.

c. Click a process or several processes to see only those processes.
Result
If some processes are selected, only those processes are displayed.

d. **Optional:** Click **Done**.

9. Click **Done**.
10. **Optional:** Bookmark the dashboard to save your settings.
Settings are saved in the URL. After you bookmark the dashboard, you can share your settings by sharing the URL.

Reporting

You can create reports about system activity, build lives, job execution, projects and their immediate dependencies, and several others. You can customize reports and save the results.

1. On the left navigational panel, click **Reporting**.
Result
The **Reporting** page provides tools to create and run reports.
2. Click **New Report**.
3. Type a name for the report in the **Name** field.
4. Select a table to add to the report from the **Tables** list, then click Select. **Select**.
Result
The table is added to the report and several options to customize the report are available.
5. **Optional:** Modify or add report columns by completing the following steps.

a. Click **Columns**.
Result

The columns for the selected table are displayed.

b. To rearrange column order, click a column and drag into the new location.

c. To rename a column, type the name in the **Alias** field that is associated with the column.

d. To remove a column from the report, use the delete icon associated with the column.

e. **Optional:** To add a function to a column, select the function from the **Function** list that is associated with the column.
The filter types are Boolean operators.

f. **Optional:** To add a compound column to the report, click **Add Compound Column** then type a name for the column in the **Included Columns** field.
All columns are included in the compound column. To remove a column, click the delete icon that is associated with the column.

g. Click **Apply**.

6. **Optional:** Filter the report by completing the following steps.

a. Click **Filter**.
Result
The columns for the selected table are available to be filtered.

b. Type a name for the report in the **Name** field.

c. Select a column to filter from the **Column** list.
The available columns depend on the selected table.

d. **Optional:** Select a type **Filter Type** list.
The filter types are Boolean operators.

e. **Optional:** Select a value from the **Value** options, then type or select a specific value.
Result
Selectable values depend on the table you choose.

f. Click **Apply**.

Result

The filter is added to the report. To delete a filter, click the remove icon . To modify a filter, click the edit icon .

7. **Optional:** Reorder report columns by completing the following steps.

a. Click **Order**.
Result
The columns for the selected table are available to be reordered.

b. Click **Add Ordering**.

c. Select the order key column from the **Column** list.
Result
The report is ordered by the selected column

d. **Optional:** Select an order direction from the **Order** list.
Columns can be in **Ascending** or **Descending** order.

e. **Optional:** Select a secondary order key from the **Column** list.

f. Click **Apply**.

8. **Optional:** Reorder report columns by completing the following steps.

a. Click **Order**.
Result
The columns for the selected table are available to be reordered.

b. Click **Add Ordering**.

c. Select the order key column from the **Column** list.
Result
The report is ordered by the selected column

d. **Optional:** Select an order direction from the **Order** list.
Columns can be in **Ascending** or **Descending** order.

e. **Optional:** Select a secondary order key from the **Column** list.

f. Click **Apply**.

9. **Optional:** If you want to represent the report's output in a chart, complete the following steps.

a. Click **Output**.
Result
Several chart types are available.

b. Define the chart's x-axis:
   i. Type the name for the x-axis in the **Name** field.
   ii. Select a column key from the **Value** list.
   iii. Select a column from the **Category** list. The default option is **None**.

c. Define the chart's y-axis:

i. Type the name for the y-axis in the **Name** field.
ii. Select a column key from the **Value** list.

d. Click **Apply**.

10. **Optional:** Modify the script that generates the report by completing the following steps.

a. Click **Text**.
Result
The JSON script that is generated by your selections is displayed. This script actually runs the report. You can directly modify the script.

b. Edit the JSON script.

11. Click **Run**.
Result
The report is displayed in the **Report** window. Report data is displayed in columns and rows unless you selected a chart-type output option.

What to do next

To save the generated report as a comma-separated values (CSV) file, use the download as CSV icon

.

Extending Product Functions

You can create your own plug-ins to extend the product's capabilities.

Plug-ins

Build plug-ins provide tools for creating workflows and integrating with external tools.

Plug-ins provide processing and integration functions. There are two types of plug-ins:

- *Source-type* plug-ins integrate with SCM systems.
- *Automation-type* plug-ins integrate with external systems and provide job steps.

Both types of plug-ins consist of distinct processes called *steps*. Each step consists of a number of properties, a command that runs the step, and post processing instructions. (Post processing typically ensures that expected results occur.) Step properties supply values to the plug-in step. Automation-type plug-in properties can be set at design time or at run time in the user interface. Source-type plug-in properties are typically defined when a component is created.

Automation-type plug-ins

You use automation plug-ins to run build job steps or otherwise manage builds. Each step is a self-contained unit with inputs, outputs, and properties. By combining automation plug-in steps, you can create fully automated build processes. When you create a job, you insert steps onto the design area and define the properties as you go. Property values can be specified when you define the process or at run time.

For information about creating jobs, see Creating jobs on page 376.

At build time, processes are run by agents that are installed in the target environment. For a process to run, the agent must have access to all resources, tools, and files that are required by the plug-in steps in the process. When you install an agent, ensure that these conditions are met:

- The agent that runs the build process has the necessary user permissions to run commands and can access required resources. Assigning these permissions typically entails granting permissions if an external tool is installed as a different user; installing the agent as a service; or impersonating the appropriate user.
- External tools that plug-in steps require are installed in the target environment.
- The required minimum version of an external tool is installed.

Source-type plug-ins

You use source plug-ins to import build artifacts and create builds. A source plug-in defines the type of artifacts that can be imported and identifies where the artifacts are located. Source-type plug-ins are configured when source items are created, you do not use the process editor to configure source-type plug-ins.

Source artifacts are imported by agents that are running in the environment where the artifacts are located. For source material to be created, the agent must have the required permissions and access to all required resources and files.

Viewing and obtaining plug-ins

A number of plug-ins come with the product and many others are available that can be downloaded and installed. For information about installing plug-ins, see Installing plug-ins on page 351.

View plug-ins that are installed by using the user interface. To view plug-ins, click **System > Plug-ins**. The plug-in type is displayed in the Type column.

Plug-ins can be developed and updated more frequently than Build provides release cycles.

Browse, download, and get documentation for plug-ins at the Build plug-ins website. The site contains many more plug-ins than are packaged with the Build product.

The site includes plug-ins that are developed by these sources:

IBM® Corporation

Your Build license entitles you to download and install the plug-ins that are developed by IBM® Corporation.

Support is provided through the developerWorks® community and through IBM® technical support.

Partners

Plug-ins that are provided by partners can be purchased from the partner website.

Support for each partner plug-in is provided exclusively by the partner who provided the plug-in.

Community

Plug-ins are provided by members of the Build community on Build plug-ins websiteBuild plug-ins website. Search with name of the plug-in to find plug-ins. You can contribute to code in the community or use code posted there to incorporate into your own.

Support is provided exclusively through the community.

For information about creating plug-ins, see Creating plug-ins on page 404.

Installing plug-ins

You install plug-ins by downloading the installation files and loading them into Build.

About this task

Plug-ins can be installed at any time. You do not have to restart the server after you install a plug-in. You can upgrade a plug-in by installing the new version over the old version.

1. Download the installation files for one or more plug-ins from Buildprovides plug-ins website.

   Documentation for plug-ins and the steps in the plug-ins is available on that site.

2. Load the plug-ins:
   a. On the left navigational panel, click **System > Plug-ins**.

   a. On the **Plug-ins** page, click **Browse** and select the downloaded plug-in file.
   You do not have to extract the compressed file.

   b. Click **Load**.

   c. Click **Done**.

Results

The plug-in is listed in **Loaded Plug-ins** list. After the plug-in is installed, it is available immediately.

Plug-ins at run time

Agents that are installed in the target environment run build processes. For a process to run, the agent must have access to all resources, tools, and files that are required by the plug-in steps that the process uses. When you install an agent, ensure that these conditions are met:

- The agent that runs the process has the required user permissions to run commands and access required resources. This permission status typically entails these actions:
  - Granting permissions if an external tool is installed as a different user
  - Installing the agent as a service
  - Impersonating the appropriate user

- External tools that plug-in steps require are installed in the target environment.
- The required minimum versions of external tools are installed.

Creating plug-ins

A plug-in consists of XML files and supporting script files that the plug-in requires.

- The `plugin.xml` file defines the steps that the plug-in consists of. A plug-in's steps define its functionality. Each step is an independently configurable entity in the Build editor.
- The `upgrade.xml` file is used to upgrade the plug-in to a new version.
- The `info.xml` file contains a version ID and other information that describes the plug-in.

Note: The plug-in files must use UTF-8 encoding.

A plug-in step is defined by a `<step-type>` element that contains these elements:

- One `<properties>` element.
- One `<command>` element.
- One `<post-processing>` element

The `<properties>` element is a container for `<property>` child elements, and can contain any number of `<property>` elements. You can specify property values design time or run time. The `<post-processing>` element provides error-handling capabilities and sets property values that can be used by other steps. The `<command>` element runs the step's function. The function can be defined completely by the element, or be constructed in part or entirely from the step's properties at design time or run time.

In addition to a step's own properties, a command has access to properties set earlier by other steps within the process.

Plug-in steps are run by an agent that is installed in the target environment. Thus, plug-ins can be written in any scripting language while the agent can access the required scripting tools on the host. After a plug-in is created, upload it into Build to make it available to users. To upload a plug-in, create an archive file that contains the XML files (`plugin.xml` and `upgrade.xml`) and scripts that the plug-in requires. Then, import the archive file with the **Plug-ins** page.

The `plugin.xml` file for automation plug-ins

An automation plug-in is defined with the `plugin.xml` file.

The structure of this file consists of a `header` element and one or more `step-type` elements. The `header` element identifies the plug-in. Each `step-type` element defines a step. Steps are available to users in the Build process editor and are used to construct component processes.

After the document-type declaration, the `plugin` root element identifies the XML schema type, `PluginXMLSchema_v1.xsd`, which all plug-ins use. The following code fragment presents the basic structure of the `plugin.xml` file for automation plug-ins:

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin xmlns="http://www.urbancode.com/PluginXMLSchema_v1"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <header>
    <identifier id="com.urbancode.air.plugin.Shell" version="4" name="Shell"/>
    <description>The Shell plugin allows users to run custom shell scripts during the deployment
 process.</description>
    <tag>Scripting/Shell</tag>
    <server:plugin-type>Automation</server:plugin-type>
  </header>
  <step-type name="Shell">
    <description>Execute a shell or batch script.</description>
    <properties>
      <property name="shellInterpreter">
        <property-ui type="textBox" label="Interpreter"
                        description="Optionally specify the interpreter to use to evaluate the command.
                        If left blank the following platform-specific behavior will be used:
                        Command Line will use .bat file interpreter on Windows and .com file interpreter on VMS.
 On other
                        systems it will use the shell specified by 'air/shell' agent variable if present. *nix
 systems
                        may override this by having the Command Line starts with a #! sequence."/>
      </property>
      <property name="scriptBody" required="true">
        <property-ui type="textAreaBox" label="Shell Script" description="Enter the script code to execute."/>
      </property>
      <property name="runAsDaemon">
        <property-ui type="checkBox" label="Daemon" description="Check this option to run the command in the
 background while permitting the step to
                complete immediately. The output will not be captured if running as a daemon."/>
      </property>
      <property name="outputFile">
        <property-ui type="textBox" label="Output File" description="Only set this value if Daemon is checked.
 Enter the
              path of the file to which the command output is directed. Leave blank to discard the output. The
 output
              will not be captured if an output file is specified."/>
      </property>
    </properties>
    <post-processing>
      <![CDATA[
        if (properties.get("exitCode") != 0) {
            properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
        }
        else {
            properties.put("Status", "Success");
        }
     ]]>
    </post-processing>

    <command program="${GROOVY_HOME}/bin/groovy">
      <arg value="-cp"/>
      <arg path="lib/shell.jar:lib/CommonsUtil.jar:lib/log4j.jar:lib/NativeProcess.jar:lib/WinAPI.jar"/>
      <arg file="shell.groovy"/>
      <arg file="${PLUGIN_INPUT_PROPS}"/>
      <arg file="${PLUGIN_OUTPUT_PROPS}"/>
    </command>
  </step-type>
```

For information about the structure of the `plugin.xml` file for source plug-ins, see Creating source plug-ins on page 407.

The `header` element

The mandatory `header` element identifies the plug-in and contains three mandatory child elements and one optional child element:

Table 21. Contents of the `header` element

`header` child elements	Description
`<identifier>`	This element's three attributes identify the plug-in: • `version` Specifies the API version (the version number for upgrading plug-ins is defined in the `info.xml` file). • `id` Identifies the plug-in. • `name` Defines the plug-in name that is shown on the **Automation Plugins** pane, and on informational pages for the plug-in. All values must be enclosed in single quotation marks.
`<description>`	Describes the plug-in. This element is shown on the **Automation Plugins** pane, and on informational pages for the plug-in.
`<tag>`	Defines where the plug-in is listed in the process editor's hierarchy of available plug-ins. The location is defined by a string that is separated by slashes. For example, the Tomcat definition is the following string: `Application Server/Java/Tomcat`. The Tomcat steps are listed after the Tomcat item, which in turn is nested under the other two. **Note:** Do not include underscore character (_) in this element.

The following sample shows a header element definition:

```
<header>
  <identifier version="3" id="com.&company;.air.plugin.Tomcat" name="Tomcat"/>
  <description>
  The Tomcat plugin is used during deployments to run Tomcat run-book
  automations and deploy or undeploy Tomcat applications.
  </description>
  <tag>Application Server/Java/Tomcat</tag>
</header>
```

Creating source plug-ins

Source-type plug-ins are defined with `upgrade.xml`, `info.xml`, and `plugin.xml` files.

Like automation plug-ins, source plug-ins are defined with three files: `upgrade.xml`, `info.xml`, and `plugin.xml`. The structure of the first two files is identical for both plug-in types. The structure of the `plugin.xml` file for the two plug-in types is different. Source-type plug-ins contain five SCM-type steps and the `server:plugin-type` property is `Source`.

The following code fragment contains a typical example of a source plug-in `header` element:

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin xmlns="http://www.urbancode.com/PluginXMLSchema_v1"
   xmlns:server="http://www.urbancode.com/PluginServerXMLSchema_v1"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <header>
    <identifier id="com.urbancode.air.plugin.git" name="Git" version="4"/>
    <description>
       The Git Plugin automates cloning a Git repo, tagging source, and publishing source changes to the
 Changes tab of the Build Life.
    </description>
    <tag>SCM/Git</tag>
    <server:plugin-type>Source</server:plugin-type>
  </header>

    <!-- ==================================== -->
    <!--   SCM STEPS                          -->
    <!-- ==================================== -->

    <step-type name="Git Cleanup">
      <description>Perform a cleanup of the Git working directory</description>
      <properties>
        <property name="source">
          <server:property-ui type="sourcePropSheetRef"
                              label="Source Config"
                              hidden="true"/>
        </property>
      </properties>
      <post-processing><![CDATA[
        if (properties.get("exitCode") != 0) {
            properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
        }
        else {
            properties.put("Status", "Success");
        }
     ]]></post-processing>

      <command program="${GROOVY_HOME}/bin/groovy">
        <arg value="-cp"/>
        <arg path="classes"/>
        <arg file="cleanup.groovy"/>
        <arg file="${PLUGIN_INPUT_PROPS}"/>
        <arg file="${PLUGIN_OUTPUT_PROPS}"/>
      </command>

      <server:type>SCM_Cleanup</server:type>
      <server:validation language="javascript">
      </server:validation>
```

```
    </step-type>
```

Cleanup step

The Cleanup step requires the **sourcePropSheetRef** property. The step type must be `SCM_Cleanup`.

The following code fragment contains an example of a source plug-in `SCM_Cleanup` step:

```
<step-type name="Git Cleanup">
  <description>Perform a cleanup of the Git working directory</description>
  <properties>
    <property name="source">
      <server:property-ui type="sourcePropSheetRef"
                          label="Source Config"
                          hidden="true"/>
    </property>
  </properties>
  <post-processing><![CDATA[
    if (properties.get("exitCode") != 0) {
        properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
    }
    else {
        properties.put("Status", "Success");
    }
 ]]></post-processing>

  <command program="${GROOVY_HOME}/bin/groovy">
    <arg value="-cp"/>
    <arg path="classes"/>
    <arg file="cleanup.groovy"/>
    <arg file="${PLUGIN_INPUT_PROPS}"/>
    <arg file="${PLUGIN_OUTPUT_PROPS}"/>
  </command>

  <server:type>SCM_Cleanup</server:type>
  <server:validation language="javascript">
  </server:validation>
</step-type>
```

Checkout/Populate step

The Checkout/Populate step type must be `SCM_Populate`. The Checkout/Populate step has the following properties:

- **sourcePropSheetRef**
- **date**
- **cleanWorkspace**

The following code fragment contains an example of a source plug-in `SCM_Populate` step:

```
<step-type name="Git Checkout">
  <description>Perform a Git checkout of the workflow's source</description>
  <properties>
    <property name="cleanWorkspace">
```

```
      <server:property-ui type="checkBox"
                          label="Clean Workspace"
                          description="Erase all files from the workspace before performing checkout" />
    </property>
    <property name="date">
      <server:property-ui type="textBox"
                          label="Date"
                          description="Date of sourcecode to checkout ('yyyy-MM-dd HH:mm:ss z' OR
                          'E MMM dd HH:mm:ss zzz yyyy' OR milliseconds since Unix Epoch). Defaults to the
 current time." />
    </property>
    <property name="source">
      <server:property-ui type="sourcePropSheetRef"
                          label="Source Config"
                          hidden="true"/>
    </property>
  </properties>
  <post-processing><![CDATA[
    if (properties.get("exitCode") != 0) {
        properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
    }
    else {
        properties.put("Status", "Success");
    }
 ]]></post-processing>

  <command program="${GROOVY_HOME}/bin/groovy">
    <arg value="-cp"/>
    <arg path="classes"/>
    <arg file="checkout.groovy" />
    <arg file="${PLUGIN_INPUT_PROPS}"/>
    <arg file="${PLUGIN_OUTPUT_PROPS}"/>
  </command>

  <server:type>SCM_Populate</server:type>
  <server:validation language="javascript">
  </server:validation>
</step-type>
```

Label step

The Tag/Label step type must be `SCM_Label`. The Tag /Label step has the following properties:

- **sourcePropSheetRef**
- **message**
- **label**

The following code fragment contains an example of a source plug-in `SCM_Label` step:

```
<step-type name="Git Create Tag">
  <description>Create a tag in Git of the specified working copy.</description>
  <properties>
    <property name="message" required="true">
      <server:property-ui type="textBox"
                          label="Message"
```

```
                          description="A message for the commit" />
    </property>
    <property name="label" required="true">
      <server:property-ui type="textBox"
                          label="Tag"
                          description="The tag name to create" />
    </property>
    <property name="source">
      <server:property-ui type="sourcePropSheetRef"
                          label="Source Config"
                          hidden="true"/>
    </property>
  </properties>
  <post-processing><![CDATA[
    if (properties.get("exitCode") != 0) {
        properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
    }
    else {
        properties.put("Status", "Success");
    }
 ]]></post-processing>

  <command program="${GROOVY_HOME}/bin/groovy">
    <arg value="-cp"/>
    <arg path="classes"/>
    <arg file="tag.groovy"/>
    <arg file="${PLUGIN_INPUT_PROPS}"/>
    <arg file="${PLUGIN_OUTPUT_PROPS}"/>
  </command>

  <server:type>SCM_Label</server:type>
  <server:validation language="javascript">
  </server:validation>
</step-type>
```

Changelog step

The Changelog step type must be `SCM_Changelog`. The Changelog step has the following properties:

- **sourcePropSheetRef**
- **changesURL**
- **startBuildLifeId**
- **endDate**
- **startDate**

Use these properties to define the date range used when searching for changes.

The following code fragment contains an example of a source plug-in `SCM_Changelog` step:

```
<step-type name="Git Changelog">
  <description>Perform a Git changelog and publish the results.</description>
  <properties>
    <property name="startBuildlifeId">
      <server:property-ui type="textBox"
```

```
                        label="Start BuildLife Id"
                        description="The ID of the start buildlife. Captures changes since that build
 life." />
    </property>
    <property name="startDate">
      <server:property-ui type="textBox"
                        label="Start Date"
                        description="Start changelog at this date ('yyyy-MM-dd HH:mm:ss z' OR
                        'E MMM dd HH:mm:ss zzz yyyy' OR milliseconds since Unix Epoch)" />
    </property>
    <property name="endDate">
      <server:property-ui type="textBox"
                        label="End Date"
                        description="End changelog at this date ('yyyy-MM-dd HH:mm:ss z' OR
                        'E MMM dd HH:mm:ss zzz yyyy' OR milliseconds since Unix Epoch)" />
    </property>
    <property name="changesUrl">
      <server:property-ui type="textBox"
                        label="Changes URL"
                        hidden="true" />
    </property>
    <property name="source">
      <server:property-ui type="sourcePropSheetRef"
                        label="Source Config"
                        hidden="true"/>
    </property>
  </properties>
  <post-processing><![CDATA[
    if (properties.get("exitCode") != 0) {
        properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
    }
    else {
        properties.put("Status", "Success");
    }
 ]]></post-processing>

  <command program="${GROOVY_HOME}/bin/groovy">
    <arg value="-cp"/>
    <arg path="classes"/>
    <arg file="changelog.groovy"/>
    <arg file="${PLUGIN_INPUT_PROPS}"/>
    <arg file="${PLUGIN_OUTPUT_PROPS}"/>
  </command>

  <server:type>SCM_Changelog</server:type>
  <server:validation language="javascript">
  </server:validation>
</step-type>
```

QuietPeriod step

The QuietPeriod step type must be `SCM_QuietPeriod`. The QuietPeriod step has the following properties:

- **sourcePropSheetRef**
- **endDate**
- **startDate**

The QuietPeriod step typically runs the same command as the Changelog step. It always looks for the date of the latest change in the source repository.

The following code fragment contains an example of a source plug-in `SCM_QuietPeriod` step:

```
<step-type name="Git Quiet Period">
  <description>Perform a Git changelog for quiet period detection and publish most recent change date within
 the period.</description>
  <properties>
    <property name="startDate">
      <server:property-ui type="textBox"
                          label="Start Date"
                          description="Start changelog at this date ('yyyy-MM-dd HH:mm:ss z' OR
                          'E MMM dd HH:mm:ss zzz yyyy' OR milliseconds since Unix Epoch)" />
    </property>
    <property name="endDate">
      <server:property-ui type="textBox"
                          label="End Date"
                          description="End changelog at this date ('yyyy-MM-dd HH:mm:ss z' OR
                          'E MMM dd HH:mm:ss zzz yyyy' OR milliseconds since Unix Epoch)" />
    </property>
    <property name="source">
      <server:property-ui type="sourcePropSheetRef"
                          label="Source Config"
                          hidden="true"/>
    </property>
  </properties>
  <post-processing><![CDATA[
    if (properties.get("exitCode") != 0) {
        properties.put(new java.lang.String("Status"), new java.lang.String("Failure"));
    }
    else {
        properties.put("Status", "Success");
    }
 ]]></post-processing>

  <command program="${GROOVY_HOME}/bin/groovy">
    <arg value="-cp"/>
    <arg path="classes"/>
    <arg file="quietperiod.groovy"/>
    <arg file="${PLUGIN_INPUT_PROPS}"/>
    <arg file="${PLUGIN_OUTPUT_PROPS}"/>
  </command>

  <server:type>SCM_QuietPeriod</server:type>
  <server:validation language="javascript">
  </server:validation>
</step-type>
```

Plug-in steps: The `step-type` element

Plug-in steps are defined with the `step-type` element; each `step-type` represents a single step in the Build process editor.

A `step-type` element has a name attribute and several child elements:

- `description`
- `properties`
- `command`
- `post-processing`

The mandatory name attribute identifies the step. The description and name are shown in the web application and on informational pages for the plug-in..

```
<step-type name="Start">
<description>Start Apache HTTP server</description>
```

Note: A step name cannot contain the forward slash character (/).

Step properties: The `properties` element

The `properties` element is a container for properties, which are defined with the `property` tag.

Each step has a single `properties` element; a `properties` element can contain any number of `property` child elements.

A `property` tag has a mandatory `name` attribute, and an optional `required` attribute. This tag has two child elements: the `property-ui` element and `value` element, which are defined in the following table.

Table 22. The `property` element

`property` child elements	Description
`<server:property-ui>`	Defines how the property is presented to users in the Build editor. This element has several attributes: • `label` Identifies the property in the editor's **Edit Properties** dialog box. • `description` Contains the text that is displayed to users in the associated roll-over help box. • `default-value` Provides the property value that is displayed when the **Edit Properties** dialog box is displayed; used if unchanged.

Table 22. The `property` element (continued)

`property` child elements	Description
	• `type` Identifies the type of widget that is displayed to users. Possible values are as follows: ◦ `textBox` Enables users to enter an arbitrary amount of text, which is limited to 4064 characters. ◦ `textAreaBox` Enables users to enter an arbitrary amount of text in a larger input area than `textBox`. The limit is to 4064 characters. ◦ `secureBox` Accepts passwords. Similar to textBox except values are redacted. ◦ `checkBox` Displays a check box. If selected, a value of `true` is used; otherwise the property is not set. ◦ `selectBox` Requires a list of one or more values, which are displayed in a list. Configuring a value is described later.
`<value>`	Specifies values for a `selectBox` selection. Each value has a mandatory `label` attribute, which is displayed to users, and a value that is used by the property when selected. Values are displayed in the order they are defined.

The following code sample shows a `property` element definition:

```
<property name="onerror" required="true">
  <server:property-ui type="selectBox"
    default-value="abort"
    description="Action to perform when statement fails: continue, stop, abort."
    label="Error Handling"/>
  <value label="Abort">abort</value>
  <value label="Continue">continue</value>
  <value label="Stop">stop</value>
</property>
```

The `command` element

Steps are run by starting the scripting tool or interpreter specified by the `<command>` element. The `program` attribute defines the location of the tool that will perform the command.

It bears repeating that the tool must be located on the host and the agent invoking the tool must have access to it. In the following example, the location of the tool that will perform the command, the Java-based scripting tool *groovy* in this instance, is defined.

```
    <command program='${GROOVY_HOME}/bin/groovy'>
```

The actual command and any parameters it requires are passed to the tool by the `<arg>` child element. Any number of `<arg>` elements can be used. The `<arg>` element has several attributes:

Table 23. `<arg>` Attributes

Attribute	Description
`<value>`	Specifies a parameter passed to the tool. Format is tool-specific; must be enclosed by single-quotes or double-quotes.
`<path>`	Path to files or classes required by the tool. Must be enclosed by single-quotes or double-quotes.
`<file>`	Specifies the path to any files or classes required by the tool. Format is tool-specific; must be enclosed by single-quotes or double-quotes.

Becasue `<arg>` elements are processed in the order they are defined, ensured the order conforms to that expected by the tool.

```
    <command program='${GROOVY_HOME}/bin/groovy'>
      <arg value='-cp' />
      <arg path='classes:${sdkJar}:lib/commons-codec.jar:
                 lib/activation-1.1.1.jar:
                 lib/commons-logging.jar:lib/httpclient-cache.jar:
                 lib/httpclient.jar:lib/httpcore.jar:
                 lib/httpmime.jar:lib/javamail-1.4.1.jar' />
      <arg file='registerInstancesWithLB.groovy' />
      <arg file='${PLUGIN_INPUT_PROPS}' />
      <arg file='${PLUGIN_OUTPUT_PROPS}' />
   </command>
```

The `<arg file='${PLUGIN_INPUT_PROPS}' />` specifies the location of the tool-supplied properties file. The `<arg file='${PLUGIN_OUTPUT_PROPS}' />` specifies the location of the file that will contain the step-generated properties.

Note:

New lines are not supported by the `<arg>` element and are shown in this example only for presentation.

The `post-processing` element

When a plug-in step's `command` element finishes processing, the step's mandatory `post-processing` element runs.

The `post-processing` element sets the step's output properties and provides error handling. The `post-processing` element can contain any valid JavaScript™ script. Unlike the `command` element, `post-processing` scripts must be written in JavaScript™).

You have access to a *java.util.Properties* variable called `properties`. The `properties` variable has several special properties: `exitCode` contains the process exit code, and `Status` contains the step's status. A `Status` value of `Success` means that the step is complete. The Create File step's post-processing examines the command's `exitCode` and then sets the `Status` property accordingly.

Another available variable *scanner* can scan the step's output log and run commands that are based on the results.

You can use a post-processing script to set output properties that can be used in other steps in the same process, which enables complex workflows.

The script that is defined in the `post-processing` element is the step's default behavior. Users can also provide their own script, overriding the default behavior, when they define the step in the Build editor.

Upgrading plug-ins

The `upgrade.xml` file tells the server how to update a step or a property. The server scans every process that has been created on the server and upgrades the steps that you are upgrading.

The `upgrade.xml` file tells the server how to update a step or a property. The server scans every process that has been created on the server and upgrades the steps that you are upgrading.

To upgrade a plug-in, do the following:

1. Increment the number of the `version` attribute of the `<identifier>` element in `plugin.xml`.
2. Create a `<migrate>` element in `upgrade.xml` with a `to-version` attribute that contains the new number.
3. Place the property and step-type elements that match the updated `plugin.xml` file within the `<migrate>` element, as shown in the following example.

Considerations

Use the `<migrate-command>` element to upgrade steps.

- Upgrades to scripts and files for a step do not require changes to the `upgrade.xml` file. However, updating the version number in the `upgrade.xml` file is a good practice. For script changes to take affect, load the plug-in again.
- Keep a step by including a `<migrate-command>` element for each step to remain in the plug-in.

```
<migrate to-version="3">
    <migrate-command name="step_name"/>
</migrate>
```

- Add a new step does not require changes to the `upgrade.xml` file. Again, the version number of the plug-in should be updated.
- Delete a step by not including a `<migrate-command>` element for the steps to be removed from the plug-in.
- Rename a step by coding both the old and new name of the step using the `name` and `old` attributes.

```
<migrate to-version="3">
    <migrate-command name="new_step_name" old="old_step_name"/>
</migrate>
```

Use the `<migrate-properties>` elements to upgrade step properties.

- Delete a step property by using the `<remove-property>` element within the `<remove-properties>` element for the step with the removed property.

```
<migrate to-version="3">
    <migrate-command name="step_name"
        <remove-properties>
          <remove-property name="old_property_name" />
        </remove-properties>
   </migrate-command>
</migrate>
```

- Rename a step property by using the `name` and `old` attributes on the `<migrate-property>` element within the `<migrate-properties>` element for the step with the changed property.

```
<migrate to-version="3">
    <migrate-command name="step_name"
        <migrate-properties>
          <migrate-property name="new_property_name" old="old_property_name />
        </migrate-properties>
   </migrate-command>
</migrate>
```

- Change the default value for a step property by using the `default` attribute on the `<migrate-property>` element.

```
        <migrate-properties>
          <migrate-property name="new_property_name" old="old_property_name default="new_default_value" />
        </migrate-properties>
   </migrate-command>
</migrate>
```

Example

The following example shows how to add a `migrate` element in the upgrade.xml file to specify the command to use in the upgrade.

```
<?xml version="1.0" encoding="UTF-8"?>
<plugin-upgrade
        xmlns="http://www.&company;.com/UpgradeXMLSchema_v1"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <migrate to-version="3">
    <migrate-command name="Run SQLPlus script">
```

```
      <migrate-properties>
        <migrate-property name="sqlFiles" old="sqlFile"/>
      </migrate-properties>
      <remove-properties>
        <remove-property name="jvmProperties"/>
      </remove-properties>
    </migrate-command>
  </migrate>
  <migrate to-version="4">
    <migrate-command name="Run SQLPlus script" />
  </migrate>
  <migrate to-version="5">
    <migrate-command name="Run SQLPlus script" />
  </migrate>
</plugin-upgrade>
```

You can also make a script-only upgrade, which is an upgrade that contains changes to the step's associated scripts and files but does not change the `plugin.xml` file. This mechanism can be useful for plug-in development and for minor bug-fixes or updates.

The `info.xml` file

Use the `info.xml` file to describe the plug-in and provide release notes to users. The file's `<release-version>` element can be used for version releases.

This file is required for each plug-in.

Example plug-in

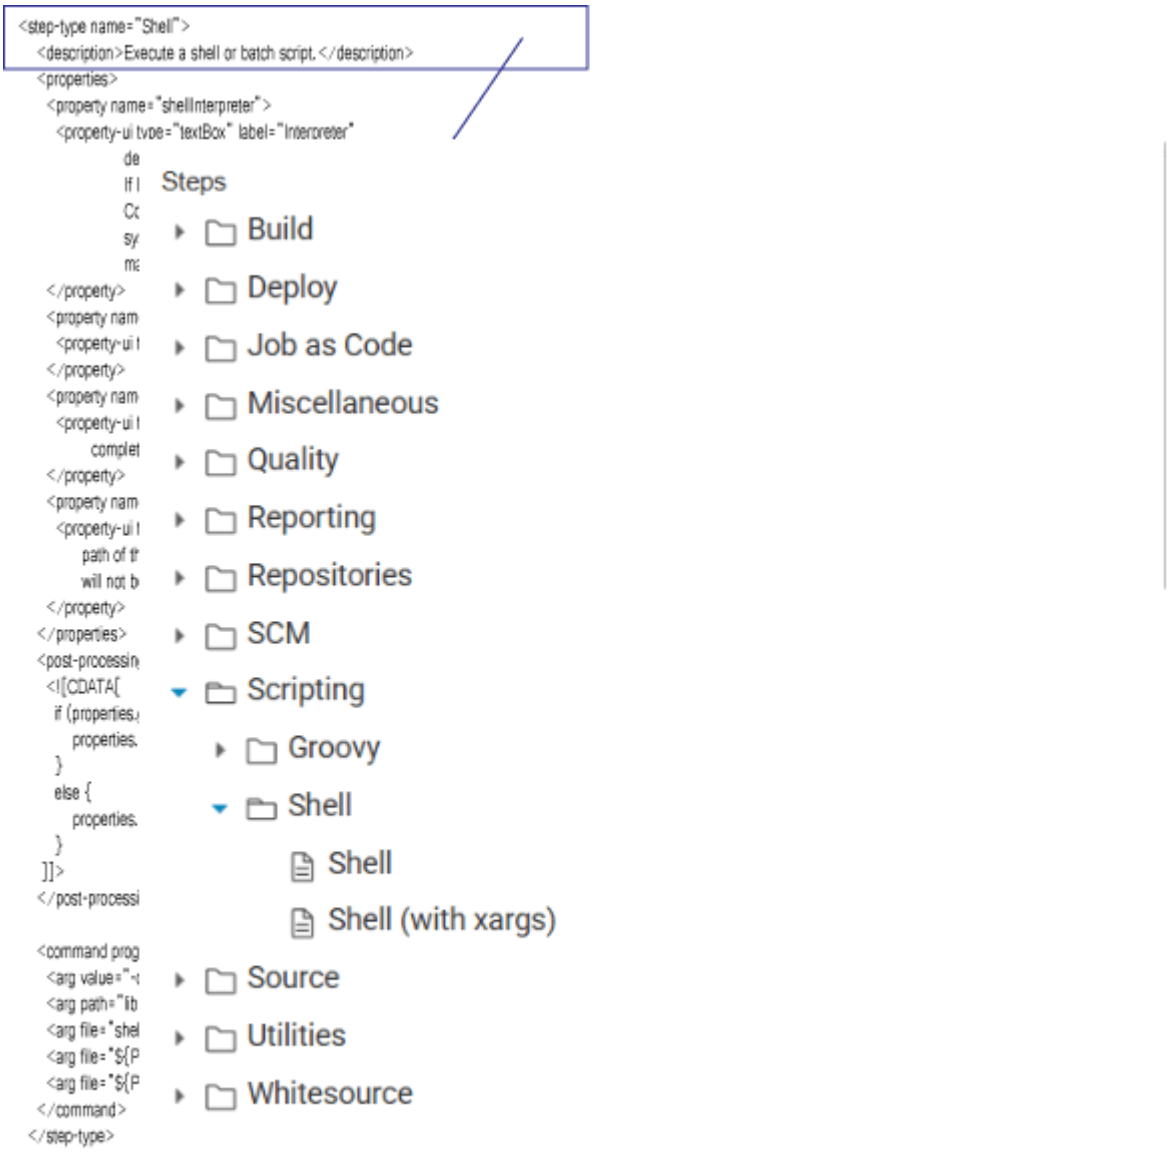
A plug-in consists of one or more steps. A step represents a unit of functionality that a user can configure and combine with other steps into a process. Creating a plug-in consists of defining its individual steps and then grouping them for presentation in Build.

Plug-in steps are run by an agent that is installed in the target environment. This means that plug-ins can be written in any scripting language provided that the agent can access the required scripting tools on the host.

The mechanics of plug-ins are covered by examining a plug-in step in detail. The example plug-in is *Shell*, which contains several steps that are related to shell scripts. The Shell plug-in comes with Build.

Each plug-in step is an individually configurable object. In the following illustration, you can see Shell plug-in's individual steps in the **Steps** window. The Shell step's label is derived from the `description` element in the plug-in file.

Plug-ins in the **Steps** window



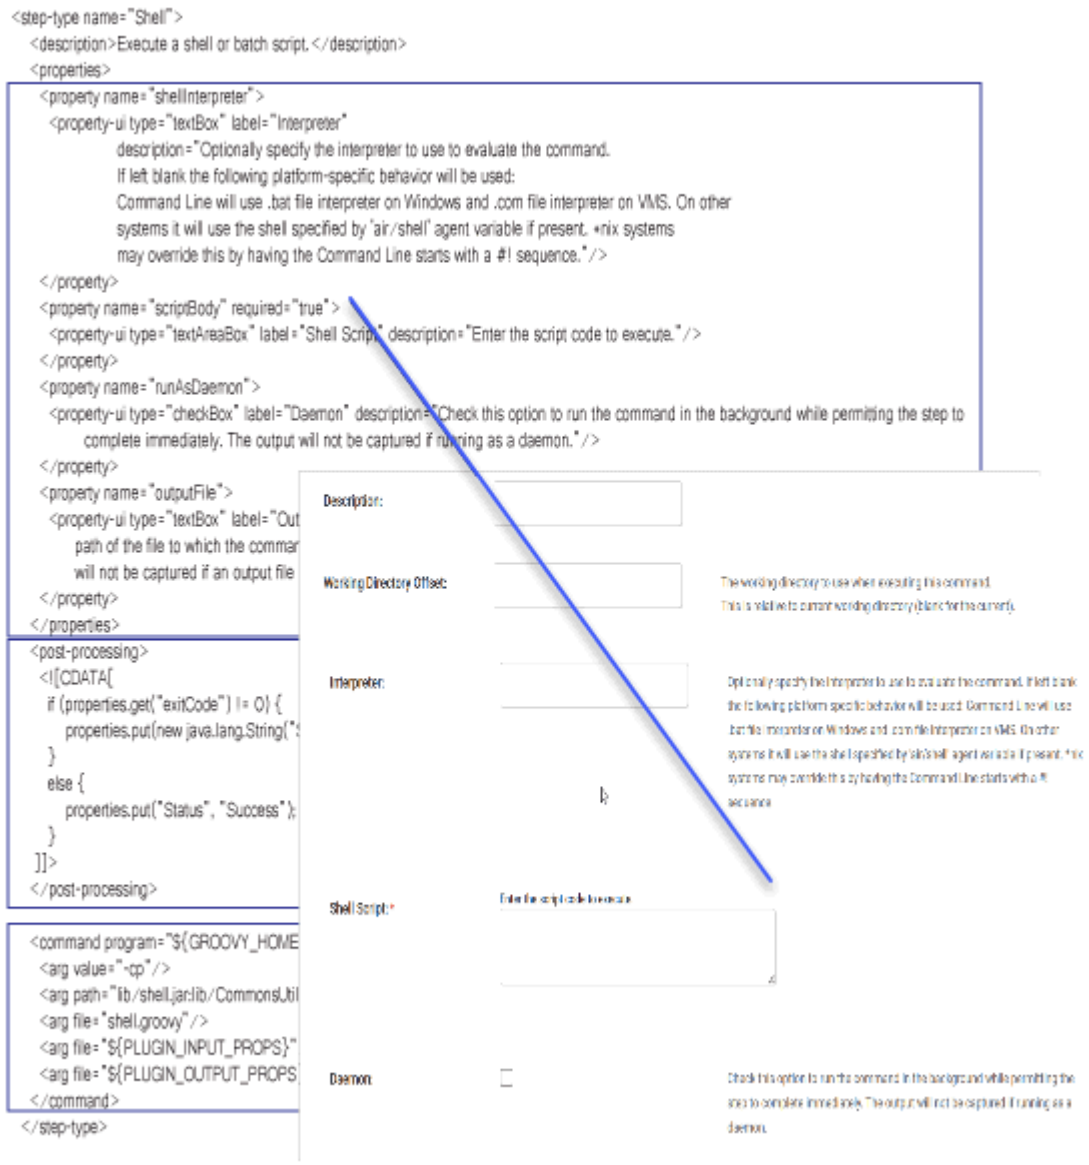
This example covers the *Shell* step. The Shell step executes a shell script or batch file that that you supply.

Each step (`step-type` element has the same structure:

- The `properties` element can contain any number of `property` child elements. Property values can be supplied at design time or run time.
- The `post-processing` element provides error-handling functions and sets property values that can be used by other steps.
- The `command` element performs the step's function. The function can be defined completely by the element, or be constructed in part or entirely from the step's properties at design time or run time.

The following figure shows how the Shell plug-in property definitions are displayed in the plug-in window.

Plug-in elements in the plug-in window



Step properties

In the context of plug-ins and steps, properties are values that the step's command uses. Step properties are defined with the `property` element.

The Create File step has three properties:

- The `file` property contains the name of the file that the command creates. This property is represented as a text box in the process designer
- The `contents` property contains the content of the file. This property is represented by a text-area box, which can contain a large amount of data
- The `overwrite` property specifies whether the file can overwrite an existing file. This property is represented by a check box in the process designer

These properties are displayed in the dialog box that opens when the step is added to a process. The other properties in the dialog are displayed for every step. Post processing is discussed later. Property values can be entered into the dialog box by the process designer at design time, or can be provided at run time by the user.

You can configure most properties with the `property-ui` child element (the `selectBox` type requires the `value` child element also). Default values can be defined when you create the step.

In addition to a step's own properties, a command has access to properties that are set earlier by other steps within the process, and to properties set by the process.

Step property values become unavailable after the process ends. Properties that are defined at run time are combined with the properties that were defined earlier and together are sent to the agent. Earlier properties (those properties that were defined outside the current process) are retrieved from the database. The way properties are processed and consumed is discussed further in the next section.

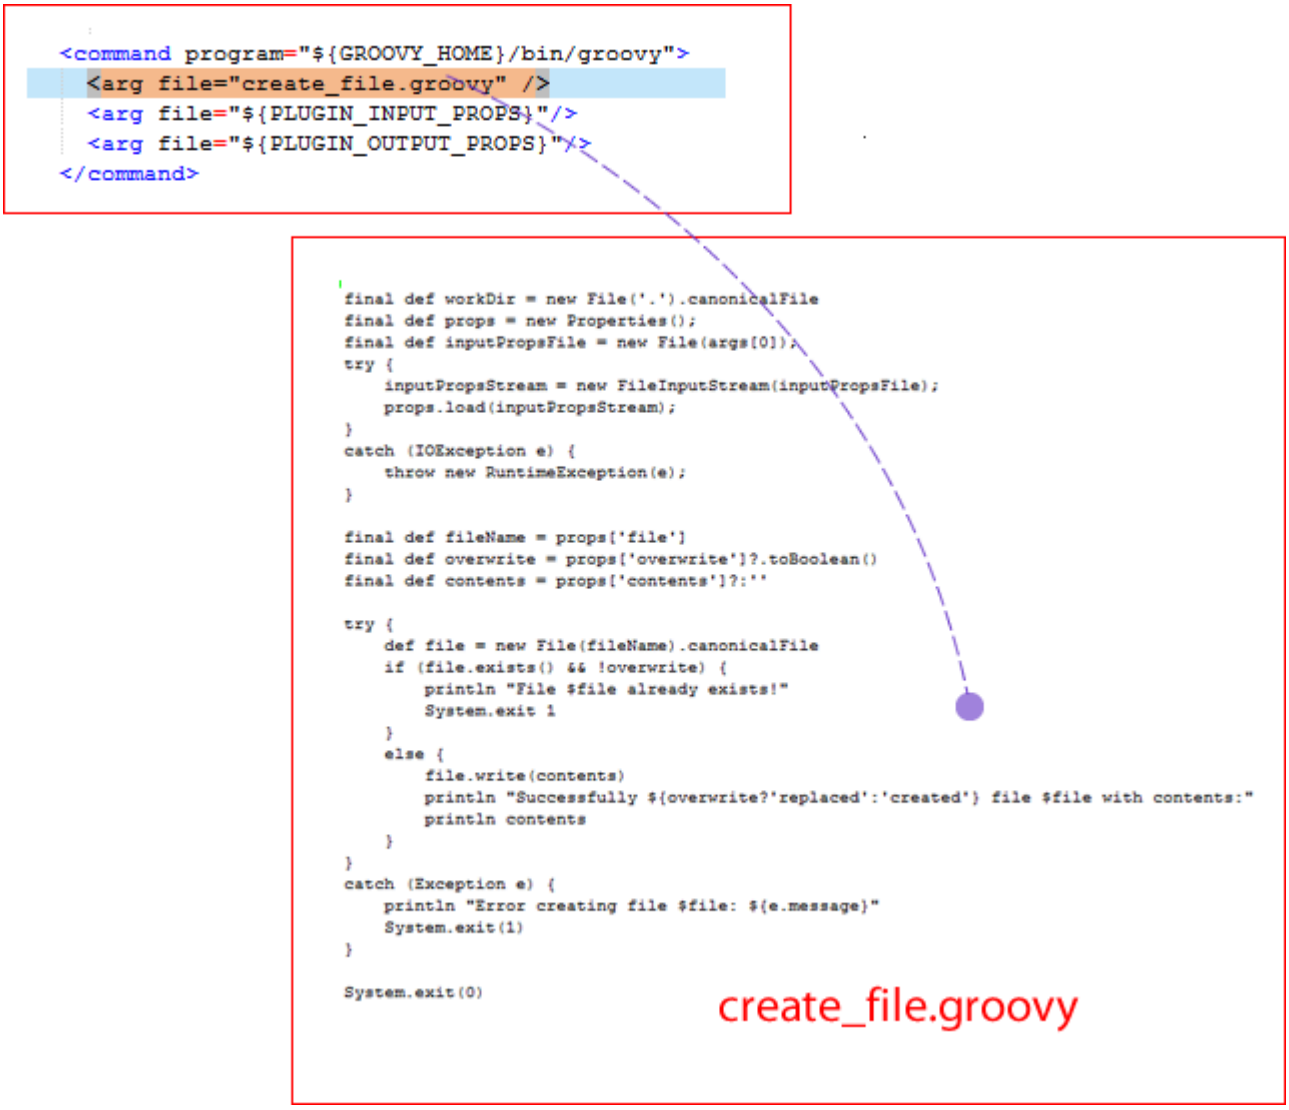
Step commands

The step's `command` element specifies the scripting tool that runs the step and identifies the file that contains the actual script.

The agent that runs the step downloads the plug-in and seeks the script among the downloaded files. The agent must also have access to the scripting tool. Other arguments that are required by the script or tool can also be specified with the `arg file` attribute. The `arg file` attributes must be defined so that they are compatible with the scripting tool.

The Create File command script is written in Groovy. Groovy is scripting language that is similar to Java™.

Figure 2. `create_file.groovy`



This command instructs the Groovy interpreter to run the `create_file.groovy` command. The next topic provides more information about Groovy and the particulars of this file.

The following line, which is part of every command, sends a file that contains the properties that are required by the step to the agent:

```
<arg file="${PLUGIN_INPUT_PROPS}"/>
```

The properties in the file are furnished at runtime and others that are defined earlier that are required by the step. The `${PLUGIN_INPUT_PROPS}` variable resolves to the location of this properties file.

The following line, which is also part of every command, refers to the file that the agent returns after it finishes the step:

```
<arg file="${PLUGIN_OUTPUT_PROPS}"/>
```

The properties in this file are available to later steps in the process. The `${PLUGIN_OUTPUT_PROPS}` variable resolves to the location of this properties file.

create_file.groovy

The `create_file.groovy` file contains the Groovy script that runs the step's command.

Groovy is a dynamic scripting language, which is similar to Python, Ruby, and Perl, for the Java™ platform. Most Java™ code is also syntactically valid Groovy, which makes Groovy popular with Java™ programmers. Groovy supports regular expressions.

The first lines of the script create a properties object, `props`. Then the script attempts to load the properties from the file that is sent from the server and which is specified by the `${PLUGIN_OUTPUT_PROPS}` variable. If it can load the file, it populates the `props` object; otherwise, it throws an exception.

```
final def workDir = new File('.').canonicalFile
final def props = new Properties();
final def inputPropsFile = new File(args[0]);
try {
inputPropsStream = new FileInputStream(inputPropsFile);
props.load(inputPropsStream);
}
catch (IOException e) {
throw new RuntimeException(e);
}
```

To run the command (create a file), the script uses the properties that are defined by the step itself. The script retrieves the three properties from the `props` object and creates corresponding local variables.

Next, the script creates a file with a name that is specified by `fileName` property, and tests the `overwrite` Boolean variable. If a file with the same name exists and `overwrite` is set to false, the script ends, or fails, with an exit code of 1. Exit codes can be examined during post-processing.

Otherwise, the file is written with the content of the `contents` property. A message is written to the output log, and the exit code is set to 0 (success).

```
final def fileName = props['file']
final def overwrite = props['overwrite']?.toBoolean()
final def contents = props['contents']?:''

try {
def file = new File(fileName).canonicalFile
if (file.exists() && !overwrite) {
println "File $file already exists!"
System.exit 1
}
else {
file.write(contents)
println "Successfully ${overwrite?'replaced':'created'} file
$file with contents:"
println contents
}
}
```

```
catch (Exception e) {
println "Error creating file $file: ${e.message}"
System.exit(1)
}

System.exit(0)
```

Build Scripting

The scripting API describes the various types of supported scripts.

The scripting API describes each type of script and how to create and maintain scripts for the Build server. Sample scripts are provided. Scripting objects and methods are described and examples are provided for each method.

To access the scripting API documentation, click the **Tools** link from any Build page.

Properties in Build

Properties can be set for many different things, including projects, build configurations, process configurations, build requests, and the server. You can also set and retrieve agent properties.

The scripting API can be found at the following location:

```
server_url/tools/scripting/ibm-ucb-scripting/
```

The API documentation contains many useful scripting examples.

Properties can be referenced by processes and passed to other objects. Property values can be defined when a property is created, or at some other point. The following syntax is used to reference properties:

```
${p:property_name}
```

You can also use this syntax:

```
${property:property_name}
```

If the property is not in the current context or scope, you add a prefix to the name to identify the context. The following syntax is used to reference properties outside the current context:

```
${p:prefix/property_name
```

For example, you can refer to a project property named `URL` by using the following syntax:

```
${p:project/URL}
```

To retrieve the value of a specific property, you can use the `@name=` syntax. For example, to retrieve the value of a project property that is named `specific.property`, you can use the following syntax:

```
${p:project/properties[@name='specific.property'}
```

If you do not use a prefix, the property is resolved by the property order of precedence. The following table provides the property order of precedence and the prefix that is used for every context. The property is always resolved in the current context, if possible; otherwise, the property is resolved according to the property order of precedence. The order is resolved from top of the list to bottom.

For example, if you have a variable that is named `URL` in both the step and job contexts, both contexts can refer to its own property by using the property name:

```
${p:URL}
```

If either context refers to the property in the other context, the prefix can be used. For example, the job can refer to the step property by using this syntax:

```
${p:step/URL}
```

If a step and a request both have a property that is named `URL`, then if a job refers to the property without using a prefix, the property resolves to the step property value. In this instance, if you want the job to refer to the request context, you must use the prefix: `${p:request/URL}`.

To retrieve the value of a property in another context that is itself retrieved from another context, you can chain prefixes. For example, to retrieve the project name from a build life, you might use this syntax:

```
${p:buildlife/workflow/project/name}
```

In most cases you can retrieve the project name with the more straightforward `${p:project/name}`, but this example illustrates how you might handle complicated contexts.

Table 24. Property order of precedence and context prefixes

Context	Description
Step	Context: Plug-in job steps. Syntax: `${p:step/property_name}`.
Job	Context: jobs. Syntax: `${p:job/property_name}`.
Request	Context: build requests. Syntax: `${p:request/property_name}`.
Source configuration (source plug-in steps only)	Context: source configuration template steps. Syntax: `${p:source/property_name}`.
Source configuration	Context: source configurations. Syntax: `${p:process/sourceConfigs/properties[@name='property_name']}`.

Table 24. Property order of precedence and context prefixes (continued)

Context	Description
	Source configurations are defined for build processes.
Process	Context: processes. Syntax: `${p:process/property_name}`.
Build life	Context: build life. Syntax: `${p:buildlife/property_name}`.
Build life	Context: build life. Syntax: `${p:buildlife/id}`. Returns the current build life ID. The Groovy equivalent is `${gvy:BuildLifeLookup.current.id}`
Build life build process	Context: build process. Syntax: `${p:originatingProcess/property_name}`.
Build life build request	Context: build request. Syntax: `${p:originatingRequest/property_name}`.
Project	Context: project. Syntax: `${p:project/property_name}`.
Server	Context: server. Syntax: `${p:property_name}`.

Table 24. Property order of precedence and context prefixes (continued)

Context	Description
	Note: There is no context prefix for server properties. Ensure that the names of your server properties are not duplicated by properties in other scopes.

Agent properties

Agent properties have a separate context. You can access agent properties directly, and you can access the agent environment variables. To refer to an agent property, use the following syntax:

```
${property_name}
```

You can also use this syntax:

```
${a:property_name}
```

or

```
${agent:property_name}
```

To access an agent environment variable, use the following syntax:

```
${env/PATH}
```

Property options

Many property elements are scripts. The scripts can be written in JavaScript™, Groovy, and BeanShell script. Scripts usually return an object or a value. Property prefixes are scripts that are used to dynamically reference properties in other contexts or scopes. The following table describes the property syntax options.

Table 25. Property syntax options

Property	Description
`${p:property_name}`	If defined as a non-agent property, return the property value. If the property is not defined, leave the property expression.
`${p?:property_name}`	If defined as a non-agent property, return the property value. If the property is not defined, return an empty string.
`${property_name}`	If defined as an agent property, return the property value. If the property is not defined, leave the property expression. You can also use the following syntax: `${a:property_name}`, or `${agent:property_name}`.

Table 25. Property syntax options (continued)

Property	Description
`${?:property_name}`	If defined as an agent property, return the property value. If the property is not defined, return an empty string. You can also use the following syntax: `${a?:property_name}`, or `${agent?:property_name}`.
`${gvy:script_body}`	Run `script_body` as Groovy and replace it with the return value.
`${bsh:script_body}`	Run `script_body` as BeanShell and replace it with the return value.

The `startsWith`, `contains`, and `matches` functions

You can retrieve all property values based on a property name. To retrieve all values, use the `startsWith`, `contains`, or `matches` functions, as shown in the following code examples:

```
    ${p:fn:startsWith(project/properties, 'prefix')}
    ${p:fn:contains(project/properties, 'text')}
    ${p:fn:matches(project/properties, 'prefix.*')}

    ${p:fn:startsWith(originatingProcess/properties, 'prefix')}
    ${p:fn:contains(originatingProcess/properties, 'text')}
    ${p:fn:matches(originatingProcess/properties, 'prefix.*')}

    ${p:fn:startsWith(process/properties, 'prefix')}
    ${p:fn:contains(process/properties, 'text')}
    ${p:fn:matches(process/properties, 'prefix.*')}

    ${p:fn:startsWith(request/properties, 'prefix')}
    ${p:fn:contains(request/properties, 'text')}
    ${p:fn:matches(request/properties, 'prefix.*')}

    ${p:fn:startsWith(buildlife/properties, 'prefix')}
    ${p:fn:contains(buildlife/properties, 'text')}
    ${p:fn:matches(buildlife/properties, 'prefix.*')}

    ${p:fn:startsWith(agent/properties, 'prefix')}
    ${p:fn:contains(agent/properties, 'text')}
    ${p:fn:matches(agent/properties, 'prefix.*')}
```

Cascading property values

Property values can be passed down from a parent process to a dependent process. The value can *cascade* from a direct dependent relationship or from an indirect relationship.

For example, using the table below Process A is the top level process that depends directly on Process B and Process C. Process B depends on Process D. Process C and Process D do not have any dependencies.

- Properties that meet the necessary requirements can be passed down from Process A to Process B and Process C.
- The property also cascades down to Process D, the inheritance flow is Process A to Process B to Process D.

Table 26. Dependent process example

Parent	Child	Child
Process A	Process B	Process C
Process B	Process D	

In order to cascade a property value to a dependent process, the following requirements must be met:

- ◦ The **Cascade Properties to Dependencies** option must be enabled. Click **System > Server Settings > Misc** to enable the option.
  ◦ Define the property on process template of the top level process.
    ▪ The property must be defined in both the parent process and the dependent processes.
    ▪ The **User May Override** option must be enabled for the property. This option is on the **Properties** page. This option indicates that there will be a prompt for the value of the property when the process runs instead of when the process is configured.

      Note: This option must be enabled on the process template for each dependent process that the property value is cascaded to if the dependent process is using a different process template than the high-level process.

  ◦ The dependency trigger between the high-level process and its dependent processes that the property is cascaded is either **Pull** or **Push**. The property value is not cascaded to a dependent process if the **No Trigger** is specified.

REST API reference

The Build server has a REST interface, which you can use to automate tasks on the server.

Running REST commands

Many different programs can run REST commands. To run the command, you call a method on a REST resource and pass parameters or a request in JSON format.

Note: Using REST commands requires the same permissions as using the web interface. For information about permissions, see Roles and permissions on page 319.

Example: Running simple REST commands with curl

The Linux™ program curl is a simple way to run REST commands. To run a REST command, put together the URL of one of the REST resources, specify the method to use, and add any parameters. For example, the following curl command retrieves a list of all initiatives. The command calls the GET method of the `agent` resource:

```
curl -k -u jsmith:passw0rd
  https://hostname:port/build/agents/
  -X GET -H "Accept: application/json"
```

Note: You must enter this command on a single line. It is split onto different lines here for clarity.

Note: This example uses the `-k` switch to connect to the server without checking SSL certificate validity. To set up authentication, see Authenticating for REST commands on page 432.

This example uses the user name `jsmith` and the password `passw0rd`. In most cases, create a dedicated user account for the REST commands to use and give that account the appropriate permissions.

Use the host name and port of your server for *`hostname`* and *`port`*. For example, if the host name is `ubuild.example.org` and the port is the default value of 8080, the `curl` command might look like the following example:

```
curl -k -u jsmith:passw0rd
  https://ubuild.example.org:8080/build/jobs/
  -X GET -H "Accept: application/json"
```

The response for this command is a JSONArray list of all jobs on the server, as in the following example:

```
[
  {
        "id": 32,
        "name": "Ant Build Job",
        "active": true,
        "description": null,
        "location": "/rest2/jobs/32"
    },
    {
        "id": 31,
        "name": "Demo Job",
        "active": true,
        "description": null,
        "location": "/rest2/jobs/31"
    },
]
```

Passing parameters to REST commands

Many REST commands have one or more parameters. Some parameters are added to the base of the URL and others are added at the end of the URL.

For example, the GET method of the `/jobs/{id}` resource returns information about a job. This method has a parameter in the base of its URL. The parameter **{id}** refers to the ID of a job. To use the GET method of this resource, you must substitute the ID of a job in the URL. For example, if the initiative ID is `31`, you might run the following command:

```
curl -k -u jsmith:passw0rd
  https://ubuild.example.org:8080/build/jobs/31/
  -X GET -H "Accept: application/json"
```

Some methods accept parameters at the end of the URL. For example, the GET method of the `projects` resource accepts the **format** parameter. This parameter specifies the format of the returned JSON. For example, to show additional detail about the projetcs on the server, pass the value `detail` to the **format** parameter, as in the following example:

```
curl -k -u jsmith:passw0rd
  https://ubuild.example.org:8080/build/projects/
  ?format=detail
  -X GET -H "Accept: application/json"
```

The resulting JSON code is more detailed than if you omitted the parameter.

Note: All parameter values must be URL encoded. For example, if a parameter includes a space, you must substitute the URL encoded value `%20`.

Passing JSON strings to commands

For more complex commands, you must send a JSON string or file instead of or in addition to the parameters.

For example, the POST method of the `initiatives` resource creates an initiative. To use this command, you must pass a JSON string that specifies the name and description of the new initiative. The JSON string for this command must follow this template:

```
{
  "name": "Initiative name",
  "description": "Initiative description"
}
```

This template is listed in the reference information for the command. See REST commands on page 439.

To pass this JSON string to the `projects` resource, you can either save the string to a file or include it in the command. For example, if you save the string to a file that is named `newProject.json`, the command looks like the following example:

```
curl -k -u jsmith:passw0rd
  https://ubuild.example.org:8080/build/projects/
  -d @newProjects.json
  -X POST -H "Content-Type: application/json"
```

You can also pass the string directly to the command, as shown in the following example:

```
curl -k -u jsmith:passw0rd
  https://ubuild.example.org:8080/build/projects/
  -d '{"name":"myProject","description":"My New Project"}'
  -X POST -H "Content-Type: application/json"
```

Note: The string that you pass to the command must be a valid JSON string.

Responses

After a successful command, most commands return either a simple string value or a JSON string.

In addition to the result of the command, the commands return standard HTTP status codes. The following list includes the most common status codes that REST commands return.

200

The command was successful.

400

- You do not have permission to run the command.
- You did not specify a required parameter.
- The resource path in the URL is incorrect.

404

The object that you are trying to retrieve does not exist.

405

The HTTP method name is incorrect.

415

The content type in the request header is incorrect.

500

The server encountered an error.

Authenticating for REST commands

The way that you authenticate to run REST commands depends on how the server is set up and the tool that you are using to run the commands.

Note: Using REST commands requires the same permissions as using the web interface. For information about permissions, see Roles and permissions on page 319.

Authenticating with a user name and password

The simplest way to authenticate for REST commands is to use a user name and password. For example, if you are using the `curl` program, you can specify the user name and password in the command, as in the following code:

```
curl -k -u jsmith:passw0rd
  https://ucrelease.example.org:8080/build/initiatives/
  -X GET -H "Accept: application/json"
```

Authenticating with a session key

For maximum performance, clients that perform multiple REST API requests should establish an HTTP session and reuse it for the duration of each batch of requests. An HTTP session is established after each successful request using HTTP Basic authentication and is identified by the `JSESSIONID` and `UCR_SESSION_KEY` cookies. In addition, clients that wish to use an HTTP session must place the `UCR_SESSION_KEY` into an HTTP request header for each request, as described below.

To get a session key, the client program first runs a command with a user name and password. The response headers include the session key. The header with the key typically has the name `Set-Cookie` and a value that is similar to the following example:

```
UCR_SESSION_KEY=6286eb44-b867-5243-875b-e61c5d8b4301;
Expires=Wed, 09-Sep-2082 16:51:45 GMT; Path=/; Secure
```

The client program must extract the session key from this header. In the previous example, the session key is `6286eb44-b867-5243-875b-e61c5d8b4301`. Then, for additional PUT, POST, and DELETE commands, include the following header:

```
UCR_SESSION_KEY:sessionKey
```

Use the session key for *`sessionKey`*.
In addition, to reuse the HTTP session, include the `JSESSIONID` cookie in the standard Cookie HTTP request header.

Authenticating in scripts and programs

Many programming and scripting languages can call REST commands.

The following example is a Python script that authenticates by adding the password to the request header.

```
#!/usr/bin/env python

import urllib2
import json
import base64
import sys

if not len(sys.argv) == 3:
  print 'usage: script <username> <password>'
  exit(1)

username = sys.argv[1]
password = sys.argv[2]

epass = base64.b64encode(username + ':' + password)
print 'base64 encoded: ' + epass
baseUrl = 'ubuild.example.org:8080'

url = 'http://' + baseUrl + '/applications/name'

opener = urllib2.build_opener(urllib2.HTTPHandler)
req = urllib2.Request(url)
req.add_header('Authorization', 'Basic '+epass)
req.get_method = lambda: 'GET'

resp = opener.open(req)
print resp.read()
```

Importing the server certificate

The default server certificate is unsigned. Some tools do not connect to servers with unsigned certificates by default. To access a server with a self-signed certificate, you can instruct the tool to connect insecurely, or you can import the certificate into your client. Follow these steps to import the certificate into your client:

1. Export the server certificate to a file:
    a. On the computer that hosts the Build server, open the `server.xml` file in a text editor. By default, this file is in the location *`server_install`*`/opt/tomcat/conf/server.xml`.
    b. In the `server.xml` file, find the following lines of code and note the values of the **keystoreFile** and **keystorePass** attributes:

    ```
    sslProtocol="TLS"
    keystoreFile="conf/tomcat.keystore"
    keystorePass="changeit" />
    ```

    c. In a command-line window, run the following command:

    ```
    keytool -v -list -keystore keyStoreFileName
    ```

    The `keytool` application is included in the Java™ developer kit and is not part of Build. Use the name of the **keystoreFile** attribute from the `server.xml` file for *`keyStoreFileName`*. When the command prompts you for a password, specify the value of the **keystorePass** attribute. The default value is `changeit`.
    d. From the result of the command, find the alias of the server. For example, the result of the command might look like the following code:

    ```
    Keystore type: JKS
    Keystore provider: SUN

    Your keystore contains 1 entry

    Alias name: server
    Creation date: Mar 2, 2016
    Entry type: PrivateKeyEntry
    ```

    In this code, the alias is `server`.
    e. Run the following command to export the certificate to a file and specify the password again:

    ```
    keytool -exportcert
      -alias serverAlias
      -keystore keyStoreFileName
      -storetype jks
      -file server.cert
    ```

    Use the alias of the server for *`serverAlias`*.
2. Copy the `server.cert` file to the client computer.
3. Import the `server.cert` file into the keystore of the client computer:
    a. In a command-line window on the client computer, run the following command and specify the password for the keystore on the client. The default is `changeit`.

    ```
    jreLocation\jre\bin\keytool.exe -importcert
      -alias serverAlias
      -file tomcat.cert
    ```

```
-storetype jks
-keystore jreLocation\jre\lib\security\cacerts
```

Use the location of the JRE or JDK for *`jreLocation`*.

Now, some tools that use this JRE or JDK accept the server certificate. Other tools, such as `curl`, might still not accept the server certificate because it is unsigned. To resolve this problem, set up a signed certificate for the server.

REST API conventions

The Build REST API follows a set of conventions to make interacting with it more consistent.

REST URLs

Each element type on the server is represented as a top-level URL with a plural form. In most cases, the URL uses the same terms as in the user interface, formatted with the camel case convention. For example, process templates are represented at the URL `http://base_url/build/processTemplates/`, agent pools are at the URL `http://base_url/build/agentPools/`, and workflows are at the URL `http://base_url/build/workflows/`, where `base_url` is the host name and path to the server.

Required HTTP headers

Most operations in the REST API accept an input in JSON format, return an output in JSON format, or both. Following HTTP conventions, the `Content-Type` request header is required for operations that provide JSON input, and the `Accept` request header is required for operations that produce JSON output, with the media type value of `application/json`. As a convenience for developers, the GET method for lists and individual items (described below) also produces JSON output if the media type is `text/html` and the query parameter `json` is appended to the request URL with any value. This parameter is useful for rendering JSON output from a web browser without special tools to modify the `Accept` header. For example, to display the JSON output for all plug-ins, type `http://base_url/build/plugins/?json` into the location bar of a web browser.

The `id` property

Elements such as projects have a unique ID (UUID) property, which appears in the JSON object representation as the `id` property as a JSON string. You can refer to a specific element by its UUID. You can use this UUID in places such as the URLs of REST API operations and within JSON representations of elements.

Basic operations

The basic create, read, update, delete operations are provided according to common REST API conventions. The top-level URL for an element type represents the collection of items of that type. To render the list of all elements of that type as an array of JSON objects, use the HTTP method GET with appropriate HTTP headers or the `json` query parameter. To create a new element, use the HTTP method POST to the top-level URL for the appropriate type and provide JSON data for the element in the body of the request. The response body includes a full JSON representation of the new element, including the server-generated `id` property. You can also provide an array of JSON objects to create multiple elements in a single request. In this case, the response body contains a JSON array of the new elements in the same order that they were provided in the request. Similarly, you can update the data for multiple elements by using the HTTP PUT method with a JSON array of elements. You can delete multiple elements by using the HTTP DELETE method with a JSON array that contains either full JSON elements or only the UUIDs of the elements.

To run an operation on a single existing element, append the UUID for the element to the top-level URL for the type. For example, to access the JSON data for the Ant plug-in that is provided, use the HTTP method GET with the URL `http://base_url/build/plugins/d43aa71e-5acc-4e28-8b4c-b19ee2b214be/`. To update the data for an element, use HTTP PUT method and provide an updated JSON object in the request body. (In this case, the UUID in the request URL takes precedence over the `id` property in the request body.) To delete the element, use the HTTP DELETE method; no request body is required in that case.

Output formats

When you use the create, read, and update operations (POST, GET, and PUT), you can include the optional **format** query parameter to adjust the JSON output for specific use cases. If you do not provide this parameter, or if the value of the parameter is not recognized, a default format is used. Each element type supports a different set of formats; these formats are listed with the reference information for the element type. Some formats show a large amount of detail and others show a small amount of detail, but the difference is only in the information that is shown; the values are the same.

You can use the `list` and `detail` formats with any element type. The `list` format provides summary information, such as you might show in a table of items. The `detail` format provides more detailed information. This format often includes the content of related elements. For some elements, these formats are identical. In addition, element types that have a `name` property also have a `name` format. This format includes only the `id` and `name` properties, which can be useful for displaying a list of items for selection by name. As a convenience, the `name` format for an element type can also be produced by appending `name` to the top-level URL for the type, for example, `GET http://base_url/build/jobs/name`.

JSON input conventions

When you provide JSON data as input for the create or update operations, the REST API takes into account only the properties that are writable on the element. The API ignores all other data. Read-only properties, such as computed counts or creation dates, are not updated. The API ignores unrecognized properties. Properties of related elements, other than the `id` property used to establish a reference, are also not updated.

For example, assume that you provide the following JSON input to create a project:

```
{
  "name": "New Project",
  "teams": "My Team",
  "totalChanges": 42,
  "tags": ["green"],
  "BadProperty": "xxxx"
}
```

When the API processes this input, it recognizes only the properties that are required for creating a release. Therefore, it ignores the unrecognized property `BadProperty` and the computed value `totalChanges`. In this case, the input above is equivalent to the simpler input below:

```
{
  "name": "New Project",
  "teams": "My Team",
  "tags": ["green"],
}
```

Similarly, when you update an existing element, the API changes only the properties that you specify in the JSON input. The API does not change properties that you omit. To clear the value of a property, specify an explicit JSON null value for that property.

For example, the following input changes the `tags` property in the sample project, but does not update any other properties:.

```
{
  "id": "123456789000",
  "name": "New Project",
  "tags": ["green","blue"],
  }
```

References

In most cases, you can refer to a single element with either a JSON string that contains the UUID of the element or a JSON object that contains an `id` property with the same value. As described above, any other properties of the referenced element are ignored. For example, all of the following JSON objects are equivalent when you are associating a change to a project.

```
{
  "id": "00000000-0000-0000-0000-123456789000",
  "project": "00000000-0000-0000-0000-000000000036"
}
```

```
{
  "id": "00000000-0000-0000-0000-123456789000",
  "project": {"id":"00000000-0000-0000-0000-000000000036"}
}
```

```
{
  "id": "00000000-0000-0000-0000-123456789000",
  "project": {
    "id":"00000000-0000-0000-0000-000000000036",
    "name":"Sample Project"}
}
```

```
{
  "id": "00000000-0000-0000-0000-123456789000",
  "project": {
    "id":"00000000-0000-0000-0000-000000000036",
    "name":"Not the actual Project name"}
}
```

In most cases, you can refer to a single element with either a JSON string that contains the UUID of the element or a JSON object that contains an `id` property with the same value. As described above, any other properties of the referenced element are ignored.

Multiple-value (collection) references

Some relationships can have multiple values. For example, a single project can be associated with multiple processes. In some cases, these relationships are not updated when you create or update the single-value side of the relationship. For example, when you create a project, the values that you provide for the `buildprocesses` property have no effect. Instead, use other URLs to add or remove build processes from projects.

Key-value properties

Some element types support the storage and retrieval of free-form key-value pairs in addition to statically defined properties. This type of property often represents data that is linked in some way.

Key-value properties are represented in the JSON data as a related element under the `properties` property. For example, the following code represents a change with key-value properties that are named `first`, `second`, and `third`:

```
{
  "id": "00000000-0000-0000-0000-123456789000",
  "name": "New Feature",
  "description": "",
  "status": "In Progress",
  "type": {
    "id":"00000000-0000-1201-0000-000000000001",
    "name":"Feature",
    "icon":"feature"},
  "properties": {
    "first":"first value",
    "second":"second value",
    "third":"third value"}
}
```

Both the key and value must be represented as JSON strings. As with statically defined properties, if a key is omitted from input, update operations do not change it. To clear a key-value pair, assign a JSON null value to the key.

Pagination

For some element types, the top-level GET request can provide a subset of elements rather than the full list. Retrieving subsets of elements like this is commonly referred to as "pagination," because it involves loading only a single "page" of data in each request.

Two alternative forms of paging are available, using either query parameters or the HTTP `Range` header.

To use query parameters for pagination, specify both a **rowsPerPage** and a **pageNumber** query parameter in the HTTP GET request. To retrieve the first page, specify the code `pageNumber=1`. For example, to retrieve the first five applications, use the request `GET http://base_url/build/jobs/?rowsPerPage=5&pageNumber=1`.

To use the HTTP `Range` header, specify the start and end values for the range of items, specifying zero-based and inclusive values. For example, to retrieve the first five jobs, add the following header to the request `GET http://base_url/jobs/`:

```
Range: items=0-4
```

Regardless of how you request the pagination, the HTTP response uses the `Content-Range` header to specify the actual range that is retrieved and the total number of available items. For example, if you requested the first five jobs of a list of 10, the response includes the following header:

```
Content-Range: 0-4/10
```

If you requested the first five job lives, and only three are available, the header looks like this:

```
Content-Range: 0-2/3
```

Sorting

To sort the results of the top-level GET operation, specify the **orderField** and **sortType** parameters. The **orderField** parameter must contain the name of a single property to sort by. The **sortType** parameter must contain either the value `asc` to sort in ascending order, or the value `desc` to sort in descending order.

REST commands

The following list shows the commands that are available.

agentPools resource

Get information about all agent pools

Return a JSON Array representation of all agent pools.

Request

```
GET https://{hostname}:{port}
  /build/rest2/agentPools
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "id": "The id of the agent pool.",
  "name": "The name of the agent pool."
}]
```

agents resource

Resources for working with agents.

Create a environment in agent environments

Request

```
POST https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/environment
```

Table 27. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Configure all unconfigured agents

Request

```
POST https://{hostname}:{port}
  /build/rest2/agents/configureAgents
```

Create a property in agent propertes

Request

```
POST https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/agent
```

Table 28. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Delete a specified name environment in agent environments

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/environment/{name}
```

Table 29. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent
name	string	true	The name of the environment

Delete a specified name property in agent propertes

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/agent/{name}
```

Table 30. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Table 30. URL parameters (continued)

Parameter	Type	Required	Description
name	string	true	The name of the property

Delete an agent

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/agents/{id}
```

Table 31. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get agent properties on an agent

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/agent?{parameters}
```

Table 32. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of agent properties to return per page.
pageNumber	string	false	The page of agent properties that should be returned.
orderField	string	false	The field to use when sorting the agent properties. This would be 'name'.
sortType	string	false	The order to use when sorting the agent properties. This would either be 'asc' or 'desc'.

Table 33. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get all properties on an agent

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}/properties
```

Table 34. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get environments on an agent

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/environment?{parameters}
```

Table 35. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of environment properties to return per page.
pageNumber	string	false	The page of environment properties that should be returned.
orderField	string	false	The field to use when sorting the environment properties. This would be 'name'.
sortType	string	false	The order to use when sorting the environment properties. This would either be 'asc' or 'desc'.

Table 36. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get information about all agents

Return a JSON representation of all agents.

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents?{parameters}
```

Table 37. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	If specified, the number of agents per page
pageNum	string	false	If specified, the page of agents to retrieve

Get information about an agent

Return a JSON representation of an agent.

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}?{parameters}
```

Table 38. Request parameters

Parameter	Type	Required	Description
extended	boolean	false	If set to true, retrieve information about the agent's properties.

Table 39. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get locked properties on an agent

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/locked?{parameters}
```

Table 40. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of locked properties to return per page.
pageNumber	string	false	The page of locked properties that should be returned.
orderField	string	false	The field to use when sorting the locked properties. This would be 'name'.
sortType	string	false	The order to use when sorting the locked properties. This would either be 'asc' or 'desc'.

Table 41. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Get system properties on an agent

Request

```
GET https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/system?{parameters}
```

Table 42. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of system properties to return per page.
pageNumber	string	false	The page of system properties that should be returned.
orderField	string	false	The field to use when sorting the system properties. This would be 'name'.
sortType	string	false	The order to use when sorting the system properties. This would either be 'asc' or 'desc'.

Table 43. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Update an agent

Request

```
PUT https://{hostname}:{port}
  /build/rest2/agents/{id}
```

Table 44. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agentPools": [{
    "dynamic": "Whether or not the agent pool is dynamic
  agent pool",
    "name": "The name of the agent pool"
  }],
  "description": "The agent description",
  "ignored": "Whether or not the server is ignoring the
  agent.",
  "maxJobs": "The Maximum number of jobs that can run on
  this Agent at any single time.",
  "name": "The name of the agent",
  "properties": [{
    "name": "Property name",
    "value": "Property value"
  }],
  "throughput": "The throughput metric setting is used to
  determine how likely an agent is to be used for another
  job.A weight is applied to the agent using a formula based
  on the throughput and the number of active jobs for the
  agent.A higher weight means that the agent is more likely
  to be chosen for an additional job.The formula is as
  follows: Weight = Throughput / (Number of Active Jobs + 1)"
}
```

Update environment in agent environments

Request

```
PUT https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/environment
```

Table 45. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

Update property in agent propertes

Request

```
PUT https://{hostname}:{port}
  /build/rest2/agents/{id}/properties/agent
```

Table 46. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an agent. This can be the name or ID of the agent

artifactsets resource

Create an artifact set

Request

```
POST https://{hostname}:{port}
  /build/rest2/artifactsets
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The description of the artifact set",
  "name": "The name of the artifact set"
}
```

Delete the artifact set

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/artifactsets/{id}
```

Table 47. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an artifact set. This is the ID of the artifact set

Get information about all artifact sets

Return a JSON representation of all artifact sets.

Request

```
GET https://{hostname}:{port}
  /build/rest2/artifactsets
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "The active status of the artifact set",
  "description": "The description of the artifact set",
  "id": "The id of the artifact set",
  "inactive": "The inactive status of the artifact set",
  "location": "The The URL that can be used to get the
  JSON representation of the artifact set",
  "name": "The name of the artifact set"
}]
```

Get information about the artifact set

Return a JSON representation of the artifact set

Request

```
GET https://{hostname}:{port}
  /build/rest2/artifactsets/{id}
```

Table 48. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an artifact set. This is the ID of the artifact set

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "The active status of the artifact set",
  "description": "The description of the artifact set",
  "id": "The id of the artifact set",
  "inactive": "The inactive status of the artifact set",
  "location": "The The URL that can be used to get the
  JSON representation of the artifact set",
  "name": "The name of the artifact set"
}
```

Update the artifact set

Request

```
PUT https://{hostname}:{port}
  /build/rest2/artifactsets/{id}
```

Table 49. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up an artifact set. This is the ID of the artifact set

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The description of the artifact set",
  "inactive": "The inactive status of the artifact set",
  "name": "The name of the artifact set"
}
```

authenticationRealm resource

authenticationRealm GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authenticationRealm
```

authenticationRealm POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/authenticationRealm
```

authenticationRealm/{realm} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}
```

Table 50. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}
```

Table 51. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}
```

Table 52. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm}/users GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}/users
```

Table 53. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm}/moveUp PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}/moveUp
```

Table 54. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm}/moveDown PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}/moveDown
```

Table 55. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm}/updateUsers PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}/updateUsers
```

Table 56. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authenticationRealm/{realm}/importUsers/{name} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authenticationRealm/{realm}/importUsers/{name}
```

Table 57. URL parameters

Parameter	Type	Required	Description
name	string	true	
realm	string	true	

authorizationRealm resource

authorizationRealm GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authorizationRealm
```

authorizationRealm POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/authorizationRealm
```

authorizationRealm/{realm} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authorizationRealm/{realm}
```

Table 58. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authorizationRealm/{realm} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authorizationRealm/{realm}
```

Table 59. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authorizationRealm/{realm} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/authorizationRealm/{realm}
```

Table 60. URL parameters

Parameter	Type	Required	Description
realm	string	true	

authtoken resource

authtoken GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authtoken
```

authtoken PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authtoken
```

authtokentable GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authtokentable
```

authtoken{token} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/authtoken{token}
```

Table 61. URL parameters

Parameter	Type	Required	Description
token	string	true	

authtoken{token} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/authtoken{token}
```

Table 62. URL parameters

Parameter	Type	Required	Description
token	string	true	

authtoken/getOrCreateToken PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/authtoken/getOrCreateToken
```

authtokens resource

Create an authtoken

Request

```
POST https://{hostname}:{port}
  /build/rest2/authtokens
```

This command takes a JSON request string or file. Use the following template for the request:

```
{}
```

Delete an authtoken

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/authtokens/{token}
```

Table 63. URL parameters

Parameter	Type	Required	Description
token	string	true	The authtoken string

Get information about queried tokens

Request

```
GET https://{hostname}:{port}
  /build/rest2/authtokens
```

Get information about the authtoken

Return a JSON representation of the authtoken

Request

```
GET https://{hostname}:{port}
  /build/rest2/authtokens/{token}
```

Table 64. URL parameters

Parameter	Type	Required	Description
token	string	true	The authtoken string

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "expiration": "The date and time at which this auth
  token should expire",
  "location": "The The URL that can be used to get the
  JSON representation of the anthtoken",
  "token": "The token string",
  "userId": "The security user id of the user who
  associates with this token",
  "userName": "The name of user who associates with this
  token"
}
```

build-lives resource

/build-lives/ GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives/?{parameters}
```

Table 65. Request parameters

Parameter	Type	Required	Description
includeInactive	string	false	

/build-lives//latest GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives/latest
```

/build-lives//latest/dependencies GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/dependencies
```

/build-lives//latest/dependencies POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//latest/dependencies
```

/build-lives//latest/artifact-configs GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifact-configs
```

/build-lives//latest/dependencies-xml GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/dependencies-xml
```

/build-lives//latest/artifactSets GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactSets
```

/build-lives//latest/artifactSets/{set} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactSets/{set}
```

Table 66. URL parameters

Parameter	Type	Required	Description
set	string	true	

/build-lives//latest/artifactSets/{set}/artifacts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactSets/{set}/artifacts?{parameters}
```

Table 67. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 68. URL parameters

Parameter	Type	Required	Description
set	string	true	

/build-lives//latest/artifactSets/{set}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactSets/{set}/artifacts/{path}
```

Table 69. URL parameters

Parameter	Type	Required	Description
set	string	true	
path	string	true	

/build-lives//latest/artifactRepositories GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactRepositories
```

/build-lives//latest/artifactRepositories/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactRepositories/{id}
```

Table 70. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//latest/artifactRepositories/{id}/artifacts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactRepositories/{id}/artifacts?{parameters}
```

Table 71. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 72. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//latest/artifactRepositories/{id}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/artifactRepositories/{id}/artifacts/{path}
```

Table 73. URL parameters

Parameter	Type	Required	Description
id	string	true	
path	string	true	

/build-lives//{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}
```

Table 74. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/dependencies GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/dependencies
```

Table 75. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/dependencies POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//{id}/dependencies
```

Table 76. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/artifact-configs GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifact-configs
```

Table 77. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/dependencies-xml GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/dependencies-xml
```

Table 78. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/artifactSets GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactSets
```

Table 79. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/artifactSets/{set} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactSets/{set}
```

Table 80. URL parameters

Parameter	Type	Required	Description
id	string	true	
set	string	true	

/build-lives//{id}/artifactSets/{set}/artifacts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactSets/{set}/artifacts?{parameters}
```

Table 81. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 82. URL parameters

Parameter	Type	Required	Description
id	string	true	
set	string	true	

/build-lives//{id}/artifactSets/{set}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactSets/{set}/artifacts/{path}
```

Table 83. URL parameters

Parameter	Type	Required	Description
id	string	true	
set	string	true	
path	string	true	

/build-lives//{id}/artifactRepositories GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactRepositories
```

Table 84. URL parameters

Parameter	Type	Required	Description
id	string	true	

/build-lives//{id}/artifactRepositories/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactRepositories/{id}
```

Table 85. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

/build-lives//{id}/artifactRepositories/{id}/artifacts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactRepositories/{id}/artifacts?{parameters}
```

Table 86. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 87. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

/build-lives//{id}/artifactRepositories/{id}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/artifactRepositories/{id}/artifacts/{path}
```

Table 88. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	
path	string	true	

Create a label.

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//latest/labels
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "label": "The name of the label.",
  "labelDependencies": "Determines which dependencies to
  which the label should also be applied. This is not
  required. The value should be 'NONE', 'DIRECT' or 'ALL'."
}
```

Create a label.

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//{id}/labels
```

Table 89. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "label": "The name of the label.",
  "labelDependencies": "Determines which dependencies to
  which the label should also be applied. This is not
  required. The value should be 'NONE', 'DIRECT' or 'ALL'."
}
```

Create a status.

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//latest/statuses
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "externalMessage": "The message of the status if the
  status is created by an external source.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "status": "The name of the status."
}
```

Create a status.

Request

```
POST https://{hostname}:{port}
  /build/rest2/build-lives//{id}/statuses
```

Table 90. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "externalMessage": "The message of the status if the
  status is created by an external source.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "status": "The name of the status."
```

```
}
```

Get a summary of all the findings in the source analytic report

Return a JSON representation of the summary of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analyticSummaries/{name}/summaries
```

Table 91. URL parameters

Parameter	Type	Required	Description
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get a summary of all the findings in the source analytic report

Return a JSON representation of the summary of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analyticSummaries/{name}/summaries
```

Table 92. URL parameters

Parameter	Type	Required	Description
id	string	true	
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
```

```
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get all the source analytic reports

Return a JSON representation of all source analytic reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analytics
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic report.",
    "count": "The count of findings in the source analytic
  report.",
    "id": "The id of the source analytic report.",
    "location": "The REST location to get the source
  analytic report.",
    "name": "The name of the source analytic report.",
    "type": "The type of the source analytic report.",
    "url": "The URL of the source analytic report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic reports

Return a JSON representation of all source analytic reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analytics
```

Table 93. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
```

```
  the source analytic report.",
    "count": "The count of findings in the source analytic
  report.",
    "id": "The id of the source analytic report.",
    "location": "The REST location to get the source
  analytic report.",
    "name": "The name of the source analytic report.",
    "type": "The type of the source analytic report.",
    "url": "The URL of the source analytic report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic summary reports

Return a JSON representation of all source analytic summary reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analyticSummaries
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
    "count": "The count of findings in the source analytic
  summary report.",
    "id": "The id of the source analytic summary report.",
    "location": "The REST location to get the source
  analytic summary report.",
    "name": "The name of the source analytic summary
  report.",
    "type": "The type of the source analytic summary
  report.",
    "url": "The URL of the source analytic summary report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic summary reports

Return a JSON representation of all source analytic summary reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analyticSummaries
```

Table 94. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
    "count": "The count of findings in the source analytic
  summary report.",
    "id": "The id of the source analytic summary report.",
    "location": "The REST location to get the source
  analytic summary report.",
    "name": "The name of the source analytic summary
  report.",
    "type": "The type of the source analytic summary
  report.",
    "url": "The URL of the source analytic summary report."
  }],
  "totalRecords": "The number of reports."
}
```

Get build lives for a project

Return the details of all the build lives for a project.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildLives?{parameters}
```

Table 95. URL parameters

Parameter	Type	Required	Description
id	string	true	Project id or project name

Table 96. Request parameters

Parameter	Type	Required	Description
limit	integer	false	Specifies the number of records to be fetched.
offset	integer	false	Indicates the starting point from which the data should be fetched.
extended	string	false	Boolean value to determine whether to fetch extended properties.

Table 96. Request parameters (continued)

Parameter	Type	Required	Description
modifiedSince	string	false	Represents the timestamp (in milliseconds) to fetch resources modified after this time.
preflightType	string	false	You can filter the build lives based on prefight type using the following values: • NOT_PREFLIGHT • ONLY_PREFLIGHT • ALL

Get information about all code coverage reports

Return a JSON representation of all code coverage reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/codeCoverage
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "branchPercentage": "The branch percentage of the code
  coverage report.",
    "buildLifeId": "The id of the build life that contains
  the code coverage report.",
    "groups": [{
      "branchPercentage": "The branch percentage of the
  group in the code coverage report.",
      "complexity": "The complexity of the group in the
  code coverage report.",
      "linePercentage": "The line percentage of the group
  in the code coverage report.",
      "methodPercentage": "The method percentage of the
  group in the code coverage report.",
      "name": "The name of the group in the code coverage
  report."
    }],
    "linePercentage": "The line percentage of the code
  coverage report.",
    "methodPercentage": "The method percentage of the code
  coverage report.",
    "name": "The name of the code coverage report.",
    "type": "The type of the code coverage report."
  }],
  "totalReports": "The number of the code coverage reports."
}
```

Get information about all code coverage reports

Return a JSON representation of all code coverage reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/codeCoverage
```

Table 97. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "branchPercentage": "The branch percentage of the code
  coverage report.",
    "buildLifeId": "The id of the build life that contains
  the code coverage report.",
    "groups": [{
      "branchPercentage": "The branch percentage of the
  group in the code coverage report.",
      "complexity": "The complexity of the group in the
  code coverage report.",
      "linePercentage": "The line percentage of the group
  in the code coverage report.",
      "methodPercentage": "The method percentage of the
  group in the code coverage report.",
      "name": "The name of the group in the code coverage
  report."
    }],
    "linePercentage": "The line percentage of the code
  coverage report.",
    "methodPercentage": "The method percentage of the code
  coverage report.",
    "name": "The name of the code coverage report.",
    "type": "The type of the code coverage report."
  }],
  "totalReports": "The number of the code coverage reports."
}
```

Get information about all issues.

Return a JSON representation of all issues.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/issues
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "count": "The number of the issues.",
  "issues": [{
    "id": "The id of the issue.",
    "name": "The name of the issue."
  }]
}
```

Get information about all issues.

Return a JSON representation of all issues.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/issues
```

Table 98. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "count": "The number of the issues.",
  "issues": [{
    "id": "The id of the issue.",
    "name": "The name of the issue."
  }]
}
```

Get information about all labels

Return a JSON Array representation of all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/labels
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "assignedDate": "The assigned date of the label.",
  "assignedDateFormat": "The format of the assigned date.",
  "buildLifeId": "The id of the build life.",
  "label": "The name of the label.",
  "labelId": "The id of the label.",
  "user": "The user that applied the label."
}]
```

Get information about all labels

Return a JSON Array representation of all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/labels
```

Table 99. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "assignedDate": "The assigned date of the label.",
  "assignedDateFormat": "The format of the assigned date.",
  "buildLifeId": "The id of the build life.",
  "label": "The name of the label.",
  "labelId": "The id of the label.",
  "user": "The user that applied the label."
}]
```

Get information about all of the findings in the source analytic report

Return a JSON representation of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analytics/{id}/findings
```

Table 100. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
```

```
  }],
  "totalRecords": "The number of findings."
}
```

Get information about all of the findings in the source analytic report

Return a JSON representation of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analytics/{id}/findings
```

Table 101. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get information about all source change sets

Return a JSON Array representation of all source change sets.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/sourceChange
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "comment": "The comment of the source change set.",
  "commitDate": "The commit date of the source change set.",
  "id": "The id of the source change set.",
  "paths": [{
    "path": "The path of the change.",
```

```
    "type": "The type of the change."
  }],
  "user": "The user name who submitted the source change
  set.",
  "version": "The version of the source change set."
}]
```

Get information about all source change sets

Return a JSON Array representation of all source change sets.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/sourceChange
```

Table 102. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "comment": "The comment of the source change set.",
  "commitDate": "The commit date of the source change set.",
  "id": "The id of the source change set.",
  "paths": [{
    "path": "The path of the change.",
    "type": "The type of the change."
  }],
  "user": "The user name who submitted the source change
  set.",
  "version": "The version of the source change set."
}]
```

Get information about all statuses

Return a JSON Array representation of all statuses.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/statuses
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "buildLifeId": "The id of the build life.",
  "dateAssigned": "The assigned date of the status.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "message": "The message of the status if the status is
  created by a user or external source.",
  "origin": "The origin of the status.",
```

```
  "status": "The status.",
  "statusColor": "The color of the status.",
  "statusName": "The name of the status.",
  "user": "The name of the user if the status is created
  by a user."
}]
```

Get information about all statuses

Return a JSON Array representation of all statuses.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/statuses
```

Table 103. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "buildLifeId": "The id of the build life.",
  "dateAssigned": "The assigned date of the status.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "message": "The message of the status if the status is
  created by a user or external source.",
  "origin": "The origin of the status.",
  "status": "The status.",
  "statusColor": "The color of the status.",
  "statusName": "The name of the status.",
  "user": "The name of the user if the status is created
  by a user."
}]
```

Get information about all test reports

Return a JSON representation of all test reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/tests
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "failure": "The number of failures in the test report.",
    "name": "The name of the test report.",
    "success": "The number of successes in the test
  report.",
```

```
    "successPercent": "The success percent of the test
  report.",
    "suites": [{
      "failure": "The number of failures in the test
  suite.",
      "name": "The name of the test suite.",
      "success": "The number of successes in the test
  suite.",
      "successPercent": "The success percent of the test
  suite."
    }]
  }],
  "successPercent": "The success percent of all the test
  reports."
}
```

Get information about all test reports

Return a JSON representation of all test reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/tests
```

Table 104. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "failure": "The number of failures in the test report.",
    "name": "The name of the test report.",
    "success": "The number of successes in the test
  report.",
    "successPercent": "The success percent of the test
  report.",
    "suites": [{
      "failure": "The number of failures in the test
  suite.",
      "name": "The name of the test suite.",
      "success": "The number of successes in the test
  suite.",
      "successPercent": "The success percent of the test
  suite."
    }]
  }],
  "successPercent": "The success percent of all the test
  reports."
}
```

Get information about the source analytic report

Return a JSON representation of the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analytics/{id}
```

Table 105. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic report.",
  "count": "The count of findings in the source analytic
  report.",
  "findings": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic report.",
  "location": "The REST location to get the source
  analytic report.",
  "name": "The name of the source analytic report.",
  "type": "The type of the source analytic report.",
  "url": "The URL of the source analytic report."
}
```

Get information about the source analytic report

Return a JSON representation of the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analytics/{id}
```

Table 106. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic report.",
  "count": "The count of findings in the source analytic
  report.",
  "findings": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic report.",
  "location": "The REST location to get the source
  analytic report.",
  "name": "The name of the source analytic report.",
  "type": "The type of the source analytic report.",
  "url": "The URL of the source analytic report."
}
```

Get information about the source analytic summary report

Return a JSON representation of the source analytic summary report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//latest/analyticSummaries/{name}
```

Table 107. URL parameters

Parameter	Type	Required	Description
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
```

```
  the source analytic summary report.",
  "count": "The count of findings in the source analytic
  summary report.",
  "findings": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic summary report.",
  "location": "The REST location to get the source
  analytic summary report.",
  "name": "The name of the source analytic summary report.",
  "type": "The type of the source analytic summary report.",
  "url": "The URL of the source analytic summary report."
}
```

Get information about the source analytic summary report

Return a JSON representation of the source analytic summary report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/build-lives//{id}/analyticSummaries/{name}
```

Table 108. URL parameters

Parameter	Type	Required	Description
id	string	true	
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
  "count": "The count of findings in the source analytic
  summary report.",
  "findings": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic summary report.",
  "location": "The REST location to get the source
  analytic summary report.",
  "name": "The name of the source analytic summary report.",
  "type": "The type of the source analytic summary report.",
  "url": "The URL of the source analytic summary report."
```

```
}
```

buildProcessTemplates resource

Resources for working with build process templates.

/buildProcessTemplates/{id}/workflow GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow
```

Table 109. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/buildProcessTemplates/{id}/workflow/graph GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph
```

Table 110. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/buildProcessTemplates/{id}/workflow/graph POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph
```

Table 111. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/buildProcessTemplates/{id}/workflow/graph PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph
```

Table 112. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/buildProcessTemplates/{id}/workflow/graph/insert POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/insert
```

Table 113. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/buildProcessTemplates/{id}/workflow/graph/{id} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}
```

Table 114. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/buildProcessTemplates/{id}/workflow/graph/{id}/iterate DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}/iterate
```

Table 115. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/buildProcessTemplates/{id}/workflow/graph/{id}/iterate POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}/iterate
```

Table 116. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 117. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 118. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName}
```

Table 119. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.
propertyName	string	true	The identifier of a job config.

Create a new property by copy on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/copyproperty
```

Table 120. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Create a process template

Request

```
POST https://{hostname}:{port}
  /build/rest2/buildProcessTemplates
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
```

```
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "teams": [{
    "resourceRoleId": "The id of the resource role",
    "teamId": "The id of the team"
  }]
}
```

Delete a job in the process definition.

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/workflow/graph/{id}
```

Table 121. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

Delete a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}
```

Table 122. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Delete a specified name property on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/property/{name}
```

Table 123. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
name	string	true	The name of the property

Delete the artifact on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/artifacts/{id}
```

Table 124. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	long	true	The id of the artifact

Delete the resource on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/resources/{seq}
```

Table 125. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
seq	int	true	The sequence of the resource

Get a list of processes that use the specified process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/processes?{parameters}
```

Table 126. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process templates to return per page.
pageNumber	string	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'asc' or 'desc'.

Table 127. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process using this process
  template is active",
  "description": "The description of the process using
  this process template",
  "id": "The ID of the process using this process template",
  "name": "The name of the process using this process
  template",
  "project": "The name of the project to which the process
  using this process template belongs"
}]
```

Get all artifacts on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/artifacts?{parameters}
```

Table 128. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template artifacts to return per page.
pageNumber	string	false	The page of process template artifacts that should be returned.

Table 129. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all properties on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/properties?{parameters}
```

Table 130. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template properties to return per page.
pageNumber	string	false	The page of process template properties that should be returned.

Table 131. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/resources
```

Table 132. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get avaiable resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/resourceOptions/{id}
```

Table 133. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	int	true	The id of the selected resource

Get information about a process template

Return a JSON representation of a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}
```

Table 134. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
```

```
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Get information about all build process templates

Return a JSON representation of all build process templates.

Request

```
GET https://{hostname}:{port}
  /build/rest2/buildProcessTemplates?{parameters}
```

Table 135. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of process templates to return per page.

Table 135. Request parameters (continued)

Parameter	Type	Required	Description
pageNumber	int	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'ASC' or 'DESC'.
filterValue_name	string	false	The name pattern of the process template to search for.
filterValue_type	string	false	The type of the process template to search for. Possible values are Any/Build/Secondary

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
```

```
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}]
```

Update a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}
```

Table 136. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
```

```
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Update artifacts on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/artifacts
```

Table 137. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update properties on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/properties
```

Table 138. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update resources on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/buildProcessTemplates/{id}/resources
```

Table 139. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

codestation-build-lives resource

/codestation-build-lives//latest GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest
```

/codestation-build-lives//{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}
```

Table 140. URL parameters

Parameter	Type	Required	Description
id	string	true	

Create a property in codestation buildLife

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest/properties
```

Create a property in codestation buildLife

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}/properties
```

Table 141. URL parameters

Parameter	Type	Required	Description
id	string	true	

Delete the Version of CodeStation project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest
```

Delete the Version of CodeStation project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}
```

Table 142. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get Versions of a CodeStation project

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives/?{parameters}
```

Table 143. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of Versions of a CodeStation project to return per page.
pageNumber	string	false	The page of Versions of a CodeStation project that should be returned.

Table 143. Request parameters (continued)

Parameter	Type	Required	Description
orderField	string	false	The field to use when sorting the Versions of a CodeStation project. This would be 'name' or 'description'.
sortType	string	false	The order to use when sorting the Versions of a CodeStation project. This would either be 'asc' or 'desc'.

Get the dependencies of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest/dependencies?{parameters}
```

Table 144. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of dependencies to return per page.
pageNumber	string	false	The page of dependencies that should be returned.
orderField	string	false	The field to use when sorting the dependencies. This would be 'codestationProjectName', 'startDate', 'id', 'status' or 'stamp'.
sortType	string	false	The order to use when sorting the dependencies. This would either be 'asc' or 'desc'.

Get the dependencies of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}/dependencies?{parameters}
```

Table 145. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of dependencies to return per page.

Table 145. Request parameters (continued)

Parameter	Type	Required	Description
pageNumber	string	false	The page of dependencies that should be returned.
orderField	string	false	The field to use when sorting the dependencies. This would be 'codestationProjectName', 'startDate', 'id', 'status' or 'stamp'.
sortType	string	false	The order to use when sorting the dependencies. This would either be 'asc' or 'desc'.

Table 146. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the properties of a Version of a CodeStation Project.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest/properties?{parameters}
```

Table 147. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of properties to return per page.
pageNumber	string	false	The page of properties that should be returned.
orderField	string	false	The field to use when sorting the properties. This would be 'name' or 'value'.
sortType	string	false	The order to use when sorting the properties. This would either be 'asc' or 'desc'.

Get the properties of a Version of a CodeStation Project.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}/properties?{parameters}
```

Table 148. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of properties to return per page.
pageNumber	string	false	The page of properties that should be returned.
orderField	string	false	The field to use when sorting the properties. This would be 'name' or 'value'.
sortType	string	false	The order to use when sorting the properties. This would either be 'asc' or 'desc'.

Table 149. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the statuses of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest/statuses?{parameters}
```

Table 150. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of statuses to return per page.
pageNumber	string	false	The page of statuses that should be returned.
orderField	string	false	The field to use when sorting the statuses. This would be 'name' or 'userName'.
sortType	string	false	The order to use when sorting the statuses. This would either be 'asc' or 'desc'.

Get the statuses of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}/statuses?{parameters}
```

Table 151. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of statuses to return per page.
pageNumber	string	false	The page of statuses that should be returned.
orderField	string	false	The field to use when sorting the statuses. This would be 'name' or 'userName'.
sortType	string	false	The order to use when sorting the statuses. This would either be 'asc' or 'desc'.

Table 152. URL parameters

Parameter	Type	Required	Description
id	string	true	

Update property in codestation buildLife

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-build-lives//latest/properties
```

Update property in codestation buildLife

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-build-lives//{id}/properties
```

Table 153. URL parameters

Parameter	Type	Required	Description
id	string	true	

codestation-projects resource

/codestation-projects/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}
```

Table 154. URL parameters

Parameter	Type	Required	Description
id	string	true	

/codestation-projects/{id}/build-lives/latest GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest
```

Table 155. URL parameters

Parameter	Type	Required	Description
id	string	true	

/codestation-projects/{id}/build-lives/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}
```

Table 156. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Create a codestation project

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-projects
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The codestation project description",
```

```
  "name": "The name of the codestation project",
  "teams": [{
    "resourceRoleId": "The id of the resource role",
    "teamId": "The id of the team"
  }]
}
```

Create a property in codestation buildLife

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest/properties
```

Table 157. URL parameters

Parameter	Type	Required	Description
id	string	true	

Create a property in codestation buildLife

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}/properties
```

Table 158. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Create a property in codestation project

Request

```
POST https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/properties
```

Table 159. URL parameters

Parameter	Type	Required	Description
id	string	true	

Delete the CodeStation project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}
```

Table 160. URL parameters

Parameter	Type	Required	Description
id	string	true	

Delete the Version of CodeStation project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest
```

Table 161. URL parameters

Parameter	Type	Required	Description
id	string	true	

Delete the Version of CodeStation project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}
```

Table 162. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Get CodeStation projects

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects?{parameters}
```

Table 163. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of CodeStation projects to return per page.
pageNumber	string	false	The page of CodeStation projects that should be returned.
orderField	string	false	The field to use when sorting the CodeStation projects. This would be 'name' or 'description'.
sortType	string	false	The order to use when sorting the CodeStation projects. This would either be 'asc' or 'desc'.

Get Versions for a new CodeStation project

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/new/build-lives
```

Get Versions of a CodeStation project

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives?{parameters}
```

Table 164. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of Versions of a CodeStation project to return per page.
pageNumber	string	false	The page of Versions of a CodeStation project that should be returned.
orderField	string	false	The field to use when sorting the Versions of a CodeStation project. This would be 'name' or 'description'.
sortType	string	false	The order to use when sorting the Versions of a CodeStation project. This would either be 'asc' or 'desc'.

Table 165. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get all properties on a CodeStation Project

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/properties?{parameters}
```

Table 166. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of CodeStation Project properties to return per page.
pageNumber	string	false	The page of CodeStation Project properties that should be returned.
orderField	string	false	The field to use when sorting the CodeStation Project properties. This would be 'name' or 'value'.
sortType	string	false	The order to use when sorting the CodeStation Project properties. This would either be 'asc' or 'desc'.

Table 167. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the dependencies of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest/dependencies?{parameters}
```

Table 168. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of dependencies to return per page.
pageNumber	string	false	The page of dependencies that should be returned.
orderField	string	false	The field to use when sorting the dependencies. This would be 'codestationProjectName', 'startDate', 'id', 'status' or 'stamp'.
sortType	string	false	The order to use when sorting the dependencies. This would either be 'asc' or 'desc'.

Table 169. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the dependencies of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}/dependencies?{parameters}
```

Table 170. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of dependencies to return per page.
pageNumber	string	false	The page of dependencies that should be returned.
orderField	string	false	The field to use when sorting the dependencies. This would be 'codestationProjectName', 'startDate', 'id', 'status' or 'stamp'.
sortType	string	false	The order to use when sorting the dependencies. This would either be 'asc' or 'desc'.

Table 171. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Get the properties of a Version of a CodeStation Project.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest/properties?{parameters}
```

Table 172. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of properties to return per page.
pageNumber	string	false	The page of properties that should be returned.
orderField	string	false	The field to use when sorting the properties. This would be 'name' or 'value'.
sortType	string	false	The order to use when sorting the properties. This would either be 'asc' or 'desc'.

Table 173. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the properties of a Version of a CodeStation Project.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}/properties?{parameters}
```

Table 174. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of properties to return per page.

Table 174. Request parameters (continued)

Parameter	Type	Required	Description
pageNumber	string	false	The page of properties that should be returned.
orderField	string	false	The field to use when sorting the properties. This would be 'name' or 'value'.
sortType	string	false	The order to use when sorting the properties. This would either be 'asc' or 'desc'.

Table 175. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Get the statuses of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest/statuses?{parameters}
```

Table 176. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of statuses to return per page.
pageNumber	string	false	The page of statuses that should be returned.
orderField	string	false	The field to use when sorting the statuses. This would be 'name' or 'userName'.
sortType	string	false	The order to use when sorting the statuses. This would either be 'asc' or 'desc'.

Table 177. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the statuses of a CodeStation Project Version.

Request

```
GET https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}/statuses?{parameters}
```

Table 178. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of statuses to return per page.
pageNumber	string	false	The page of statuses that should be returned.
orderField	string	false	The field to use when sorting the statuses. This would be 'name' or 'userName'.
sortType	string	false	The order to use when sorting the statuses. This would either be 'asc' or 'desc'.

Table 179. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Update a codestation project

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}
```

Table 180. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The codestation project description",
  "name": "The name of the codestation project"
}
```

Update property in codestation buildLife

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/latest/properties
```

Table 181. URL parameters

Parameter	Type	Required	Description
id	string	true	

Update property in codestation buildLife

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/build-lives/{id}/properties
```

Table 182. URL parameters

Parameter	Type	Required	Description
id	string	true	
id	string	true	

Update property in codestation project

Request

```
PUT https://{hostname}:{port}
  /build/rest2/codestation-projects/{id}/properties
```

Table 183. URL parameters

Parameter	Type	Required	Description
id	string	true	

conf/locale resource

/conf/locale/{language}.json GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/conf/locale/{language}.json
```

Table 184. URL parameters

Parameter	Type	Required	Description
language	string	true	

currentActivity resource

/currentActivity/agentDirLocks GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/currentActivity/agentDirLocks
```

/currentActivity/schedules GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/currentActivity/schedules
```

/currentActivity/lockableResources GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/currentActivity/lockableResources
```

dashboard resource

/dashboard/activity GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/dashboard/activity?{parameters}
```

Table 185. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of projects to return per page.
pageNumber	string	false	The page of projects that should be returned.

Table 185. Request parameters (continued)

Parameter	Type	Required	Description
sortType	string	false	The order to use when sorting the projects. This would either be 'asc' or 'desc'.
showInactive	boolean	false	When set to true, only show inactive projects. When set to false, only show active projects.

/dashboard/activity/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/dashboard/activity/{id}?{parameters}
```

Table 186. Request parameters

Parameter	Type	Required	Description
showInactive	boolean	false	When set to true, show all processes for inactive projects. When set to false, only show active workflos for active projects.

Table 187. URL parameters

Parameter	Type	Required	Description
id	long	true	

/dashboard/projects GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/dashboard/projects?{parameters}
```

Table 188. Request parameters

Parameter	Type	Required	Description
name	string	false	The project name pattern, * is allowed as a wildcard character
showInactive	boolean	false	When set to true, only show inactive projects. When set to false, only show active projects.

/dashboard/tags GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/dashboard/tags?{parameters}
```

Table 189. Request parameters

Parameter	Type	Required	Description
name	string	false	The tag name pattern, * is allowed as a wildcard character
showInactive	boolean	false	When set to true, only show inactive projects. When set to false, only show active projects.

dependencyConfig resource

Retrieve information about addable dependencies

Retrieve information about other processes that can bee added as dependencies to a process

Request

```
GET https://{hostname}:{port}
  /build/rest2/dependencyConfig?{parameters}
```

Table 190. Request parameters

Parameter	Type	Required	Description
fullName	string	false	The name pattern to use when looking up the dependency projects/processes to add.
projectId	long	true	The ID of the project to which dependencies are to be added.
processId	long	true	The ID of the process to which dependencies are to be added.

Example response sent by this endpoint:

```
{
  "fullName" : "The full name of the process in format \"Project - Process\" or the name of the codestation
 project",
  "processId" : "The ID of the process only if this is a non-Codestation project",
  "codestationId" : "The ID of the Codestation project only if this is a Codestation project"
}
```

dynamicAgentPools resource

Create a group rule

Request

```
PUT https://{hostname}:{port}
  /build/rest2/dynamicAgentPools/{id}
```

Table 191. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a dynamic agent pool.

This command takes a JSON request string or file. Use the following template for the request:

```
{"group": {
  "groups": "The list of group rules.",
  "logic": "The logic of the group rule. This should be
  'AND' or 'OR'.",
  "rules": [{
    "condition": "The condition of the rule. This should
  be 'IS_EQUAL_TO', 'IS_NOT_EQUAL_TO', 'CONTAINS',
  'DOES_NOT_CONTAIN', 'IS_GREATER_THAN', 'IS_LESS_THAN',
  'IS_GREATER_THAN_OR_EQUAL_TO', 'IS_LESS_THAN_OR_EQUAL_TO',
  'EXISTS' or 'DOES_NOT_EXIST'.",
    "conditionValue": "The value of the condition.",
    "type": "The type of the rule. This should be 'NAME',
  'PROPERTY', 'THROUGHPUT', 'MAX_JOBS' or 'DESCRIPTION'."
  }]
}}
```

Get information about all dynamic agent pools

Return a JSON Array representation of all dynamic agent pools.

Request

```
GET https://{hostname}:{port}
  /build/rest2/dynamicAgentPools
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "group": {
    "groups": "The list of group rules.",
    "logic": "The logic of the group rule. This should be
  'AND' or 'OR'.",
    "rules": [{
      "condition": "The condition of the rule. This should
  be 'IS_EQUAL_TO', 'IS_NOT_EQUAL_TO', 'CONTAINS',
  'DOES_NOT_CONTAIN', 'IS_GREATER_THAN', 'IS_LESS_THAN',
  'IS_GREATER_THAN_OR_EQUAL_TO', 'IS_LESS_THAN_OR_EQUAL_TO',
  'EXISTS' or 'DOES_NOT_EXIST'.",
      "conditionValue": "The value of the condition.",
      "type": "The type of the rule. This should be
  'NAME', 'PROPERTY', 'THROUGHPUT', 'MAX_JOBS' or
  'DESCRIPTION'."
```

```
    }]
  },
  "id": "The id of the dynamic agent pool.",
  "name": "The name of the dynamci agent pool."
}]
```

Get information about rule conditions

Return a JSON representation of rule conditions.

Request

```
GET https://{hostname}:{port}
  /build/rest2/dynamicAgentPools/ruleConditions
```

Get information about rule types

Return a JSON representation of rule types.

Request

```
GET https://{hostname}:{port}
  /build/rest2/dynamicAgentPools/ruleTypes
```

Get information about the dynamic agent pool

Return a JSON representation of the dynamic agent pool.

Request

```
GET https://{hostname}:{port}
  /build/rest2/dynamicAgentPools/{id}
```

Table 192. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a dynamic agent pool.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "group": {
    "groups": "The list of group rules.",
    "logic": "The logic of the group rule. This should be
  'AND' or 'OR'.",
    "rules": [{
      "condition": "The condition of the rule. This should
  be 'IS_EQUAL_TO', 'IS_NOT_EQUAL_TO', 'CONTAINS',
  'DOES_NOT_CONTAIN', 'IS_GREATER_THAN', 'IS_LESS_THAN',
  'IS_GREATER_THAN_OR_EQUAL_TO', 'IS_LESS_THAN_OR_EQUAL_TO',
  'EXISTS' or 'DOES_NOT_EXIST'.",
      "conditionValue": "The value of the condition.",
      "type": "The type of the rule. This should be
```

```
  'NAME', 'PROPERTY', 'THROUGHPUT', 'MAX_JOBS' or
  'DESCRIPTION'."
    }]
  },
  "id": "The id of the dynamic agent pool.",
  "name": "The name of the dynamci agent pool."
}
```

file resource

/file/{hash} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/file/{hash}
```

Table 193. URL parameters

Parameter	Type	Required	Description
hash	string	true	

files resource

/files POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/files
```

fixedAgentPools resource

Create a fixed agent pool

Request

```
POST https://{hostname}:{port}
  /build/rest2/fixedAgentPools
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agents": "The JSON Array of agent ids in the fixed
  agent pool.",
  "description": "The description of the fixed agent pool.",
  "name": "The name of the fixed agent pool.",
  "teams": "The JSON Array of team names for the fixed
  agent pool."
```

```
}
```

Delete the fixed agent pool.

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/fixedAgentPools/{id}
```

Table 194. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a fixed agent pool.

Get information about all fixed agent pool

Return a JSON Array representation of all fixed agent pool.

Request

```
GET https://{hostname}:{port}
  /build/rest2/fixedAgentPools
```

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "agents": "The JSON Array of agent ids in the fixed
  agent pool.",
  "description": "The dexcription of the fixed agent pool.",
  "id": "The id of the fixed agent pool.",
  "location": "The REST URI to get the information of
  fixed agent pool.",
  "name": "The name of the fixed agent pool."
}]
```

Get information about the fixed agent pool

Return a JSON representation of the fixed agent pool.

Request

```
GET https://{hostname}:{port}
  /build/rest2/fixedAgentPools/{id}
```

Table 195. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a fixed agent pool.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agents": "The JSON Array of agent ids in the fixed
  agent pool.",
  "description": "The dexcription of the fixed agent pool.",
  "id": "The id of the fixed agent pool.",
  "location": "The REST URI to get the information of
  fixed agent pool.",
  "name": "The name of the fixed agent pool."
}
```

Update the fixed agent pool

Request

```
PUT https://{hostname}:{port}
  /build/rest2/fixedAgentPools/{id}
```

Table 196. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a fixed agent pool.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agents": "The JSON Array of agent ids in the fixed
  agent pool.",
  "description": "The dexcription of the fixed agent pool.",
  "name": "The name of the fixed agent pool."
}
```

group resource

group GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/group
```

group POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/group
```

group/{group} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/group/{group}
```

Table 197. URL parameters

Parameter	Type	Required	Description
group	string	true	

group/{group} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/group/{group}
```

Table 198. URL parameters

Parameter	Type	Required	Description
group	string	true	

group/{group} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/group/{group}
```

Table 199. URL parameters

Parameter	Type	Required	Description
group	string	true	

group/{group}/members GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/group/{group}/members
```

Table 200. URL parameters

Parameter	Type	Required	Description
group	string	true	

group/{group}/members/{user} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/group/{group}/members/{user}
```

Table 201. URL parameters

Parameter	Type	Required	Description
user	string	true	
group	string	true	

group/{group}/members/{user} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/group/{group}/members/{user}
```

Table 202. URL parameters

Parameter	Type	Required	Description
user	string	true	
group	string	true	

import resource

/import PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/import
```

jobPreConditions resource

Get information about all job preConditions

Return a JSON representation of all job preConditions.

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobPreConditions
```

jobPreConditionScripts resource

/jobPreConditionScripts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobPreConditionScripts
```

/jobPreConditionScripts POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/jobPreConditionScripts
```

/jobPreConditionScripts/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobPreConditionScripts/{id}
```

Table 203. URL parameters

Parameter	Type	Required	Description
id	string	true	

/jobPreConditionScripts/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/jobPreConditionScripts/{id}
```

Table 204. URL parameters

Parameter	Type	Required	Description
id	string	true	

/jobPreConditionScripts/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/jobPreConditionScripts/{id}
```

Table 205. URL parameters

Parameter	Type	Required	Description
id	string	true	

jobs resource

/jobs/{id}/steps GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobs/{id}/steps
```

Table 206. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

/jobs/{id}/steps POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/jobs/{id}/steps
```

Table 207. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

/jobs/{id}/steps/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobs/{id}/steps/{id}
```

Table 208. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job
id	string	true	

/jobs/{id}/steps/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/jobs/{id}/steps/{id}
```

Table 209. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job
id	string	true	

/jobs/{id}/steps/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/jobs/{id}/steps/{id}
```

Table 210. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job
id	string	true	

Create a job

Request

```
POST https://{hostname}:{port}
  /build/rest2/jobs
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The job description",
  "name": "The name of the job"
}
```

Delete the job

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/jobs/{id}
```

Table 211. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

Get a JSON representation of process templates that use the specified job

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobs/{id}/processTemplates?{parameters}
```

Table 212. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process templates to return per page.
pageNumber	string	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'asc' or 'desc'.

Table 213. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

Get information about all jobs

Return a JSON representation of all jobs.

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobs?{parameters}
```

Table 214. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of jobs to return per page.
pageNumber	string	false	The page of jobs that should be returned.
orderField	string	false	The field to use when sorting the jobs. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the jobs. This would either be 'asc' or 'desc'.

Get information about the job

Return a JSON representation of the job

Request

```
GET https://{hostname}:{port}
  /build/rest2/jobs/{id}
```

Table 215. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "The ID of the project that contains the job",
  "description": "The job description",
  "id": "The ID of the job",
  "location": "The URL that can be used to get the JSON
  representation of the job",
  "name": "The name of the job"
}
```

Update the job

Request

```
PUT https://{hostname}:{port}
  /build/rest2/jobs/{id}
```

Table 216. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a job. This can be the name or ID of the job

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The job description",
  "name": "The name of the job"
}
```

label resource

Add a label to buildlives.

Request

```
POST https://{hostname}:{port}
  /build/rest2/label/addToBuild
```

Delete the label of buildlives.

Request

```
POST https://{hostname}:{port}
  /build/rest2/label/deleteLabel
```

Get all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/label/gridSelect?{parameters}
```

Table 217. Request parameters

Parameter	Type	Required	Description
name	string	false	

Get all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/label/itemFileReadStore?{parameters}
```

Table 218. Request parameters

Parameter	Type	Required	Description
name	string	false	

Replace the label of buildlives.

Request

```
POST https://{hostname}:{port}
  /build/rest2/label/replaceLabel
```

logs resource

/logsjob/{jobTraceId}/step/{stepSeq}/{fileName} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/logsjob/{jobTraceId}/step/{stepSeq}/{fileName}
```

Table 219. URL parameters

Parameter	Type	Required	Description
stepSeq	int	true	
jobTraceId	long	true	
fileName	string	true	

myactivity resource

/myactivity GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/myactivity
```

/myactivity/project/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/myactivity/project/{id}
```

Table 220. URL parameters

Parameter	Type	Required	Description
id	string	true	

/myactivity/workflow/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/myactivity/workflow/{id}
```

Table 221. URL parameters

Parameter	Type	Required	Description
id	string	true	

notificationSubscriptions resource

notificationSubscriptions GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/notificationSubscriptions
```

notificationSubscriptions POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/notificationSubscriptions
```

notificationSubscriptions/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/notificationSubscriptions/{id}
```

Table 222. URL parameters

Parameter	Type	Required	Description
id	string	true	

notificationSubscriptions/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/notificationSubscriptions/{id}
```

Table 223. URL parameters

Parameter	Type	Required	Description
id	string	true	

notificationSubscriptions/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/notificationSubscriptions/{id}
```

Table 224. URL parameters

Parameter	Type	Required	Description
id	string	true	

notificationSubscriptions/{id}/children GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/notificationSubscriptions/{id}/children
```

Table 225. URL parameters

Parameter	Type	Required	Description
id	string	true	

plugins resource

Create an integration

Request

```
POST https://{hostname}:{port}
  /build/rest2/plugins{id}/integrations
```

Table 226. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "propName": "propValue, if having multi properties,
  repeat this. If the propValue is an array, please use
  JSONArray format.",
```

```
  "propSheetName": "The name of the plugin"
}
```

Delete the integration

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/plugins{id}/integrations{id}
```

Table 227. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin
id	string	true	The identifier to use when looking up an integration. This is ID of the integration

Delete the plugin

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/plugins{id}
```

Table 228. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin

Get information about all integrations of the specified plugin

Return a JSON representation of all integrations of the specified plugin.

Request

```
GET https://{hostname}:{port}
  /build/rest2/plugins{id}/integrations
```

Table 229. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "propName": "propValue, if having multi properties,
  repeat this. If the propValue is an array, please use
  JSONArray format.",
  "propSheetId": "The id of the integration",
  "propSheetName": "The name of the plugin"
}]
```

Get information about all plugins

Return a JSON representation of all plugins.

Request

```
GET https://{hostname}:{port}
  /build/rest2/plugins?{parameters}
```

Table 230. Request parameters

Parameter	Type	Required	Description
type	string	false	The type of plugin. This would either be 'Automation' or 'Source'.

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "apiVersion": "The API version of the plugin",
  "commands": [{
    "description": "The description of the command",
    "id": "The id of the command",
    "name": "The name of the command",
    "postProcessingScript": "The post processing script of
  the command",
    "propSheetDefs": [{
      "description": "The description of the plugin",
      "id": "The id of the Property sheet",
      "name": "The name of the plugin",
      "properties": [{
        "allowedValuePropSheetDef": "The id of the
  PropSheetDef containing the allowed values for the
  property",
        "allowedValues": [{
          "id": "The id of the allowed value",
          "label": "The label of the allowed value",
          "value": "The value of the allowed value"
        }],
        "default-value": "The default value of the
  property",
        "description": "The description of the property",
        "hidden": "Whether or not the property is hidden",
        "id": "The id of the property",
        "label": "A label for this property shown when
  prompting users for a value",
```

```
      "name": "The name of the property",
      "required": "Whether or not the value of the
  property is required",
      "secure": "Whether or not the value of the
  property is secure",
      "type": "The type of the property",
      "value": "The value of the property. This is only
  used for properties on non-template objects (project, but
  not project template, etc)"
    }]
  }],
  "type": "The type of the command",
  "validationScript": "The validation script of the
  command",
  "validationScriptLanguage": "The language of the
  validation script"
  }],
  "description": "The description of the plugin",
  "hash": "The hash value of the plugin",
  "id": "The id of the plugin",
  "location": "The URL that can be used to get the JSON
  representation of the plugin",
  "name": "The name of the plugin",
  "pluginId": "The Plug-in ID of the plugin",
  "pluginVersion": "The version of the plugin",
  "propSheetDefs": [{
    "description": "The description of the plugin",
    "id": "The id of the Property sheet",
    "name": "The name of the plugin",
    "properties": [{
      "allowedValuePropSheetDef": "The id of the
  PropSheetDef containing the allowed values for the
  property",
      "allowedValues": [{

      "value": "The value of the property. This is only
  used for properties on non-template objects (project, but
  not project template, etc)"
    }]
  }],
  "tag": "The tag of the plugin",
  "type": "The type of the plugin"
}]
```

Get information about the integration

Return a JSON representation of the integration

Request

```
GET https://{hostname}:{port}
  /build/rest2/plugins{id}/integrations{id}
```

Table 231. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin
id	string	true	The identifier to use when looking up an integration. This is ID of the integration

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "propName": "propValue, if having multi properties,
  repeat this. If the propValue is an array, please use
  JSONArray format.",
  "propSheetId": "The id of the integration",
  "propSheetName": "The name of the plugin"
}
```

Get information about the plugin

Return a JSON representation of the plugin

Request

```
GET https://{hostname}:{port}
  /build/rest2/plugins{id}
```

Table 232. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "apiVersion": "The API version of the plugin",
  "commands": [{
    "description": "The description of the command",
    "id": "The id of the command",
    "name": "The name of the command",

}
```

Update the integration

Request

```
PUT https://{hostname}:{port}
  /build/rest2/plugins{id}/integrations{id}
```

Table 233. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up plugin. This is the ID or name of the plugin
id	string	true	The identifier to use when looking up an integration. This is ID of the integration

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "propName": "propValue, if having multi properties,
  repeat this. If the propValue is an array, please use
  JSONArray format.",
  "propSheetName": "The name of the plugin"
}
```

Upload a plugin

Request

```
PUT https://{hostname}:{port}
  /build/rest2/plugins
```

Upload a plugin and allow downgrading if necessary

Request

```
PUT https://{hostname}:{port}
  /build/rest2/plugins/allowdowngrade
```

preferences resource

preferencesavailableLocales GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/preferencesavailableLocales
```

preflight resource

/preflight/lookupArtifactSets POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/preflight/lookupArtifactSets
```

/preflight/request POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/preflight/request
```

/preflight/request/{requestId} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/preflight/request/{requestId}
```

Table 234. URL parameters

Parameter	Type	Required	Description
requestId	long	true	

/preflight/build/{buildLifeId} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/preflight/build/{buildLifeId}
```

Table 235. URL parameters

Parameter	Type	Required	Description
buildLifeId	long	true	

processRequests resource

/processRequests POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processRequests
```

/processRequests{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/processRequests{id}
```

Table 236. URL parameters

Parameter	Type	Required	Description
id	long	true	

processTemplates resource

Resources for working with process templates.

/processTemplates/{id}/workflow GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow
```

Table 237. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/processTemplates/{id}/workflow/graph GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph
```

Table 238. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/processTemplates/{id}/workflow/graph POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph
```

Table 239. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/processTemplates/{id}/workflow/graph PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph
```

Table 240. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/processTemplates/{id}/workflow/graph/insert POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/insert
```

Table 241. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/processTemplates/{id}/workflow/graph/{id} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}
```

Table 242. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/processTemplates/{id}/workflow/graph/{id}/iterate DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}/iterate
```

Table 243. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/processTemplates/{id}/workflow/graph/{id}/iterate POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}/iterate
```

Table 244. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/processTemplates/{id}/workflow/graph/{id}/iterate/property POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 245. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/processTemplates/{id}/workflow/graph/{id}/iterate/property GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 246. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/processTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName}
```

Table 247. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.
propertyName	string	true	The identifier of a job config.

Create a new property by copy on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/copyproperty
```

Table 248. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Create a process template

Request

```
POST http://{hostname}:{port}
  /rest2/processTemplates
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "teams": [{
    "resourceRoleId": "The id of the resource role",
    "teamId": "The id of the team"
  }]
}
```

Delete a job in the process definition.

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/workflow/graph/{id}
```

Table 249. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

Delete a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}
```

Table 250. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Delete a specified name property on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/property/{name}
```

Table 251. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
name	string	true	The name of the property

Delete the artifact on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/artifacts/{id}
```

Table 252. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	long	true	The id of the artifact

Delete the resource on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/resources/{seq}
```

Table 253. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
seq	int	true	The sequence of the resource

Get a list of processes that use the specified process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/processes?{parameters}
```

Table 254. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process templates to return per page.
pageNumber	string	false	The page of process templates that should be returned.

Table 254. Request parameters (continued)

Parameter	Type	Required	Description
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'asc' or 'desc'.

Table 255. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process using this process
  template is active",
  "description": "The description of the process using
  this process template",
  "id": "The ID of the process using this process template",
  "name": "The name of the process using this process
  template",
  "project": "The name of the project to which the process
  using this process template belongs"
}]
```

Get all artifacts on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/artifacts?{parameters}
```

Table 256. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template artifacts to return per page.
pageNumber	string	false	The page of process template artifacts that should be returned.

Table 257. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all properties on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/properties?{parameters}
```

Table 258. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template properties to return per page.
pageNumber	string	false	The page of process template properties that should be returned.

Table 259. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/resources
```

Table 260. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get avaiable resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/resourceOptions/{id}
```

Table 261. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	int	true	The id of the selected resource

Get information about a process template

Return a JSON representation of a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates/{id}
```

Table 262. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
```

```
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Get information about all process templates

Return a JSON representation of all process templates.

Request

```
GET https://{hostname}:{port}
  /build/rest2/processTemplates?{parameters}
```

Table 263. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of process templates to return per page.
pageNumber	int	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'ASC' or 'DESC'.

Table 263. Request parameters (continued)

Parameter	Type	Required	Description
filterValue_name	string	false	The name pattern of the process template to search for.
filterValue_type	string	false	The type of the process template to search for. Possible values are Any/Build/Secondary

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
```

```
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}]
```

Update a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}
```

Table 264. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
```

```
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Update artifacts on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/artifacts
```

Table 265. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update properties on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/properties
```

Table 266. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update resources on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/processTemplates/{id}/resources
```

Table 267. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

projects resource

Get project details

Returns the details of the project

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}
```

Table 268. URL parameters

Parameter	Type	Required	Description
id	string	true	Project id or project name

/projects/{id}/buildProcesses/{id}/buildLives GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives?{parameters}
```

Table 269. Request parameters

Parameter	Type	Required	Description
includeInactive	string	false	

Table 270. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 270. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
preflightType	string	false	You can filter the build lives based on prefight type using the following values: • NOT_PREFLIGHT • ONLY_PREFLIGHT • ALL

/projects/{id}/buildProcesses/{id}/buildLives/latest GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest
```

Table 271. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies
```

Table 272. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies
```

Table 273. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/buildLives/latest/artifact-configs GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/artifact-configs
```

Table 274. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies-xml GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/dependencies-xml
```

Table 275. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 275. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/buildLives/latest/artifactSets GET

Request

```

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

Table 285. URL parameters (continued)

Parameter	Type	Required	Description
path	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}
```

Table 286. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies
```

Table 287. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies
```

Table 288. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifact-configs GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifact-configs
```

Table 289. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies-xml GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/dependencies-xml
```

Table 290. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets
```

Table 291. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set}
```

Table 292. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 292. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
set	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set}/artifacts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set}/artifacts?{parameters}
```

Table 293. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 294. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
set	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactSets/{set}/artifacts/{path}
```

Table 295. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
set	string	true	
path	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories
```

Table 296. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id}
```

Table 297. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id}/artifacts GET

Request

```
GET https://{hostname}:{port}

 /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id}/artifacts?{parameters}
```

Table 298. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of artifacts to return per page.
pageNumber	string	false	The page of artifacts that should be returned.

Table 299. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
id	string	true	

/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id}/artifacts/{path} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/artifactRepositories/{id}/artifacts/{path}
```

Table 300. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
id	string	true	
path	string	true	

/projects/{id}/buildProcesses/{id}/dependencies GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies
```

Table 301. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/dependencies PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies
```

Table 302. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/dependencies POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies
```

Table 303. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/dependencies/complex GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies/complex
```

Table 304. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/dependencies/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies/{id}
```

Table 305. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/dependencies/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies/{id}
```

Table 306. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/dependencies/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencies/{id}
```

Table 307. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/triggers GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/triggers
```

Table 308. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/triggers POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/triggers
```

Table 309. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/triggers/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/triggers/{id}
```

Table 310. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/triggers/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/triggers/{id}
```

Table 311. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/triggers/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/triggers/{id}
```

Table 312. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

/projects/{id}/buildProcesses/{id}/successRateReport GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/successRateReport?{parameters}
```

Table 313. Request parameters

Parameter	Type	Required	Description
time	string	false	
type	string	false	

Table 314. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

/projects/{id}/buildProcesses/{id}/successRateReport PUT

Request

```
PUT https://{hostname}:{port}

```

Table 321. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process
id	string	true	

/projects/{id}/notificationSubscriptions GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/notificationSubscriptions
```

Table 322. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

/projects/{id}/recentProcessActivity GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/recentProcessActivity
```

Table 323. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

/projects/{id}/latestStatus GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/latestStatus
```

Table 324. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

/projects/{id}/latestBuilds GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/latestBuilds
```

Table 325. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

/projects/{id}/sourceChanges GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/sourceChanges?{parameters}
```

Table 326. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of source changes to return per page.
pageNumber	string	false	The page of source changes that should be returned. The first page is 1
from	string	false	The field to use when getting the source changes from this date.
to	string	false	The field to use when getting the source chagnes to this date.

Table 327. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

/projects/{id}/sourceChangesByUser GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/sourceChangesByUser?{parameters}
```

Table 328. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of source changes to return per page.
pageNumber	string	false	The page of source changes that should be returned. The first page is 1
from	string	false	The field to use when getting the source changes from this date.
to	string	false	The field to use when getting the source chagnes to this date.

Table 329. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Create a build process

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses
```

Table 330. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The build process description",
  "name": "The name of the build process",
  "notificationScheme": "The notification scheme of the
  build process",
  "priority": "The priority of the build process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "teams": "The array of team names that have access to
  the build process",
  "template": "The process template for this build process",
```

```
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Create a label.

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/labels
```

Table 331. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "label": "The name of the label.",
  "labelDependencies": "Determines which dependencies to
  which the label should also be applied. This is not
  required. The value should be 'NONE', 'DIRECT' or 'ALL'."
}
```

Create a label.

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/labels
```

Table 332. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "label": "The name of the label.",
  "labelDependencies": "Determines which dependencies to
  which the label should also be applied. This is not
  required. The value should be 'NONE', 'DIRECT' or 'ALL'."
}
```

Create a project

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The project description",
  "name": "The name of the project",
  "tags": "The array of tag names of the project",
  "teams": "The array of team names of the project",
  "template": "The project template for this project",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Create a secondary process

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses
```

Table 333. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The secondary process description",
  "name": "The name of the secondary process",
  "notificationScheme": "The notification scheme of the
  secondary process",
  "priority": "The priority of the secondary process",
  "properties": [{
    "allowed-values": "The values users are allowed to
```

```
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "teams": "The array of team names that have access to
  the secondary process",
  "template": "The process template for this secondary
  process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Create a source config

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/sourceConfigs
```

Table 334. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "ignoreRepositoryTrigger": "Whether or not the source
  config should ignore repository triggers",
  "name": "The name of the source config",
  "respository": "The repository that the source config
  will use",
  "templateId": "The source config template ID for this
  source config",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Create a status.

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/statuses
```

Table 335. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "externalMessage": "The message of the status if the
  status is created by an external source.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "status": "The name of the status."
}
```

Create a status.

Request

```
POST https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/statuses
```

Table 336. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "externalMessage": "The message of the status if the
  status is created by an external source.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "status": "The name of the status."
}
```

Delete a specified name property in process propertes

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/processes/{id}/properties/{name}
```

Table 337. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a process. This can be the name or ID of the process
name	string	true	The name of the property

Delete a specified name property in process propertes

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/properties/{name}
```

Table 338. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
name	string	true	The name of the property

Delete a specified name property in process propertes

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}/properties/{name}
```

Table 339. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process
name	string	true	The name of the property

Delete the build process

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}
```

Table 340. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 340. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Delete the project

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}
```

Table 341. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Delete the secondary process

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}
```

Table 342. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process

Delete the source config

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/sourceConfigs/{id}
```

Table 343. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config

Get a summary of all the findings in the source analytic report

Return a JSON representation of the summary of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analyticSummaries/{name}/summaries
```

Table 344. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get a summary of all the findings in the source analytic report

Return a JSON representation of the summary of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analyticSummaries/{name}/summaries
```

Table 345. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get activities shown on the process dashboard

Return a JSON representation of the activities on the process dashboard

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dashboardActivity
```

Table 346. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get all the source analytic reports

Return a JSON representation of all source analytic reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analytics
```

Table 347. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic report.",
    "count": "The count of findings in the source analytic
  report.",
    "id": "The id of the source analytic report.",
    "location": "The REST location to get the source
  analytic report.",
    "name": "The name of the source analytic report.",
    "type": "The type of the source analytic report.",
    "url": "The URL of the source analytic report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic reports

Return a JSON representation of all source analytic reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analytics
```

Table 348. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 348. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic report.",
    "count": "The count of findings in the source analytic
  report.",
    "id": "The id of the source analytic report.",
    "location": "The REST location to get the source
  analytic report.",
    "name": "The name of the source analytic report.",
    "type": "The type of the source analytic report.",
    "url": "The URL of the source analytic report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic summary reports

Return a JSON representation of all source analytic summary reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analyticSummaries
```

Table 349. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
```

```
    "count": "The count of findings in the source analytic
  summary report.",
    "id": "The id of the source analytic summary report.",
    "location": "The REST location to get the source
  analytic summary report.",
    "name": "The name of the source analytic summary
  report.",
    "type": "The type of the source analytic summary
  report.",
    "url": "The URL of the source analytic summary report."
  }],
  "totalRecords": "The number of reports."
}
```

Get all the source analytic summary reports

Return a JSON representation of all source analytic summary reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analyticSummaries
```

Table 350. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
    "count": "The count of findings in the source analytic
  summary report.",
    "id": "The id of the source analytic summary report.",
    "location": "The REST location to get the source
  analytic summary report.",
    "name": "The name of the source analytic summary
  report.",
    "type": "The type of the source analytic summary
  report.",
    "url": "The URL of the source analytic summary report."
  }],
  "totalRecords": "The number of reports."
}
```

Get dependencies of the build process

Return a XML representation of the dependencies of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependenciesXml
```

Table 351. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get dependency summaries of the build process

Return a JSON representation of the dependency summaries of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencySummaries
```

Table 352. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get general dependency configuration of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencyConfig
```

Table 353. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get information about all code coverage reports

Return a JSON representation of all code coverage reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/codeCoverage
```

Table 354. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "branchPercentage": "The branch percentage of the code
  coverage report.",
    "buildLifeId": "The id of the build life that contains
  the code coverage report.",
    "groups": [{
      "branchPercentage": "The branch percentage of the
  group in the code coverage report.",
      "complexity": "The complexity of the group in the
  code coverage report.",
      "linePercentage": "The line percentage of the group
  in the code coverage report.",
      "methodPercentage": "The method percentage of the
  group in the code coverage report.",
      "name": "The name of the group in the code coverage
  report."
    }],
    "linePercentage": "The line percentage of the code
  coverage report.",
    "methodPercentage": "The method percentage of the code
  coverage report.",
```

```
    "name": "The name of the code coverage report.",
    "type": "The type of the code coverage report."
  }],
  "totalReports": "The number of the code coverage reports."
}
```

Get information about all code coverage reports

Return a JSON representation of all code coverage reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/codeCoverage
```

Table 355. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "branchPercentage": "The branch percentage of the code
  coverage report.",
    "buildLifeId": "The id of the build life that contains
  the code coverage report.",
    "groups": [{
      "branchPercentage": "The branch percentage of the
  group in the code coverage report.",
      "complexity": "The complexity of the group in the
  code coverage report.",
      "linePercentage": "The line percentage of the group
  in the code coverage report.",
      "methodPercentage": "The method percentage of the
  group in the code coverage report.",
      "name": "The name of the group in the code coverage
  report."
    }],
    "linePercentage": "The line percentage of the code
  coverage report.",
    "methodPercentage": "The method percentage of the code
  coverage report.",
    "name": "The name of the code coverage report.",
    "type": "The type of the code coverage report."
  }],
```

```
  "totalReports": "The number of the code coverage reports."
}
```

Get information about all issues.

Return a JSON representation of all issues.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/issues
```

Table 356. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "count": "The number of the issues.",
  "issues": [{
    "id": "The id of the issue.",
    "name": "The name of the issue."
  }]
}
```

Get information about all issues.

Return a JSON representation of all issues.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/issues
```

Table 357. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Table 357. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "count": "The number of the issues.",
  "issues": [{
    "id": "The id of the issue.",
    "name": "The name of the issue."
  }]
}
```

Get information about all labels

Return a JSON Array representation of all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/labels
```

Table 358. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "assignedDate": "The assigned date of the label.",
  "assignedDateFormat": "The format of the assigned date.",
  "buildLifeId": "The id of the build life.",
  "label": "The name of the label.",
  "labelId": "The id of the label.",
  "user": "The user that applied the label."
}]
```

Get information about all labels

Return a JSON Array representation of all labels.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/labels
```

Table 359. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "assignedDate": "The assigned date of the label.",
  "assignedDateFormat": "The format of the assigned date.",
  "buildLifeId": "The id of the build life.",
  "label": "The name of the label.",
  "labelId": "The id of the label.",
  "user": "The user that applied the label."
}]
```

Get information about all of the findings in the source analytic report

Return a JSON representation of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analytics/{id}/findings
```

Table 360. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get information about all of the findings in the source analytic report

Return a JSON representation of all the findings in the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analytics/{id}/findings
```

Table 361. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "records": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "totalRecords": "The number of findings."
}
```

Get information about all source change sets

Return a JSON Array representation of all source change sets.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/sourceChange
```

Table 362. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "comment": "The comment of the source change set.",
  "commitDate": "The commit date of the source change set.",
  "id": "The id of the source change set.",
  "paths": [{
    "path": "The path of the change.",
    "type": "The type of the change."
  }],
  "user": "The user name who submitted the source change
  set.",
  "version": "The version of the source change set."
}]
```

Get information about all source change sets

Return a JSON Array representation of all source change sets.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/sourceChange
```

Table 363. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Table 363. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "comment": "The comment of the source change set.",
  "commitDate": "The commit date of the source change set.",
  "id": "The id of the source change set.",
  "paths": [{
    "path": "The path of the change.",
    "type": "The type of the change."
  }],
  "user": "The user name who submitted the source change
  set.",
  "version": "The version of the source change set."
}]
```

Get information about all source configs

Return a JSON representation of all source configs.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/sourceConfigs
```

Table 364. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "id": "The ID of the source config",
  "ignoreRepositoryTrigger": "Whether or not the source
  config should ignore repository triggers",
  "inTemplateCompliance": "Whether or not the source
  config is in compliance with its template",
  "location": "The URL that can be used to get the JSON
  representation of the source config",
  "name": "The name of the source config",
  "respository": "The repository that the source config
```

```
  will use",
  "templateId": "The source config template ID for this
  source config",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}]
```

Get information about all statuses

Return a JSON Array representation of all statuses.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/statuses
```

Table 365. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "buildLifeId": "The id of the build life.",
  "dateAssigned": "The assigned date of the status.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "message": "The message of the status if the status is
  created by a user or external source.",
  "origin": "The origin of the status.",
  "status": "The status.",
  "statusColor": "The color of the status.",
  "statusName": "The name of the status.",
  "user": "The name of the user if the status is created
  by a user."
}]
```

Get information about all statuses

Return a JSON Array representation of all statuses.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/statuses
```

Table 366. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "buildLifeId": "The id of the build life.",
  "dateAssigned": "The assigned date of the status.",
  "jobTraceId": "The id of the job trace if the status is
  created by a job.",
  "message": "The message of the status if the status is
  created by a user or external source.",
  "origin": "The origin of the status.",
  "status": "The status.",
  "statusColor": "The color of the status.",
  "statusName": "The name of the status.",
  "user": "The name of the user if the status is created
  by a user."
}]
```

Get information about all test reports

Return a JSON representation of all test reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/tests
```

Table 367. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
```

```
    "failure": "The number of failures in the test report.",
    "name": "The name of the test report.",
    "success": "The number of successes in the test
  report.",
    "successPercent": "The success percent of the test
  report.",
    "suites": [{
      "failure": "The number of failures in the test
  suite.",
      "name": "The name of the test suite.",
      "success": "The number of successes in the test
  suite.",
      "successPercent": "The success percent of the test
  suite."
    }]
  }],
  "successPercent": "The success percent of all the test
  reports."
}
```

Get information about all test reports

Return a JSON representation of all test reports.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/tests
```

Table 368. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "reports": [{
    "failure": "The number of failures in the test report.",
    "name": "The name of the test report.",
    "success": "The number of successes in the test
  report.",
    "successPercent": "The success percent of the test
  report.",
    "suites": [{
      "failure": "The number of failures in the test
  suite.",
```

```
      "name": "The name of the test suite.",
      "success": "The number of successes in the test
  suite.",
      "successPercent": "The success percent of the test
  suite."
    }]
  }],
  "successPercent": "The success percent of all the test
  reports."
}
```

Get information about build activity for a specific build life

Return a JSON representation of the build activity

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/activity/{id}
```

Table 369. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	int	true	The ID of the build life

Get information about changeset for a specific userName

Return a JSON representation of the changeset

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/sourceChanges/changeset/{userName}?{parameters}
```

Table 370. Request parameters

Parameter	Type	Required	Description
from	string	false	The field to use when getting the source changes from this date.
to	string	false	The field to use when getting the source chagnes to this date.

Table 371. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
userName	string	true	The userName of the changeset

Get information about changeset for a specific userName

Return a JSON representation of the changeset

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/sourceChangesByUser/changeset/{userName}?{parameters}
```

Table 372. Request parameters

Parameter	Type	Required	Description
from	string	false	The field to use when getting the source changes from this date.
to	string	false	The field to use when getting the source chagnes to this date.

Table 373. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
userName	string	true	The userName of the changeset

Get information about queried build processes

Return a JSON representation of build processes.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses?{parameters}
```

Table 374. Request parameters

Parameter	Type	Required	Description
nameLike	string	false	The pattern to use when looking up the process by name
pageNumber	int	false	The page of build processes that should be returned
pageLineCount	int	false	The number of build processes to return per page

Table 375. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the build process is active",
  "description": "The build process description",
  "id": "The ID of the build process",
  "location": "The URL that can be used to get the JSON
  representation of the build process",
  "name": "The name of the build process",
  "notificationScheme": "The notification scheme of the
  build process",
  "priority": "The priority of the build process",
  "projectId": "The ID of the project that contains the
  build process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
```

```
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}]
```

Get information about queried processes

Return a JSON representation of processes.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/processes?{parameters}
```

Table 376. Request parameters

Parameter	Type	Required	Description
modifiedSince	int	false	The time in millisecond
nameLike	string	false	The pattern to use when looking up the process by name
pageNumber	int	false	The page of processes that should be returned
pageLineCount	int	false	The number of processes to return per page

Table 377. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the build process is active",
  "description": "The build process description",
  "id": "The ID of the build process",
  "location": "The URL that can be used to get the JSON
  representation of the build process",
  "name": "The name of the build process",
  "notificationScheme": "The notification scheme of the
  build process",
```

```
  "priority": "The priority of the build process",
  "projectId": "The ID of the project that contains the
  build process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}]
```

Get information about queried projects

Return a JSON representation of queried projects.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects?{parameters}
```

Table 378. Request parameters

Parameter	Type	Required	Description
nameLike	string	false	The pattern to use when looking up the project by name.
pageNumber	string	false	The page of projects that should be returned.

Table 378. Request parameters (continued)

Parameter	Type	Required	Description
pageLineCount	string	false	The number of projects to return per page.
activeFilter	string	false	The active filter of projects. Possible values are active/inactive/all.

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the project is active.",
  "description": "The project description",
  "id": "The ID of the project",
  "location": "The URL that can be used to get the JSON
  representation of the project",
  "name": "The name of the project",
  "tags": "The array of tag names of the project",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}]
```

Get information about queried secondary processes

Return a JSON representation of secondary processes.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses
```

Table 379. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the secondary process is
  active",
  "description": "The secondary process description",
  "id": "The ID of the secondary process",
  "location": "The URL that can be used to get the JSON
  representation of the secondary process",
  "name": "The name of the secondary process",
  "notificationScheme": "The notification scheme of the
  secondary process",
  "priority": "The priority of the secondary process",
```

```
  "projectId": "The ID of the project containing the
  secondary process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}]
```

Get information about the build process

Return a JSON representation of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}
```

Table 380. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 380. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the build process is active",
  "description": "The build process description",
  "id": "The ID of the build process",
  "location": "The URL that can be used to get the JSON
  representation of the build process",
  "name": "The name of the build process",
  "notificationScheme": "The notification scheme of the
  build process",
  "priority": "The priority of the build process",
  "projectId": "The ID of the project that contains the
  build process",
  "properties": [{

  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Get information about the project

Return a JSON representation of the project

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}
```

Table 381. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the project is active.",
  "description": "The project description",
  "id": "The ID of the project",
  "location": "The URL that can be used to get the JSON
  representation of the project",
  "name": "The name of the project",
  "tags": "The array of tag names of the project",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Get information about the secondary process

Return a JSON representation of the secondary process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}
```

Table 382. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the secondary process is
  active",
  "description": "The secondary process description",
  "id": "The ID of the secondary process",
  "location": "The URL that can be used to get the JSON

    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Get information about the source analytic report

Return a JSON representation of the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analytics/{id}
```

Table 383. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic report.",
  "count": "The count of findings in the source analytic
  report.",
  "findings": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic report.",
  "location": "The REST location to get the source
  analytic report.",
  "name": "The name of the source analytic report.",
  "type": "The type of the source analytic report.",
  "url": "The URL of the source analytic report."
}
```

Get information about the source analytic report

Return a JSON representation of the source analytic report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analytics/{id}
```

Table 384. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 384. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	
id	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic report.",
  "count": "The count of findings in the source analytic
  report.",
  "findings": [{
    "description": "The description of the finding.",
    "file": "The file containing the finding.",
    "id": "The id of the finding.",
    "line": "The line number of the finding in the file.",
    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "status": "The status of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic report.",
  "location": "The REST location to get the source
  analytic report.",
  "name": "The name of the source analytic report.",
  "type": "The type of the source analytic report.",
  "url": "The URL of the source analytic report."
}
```

Get information about the source analytic summary report

Return a JSON representation of the source analytic summary report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/latest/analyticSummaries/{name}
```

Table 385. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

Table 385. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
  "count": "The count of findings in the source analytic
  summary report.",
  "findings": [{
    "count": "The count of the finding.",

    "name": "The name of the finding.",
    "severity": "The severity of the finding.",
    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic summary report.",
  "location": "The REST location to get the source
  analytic summary report.",
  "name": "The name of the source analytic summary report.",
  "type": "The type of the source analytic summary report.",
  "url": "The URL of the source analytic summary report."
}
```

Get information about the source analytic summary report

Return a JSON representation of the source analytic summary report.

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/buildLives/{id}/analyticSummaries/{name}
```

Table 386. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Table 386. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	
name	string	true	The identifier to use when looking up a source analytic report.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "buildLifeId": "The id of the build life that contains
  the source analytic summary report.",
  "count": "The count of findings in the source analytic
  summary report.",
  "findings": [{
    "count": "The count of the finding.",
    "description": "The description of the finding.",
    "name": "The name of the finding.",

    "url": "The url of the finding."
  }],
  "id": "The id of the source analytic summary report.",
  "location": "The REST location to get the source
  analytic summary report.",
  "name": "The name of the source analytic summary report.",
  "type": "The type of the source analytic summary report.",
  "url": "The URL of the source analytic summary report."
}
```

Get information about the source config

Return a JSON representation of the source config

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/sourceConfigs/{id}
```

Table 387. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Table 387. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "id": "The ID of the source config",
  "ignoreRepositoryTrigger": "Whether or not the source
  config should ignore repository triggers",
  "inTemplateCompliance": "Whether or not the source
  config is in compliance with its template",
  "location": "The URL that can be used to get the JSON
  representation of the source config",
  "name": "The name of the source config",
  "respository": "The repository that the source config
  will use",
  "templateId": "The source config template ID for this
  source config",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Get paginated build activity information

Return a JSON representation of the activities in pages

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/activity/{pageSize}/{page}
```

Table 388. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
pageSize	int	true	The number of activities to return per page
page	int	true	The page of activities that should be returned

Get paginated build activity information

Return a JSON representation of the activities in pages and in a specified order

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/activity?{parameters}
```

Table 389. Request parameters

Parameter	Type	Required	Description
numPerPage	int	false	The number of activities to return per page
pageNumber	int	false	The page of activities that should be returned
sortType	string	false	The order to use when sorting the activities. This would either be 'asc' or 'desc'.

Table 390. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get properties of the build process

Return a JSON representation of the properties of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/runtimeProperties
```

Table 391. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get properties on a process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/processes/{id}/properties?{parameters}
```

Table 392. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process properties to return per page.
pageNumber	string	false	The page of process properties that should be returned.

Table 393. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a process. This can be the name or ID of the process

Get properties on a process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/properties?{parameters}
```

Table 394. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process properties to return per page.
pageNumber	string	false	The page of process properties that should be returned.

Table 395. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Get properties on a process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}/properties?{parameters}
```

Table 396. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process properties to return per page.
pageNumber	string	false	The page of process properties that should be returned.

Table 397. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process

Get status summaries of the build process

Return a JSON representation of the status summaries of the build process

Request

```
GET https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/statusSummaries
```

Table 398. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Update general dependency configuration of the build process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/dependencyConfig?{parameters}
```

Table 399. Request parameters

Parameter	Type	Required	Description
conflictStrategy	string	false	Dependency conflict strategy of the build process. Options are: FAIL, FAVOR_NEW, FAVOR_OLD
triggerOnly	boolean	false	Whether or not the process dependency settings should only be used for triggering builds

Table 400. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Update or create property on a process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/processes/{id}/properties
```

Table 401. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a process. This can be the name or ID of the process

Update or create property on a process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/properties
```

Table 402. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

Update or create property on a process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}/properties
```

Table 403. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process

Update the build process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}
```

Table 404. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the build process is active",
  "description": "The build process description",
  "name": "The name of the build process",
  "notificationScheme": "The notification scheme of the
  build process",
  "priority": "The priority of the build process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
```

```
    "value": "The value of the property"
  }]
}
```

Update the project

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}
```

Table 405. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the project is active.",
  "description": "The project description",
  "name": "The name of the project",
  "tags": "The array of tag names of the project",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Update the secondary process

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/secondaryProcesses/{id}
```

Table 406. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a secondary process. This can be the name or ID of the process

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the secondary process is
  active",
  "description": "The secondary process description",
  "name": "The name of the secondary process",
  "notificationScheme": "The notification scheme of the
  secondary process",
  "priority": "The priority of the secondary process",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "skipPreProcessing": "Whether or not to skip pre-
  processing when running an unforced build for the process",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

Update the source config

Request

```
PUT https://{hostname}:{port}
  /build/rest2/projects/{id}/buildProcesses/{id}/sourceConfigs/{id}
```

Table 407. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project. This can be the name or ID of the project
id	string	true	The identifier to use when looking up a build process. This can be the name or ID of the process
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "ignoreRepositoryTrigger": "Whether or not the source
  config should ignore repository triggers",
  "name": "The name of the source config",
  "respository": "The repository that the source config
  will use",
  "templatedProperties": [{
    "name": "The name of the property",
    "value": "The value of the property"
  }]
}
```

radiator resource

/radiator GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/radiator
```

/radiator/{id} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/radiator/{id}
```

Table 408. URL parameters

Parameter	Type	Required	Description
id	long	true	

/radiator/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/radiator/{id}
```

Table 409. URL parameters

Parameter	Type	Required	Description
id	long	true	

repo resource

/repo POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/repo
```

/repo/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/repo/{id}
```

Table 410. URL parameters

Parameter	Type	Required	Description
id	string	true	

/repo/{id}/{hash} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/repo/{id}/{hash}
```

Table 411. URL parameters

Parameter	Type	Required	Description
id	string	true	

Table 411. URL parameters (continued)

Parameter	Type	Required	Description
hash	string	true	

/repo/{id}/byLabel/{label} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/repo/{id}/byLabel/{label}
```

Table 412. URL parameters

Parameter	Type	Required	Description
id	string	true	
label	string	true	

/repo/{id}/{hash}/label/{label} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/repo/{id}/{hash}/label/{label}
```

Table 413. URL parameters

Parameter	Type	Required	Description
id	string	true	
label	string	true	
hash	string	true	

/repo/{id}/{hash}/copyToServer POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/repo/{id}/{hash}/copyToServer
```

Table 414. URL parameters

Parameter	Type	Required	Description
id	string	true	
hash	string	true	

/repo/{id}/{hash}/copyToUrbanCodeDeploy POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/repo/{id}/{hash}/copyToUrbanCodeDeploy
```

Table 415. URL parameters

Parameter	Type	Required	Description
id	string	true	
hash	string	true	

reporting resource

/reporting/tables GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/tables
```

/reporting/tables POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/reporting/tables
```

/reporting/tables/{name} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/tables/{name}
```

Table 416. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/tables/{name} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/reporting/tables/{name}
```

Table 417. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/tables/{name}/expanded GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/tables/{name}/expanded
```

Table 418. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/tables/{name}/related GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/tables/{name}/related
```

Table 419. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/dimensions GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/dimensions
```

/reporting/dimensions POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/reporting/dimensions
```

/reporting/dimensions/{name} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/dimensions/{name}
```

Table 420. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/dimensions/{name}/expanded GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/dimensions/{name}/expanded
```

Table 421. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/tablesAndDimensions GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/tablesAndDimensions
```

/reporting/query POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/reporting/query
```

/reporting/query/download GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/query/download?{parameters}
```

Table 422. Request parameters

Parameter	Type	Required	Description
query	string	false	
filename	string	false	

/reporting/reports GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/reports
```

/reporting/reports POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/reporting/reports
```

/reporting/reports/{name} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/reporting/reports/{name}
```

Table 423. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/reports/{name} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/reporting/reports/{name}
```

Table 424. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/reports/{name} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reporting/reports/{name}?{parameters}
```

Table 425. Request parameters

Parameter	Type	Required	Description
download	boolean	false	

Table 426. URL parameters

Parameter	Type	Required	Description
name	string	true	

/reporting/reports/{name}/output POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/reporting/reports/{name}/output
```

Table 427. URL parameters

Parameter	Type	Required	Description
name	string	true	

reports resource

/reports/tests/projects GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reports/tests/projects
```

/reports/tests/projects/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/reports/tests/projects/{id}?{parameters}
```

Table 428. Request parameters

Parameter	Type	Required	Description
startDate	string	false	
endDate	string	false	

Table 429. URL parameters

Parameter	Type	Required	Description
id	string	true	

/reports/tests/projects/{id}/build-processes/{id} GET

Request

```
GET https://{hostname}:{port}

```

Table 456. URL parameters

Parameter	Type	Required	Description
resource	string	true	

resourceRole resource

resourceRole GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/resourceRole
```

resourceRole POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/resourceRole
```

resourceRole/{resourceRole} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/resourceRole/{resourceRole}
```

Table 457. URL parameters

Parameter	Type	Required	Description
resourceRole	string	true	

resourceRole/{resourceRole} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/resourceRole/{resourceRole}
```

Table 458. URL parameters

Parameter	Type	Required	Description
resourceRole	string	true	

resourceRole/{resourceRole} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/resourceRole/{resourceRole}
```

Table 459. URL parameters

Parameter	Type	Required	Description
resourceRole	string	true	

resourceType resource

resourceType GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/resourceType
```

resourceType/{resourceType} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/resourceType/{resourceType}
```

Table 460. URL parameters

Parameter	Type	Required	Description
resourceType	string	true	

resourceType/{resourceType}/actions GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/resourceType/{resourceType}/actions
```

Table 461. URL parameters

Parameter	Type	Required	Description
resourceType	string	true	

resourceType/{resourceType}/resourceRoles GET

Request

role/{role} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/role/{role}
```

Table 465. URL parameters

Parameter	Type	Required	Description
role	string	true	

role/{role}/actionMappings GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/role/{role}/actionMappings
```

Table 466. URL parameters

Parameter	Type	Required	Description
role	string	true	

role/{role}/actionMappings POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/role/{role}/actionMappings
```

Table 467. URL parameters

Parameter	Type	Required	Description
role	string	true	

role/{role}/actionMappings DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/role/{role}/actionMappings
```

Table 468. URL parameters

Parameter	Type	Required	Description
role	string	true	

search resource

/search/requests GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/requests?{parameters}
```

Table 469. Request parameters

Parameter	Type	Required	Description
pageNumber	int	false	The page of BuildLifeRequests that should be returned.
rowsPerPage	int	false	The number of BuildLifeRequests to return per page.
filterValue_status	string	false	The status name to search for.
filterValue_name	string	false	The project name pattern to search for.

/search/statuses GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/statuses?{parameters}
```

Table 470. Request parameters

Parameter	Type	Required	Description
pageNumber	int	false	The page of statusSummary that should be returned.
rowsPerPage	int	false	The number of statusSummary to return per page.
filterValue_status	string	false	The status name to search for.
filterValue_name	string	false	The project name pattern to search for.

/search/workflows GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/workflows?{parameters}
```

Table 471. Request parameters

Parameter	Type	Required	Description
pageNumber	int	false	The page of build life that should be returned.
rowsPerPage	int	false	The number of build life to return per page.
filterValue_processStatusName	string	false	The workflowStatus name to search for.
filterValue_name	string	false	The project name pattern to search for.
filterValue_workflowName	string	false	The workflow name pattern to search for.

/search/workflows/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/workflows/{id}?{parameters}
```

Table 472. Request parameters

Parameter	Type	Required	Description
pageNumber	int	false	The page of build life that should be returned.
rowsPerPage	int	false	The number of build life to return per page.
filterValue_processStatusName	string	false	The workflowStatus name to search for.
filterValue_name	string	false	The project name pattern to search for.

Table 473. URL parameters

Parameter	Type	Required	Description
id	string	true	

/search/projects GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/projects?{parameters}
```

Table 474. Request parameters

Parameter	Type	Required	Description
name	string	false	

Abort buildRequest

Request

```
POST https://{hostname}:{port}
  /build/rest2/search/requests?{parameters}
```

Table 475. Request parameters

Parameter	Type	Required	Description
requestId	string	false	The id of buildRequest to abort.

Deactivate a build life

Request

```
POST https://{hostname}:{port}
  /build/rest2/search/deactivateBuild
```

Delete a build life

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/search/deleteBuild
```

Delete buildLives

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/search/buildLives?{parameters}
```

Table 476. Request parameters

Parameter	Type	Required	Description
buildLifeIds	string	false	The buildLifeIds, which are separated by ','.

Delete buildRequests

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/search/requests?{parameters}
```

Table 477. Request parameters

Parameter	Type	Required	Description
requestIds	string	false	The buildRequestIds, which are separated by ','.

Get builds by label.

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/label?{parameters}
```

Table 478. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of build life to return per page.
pageNumber	int	false	The page of build life that should be returned.
orderField	string	false	The field to use when sorting the build life.
sortType	string	false	The order to use when sorting the build life. This would either be 'asc' or 'desc'.
filterValue_projectId	long	false	The filter value of project.
filterValue_labelId	long	false	The filter value of label.

Get the build by searching.

Request

```
GET https://{hostname}:{port}
  /build/rest2/search/build?{parameters}
```

Table 479. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of build life to return per page.
pageNumber	int	false	The page of build life that should be returned.
orderField	string	false	The field to use when sorting the build life.
sortType	string	false	The order to use when sorting the build life. This would either be 'asc' or 'desc'.
filterValue_buildLifeId	string	false	The filter value of build life.
filterValue_name	string	false	The filter value of project.
filterValue_statusId	string	false	The filter value of status.
filterValue_stamp	string	false	The filter value of stamp.

secondaryProcessTemplates resource

Resources for working with secondary process templates.

/secondaryProcessTemplates/{id}/workflow GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow
```

Table 480. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/secondaryProcessTemplates/{id}/workflow/graph GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph
```

Table 481. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/secondaryProcessTemplates/{id}/workflow/graph POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph
```

Table 482. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/secondaryProcessTemplates/{id}/workflow/graph PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph
```

Table 483. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/secondaryProcessTemplates/{id}/workflow/graph/insert POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/insert
```

Table 484. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

/secondaryProcessTemplates/{id}/workflow/graph/{id} POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}
```

Table 485. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate
```

Table 486. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate
```

Table 487. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 488. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property
```

Table 489. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.

/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}/iterate/property/{propertyName}
```

Table 490. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	string	true	The identifier of a job config.
propertyName	string	true	The identifier of a job config.

Create a new property by copy on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/copyproperty
```

Table 491. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Create a process template

Request

```
POST https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
```

```
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "teams": [{
    "resourceRoleId": "The id of the resource role",
    "teamId": "The id of the team"
  }]
}
```

Delete a job in the process definition.

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/workflow/graph/{id}
```

Table 492. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Table 492. URL parameters (continued)

Parameter	Type	Required	Description
id	string	true	The identifier of a job config.

Delete a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}
```

Table 493. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Delete a specified name property on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/property/{name}
```

Table 494. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
name	string	true	The name of the property

Delete the artifact on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/artifacts/{id}
```

Table 495. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	long	true	The id of the artifact

Delete the resource on a process template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/resources/{seq}
```

Table 496. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
seq	int	true	The sequence of the resource

Get a list of processes that use the specified process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/processes?{parameters}
```

Table 497. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process templates to return per page.
pageNumber	string	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'asc' or 'desc'.

Table 498. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process using this process
  template is active",
  "description": "The description of the process using
  this process template",
  "id": "The ID of the process using this process template",
  "name": "The name of the process using this process
  template",
  "project": "The name of the project to which the process
  using this process template belongs"
}]
```

Get all artifacts on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/artifacts?{parameters}
```

Table 499. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template artifacts to return per page.
pageNumber	string	false	The page of process template artifacts that should be returned.

Table 500. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all properties on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/properties?{parameters}
```

Table 501. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of process template properties to return per page.
pageNumber	string	false	The page of process template properties that should be returned.

Table 502. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get all resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/resources
```

Table 503. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Get avaiable resources on a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/resourceOptions/{id}
```

Table 504. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template
id	int	true	The id of the selected resource

Get information about a process template

Return a JSON representation of a process template

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}
```

Table 505. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
```

```
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Get information about all secondary process templates

Return a JSON representation of all secondary process templates.

Request

```
GET https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates?{parameters}
```

Table 506. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of process templates to return per page.
pageNumber	int	false	The page of process templates that should be returned.
orderField	string	false	The field to use when sorting the process templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the process templates. This would either be 'ASC' or 'DESC'.
filterValue_name	string	false	The name pattern of the process template to search for.
filterValue_type	string	false	The type of the process template to search for. Possible values are Any/Build/Secondary

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "id": "The ID of the process template",
  "location": "The URL that can be used to get the JSON
  representation of the process template",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}]
```

Update a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}
```

Table 507. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the process template is
  active.",
  "artifact-set-configuration": [{
    "artifactSet": "The name of the Artifact Sets",
    "baseDir": "The directory containing the artifact
  files",
    "excludes": "The patterns used to determine which
  files should be excluded from the artifact set even if
  they match the include patterns",
    "includes": "The patterns used to determine which
  files should be included in the artifact set"
  }],
  "description": "The process template description",
  "name": "The name of the process template",
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "type": "The type of the process template (Build or
  Secondary)"
}
```

Update artifacts on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/artifacts
```

Table 508. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update properties on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/properties
```

Table 509. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

Update resources on a process template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/secondaryProcessTemplates/{id}/resources
```

Table 510. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a process template. This can be the name or ID of the process template

security resource

/security/user GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/security/user
```

sourceTemplates resource

Resources for working with source config templates.

Create a new property by copy on a source config template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}/copyproperty
```

Table 511. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

Create a source config template

Request

```
POST https://{hostname}:{port}
  /build/rest2/sourceTemplates
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The source config template description",
  "name": "The name of thesource config template",
  "plugin": "The Plug-in ID of Source Plug-in",
  "plugin-properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
```

```
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",

}
```

Delete a source config template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}
```

Table 512. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

Delete a specified name property on a source config template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}/property/{name}
```

Table 513. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template
name	string	true	The name of the property

Get a list of source configs that use the specified source config template

Request

```
GET https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}/sourceConfigs?{parameters}
```

Table 514. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of source config templates to return per page.
pageNumber	string	false	The page of source config templates that should be returned.
orderField	string	false	The field to use when sorting the source config templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the source config templates. This would either be 'asc' or 'desc'.

Table 515. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

Get information about a source config template

Return a JSON representation of a source config template

Request

```
GET https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}
```

Table 516. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

Get information about all source config templates

Return a JSON representation of all source config templates.

Request

```
GET https://{hostname}:{port}
  /build/rest2/sourceTemplates?{parameters}
```

Table 517. Request parameters

Parameter	Type	Required	Description
rowsPerPage	int	false	The number of source config templates to return per page.
pageNumber	int	false	The page of source config templates that should be returned.
orderField	string	false	The field to use when sorting the source config templates. This would either be 'name' or 'id'.
sortType	string	false	The order to use when sorting the source config templates. This would either be 'asc' or 'desc'.
filterValue_name	string	false	The source config template name pattern to search for.

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The source config template description",
  "id": "The ID of the source config template",
  "location": "The URL that can be used to get the JSON
  representation of the source config template",
  "name": "The name of thesource config template",
  "plugin": "The Plug-in ID of Source Plug-in",
  "plugin-properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line",
    "default-value": "The default value of the property",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. Leave blank to use the name as
  the label",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required.",
    "runtime": "Whether or not the value is entered at the
  runtime of a build. When true, the property will appear by
  the Build button. When false, the property will appear in
  the Configuration tab",
    "saveToBuildConfig": "Whether or not to save the
  property to build configurations. This is only used with
  projects, processes, and their respective templates.",
    "scripted": "Whether or not the value type of the
```

```
  property is scripted",
    "value": "The value of the property. This is only used
  for properties on non-template objects (project, but not
  project template, etc."
  }],
  "work-dir-script": "The id of working directory script"
}
```

Get properties on a source template

Request

```
GET https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}/properties?{parameters}
```

Table 518. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of source templates properties to return per page.
pageNumber	string	false	The page of source templates properties that should be returned.

Table 519. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

Update a source config template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}
```

Table 520. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "description": "The source config template description",
  "name": "The name of the source config template",
  "plugin-properties": [{
    "name": "The name of the plugin property",
    "value": "The value of the plugin property"
  }],
  "properties": [{
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line if property display-type is Multi-
  Select or Select",
    "allowedValues": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line if property display-type is Multi-
  Select or Select",
    "allowedValuesScript": "The beanshell script to
  determine the allowed values to be selected from if
  property display-type is Multi-Select or Select",
    "default-value": "The default value of this property.",
    "defaultValueCheckbox": "The default value for the
  property when the property's display-type is Checkbox",
    "defaultValueText": "The default value for the
  property when the property's display-type is Text Area",
    "defaultValueTextArea": "The default value of the
  property when the property's display-type is Text Area",
    "defaultValues": "The default value of the property.",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin)",
    "job": "The id of the job when the property is a Job
  Execution property",
    "label": "A label for this property shown when
  prompting users for value. (Leave blank to use the name as
  the Label)",
    "name": "The name of the property",
    "required": "Whether or not the value of the property
  is required when creating a source config using this
  template.",
    "scripted": "Whether or not the value type of the
  property is scripted",
    "valueType": "The value type of the property
  (scripted, defined, jobExecution)"
  }],
  "work-dir-script": "The id of working directory script"
}
```

Update properties on a source config template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/sourceTemplates/{id}/properties
```

Table 521. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a source config. This can be the name or ID of the source config template

stage resource

/stage POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/stage
```

/stage/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/stage/{id}
```

Table 522. URL parameters

Parameter	Type	Required	Description
id	string	true	

/stage/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/stage/{id}
```

Table 523. URL parameters

Parameter	Type	Required	Description
id	string	true	

/stage/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/stage/{id}
```

Table 524. URL parameters

Parameter	Type	Required	Description
id	string	true	

/stage/{id}/{path:.+} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/stage/{id}/{path:.+}
```

Table 525. URL parameters

Parameter	Type	Required	Description
path	string	true	
id	string	true	

/stage/{id}/{path:.+} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/stage/{id}/{path:.+}
```

Table 526. URL parameters

Parameter	Type	Required	Description
path	string	true	
id	string	true	

statuses resource

/statuses GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/statuses
```

/statuses POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/statuses
```

/statuses/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/statuses/{id}
```

Table 527. URL parameters

Parameter	Type	Required	Description
id	string	true	

/statuses/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/statuses/{id}
```

Table 528. URL parameters

Parameter	Type	Required	Description
id	string	true	

/statuses/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/statuses/{id}
```

Table 529. URL parameters

Parameter	Type	Required	Description
id	string	true	

Get the statuses which are not archived.

Request

```
GET https://{hostname}:{port}
  /build/rest2/statuses/nonArchived
```

stepPreConditionScripts resource

/stepPreConditionScripts GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/stepPreConditionScripts
```

/stepPreConditionScripts POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/stepPreConditionScripts
```

/stepPreConditionScripts/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/stepPreConditionScripts/{id}
```

Table 530. URL parameters

Parameter	Type	Required	Description
id	string	true	

/stepPreConditionScripts/{id} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/stepPreConditionScripts/{id}
```

Table 531. URL parameters

Parameter	Type	Required	Description
id	string	true	

/stepPreConditionScripts/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/stepPreConditionScripts/{id}
```

Table 532. URL parameters

Parameter	Type	Required	Description
id	string	true	

steps resource

/steps GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/steps
```

/steps/{id} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/steps/{id}
```

Table 533. URL parameters

Parameter	Type	Required	Description
id	string	true	

system resource

/system/properties GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/system/properties?{parameters}
```

Table 534. Request parameters

Parameter	Type	Required	Description
pageNumber	int	false	The page of system properties that should be returned.
rowsPerPage	int	false	The number of system properties to return per page.

Create a property in system propertes

Request

```
POST https://{hostname}:{port}
  /build/rest2/system/properties
```

Delete a specified name property in system propertes

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/system/property/{name}
```

Table 535. URL parameters

Parameter	Type	Required	Description
name	string	true	The name of the property

Update properties in system propertes

Request

```
PUT https://{hostname}:{port}
  /build/rest2/system/properties
```

team resource

team GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team
```

team POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/team
```

team/{team} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team/{team}
```

Table 536. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/team/{team}
```

Table 537. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/team/{team}
```

Table 538. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/roleMappings GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team/{team}/roleMappings
```

Table 539. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/roleMappings POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/team/{team}/roleMappings
```

Table 540. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/roleMappings DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/team/{team}/roleMappings
```

Table 541. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/roleMappings/{role}/validMembers GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team/{team}/roleMappings/{role}/validMembers
```

Table 542. URL parameters

Parameter	Type	Required	Description
role	string	true	
team	string	true	

team/{team}/resourceMappings GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team/{team}/resourceMappings
```

Table 543. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/resourceMappings POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/team/{team}/resourceMappings
```

Table 544. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/resourceMappings DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/team/{team}/resourceMappings
```

Table 545. URL parameters

Parameter	Type	Required	Description
team	string	true	

team/{team}/resourceMappings/{type} GET

Request

Parameter	Type	Required	Description
team	string	true	
type	string	true	

team/{team}/unmappedResources/{type}/{role} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/team/{team}/unmappedResources/{type}/{role}?{parameters}
```

Table 552. Request parameters

Parameter	Type	Required	Description
name	string	false	

Table 553. URL parameters

Parameter	Type	Required	Description
role	string	true	
team	string	true	
type	string	true	

templates resource

Resources for working with project templates.

Create a new property by copy on a project template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/templates/{id}/copyproperty
```

Table 554. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

Create a project template

Request

```
POST https://{hostname}:{port}
  /build/rest2/templates
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the project template is
  active.",
  "build-pre-process": [{
    "name": "The name of the Build Pre-Processing property
  (quiet-period, merge-period, label-values, stamp-values,
  agent-pool, shouldCleanup, pre-condition-script, agent-
  pool-prop).",
    "value": "The value of the Build Pre-Processing
  property"
  }],
  "description": "The project template description",
  "name": "The name of the project template",
  "properties": [{
    "allowed-values": "The values users are allowed to
```

```
  select for this property. Separate each value by entering
  it on its own line, if property display-type is Multi-
  Select or Select",
    "default-value": "The default value of this property.",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "label": "A label for this property shown when
  prompting users for value. (Leave blank to use the Name as
  the Label)",
    "name": "The name of the property",
    "required": "whether or not the value of the property
  is required when creating a project using this template.",
    "scripted": "whether or not the value type of the
  property is scripted"
  }],
  "teams": [{
    "resourceRoleId": "The id of the resource role",
    "teamId": "The id of the team"
  }]
}
```

Delete a project template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/templates/{id}
```

Table 555. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

Delete a specified name property on a project template

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/templates/{id}/property/{name}
```

Table 556. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

Table 556. URL parameters (continued)

Parameter	Type	Required	Description
name	string	true	The name of the property

Get a list of projects that use the specified project template

Request

```
GET https://{hostname}:{port}
  /build/rest2/templates/{id}/projects?{parameters}
```

Table 557. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of projects to return per page.
pageNumber	string	false	The page of projects that should be returned.
orderField	string	false	The field to use when sorting the projects. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the projects. This would either be 'asc' or 'desc'.

Table 558. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

Get information about a project template

Return a JSON representation of a project template

Request

```
GET https://{hostname}:{port}
  /build/rest2/templates/{id}
```

Table 559. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the project template is
  active.",
  "build-pre-process": [{
    "name": "The name of the Build Pre-Processing property
  (quiet-period, merge-period, label-values, stamp-values,
  agent-pool, shouldCleanup, pre-condition-script, agent-
  pool-prop).",
    "value": "The value of the Build Pre-Processing
  property"
  }],
  "description": "The project template description",
  "id": "The ID of the project template",
  "location": "The URL that can be used to get the JSON
  representation of the project template",
  "name": "The name of the project template",
  "properties": [{
    "agentPool": "The agent pool of the property",
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line, if property display-type is Multi-
  Select or Select",
    "allowedValues": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line, if property display-type is Multi-
  Select or Select",
    "allowedValuesScript": "The beanshell script to
  determine the allowed values to be selected from, if
  property display-type is Multi-Select or Select",
    "default-value": "The default value of this property.",
    "defaultAgentPool": "The default agent pool of the
  property",
    "defaultValueCheckbox": "The default value for the
  property when the property's display-type is Checkbox",
    "defaultValueText": "The default value for the
  property when the property's display-type is Text Area",
    "defaultValueTextArea": "The default value of the
  property when the property's display-type is Text Area",
    "defaultValues": "The default value of the property.",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "isNew": "whether or not this is a new property",
    "job": "The id of the job",
    "label": "A label for this property shown when
  prompting users for value. (Leave blank to use the name as
```

```
  the Label)",
    "name": "The name of the property",
    "oldName": "The name of the property if this is an
  existing property",
    "pluginType": "The plugin type of the property",
    "required": "whether or not the value of the property
  is required when creating a project using this template.",
    "scripted": "whether or not the value type of the
  property is scripted",
    "valueType": "The value type of the property
  (scripted, defined, jobExecution)"
  }],
  "resourceId": "The security resource ID of the project
  template"
}
```

Get information about all project templates

Return a JSON representation of all project templates.

Request

```
GET https://{hostname}:{port}
  /build/rest2/templates?{parameters}
```

Table 560. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of project templates to return per page.
pageNumber	string	false	The page of project templates that should be returned.
orderField	string	false	The field to use when sorting the project templates. This would either be 'name' or 'description'.
sortType	string	false	The order to use when sorting the project templates. This would either be 'asc' or 'desc'.

This command takes a JSON request string or file. Use the following template for the request:

```
[{
  "active": "Whether or not the project template is
  active.",
  "build-pre-process": [{
    "name": "The name of the Build Pre-Processing property
  (quiet-period, merge-period, label-values, stamp-values,
  agent-pool, shouldCleanup, pre-condition-script, agent-
  pool-prop).",
    "value": "The value of the Build Pre-Processing
  property"
  }],
  "description": "The project template description",
```

```
  "id": "The ID of the project template",
  "location": "The URL that can be used to get the JSON
  representation of the project template",
  "name": "The name of the project template",
  "properties": [{

Get properties on a project template

Request

```
GET https://{hostname}:{port}
  /build/rest2/templates/{id}/properties?{parameters}
```

Table 561. Request parameters

Parameter	Type	Required	Description
rowsPerPage	string	false	The number of project template properties to return per page.
pageNumber	string	false	The page of project template properties that should be returned.

Table 562. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

Update a project template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/templates/{id}
```

Table 563. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "active": "Whether or not the project template is
  active.",
  "build-pre-process": [{
    "name": "The name of the Build Pre-Processing property
  (quiet-period, merge-period, label-values, stamp-values,
  agent-pool, shouldCleanup, pre-condition-script, agent-
  pool-prop).",
    "value": "The value of the Build Pre-Processing
  property"
  }],
  "description": "The project template description",
  "name": "The name of the project template",
  "properties": [{
    "agentPool": "The agent pool of the property",
    "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
```

```
  it on its own line, if property display-type is Multi-
  Select or Select",
    "allowedValues": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line, if property display-type is Multi-
  Select or Select",
    "allowedValuesScript": "The beanshell script to
  determine the allowed values to be selected from, if
  property display-type is Multi-Select or Select",
    "default-value": "The default value of this property.",
    "defaultAgentPool": "The default agent pool of the
  property",
    "defaultValueCheckbox": "The default value for the
  property when the property's display-type is Checkbox",
    "defaultValueText": "The default value for the
  property when the property's display-type is Text Area",
    "defaultValueTextArea": "The default value of the
  property when the property's display-type is Text Area",
    "defaultValues": "The default value of the property.",
    "description": "The description of the property",
    "display-type": "The display type of the property
  (Text, Select, Checkbox, Multi-Select, Text Area, Text
  (secure), Integration Plugin, Agent Pool)",
    "isNew": "whether or not this is a new property",
    "job": "The id of the job",
    "label": "A label for this property shown when
  prompting users for value. (Leave blank to use the name as
  the Label)",
    "name": "The name of the property",
    "oldName": "The name of the property if this is an
  existing property",
    "pluginType": "The plugin type of the property",
    "required": "whether or not the value of the property
  is required when creating a project using this template.",
    "scripted": "whether or not the value type of the
  property is scripted",
    "valueType": "The value type of the property
  (scripted, defined, jobExecution)"
  }]
}
```

Update properties on a project template

Request

```
PUT https://{hostname}:{port}
  /build/rest2/templates/{id}/properties
```

Table 564. URL parameters

Parameter	Type	Required	Description
id	string	true	The identifier to use when looking up a project template. This can be the name or ID of the project template

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "agentPool": "The agent pool of the property",
  "allowed-values": "The values users are allowed to
  select for this property. Separate each value by entering
  it on its own line, if property display-type is Multi-
  Select or Select",
  "allowedValues": "The values users are allowed to select
  for this property. Separate each value by entering it on
  its own line, if property display-type is Multi-Select or
  Select",
  "allowedValuesScript": "The beanshell script to
  determine the allowed values to be selected from, if
  property display-type is Multi-Select or Select",
  "default-value": "The default value of this property.",
  "defaultAgentPool": "The default agent pool of the
  property",
  "defaultValueCheckbox": "The default value for the
  property when the property's display-type is Checkbox",
  "defaultValueText": "The default value for the property
  when the property's display-type is Text Area",
  "defaultValueTextArea": "The default value of the
  property when the property's display-type is Text Area",
  "defaultValues": "The default value of the property.",
  "description": "The description of the property",
  "display-type": "The display type of the property (Text,
  Select, Checkbox, Multi-Select, Text Area, Text (secure),
  Integration Plugin, Agent Pool)",
  "isNew": "whether or not this is a new property",
  "job": "The id of the job",
  "label": "A label for this property shown when prompting
  users for value. (Leave blank to use the name as the
  Label)",
  "name": "The name of the property",
  "oldName": "The name of the property if this is an
  existing property",
  "pluginType": "The plugin type of the property",
  "required": "whether or not the value of the property is
  required when creating a project using this template.",
  "scripted": "whether or not the value type of the
  property is scripted",
  "valueType": "The value type of the property (scripted,
  defined, jobExecution)"
}
```

trends resource

/trends/tests/{name}/{curr}/since/{since} GET

Request

```
GET https://{hostname}:{port}

  /build/rest2/user?{parameters}
```

Table 571. Request parameters

Parameter	Type	Required	Description
name	string	false	

user POST

Request

```
POST https://{hostname}:{port}
  /build/rest2/user
```

user/{user} GET

Request

```
GET https://{hostname}:{port}
  /build/rest2/user/{user}
```

Table 572. URL parameters

Parameter	Type	Required	Description
user	string	true	

user/{user} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/user/{user}
```

Table 573. URL parameters

Parameter	Type	Required	Description
user	string	true	

user/{user} PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/user/{user}
```

Table 574. URL parameters

Parameter	Type	Required	Description
user	string	true	

user/{user}/setPassword PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/user/{user}/setPassword
```

Table 575. URL parameters

Parameter	Type	Required	Description
user	string	true	

user/{user}/unlock PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/user/{user}/unlock
```

Table 576. URL parameters

Parameter	Type	Required	Description
user	string	true	

users resource

users GET

Request

```
GET https://{hostname}:{port}

```

users/{id} DELETE

Request

```
DELETE https://{hostname}:{port}
  /build/rest2/users/{id}
```

Table 577. URL parameters

Parameter	Type	Required	Description
id	string	true	

users/{id}activate PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/users/{id}activate
```

Table 578. URL parameters

Parameter	Type	Required	Description
id	string	true	

users/{id}inactivate PUT

Request

```
PUT https://{hostname}:{port}
  /build/rest2/users/{id}inactivate
```

Table 579. URL parameters

Parameter	Type	Required	Description
id	string	true	

Create a user

Request

```
POST https://{hostname}:{port}
  /build/rest2/users
```

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "actualName": "The full name of the user.",
  "emailAddress": "The email address to use for
```

```
  notifications.",
  "imId": "The instant messaging ID for notifications.",
  "locale": "The locale of this user.",
  "name": "The user name to use to log into the product.
  Required.",
  "numDashRows": "The number of recent items to display on
  the dashboard.",
  "password": "The password for this user. Required.",
  "passwordConfirm": "Confirm the new password. Required.",
  "realmId": "The ID of Authentication Realm you wish to
  create the user in.",
  "receiveNotifications": "Receive notifications from the
  server. Clear this check box to unsubscribe all emails
  from the server.",
  "shortDateFormat": "The date and time format to use on
  the dashboard. The default is based upon the locale of the
  server.",
  "timeZone": "The time zone of the user.",
  "use24Clock": "The boolean value to indicate whether to
  use 24-Hour Clock",
  "userGroup": "The JSONArray of group ID."
}
```

Get information about a user

Return a JSON representation of the user

Request

```
GET https://{hostname}:{port}
  /build/rest2/users/{id}
```

Table 580. URL parameters

Parameter	Type	Required	Description
id	string	true	

Update a user

Request

```
POST https://{hostname}:{port}
  /build/rest2/users/{id}/update
```

Table 581. URL parameters

Parameter	Type	Required	Description
id	string	true	

This command takes a JSON request string or file. Use the following template for the request:

```
{
  "actualName": "The full name of the user.",
  "emailAddress": "The email address to use for
  notifications.",
  "imId": "The instant messaging ID for notifications.",
  "locale": "The locale of this user.",
  "name": "The user name to use to log into the product.",
  "numDashRows": "The number of recent items to display on
  the dashboard.",
  "password": "The password for this user.",
  "receiveNotifications": "The boolean value indicate
  whether to receive notifications from the server.",
  "shortDateFormat": "The date and time format to use on
  the dashboard. The default is based upon the locale of the
  server.",
  "timeZone": "The time zone of the user.",
  "use24Clock": "The boolean value indicate whether to use
  24-Hour Clock",
  "userGroup": "The JSONArray of group ID."
}

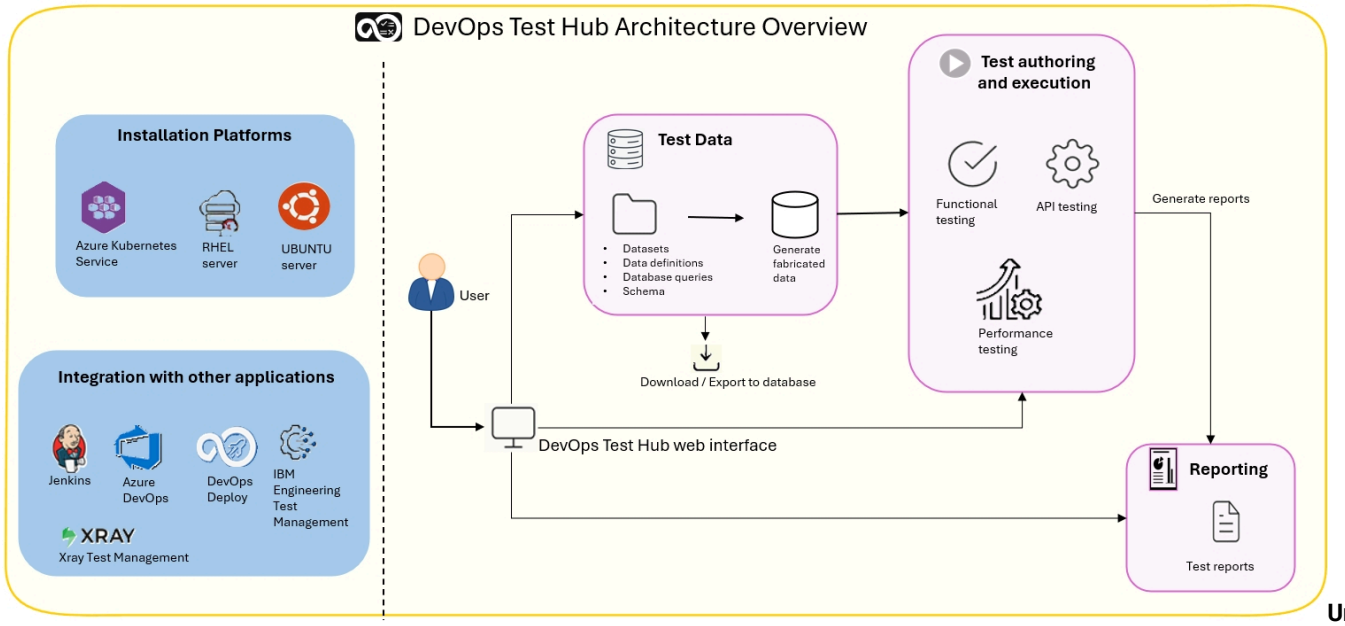
Test

The Test capability in DevOps Loop is powered by the DevOps Test application. Test centralizes test data, environments, test runs, and reports in a single web based interface within the DevOps Loop. It streamlines test management, execution, and tracking, providing greater efficiency and visibility to ensure quality throughout the loop.

Introduction to DevOps Test Hub

Test is a web-based continuous testing platform that consolidates test data, environments, test runs, and reports. It is built on cloud-native technologies and Docker, and it supports API, functional, and performance tests. Test offers scalability across cloud and on-premises systems with Kubernetes and IBM® Red Hat OpenShift support.

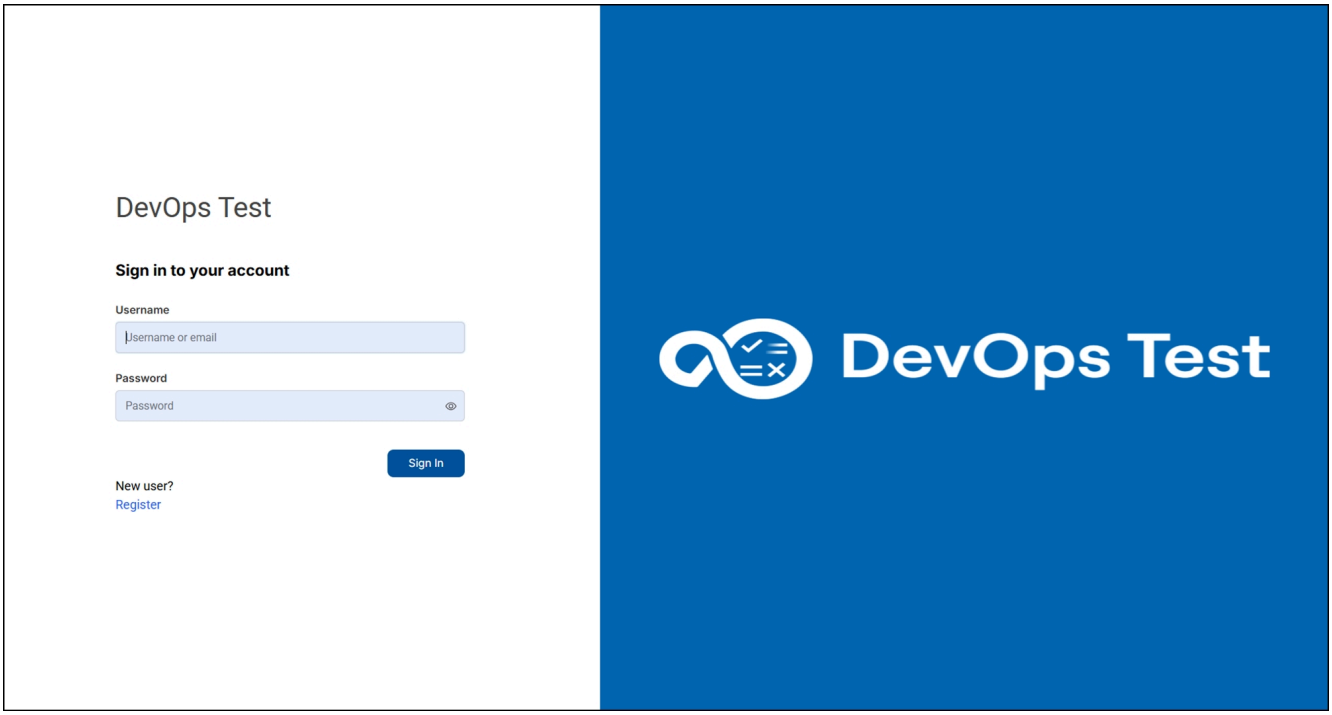


Unified test dashboard

You can use the intuitive dashboard to create, manage, and track test activities. By using the dashboard, you can efficiently manage test data and collaborate with your team on test requirements.

Login page

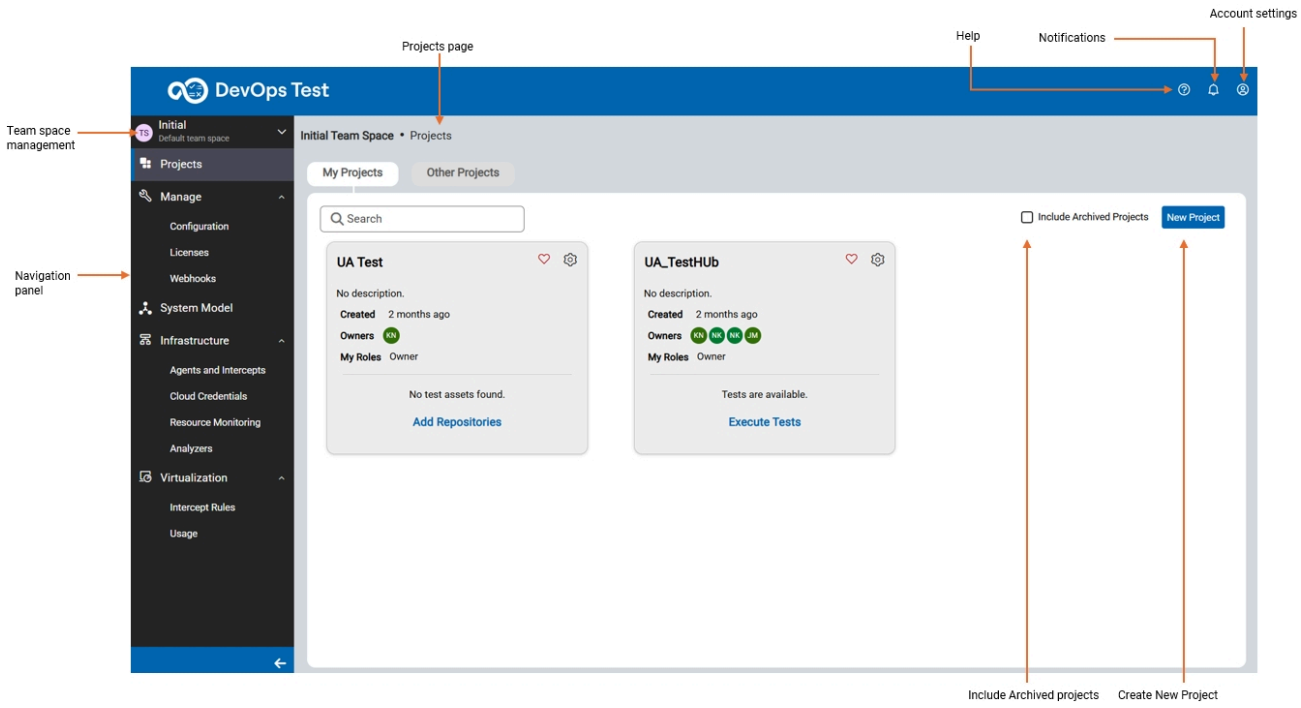
The login page is the primary access point to the platform. Only registered users can access project data and testing environments. If you are a new user, you must complete the registration process before you can log in.



Note: A session timeout prompt is displayed if you are inactive for 30 minutes. Before the session ends, a notification appears, prompting you to **continue the session** or **log out**. If no action is taken, the session is automatically terminated.

Home page

The home page lists your projects and other projects, which makes it easy for you to manage different projects within an organization. You can request access to join existing projects, create a new project, and view archived projects.



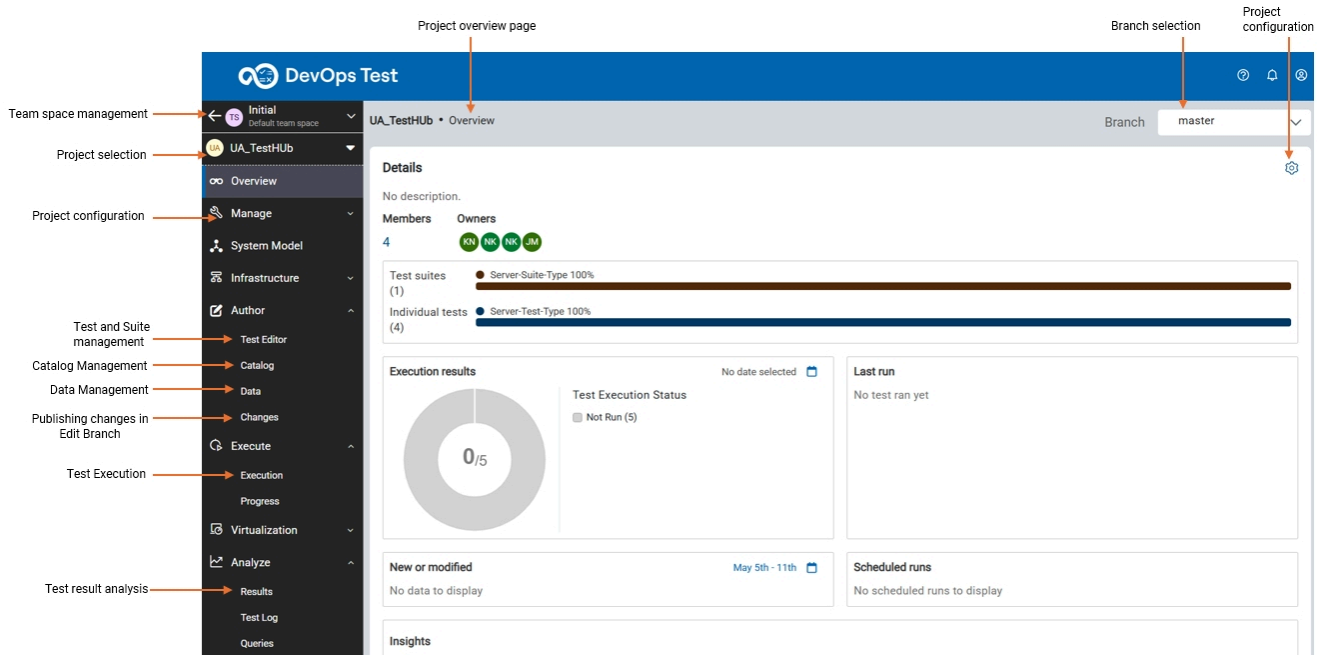
Navigation panel

The navigation panel in Test Hub provides quick access to sections such as **Projects**, **Manage**, **System Model**, **Infrastructure**, and **Virtualization**. You can easily navigate your projects, configure settings, define system models, monitor infrastructure, and manage virtualization. Each section of the dashboard is designed to support you with a specific function, making your testing workflow more efficient and intuitive.

After you select a project, the panel displays the **Author**, **Execute**, and **Analyze** sections for test creation, data management, test execution, and reporting activities.

Overview page

You can manage and monitor all testing activities in one place on the project **Overview** page.



Logout

When you want to end your session with Test, you can log out by clicking the profile icon , and selecting **Logout**.

Click here to watch the visual walkthrough.

Capabilities

Test unifies test data, test environments, execution, and reporting in a web-based platform designed for both testers and non-testers. You can efficiently manage test data, collaborate seamlessly with your team, and integrate your testing workflows with DevOps pipelines for streamlined delivery and execution.

Test data authoring and management

You can create, edit, and manage test data directly in Test. With support for concurrent multi-user editing, and teams can work on test datasets at the same time without causing conflicts or overwriting each other's changes. The built-in data generator helps to generate fabricated data for different testing scenarios.

Role-based access and security

Testoffers robust role-based access control, where project owners can assign permissions according to defined user roles. This ensures secure test data management and controlled access to sensitive assets such as credentials.

Report analysis and resource monitoring

Test Hub includes advanced reporting capabilities by offering insights into test execution, system performance, and resource utilization. It consolidates unified test results, helping teams make data-driven decisions to improve software quality.

Connected performance testing agents

You can link existing performance testing agents to Test to execute schedules and Accelerated Functional Testing (AFT) suites by using your current infrastructure for seamless integration.

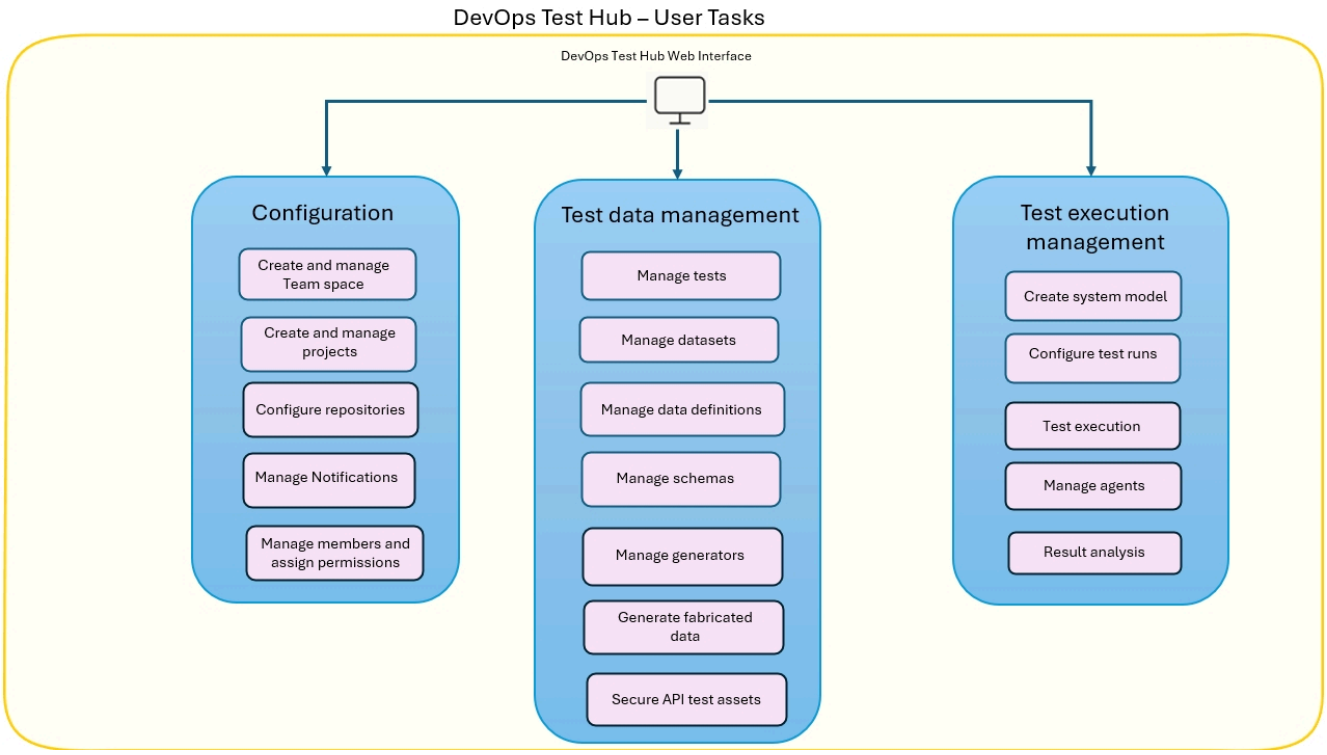
Integration with DevOps tools

You can integrate Test with popular DevOps tools like Jenkins, Azure DevOps, DevOps Deploy, Jira, and GitHub. These integrations help you automate test execution within your CI/CD pipelines and streamline defect-tracking workflows.

User tasks

Test offers a range of user tasks designed to simplify collaboration and optimize testing workflows. You can efficiently create, manage, and analyze test data to ensure a smooth and effective testing process.

You can perform the following user tasks in Test to support different stages of the testing lifecycle.



Member access and permissions

You can manage access in Test by assigning roles and permissions to control who can view, edit, or execute test assets within a project. With effective access management, you can protect your project data while making collaboration easier and more secure for your entire team.

For more information on configuring your Test account, see the Configuration of DevOps Test on page 730 section in the Administrator Guide on page 730.

For more information on roles, access, and permissions, see Managing members and their roles in a team space on page 1721 and Managing access to the server projects on page 1735 in the Test Manager Guide on page 1713.

Compatibility and supported assets

You can find information about the environments, file formats, and asset types that are compatible with Test . You can use this information to verify if your assets and environments are supported before creating or importing tests into Test.

Related information

Supported versions of assets and resources on page 705

Supported suites and tests on page 706

Supported virtual services on page 707

Supported versions of assets and resources

You can find information about the versions of assets, resources, and agents that are supported in Test . You can also find information about the versions of the desktop clients that are supported.

The following table lists the versions of assets or resources created in the desktop clients along with the agents, or proxies that are supported in Test:

Resource	Supported	Not supported
Assets or resources created in HCL DevOps Test UI (Test UI)	Assets or resources created in Test UI that is of a version earlier than or the same as Test.	Assets or resources created in any later version of Test UI that is later than the version of Test.
Assets or resources created in HCL DevOps Test Integrations and APIs (Test Integrations and APIs)	Assets or resources created in Test Integrations and APIs that is of a version earlier than or the same as Test.	Assets or resources created in any later version of Test Integrations and APIs that is later than the version of Test.
Assets or resources created in HCL DevOps Test Performance (Test Performance)	Assets or resources created in Test Performance that is of a version earlier than or the same as Test.	Assets or resources created in any later version of Test Performance that is later than the version of Test.
HCL DevOps Test Performance Agent (Test Performance Agent)	Test Performance Agent, which is the same version as Test.	Before you install the agents that are of the current version, see Management of performance agents on page 1072.
HCL DevOps Test Integrations and APIs Agent (Test Integrations and APIs Agent)	Test Integrations and APIs Agent, which is the same version as Test.	Before you install the agents that are of the current version, see Management of API agents on page 1080.
HTTP proxies	Installation of the proxy component from Test Virtualization Control Panel, which is the same version as Test.	Before you use HTTP proxies, see Setting up intercepts on page 1457.

If there is a mismatch in the versions of the assets, resources, or agents with the version of Test that you are using, any of the following events can occur:

- Warnings or Errors are displayed when you add a repository to a project in your team space.
- Warnings or Errors are displayed when you open a project that you migrated from a previous version of Test.
- Warnings or Errors are displayed when you add or manually refresh a repository to which you added assets or resources that were created on a desktop client with a version previous to or later than the version of Test that you want to use.
- Test runs that you start or schedule on an agent fail to run.
- You cannot view the proxies that are registered with Test on the **Agents and Intercepts** page.

Supported suites and tests

You can find information about the types of Test Suites and tests that you can configure for a run in a project on Test .

The following table lists the Test Suites and test types that are supported and those tests that are not supported to run on Test:

Supported Suites	Supported tests	Unsupported tests
• Accelerated Functional Testing (AFT) Suites • Compound Tests that contain any of the following types of tests: ◦ Web UI tests ◦ HTML tests ◦ Mobile tests	• Individual Web UI test • Individual Windows test • Individual Mobile test	• Traditional HTML tests • Traditional non-HTML tests
• API Suites that include the following Test Suites: ◦ Test Suites that contain scenarios with references to local stubs. ◦ Test Suites that contain stubs that virtualize services run in any Kubernetes cluster or in the Kubernetes cluster that hosts Test. • Virtual services or Stubs	API tests	Suites or tests with subscribe actions that operate in the watch mode.
• Compound Tests that contain performance tests • Rate Schedules • VU Schedules	Individual Performance test	• A single test script of any test extension. • Tests that belong to 32-bit test extensions and SOA Quality included in VU Schedule, Rate Schedule, and Compound Test. • Citrix, SAP, or Siebel as an individual test or as part of a Compound Test.
Postman resources		
JMeter tests		

Supported Suites	Supported tests	Unsupported tests
JUnit tests		
Selenium tests		

Note: You must create Compound Tests for the same type of tests. For example, you can create a Compound Test that has different mobile tests that use different mobile testing platforms.

Restriction: You cannot merge folders that contain different test projects in the same project directory. For example, you cannot create a project directory that contains a Performance test project and an API Suite project. You must create separate project directories for each test type. For example, you must create the Performance test in the project directory as `/MyPerfProject/` and the API Suite in the project directory as `/MyAPIProject`, before you commit the projects to the remote repository.

Related information

Test run configurations on page 1134

Supported virtual services

You can find information about the virtual services that are supported on Test .

You can start a running instance of the virtual services from Test to run on the following locations:

- A registered API agent.
- The default Kubernetes cluster of Test.
- A remote Kubernetes cluster.

You can run all virtual services on registered API agents except the virtual services that use CICS transport, DB2/Z transport, or Istio.

The default Kubernetes cluster or a remote Kubernetes cluster supports running of the following types of virtual services:

- Virtual services that utilize the WebSphere® MQ transport.
- Virtual services that utilize the HTTP transport.

Related information

Management of virtualized services on page 1453

Accessibility features

Accessibility features help users who have physical disabilities, such as visual and, hearing impairment, or limited mobility, to use the software products successfully.

Accessibility compliance

The product documentation is published by using Oxygen XML WebHelp Responsive. To understand the accessibility compliance status for Oxygen XML WebHelp Responsive, refer to WebHelp Responsive VPAT Accessibility Conformance Report.

Accessing UI elements

Test supports navigation in the UI by using different methods such as a mouse, keyboard, or touchpad.

You can use the keyboard keys such as **Tab**, arrow keys such as **UP**, **DOWN**, **LEFT**, and **RIGHT** to navigate to the different pages in the **Navigation** pane or to the different action labels in the right pane on the UI.

Tutorials

Learn how to perform frequently used tasks, including creating and managing Web UI tests and viewing test results through functional reports.

Creation and management of your first Web UI test

In the lessons detailed in this learning module, you can learn how to use DevOps Test to create and manage Web UI tests.

Steps to build and run a Web UI test in Test Hub

In this section, you will learn about the typical steps involved in building and running a Web UI test using DevOps Test. Throughout this tutorial, you will follow these steps to create, enhance, execute, and analyze Web UI tests.

You will perform the following tasks:

1. **Create an application**: Set up the web application that you want to test within the project.
2. **Record and manage Web UI test steps**: Capture user interactions such as clicks, text entry, and selections, and organize them into reusable test steps.
3. **Add variables and validations to tests**: Make your tests reusable and verify that the application behaves as expected.
4. **Run tests and view functional reports**: Run tests and review results to confirm whether they passed or failed.

As a real-time scenario, the tutorial uses an HR management web application to demonstrate recording user interactions such as logging in and managing employee details.

You can apply this workflow to any web application. Just use your own application URL instead of the example shown here and follow the steps outlined in this tutorial.

Prerequisites

Before you begin, ensure that your system is ready to complete the tutorial.

The prerequisites are as follows:

1. Your system must have at least one supported web browser installed, such as Google Chrome or Microsoft Edge.
2. A DevOps Test user account.
3. A project that is configured with a Git repository.

Now, you will learn how to perform the prerequisite tasks in detail, starting with creating a DevOps Test user account.

Create a new user account

In this lesson, you will learn how to create a new user account in the DevOps Test. If LDAP or Active Directory authentication is not configured, you must create a user account to get started.

About this task

To access the DevOps Test and perform Web UI testing tasks, you must have a user account. If you already have an account, you can sign in directly. Otherwise, you have to follow the steps below to create one.

1. Open a web browser and access the DevOps Test URL for your environment.
   For example:
   ```
   https://<host-name>/devops-test
   ```
2. Click **Register**.
3. Enter the following details to complete the registration:
   - **Email address**
   - **Username**
   - **Password**
   - **Confirm password**
4. Click **Register**.

Results

You have successfully created a user account and can now access the DevOps Test.

What to do next

Next, you will create a project. See Create a project on page 710.

Create a project

In this lesson, you will learn how to create a project and associate a Git repository to start recording and managing Web UI tests. A project defines the workspace where your test assets are stored and managed.

About this task

When you create a project, you are automatically assigned the Project Creator and Architect roles for the **Initial Team Space**.

1. Click **New project** to create a new project in the **Initial Team Space**.
2. Enter a name in the **Project** name field. For example, *myproj*
3. (optional) Enter a brief description in the **Description** field.
4. Click **Create**.

   The **myproj** project is created successfully.
5. On the **Configuration** page, under **Repositories**, click **Add Repository** to associate a repository with the project.
6. Enter the complete URL of the Git repository that you want to associate with the project.
   For example,

   ```
   https://github.com/<user>/<repository>.git
   ```
7. Enter the required credentials (username and password) to authenticate access to the repository.

   The Git repository is associated with the project.

Results

The project is created successfully, and the repository is associated with the project.

After completing the prerequisites, you are now ready to proceed with creating an application.

What to do next

You can now begin creating an application. See Lesson 1 on page 710.

Lesson 1: Create an application

In this lesson, you will learn how to create an application within your project to record a Web UI test for an HR management application. An application represents the web application that you want to test.

Before you begin

Ensure that you have completed all the Prerequisite on page 709 tasks.

About this task

An application stores the URL and other related configuration details of the web application that you want to record and manage Web UI tests.

Before you create an application and continue with this tutorial, it is important to understand the concept of an edit branch and how it is used in DevOps Test.

An **edit branch** is a temporary working branch that provides an isolated workspace for creating or modifying applications, tests, and test suites without impacting the master branch. Using an edit branch allows you to safely make, review, and validate changes before merging them into the master branch.

In this task, you will use an edit branch to create an application that you can use to record and manage Web UI tests.

Now, you can begin with the task after logging in to DevOps Test and selecting the project. For example, *myproj*.

1. Click **Author > Test Editor**.
   The **Test Editor** page and **Navigator** panel are displayed.
2. Create an application by performing one of the following actions:
   - Click the **Action Menu** icon and select **Application**.
   - Right-click the project repository in the Test Navigator panel and select **New Application**.
   - Click **Create Application** on the **Test Editor** page. This option is available only if no applications exist in the project.

   If you are working on the **master** branch, the **Edit Branch** dialog is displayed.
3. Perform the following action to create and edit a branch and use it throughout this tutorial:
   a. Click **Create a new edit branch**.
   b. Enter a branch name. For example, *HRM_branch*
   c. Click **Save**.

   You have created the *HRM_branch* successfully, and the **Create Application** dialog is displayed.
4. Enter a unique name in the **Name** field. For example, *HRM_application*.
5. Click **Create**.

   The application is successfully created and the **Details** tab opens for further configuration.
6. Enter the URL of the HR management application. For example, *https://opensource-demo.orangehrmlive.com/web/index.php/auth/login*.
7. Enter a summary or relevant details about the application in the **Description** field.
8. Click the **Save** icon to save the details.

Results

You have created an application successfully.

You have completed Lesson 1.

What to do next

In the next lesson, you will learn to create a Web UI test. See Lesson 2 on page 711.

Lesson 2: Create a Web UI test by recording user actions

In this lesson, you will learn how to record a Web UI test by capturing screens and user actions on the web pages.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

In this task, you will record user actions on the login page and add employees to the employee list in the HR management application to create a Web UI test by using DevOps Test.

1. In the **Test Editor** page, perform any one of the following actions to record a test:
   - Click the **Action** menu icon in the **Navigator** panel to open the menu and click the **Test** option.
   - Click the **Create Test** icon on the **Details** tab.
   - Click **Create asset > Create Test** on the **Test Editor** page.
   - Right-click the created application in the **Navigator** panel, select **New > Test**.

   The **Create Test** dialog is displayed.

   In the **Details** tab, ensure that the correct application is selected and the location is set.
2. Enter the test asset name in the **Asset Name** field. For example, *HRM_add_employee_test*.
3. Click **Next**.
   The **Source** tab is displayed.
4. Select the **By recording** option in the **Select source** drop-down list to record a test.
5. In the **Agent** section, select the installer package for your operating system.

   The following installer options are available:
   - **Windows (64-bit .msi)**
   - **Mac OS (64-bit .zip)**
   - **Debian/Ubuntu (64-bit .deb)**
   - **RHEL/Fedora/OpenSUSE (64-bit .rpm)**
6. Click **Download**.
7. Click the downloaded agent file to install the agent.
8. Click **Proceed** to accept the download of the proprietary certificate if prompted.

   For detailed installation and upgrade steps depending on the installation status of the agent, refer to the agent installation table on page 773.
9. Click **Verify** to confirm the agent installation.
10. Select a browser from the **Browser** drop-down list.
11. Click **Record** to launch the browser and start recording the test.

    A new browser window is displayed, and the application that you selected for recording is opened.
12. Perform user actions on the Login and Add Employee page of the HRM application. For example, interacting with the user name field, password field, and login button.

    You must allow a delay of a few seconds between user actions.

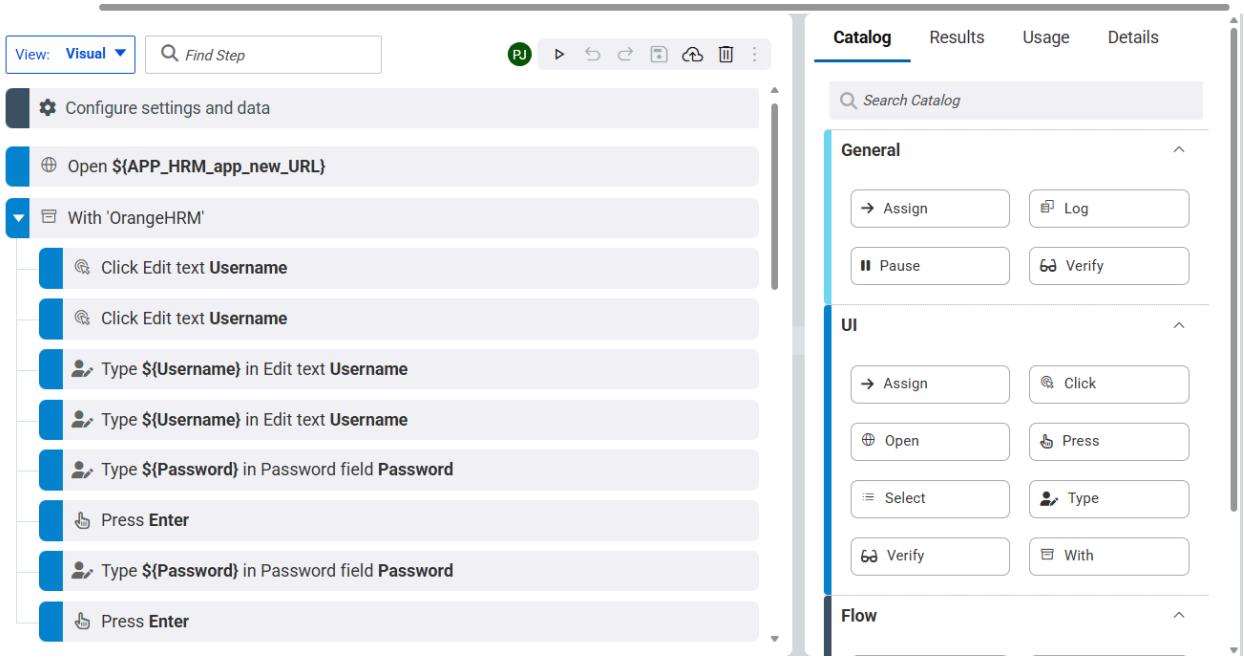
13. Close the browser to stop the recording.

    The following message is displayed in the **Create Asset** dialog.

    `The asset is now ready for your review`.

14. Click **Done**.

    The *HRM_add_employee_test* test asset is created, and the recorded steps are displayed in the **Test Editor.**



The test is displayed in the **Visual** view, which is the default view. You can switch to the **Code** view to view all the step details.

The test captured interactions with the following fields and controls:

- **First Name**
- **Middle Name**
- **Last Name**
- **Employee ID**
- **Create Login Details** toggle
- **Username**
- **Status** (Enabled)
- **Password**

- **Confirm Password**
- **Save** button

Results

You have successfully recorded the user actions for the HRM application and created a test asset.

You have completed Lesson 2.

What to do next

In the next lesson, you will learn how to add a variable to recorded Web UI test steps. See Lesson 3 on page 714.

Lesson 3: Create and add variables to a Web UI test

In this lesson, you will learn how to create and add test variables to store values and reuse them across test steps. By using variables, you can manage test data centrally and apply it dynamically during test execution.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

In the recorded test, the Employee ID value was manually entered as `012345`. In this task, you will create a test variable to store a new Employee ID `23456` and modify the recorded test step to use this variable instead of the manually entered value. This method helps make the test more flexible and reusable by separating test data from test logic.

1. In the test steps list, click **Configure settings and data**.
2. In the **Variables** section, click **Create Variable**.
3. Enter a variable name. For example, *new_EmployeeID*.
4. Enter the required value in the **Value** field. For example, *23456*.
5. Save the variable by clicking outside the **Value** field.

   The newly created variable is listed in the **Variables** section.
6. Click the **Close** icon to close **Configure settings and data**.
7. Perform the following actions to replace the Employee ID value in the recorded steps:

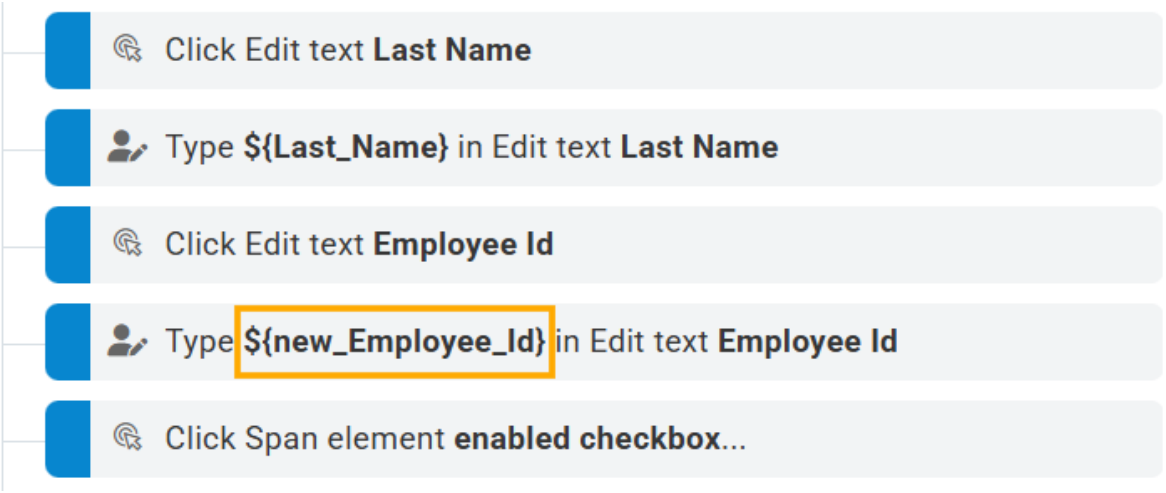
   a. Locate the recorded step that enters the Employee ID value (currently *012345*).

      The step opens in the **Details** tab.

   b. In the **Value** field, replace the manually entered Employee ID with the variable. For example, *${new_EmployeeID}*.

   c. Close the **Details** tab.

The **Employee ID** step is modified to use a ${new_EmployeeID} value, as shown in the image.



8. Click **Save** to save the modified step.

Results

You have now added the variable to the recorded step.

You have completed Lesson 3.

What to do next

In the next lesson, you will learn how to modify the test steps. See Lesson 4 on page 715.

Lesson 4: Modify test steps

In this lesson, you will learn how to modify an existing Web UI test from the **Test Editor** view.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

In this task, you will learn how to modify an existing recorded test step by changing the action from *Click* to *Double click* by using the **Smartshot** view, without re-recording the test.

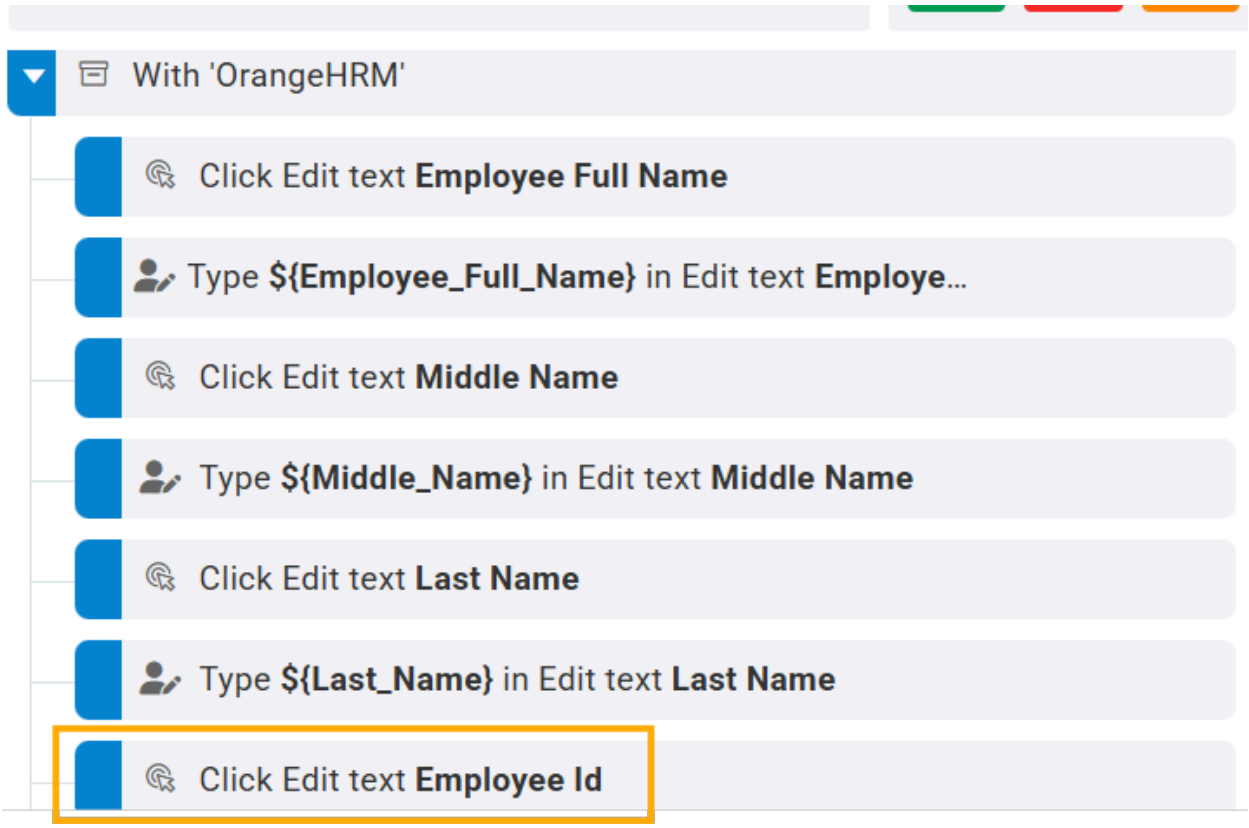
User interface changes in an application can alter the behavior of recorded test steps. For example, after a UI update, the *Employee ID* field might require a *double-click* instead of a single click to enable editing. As a result, a previously recorded *Click* action might no longer work as expected.

You will also learn how to update the target UI element and refine object identification to ensure the test continues to work correctly after UI changes.

Smartshot editing is useful when the **target element** is modified due to UI updates. A **target element** is a UI element in the application that a test step interacts with during a test run. For example, in the step *Click Edit text Employee Id*, the *Employee Id* field is the target element.

1. In the recorded test steps list, locate the *Click Edit text **Employee Id*** step and click it. For example, *Edit text – Employee Id*.

   The **Smartshot** view opens for the selected step.



2. Click the **Expand view** icon ← to expand the Smartshot view for better visibility.
3. Click the *Employee Id* field in the Smartshot. The field is highlighted now in the Smartshot.
4. Right-click the *Employee Id* field now and select **Use this element as step** target:

   a. Use this step when the Employee ID field is not captured correctly in Smartshot.

   b. This updates the step target with the correct UI element and properties before you modify the action.

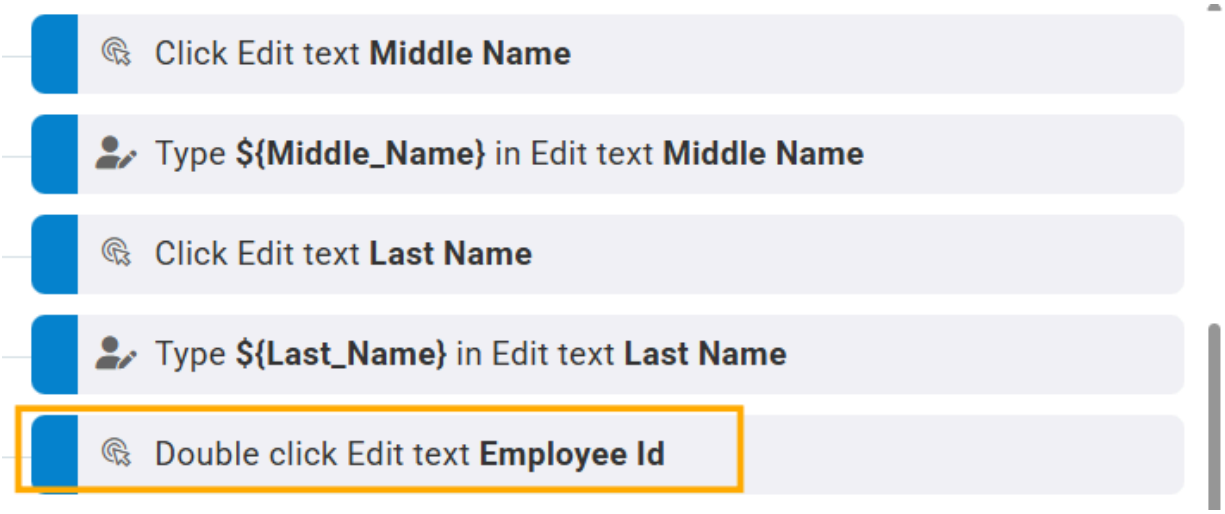
5. In the **Details** tab, review the following current configuration:

   - **UI Object**: The type of UI element. For example, **Edit text**.
   - **Action**: The action performed on the element. For example, **Click**.

6. Select a **Double Click** from the **Action** list as required by your test scenario to modify the **Action**.
7. In the **Elements** panel, you can browse and select the correct UI element.

8. Verify the selected element details in the **Properties** panel to ensure attributes like enabled, exist, and tagName match the expected UI state.
9. Click the **Close** icon to close the **Smartshot** view.

   The *Employee ID* step is modified to use a *Double click* action, as shown in the image.



10. Click **Save**.

Results

You have modified the behavior of the recorded tests using Smartshots.

You have completed Lesson 4.

What to do next

In the next lesson, you will learn how to manage steps using the right-click menu. See Lesson 5 on page 717.

Lesson 5: Manage test steps

In this lesson, you will learn how to modify and manage recorded Web UI test steps by using the right-click menu to reorder, reuse, disable, or delete steps.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

This task demonstrates how to manage recorded Web UI test steps by using the right-click menu. You will learn how to reorganize test steps, reuse existing steps, temporarily disable steps, and remove unnecessary or duplicate steps to keep your test flow clean and maintainable.

The examples in this task use the *Employee ID* step to show how these actions can be performed while editing an existing Web UI test.

1. Right-click on the *Click Edit text – Employee Id* step and click **Select**.

   Checkboxes appear next to the steps.
2. Select multiple steps, such as duplicate *Click Edit text – Employee Id* steps.
3. Right-click the selected steps to open the context menu.

   Once the steps are selected, additional options such as **Extract Steps**, **Deselect All**, and **Disable** become available.
4. Right-click the duplicate *Click Edit text – Employee Id* step and click **Disable** to disable it to temporarily skip it during test run.

   Alternatively, click the *Click Edit text – Employee Id* step, click the **Advanced** tab, and select the **Disable** checkbox.
5. Right-click the disabled step and click **Enable** to enable the step again.
6. Use the **Move Up** and **Move Down** options to ensure that the *Click Edit text – Employee Id* occurs at the correct point in the test sequence. You can reorder the steps using the following options:
   - Right-click a selected step and click to move the step earlier in the test flow.
   - Right-click a selected step and click to move the step later in the test flow.
7. Right-click the *Click Edit text – Employee Id* step and click **Copy**.
8. Right-click another step and click **Paste**.

   The copied Employee Id step is pasted immediately after the selected step.
9. Right-click the extra step and click **Delete** to permanently remove it from the test.
10. Click **Save**.

Results

Duplicate steps are disabled or removed, steps are reordered and copied as needed, and the test is updated with the new step sequence.

You have completed Lesson 5.

What to do next

In the next lesson, you will learn how to add a new test step from the **Catalog**. See Lesson 6 on page 718.

Lesson 6: Add steps from the Catalog to a Web UI test

In this lesson, you will learn how to add test steps from the catalog to the recorded Web UI test to quickly select and reuse steps based on your testing needs.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

In this task, you improve the reliability of your Web UI test by validating critical input data before allowing the test to proceed. The catalog groups commonly used actions into **General**, **UI**, and **Flow** categories, helping you quickly select the right action based on your testing requirement.

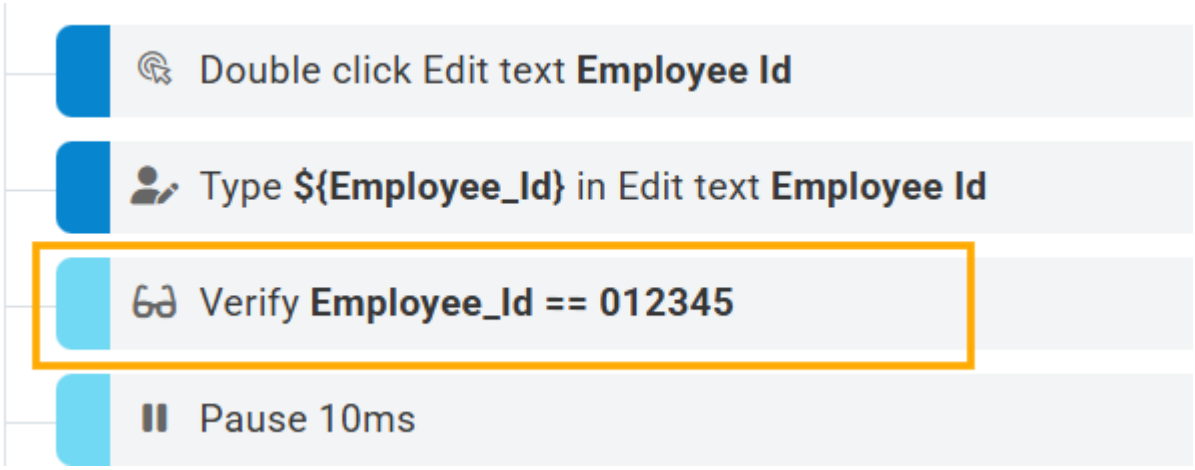
First, you verify that the *Employee_Id* matches the expected value by adding a **Verify** step from the **General** catalog. This verification ensures that the test is using the correct employee data. If the *Employee_Id* does not match, the verification step fails, and the failure is recorded in the test results.

Next, you add an **If** condition from the **Flow** catalog to validate the password value on the Add employee page. The steps that confirm the password and save the employee data will run only if the password meets the expected condition. If the condition is not met, the steps inside the **If** block are not skipped, preventing the test from continuing with invalid data.

The following catalog categories are used in this task:

1. **General Catalog** - Provides steps used for general operations such as assigning variables, logging information, pausing execution, or verifying values.
2. **UI Catalog** - Provides steps to interact with user interface elements, like clicking buttons, typing text, selecting dropdowns, or opening web pages.
3. **Flow Catalog** - Provides steps for controlling the flow of the test, such as loops, conditional logic, or handling errors.

1. Locate the recorded step that enters the *Employee_Id* value.
2. From the **General** catalog, right-click **Verify** and select **Add step**.
   Alternatively, drag and drop the **Verify** step from the **General catalog** and place it below the selected test step.
3. Click the **Verify** step, and configure the following **Verification points**:
   a. Select the variable *Employee_Id*.
   b. Set the comparison operator to **Equals**.
   c. Select the expected variable. For example, *Employee_ID*, or enter the expected value (*012345*, the value that was entered while recording the test).



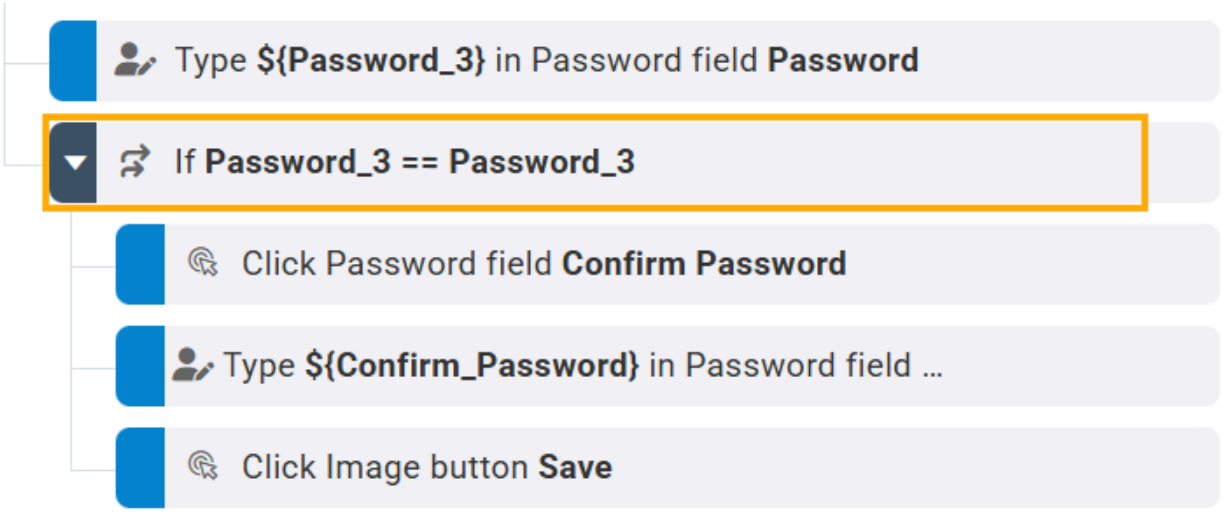
Note: If you select a different variable or enter a different value, this verification step fails while running the test.

4. From the **Flow** catalog, add an **If** step after the *Type Password in Password field* step.
5. Drag the remaining steps, such as *Confirm Password* and *Save*, into the **If** block.
6. Click the **If** step and configure the following details in the **Condition** section:

    a. From the first drop-down list, select the password variable *Password_3*.

    b. From the operator drop-down list, select **Equals**.

    c. In the value field, select the expected password variable, or enter the expected password value.
    If you select a different variable or enter a value that does not match the expected password, the **If** condition fails. When the condition fails, the steps inside the **If** block will not run, and the remaining steps stop running.



7. Click **Save** to save the test.

The following table lists all catalog elements available in DevOps Test, including **General**, **UI**, and **Flow** catalogs. Use these catalogs to try adding new test steps by selecting the actions that best fit your scenario.

Catalog	Action	Description
General	Assign	Assigns a value to a variable
	Verify	Verifies values, conditions, or expressions
	Log	Logs messages during the test run
	Wait	Pauses the test for a specified duration
UI	Click	Performs a click action on a UI element
	Double Click	Performs a double-click action on a UI element

Catalog	Action	Description
	Type Text	Enters text into an input field
	Select	Selects a value from a list or dropdown
	Verify	Verifies UI properties such as text, value, or state
Flow	If	Runs steps conditionally based on an expression
	Else	Runs steps when the If condition is false
	End If	Marks the end of an If block
	Loop	Repeats steps based on a condition
	Break	Exits a loop

Results

You have successfully added new test steps by using the catalog.

You have completed Lesson 6.

What to do next

In the next lesson, you will learn how to add Verification points using Smartshots. See Lesson 7 on page 721.

Lesson 7: Add verification points to test steps by using Smartshots

In this lesson, you will learn how to add verification points to the test steps by using the **Smartshots** to validate UI elements, values, and messages during a test run.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

In this task, you add a verification point to check whether the *Create Login Details* field is *enabled*. Verification points are evaluated when the test runs.

As each test step is performed, the following associated validations are verified:

- If the validation condition is met, the test proceeds to the next step.
- If the validation condition is not met, the step is marked as failed, and the failure is recorded in the test results.

Quick rules to remember

Use the following rules to choose the correct **Verify** action and verification point:

Table 588. Validation options

Validation requirement	Recommended Verify action
Field value displayed on the screen	Use the Verify action from the UI Catalog to validate values displayed in the UI.
Mandatory field or error message	Use the Verify action from the UI Catalog to check UI-level validation messages.
Length or format validation (for example, 5-digit Employee ID)	Use the Verify action from the General catalog to validate length and format rules.
Logical or data-based rules	Use the Verify action from the General catalog to evaluate conditions or business logic.

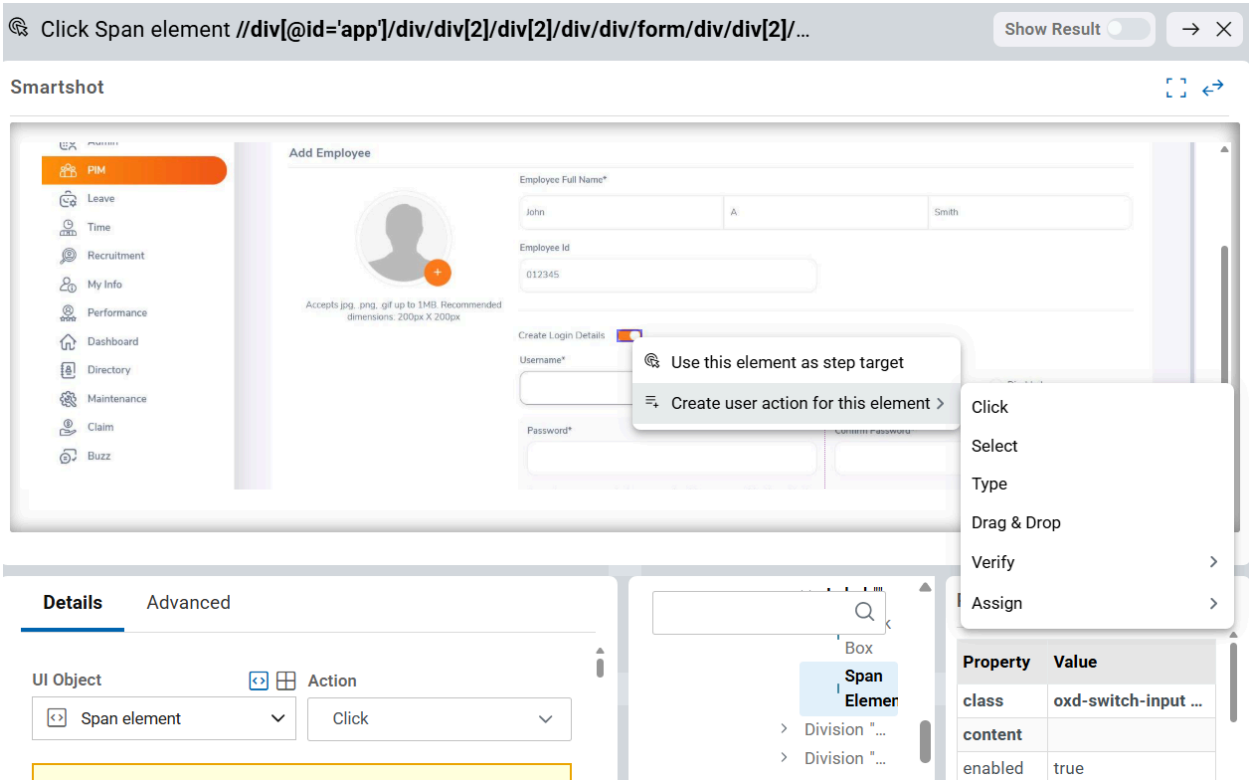
Table 589. Common UI elements and verification points

Element type	Verification point
Label text	`content`
Input field value	`value`
Field presence	`exist`
Enabled or disabled state	`enabled`

1. Locate the recorded step *Create Login Details*, and then click it.

   The step opens in the **Smartshot** view tab.

2. Click the **Expand view** icon ← to expand the Smartshot view for better visibility.
3. Select the *Create Login Details* toggle field.



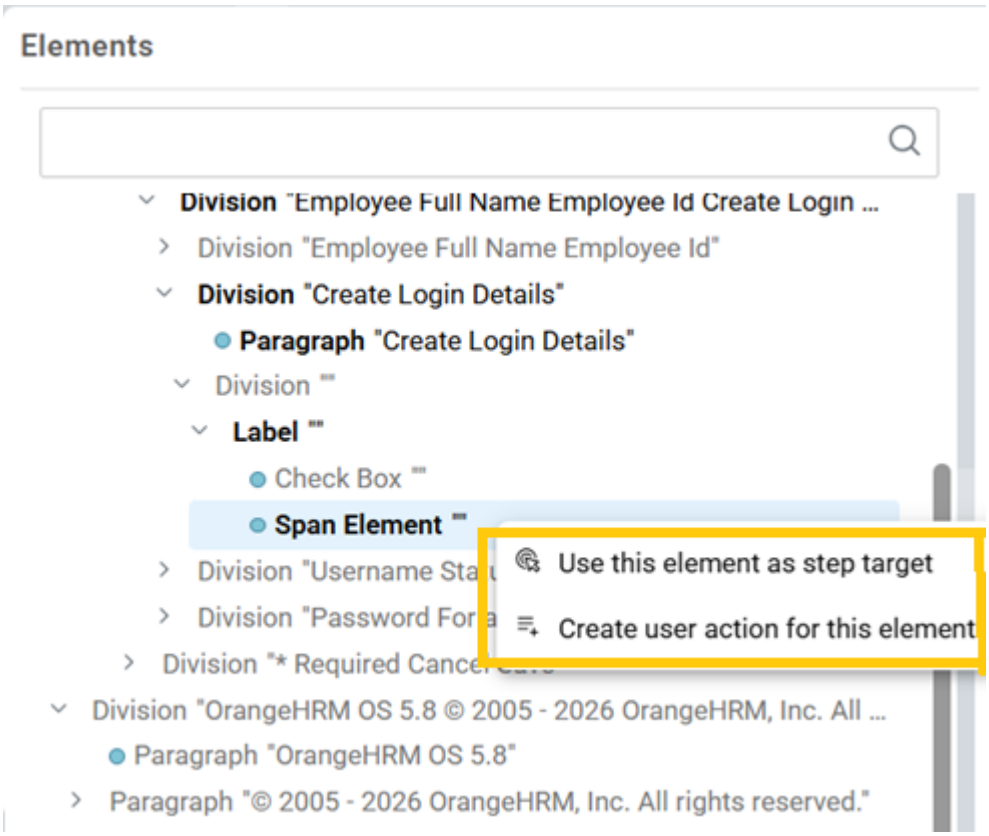
4. Right-click and select **Create user action for this element > Verify**. This allows you to add a verification that checks a specific property of the selected UI element. In this scenario, this step creates a verification point to check whether the **Create Login Details UI** element is **enabled**.
5. Select **enabled:true** option from the displayed **Verification points** list.
6. You can veiw the created the **Verification** in the **Details** tab.
7. Notice that once the UI element is selected in **Smartshot**, the same element is automatically highlighted in both the **Elements** panel and the **Properties** panel.

    - The **Elements** panel shows the UI elements captured in the recorded test.
    - The **Properties** panel displays the properties of the currently selected UI element.

    You can use either panel to add the same **Verify** step.

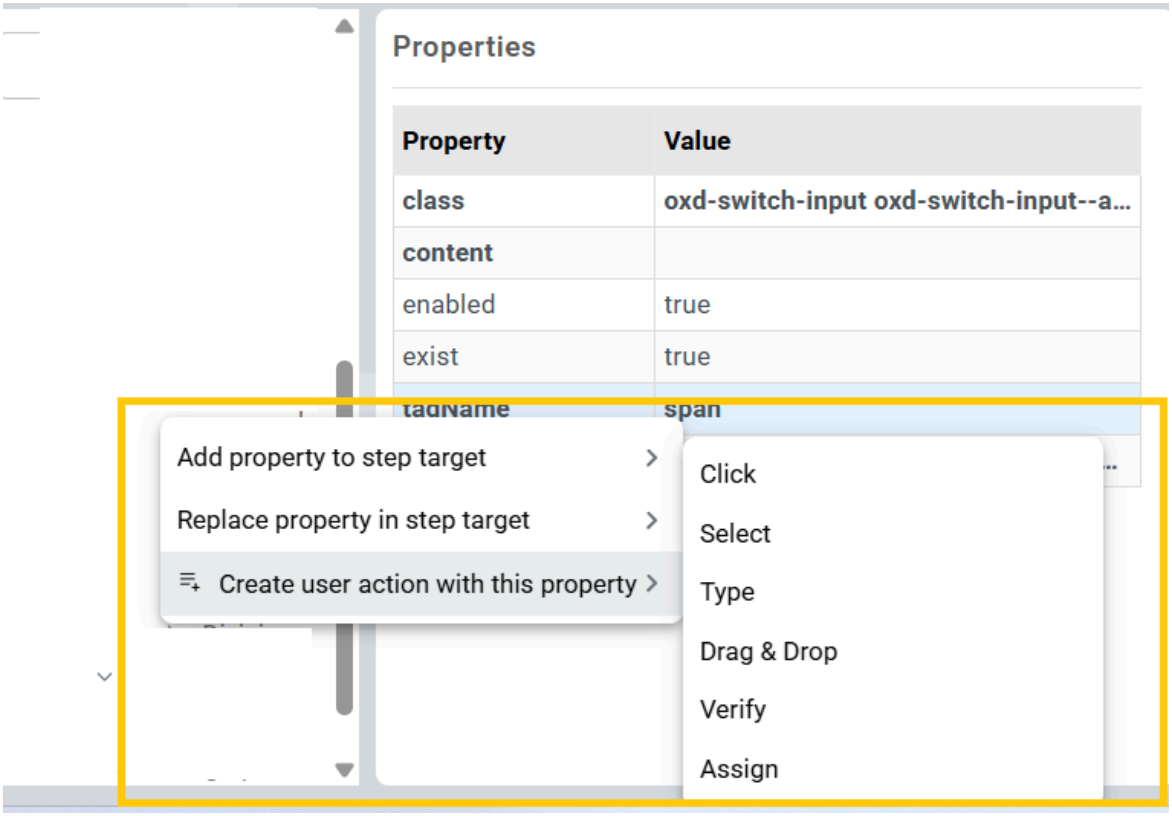
    - From the **Elements** panel, right-click the highlighted UI element and select **Create user action for this element > Verify**. For example, *Span Element* in the **Elements** panel.

      You are creating a verification based on a specific property of the UI element, rather than the entire element.

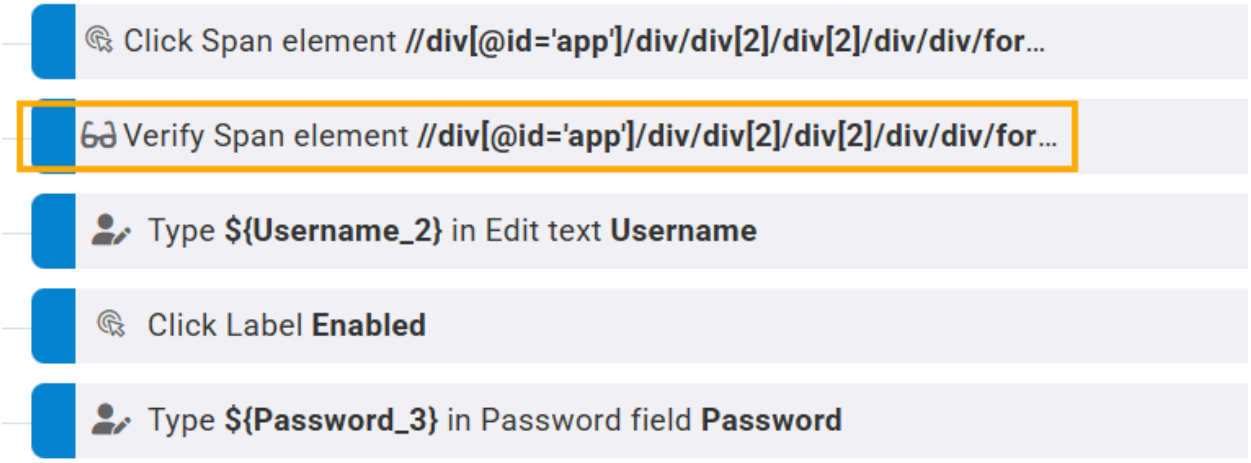


◦ From the **Properties** panel, right-click the **tagName** property and select **Create user action with this property > Verify**. For example, **span**.

You are creating a verification based on a specific property of the UI element, rather than the entire element.



8. Click **Close** to close the **Smartshot**.
   The **Verify** step is added to the recorded steps.



9. Click **Save** to save the modified test.

Results

You have added verification points to the recorded *Create Login Details* step.

You have completed Lesson 7.

What to do next

In the next lesson, you will learn how to run the test. See Lesson 8 on page 726.

Lesson 8: Run the Web UI test

In this lesson, you will learn how to run a recorded Web UI test in DevOps Test and verify that the web application performs as expected.

Before you begin

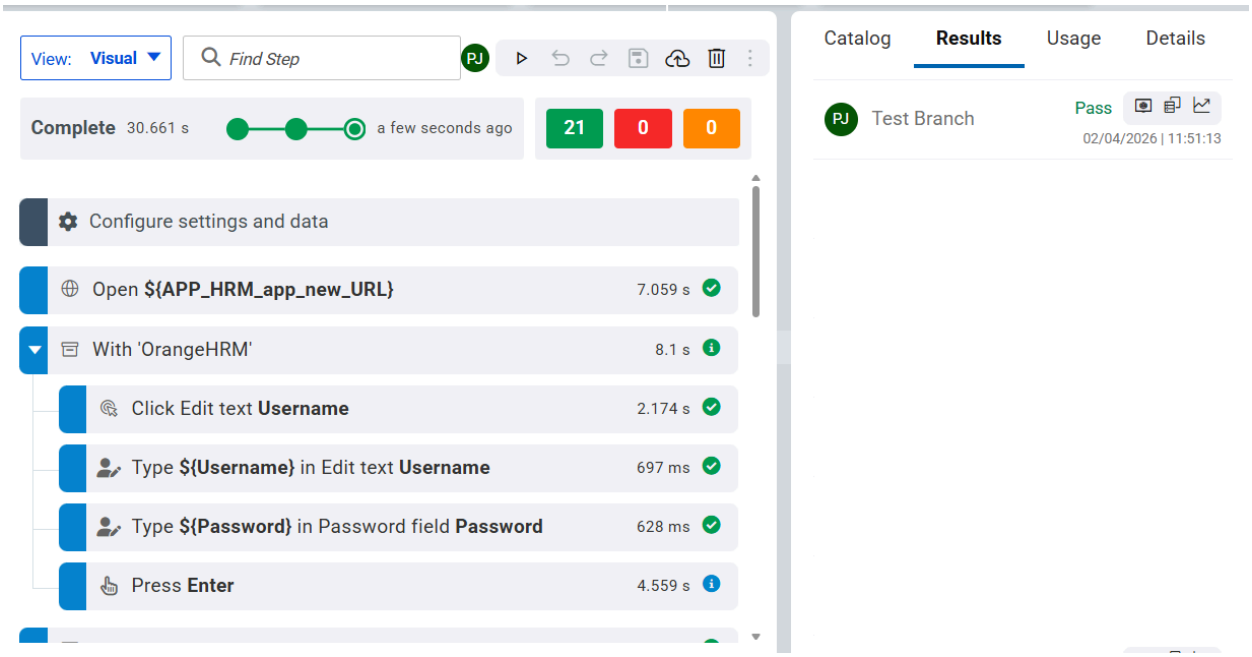
Ensure that you have completed the previous lessons in this tutorial.

About this task

In this task, you run the recorded Web UI test to simulate creating a new employee in the HR management application. This test run validates that key workflows such as Employee Id generation, role assignment, and data saving work correctly.

1. Click the icon, and then select the **Run on Default Cluster** option to start the test run for validating the recorded test for the HR management application.

   When the test run starts, the **Catalog** tab automatically switches to the **Results** tab so that you can monitor the execution status.
2. Observe the following stages during the test run on the **Test Editor** page:
   - **In transition**: The test setup is in progress.
   - **Running**: The test run is active.
   - **Complete**: The test run is completed. This section also displays the time taken for the test run.
   - The passed count, failed count, and error count are displayed on the **Test Editor** page.



3. Click the **Console** tab to view information such as error messages, logs, and the test verdict.
   You can then use this output to troubleshoot issues by reviewing details, such as session IDs and error messages.

   At any point, you can stop the test manually by clicking the **Stop playback** icon ☐. When stopped, the test status is displayed as **Stopped by User** on the progress bar and **Inconclusive** on the **Results** tab.

Results

You have successfully run the recorded Web UI test and viewed the test execution results.

You have completed Lesson 8.

What to do next

In the next lesson, you will learn how to view and analyze the test results. See Lesson 9 on page 728.

Lesson 9: View and analyze test results

In this lesson, you will learn how to view and analyze a **Functional Report** after running a Web UI test on the HR management application. You will also learn how to investigate a test failure using a real failure scenario.

Before you begin

Ensure that you have completed the previous lessons in this tutorial.

About this task

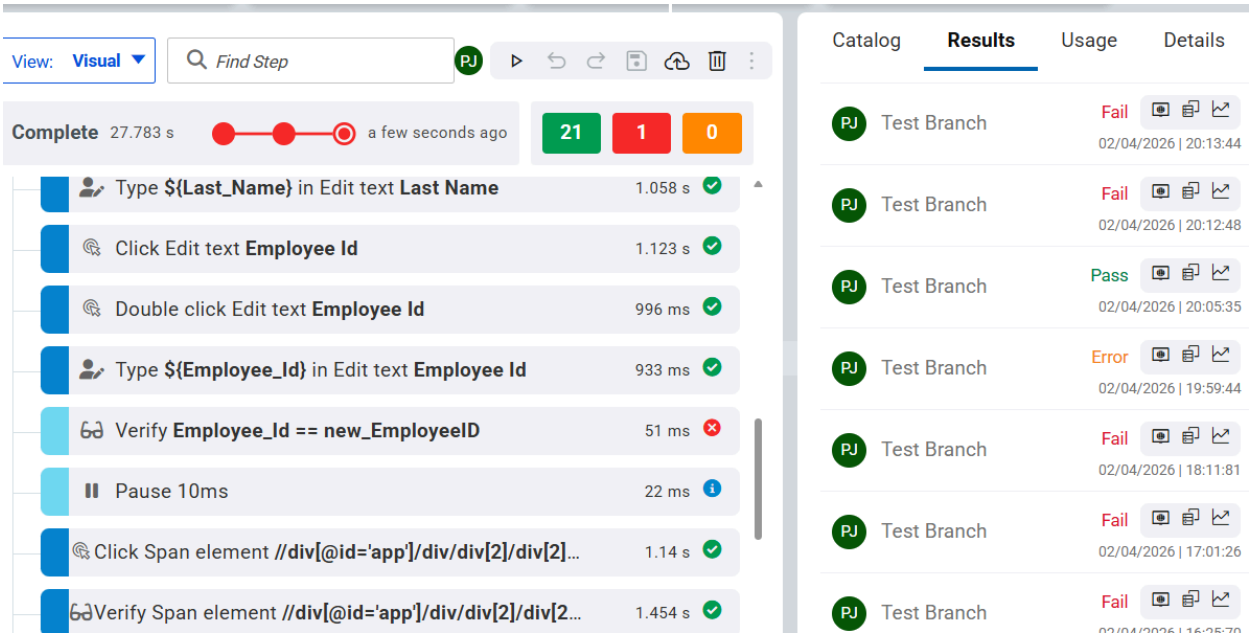
In this task, you will review a failed test run to understand why the failure occurred and identify the failed test steps. You analyze the **Functional Report** and **Test Log** generated by DevOps Test after the test run.

The **Functional Report** provides a comprehensive view of the test, including overall test status, test environment details, performed test steps, validation results, and screenshots captured during the test run. The **Test Log** shows a detailed, step-by-step record of what happened while running the test.

The Functional Report and Test Log help you confirm whether HRM application workflows, such as employee creation and verification, worked as expected and quickly pinpoint the cause of failures. The example used in this task demonstrates a test failure caused by an *Employee_Id* value mismatch.

1. Click the icon, and then select the **Run on Default Cluster** option to start the test for validating the recorded test for the HR management application.

   In the result summary, observe that the test is marked as 1 failed count.



2. Click the **Functional Report** icon to open the report in a separate window.

3. Click the **Expand** icon in the **Functional Report** to view detailed results.

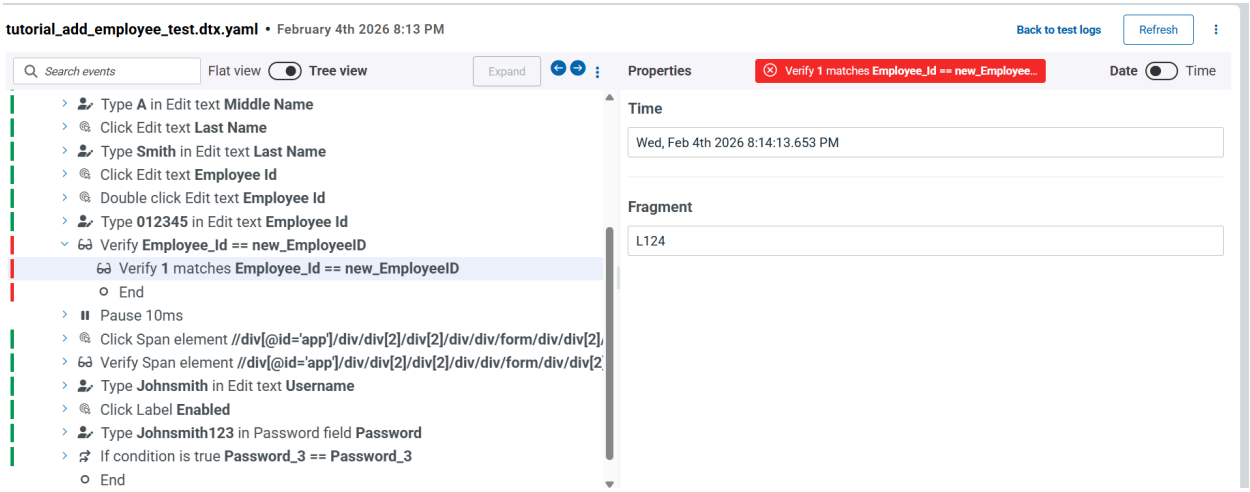
   You can now see the failed step and identify the reason for failure.

4. Click the **Open in new tab** icon to access the specific test in the **Test Editor** page, where you can review and edit the test steps.

   Review the failed step.

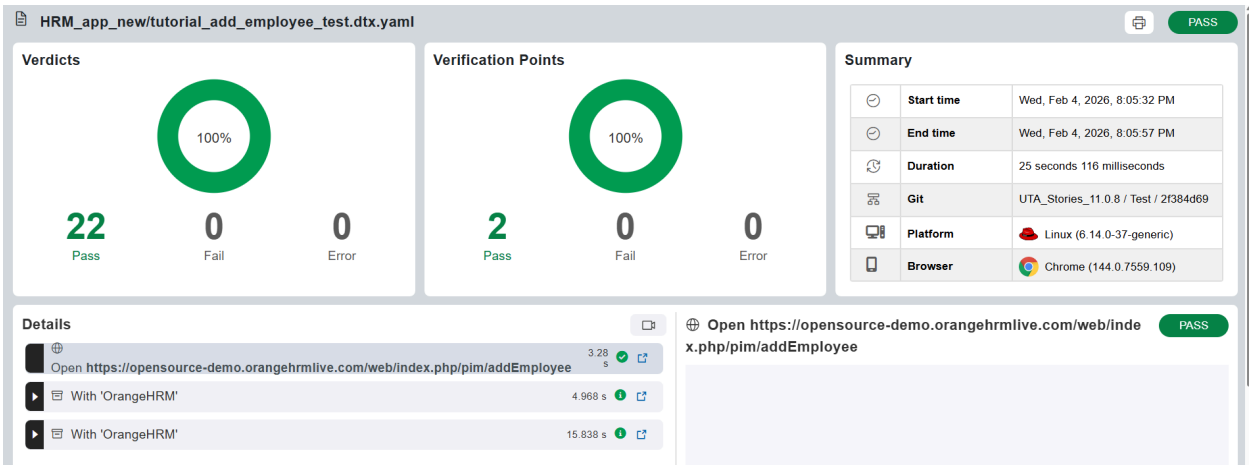
   The *Employee_ID* step failed because the value of *Employee_Id* is defined as *new_Employee_Id* in the **Verify** step.

5. In the **Verification Points**, select the correct variable value (*Employee_Id*) from the drop-down list.
6. Click the **Test Log** icon to open the **Test Log Report** to view the step-by-step details of each test step while running the test.



7. Click **Save** to update the test.
8. Click icon, and then select the **Run on Default Cluster** option to run the test again.

   - The test completes with **0 failed count**
   - The test status shows **Pass** in the Results tab
   - The Functional Report shows **100% Pass**



9. Click the **Publish** icon in the **Test Editor** page to publish the changes from the *HRM_branch* edit branch to a *master* branch in the project repository.

   After publishing, the changes are saved, the edit branch is automatically deleted, and is removed from the **Branch** drop-down list and the remote Git repository.

Results

You have successfully viewed and analyzed the Functional Report and Test Log, fixed the failure, and rerun the test with a **Pass** status.

You have successfully completed this tutorial.

Administrator Guide

This guide describes how to install the Test software.

After you install the software, you can perform administration tasks such as license configuration, user management, security, memory and disk usage management, back up and restore user data, and other tasks that a server administrator can perform. This guide is intended for administrators.

As a *Server Administrator*, you can assign the role of a *Server Administrator* to any user. For information about how to change the role, see Default user administration.

Remember: When your role is changed from a user to a *Server Administrator*, you must log out and log in again so that Test can apply the change in your role.

Configuration of DevOps Test

You can find information about the tasks that you must perform after you installed Test to configure Test.

The following table describes the tasks that you can perform as an administrator after you installed Test:

Require-ment	Tasks	More information
Required	Review the default user management to know how Test manages the users and their authentication.	User administration
Required	Import Certificate Authority (CA) into a browser to prevent certificate errors when you access the Test UI.	Certificate authority: Importing and extending lists on page 732
Optional	Copy the third-party application Jars to Kubernetes to run API Suites that uses a transport.	Copying third-party application Jars to Kubernetes on page 736
Optional	Configure multi-factor authentication (MFA) for log-ging into Test.	
Optional	Change the password seed to provide enhanced se-curity to Test.	Changing the password seed
Optional	Disable the server extensions that are enabled during the installation of Test, if you do not want the serv-er extensions to run on the cluster to save server re-sources.	Disabling server extensions on page 739

Management of third-party licenses

When you want to use built-in web browsers such as Google Chrome or Microsoft Edge, you must first accept the third-party license agreement of these browsers. You can manage third-party license agreements on the **General Settings** page in Test .

You can find the following information:

- Accepting third-party licenses on page 731
- Removing acceptance of third-party licenses on page 732

Accepting third-party licenses

You can accept any third-party license agreements on the **General Settings** page in Test .

About this task

Test prompts you to accept the third-party license agreements when you sign in or log in.. If you do not accept the third-party license agreements, Test continues to prompt whenever you log in.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Account** icon, and then click **Account Settings**.
   Result
   The **General Settings** page of your account is displayed.
3. Click the **Terms of Service** links in the **Third-Party Agreements** section to review the license agreements and terms of use for Google Chrome and Microsoft Edge.
4. Perform any of the following actions:
   - Select the checkbox for the browser that you want to use to accept the license agreement.
   - Select both **Google Chrome** and **Microsoft Edge** checkboxes, if you want to use both the browsers.
5. Click **Save**.

Results

You accepted the license agreements for either Google Chrome or Microsoft Edge browser or both the browsers.

Removing acceptance of third-party licenses

You can remove the acceptance of third-party licenses when it is no longer required.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **User** icon, and then click **Account Settings**.
   Result
   The **General Settings** page of your account is displayed.

   The **Third-Party Agreements** section displays checkboxes for **Google Chrome** and **Microsoft Edge** options.
3. Perform any of the following actions:
   - Clear the checkbox for the browser that you do not want to use.
   - Clear both the **Google Chrome** and **Microsoft Edge** checkboxes, if you do not want to use both the browsers.
4. Click **Save**.

Results

You removed your acceptance of the license agreements for either Google Chrome or Microsoft Edge browser or both the browsers.

Certificate authority: Importing and extending lists

When you want browsers and other applications to access Test , you must enable browsers to trust the certificate authority (CA) of Test. For some applications that integrate with Test, you must also extend the CA lists that are trusted by the applications.

Before you import CA and extend the CA list, you must save the CA assigned to Test. See Saving the certificate authority on page 733.

You can find the following tasks to import the certificate authority in the browser that you want to use:

- Importing the certificate authority into the Google Chrome browser on page 734
- Importing the certificate authority into the Microsoft Edge browser on page 734
- Importing the certificate authority into the Mozilla Firefox browser on page 735

You can find the following tasks when you want to extend the CA lists:

- Extending the trusted certificate authority list on Linux on page 735
- Extending the trusted certificate authority list on Windows on page 736

Saving the certificate authority

You can save the certificate authority (CA) when you want to import the CA or extend the CA lists that are trusted by the applications.

Before you begin

You must have completed the following tasks:

- Installed Test on a Kubernetes or OpenShift environment.
- Ensured that you have permissions to view the secrets that are created during installation of Test on a Kubernetes or OpenShift environment.

1. Access the Kubernetes or OpenShift cluster where you installed Test.
2. Run the following command to save the CA in `ca-master.crt` file.

```
kubectl get secret -n devops-system ingress -o "jsonpath={.data['ca\.crt']}" | base64 --decode >
 ca-master.crt
```

Remember: `devops-system` is the name of the namespace. If you created a namespace by using a different value, then you must use that value in place of the `devops-system`.

Results

You have successfully saved the CA.

What to do next

You can perform the following tasks:

- Import the CA into the Google Chrome browser. See Importing the certificate authority into the Google Chrome browser on page 734.
- Import the CA into the Microsoft Edge browser. See Importing the certificate authority into the Microsoft Edge browser on page 734.

- Import the CA into the Mozilla Firefox browser. See Importing the certificate authority into the Mozilla Firefox browser on page 735.
- Extend the trusted CA list on Windows. See Extending the trusted certificate authority list on Windows on page 736.
- Extend the trusted CA list on Linux. See Extending the trusted certificate authority list on Linux on page 735.

Importing the certificate authority into the Google Chrome browser

You must import the certificate authority (CA) into the Google Chrome browser to prevent certificate errors when accessing the Test .

Before you begin

You must have completed the following tasks:

- You must have saved the CA assigned to Test. See Saving the certificate authority on page 733.
- Installed the browser that you want to use to access Test.

1. Open the Google Chrome browser.
2. Navigate to **Customize and control Google Chrome > Settings**.
3. Click **Security** from the **Privacy and security** pane.
4. Click **Manage certificates**, and then **Import**.
5. Click **Next** in the **Certificate Import Wizard** window.
6. Click **Browse** and select the CA that you want to import, and then click **Next**.
7. Select the **Place all certificates in the following store** option to store the CA securely.
8. Click **Browse**, and then select **Trust Root Certification Authorities** as certificate store.
9. Click **OK**, and then **Finish**.

Results

You have imported the CA into the Google Chrome browser.

Importing the certificate authority into the Microsoft Edge browser

You must import the certificate authority (CA) into the Microsoft Edge browser to prevent certificate errors when accessing the Test .

Before you begin

You must have completed the following tasks:

- You must have saved the CA assigned to Test. See Saving the certificate authority on page 733.
- Installed the browser that you want to use to access Test.

1. Type `certmgr.msc` in the **Start** menu **Search** filed, and then press **Enter**.
2. Expand **Trusted Root Certification Authorities**, and then select **Certificate**.
3. Right-click on the empty space, and then select **All tasks > Import**.
4. Click **Next** in the **Certificate Import Wizard** window.

5. Click **Browse** and select the CA that you want to import, and then click **Next**.
6. Select the **Place all certificates in the following store** option to store the CA securely.
7. Click **Browse**, and then select **Trust Root Certification Authorities** as certificate store.
8. Click **Next**, and then **Finish** to import the certificate.

Results

You have imported the CA into the Microsoft Edge browser.

Importing the certificate authority into the Mozilla Firefox browser

You must import the certificate authority (CA) into the Mozilla Firefox browser to prevent certificate errors when accessing the Test .

Before you begin

You must have completed the following tasks:

- You must have saved the CA assigned to Test. See Saving the certificate authority on page 733.
- Installed the browser that you want to use to access Test.

1. Open the Mozilla Firefox browser.
2. Enter `"about:preferences#privacy"` in the address bar, and then press **Enter**.
3. Locate and click the **View Certificates** option.
4. Select **Authorities** tab, and then click **Import**.
5. Select the CA that you want to import, and then click **Open**.
6. Select **Trust this CA to identify websites** in the **Downloading Certificate** window.
7. Click **OK** to import the CA into the browser, and then close the window.
8. Restart Firefox.

Results

You have imported the CA into the Mozilla Firefox browser.

Extending the trusted certificate authority list on Linux

Test trusts the certificates signed by a recognized certificate authority (CA). When you have any additional CAs, you must extend the trusted certificates list by using an environment variable on Linux.

Before you begin

You must have saved the CA assigned to Test. See Saving the certificate authority on page 733.

1. Open the terminal.
2. Run the following command to create an environment variable on the Linux operating system:

```
export NODE_EXTRA_CA_CERTS= {path of the downloaded CA with the file extension}
```

For example,

```
export NODE_EXTRA_CA_CERTS=/opt/mycert/ca-master.crt
```

Results

You have extended the trusted CA certificates list on Linux.

Extending the trusted certificate authority list on Windows

Test trusts the certificates signed by a recognized certificate authority (CA). When you have any additional CAs, you must extend the trusted certificates list by using an environment variable on Windows.

Before you begin

You must have saved the CA assigned to Test. See Saving the certificate authority on page 733.

1. Right-click the Windows icon from the Windows taskbar, and then click **System**.
2. Click **Advanced system settings** from the **Related setting** section.
3. Click the **Advanced** tab, and then click **Environment Variables**.
4. Click **New** from the **System variables** section.
5. Enter `NODE_EXTRA_CA_CERTS` in the **Variable name** field.
6. Enter the path of the downloaded CA with the file extension in the **Variable value** field.

   For example, if you stored the `ca-master.crt` CA in the `C:\Users\Desktop\cert` location, then enter the **Variable value** field as `C:\Users\Desktop\cert\ca-master.crt`
7. Click **OK**.

Results

You have extended the trusted CA certificates list on Windows.

Copying third-party application Jars to Kubernetes

You can run API Suites in a project on Test . If the API Suite uses a transport and the transport requires third-party application `Jar` files for a successful run, you must ensure that the third-party application `Jar` files are available at the test run time. To achieve this, you must copy the third-party application `Jar` files to the computer where Test is installed on Kubernetes.

Before you begin

You must have server administrator or cluster administrator privileges.

You must have completed the following tasks:

- Identified the third-party application `Jar` files that are required and copied the files. See Test run considerations for API Suites or API tests on page 1059.
- Copied the third-party application `Jar` files from HCL DevOps Test Integrations and APIs (Test Integrations and APIs) to the directory or folder in Kubernetes from where you can run the kubectl commands.

About this task

You can copy the third-party application `Jar` files to the folder that is specific for the application under the `/data/<application_name>` folder. You need not extract the files.

You can perform this task any time after you have installed Test and you plan to run an API Suite that meets any of the following conditions:

- The API Suite uses transports and the transports require third-party application `Jar` files to be available at the test run time.
- The API Suite in the project has a results database configured.

You can copy the JDK version `Jar` files that you have used to create the JUnit tests.

You can get help on the kubectl commands by running the command: kubectl cp --help from the `/kube` directory. For more information, refer to the kubectl documentation.

1. Use the following table to find the name of the folder that corresponds to the specific third-party application for the transport used in the API Suite.

   Table 590. Name of the folder for the application

Application	Name of the folder to use
Camel	Camel
CentraSite	CentraSite
CICS	CICS
Coherence	Coherence
Database	JDBC
IMS	IMS
Integra	Integra
JMS	JMS
SAP RFC	SAP
Software AG Universal Messaging	SoftwareAGUM
TIBCO EMS	TIBCO
TIBCO Rendezvous	
TIBCO SmartSockets	
WebSphere Application Server Service Integration Bus (SiBus)	WAS

Application	Name of the folder to use
WebLogic	WebLogicJMX
Software AG webMethods	webMethods

2. Open the command prompt from the `/kube` directory and copy the `Jar` files to the folder that corresponds to the application by using the following command:

```
kubectl cp <compressed_files> devops-system/{{main}}-userlibs-0:/data/<application_name>/
```

For example, if you are copying the Database `Jar` files, then the name of the folder is *JDBC* and the command to use is:

```
kubectl cp mysql-connector-java.jar devops-system/{{main}}-userlibs-0:/data/JDBC/
```

Note: You must substitute `{main}` with the release name that you used during the installation of Test.

3. Verify whether the `Jar` files are copied by running the following command:

```
kubectl exec {{main}} -userlibs-0 -n devops-system -- ls /data/<folder_created>
```

For example, if you copied the Database `Jar` files, `mysql-connector-java.jar` to the folder *JDBC*, then the command to verify is:

```
kubectl exec {{main}} -userlibs-0 -n devops-system -- ls /data/JDBC
```

The following information is displayed for the `JDBC` folder:

```
mysql-connector-java.jar
```

Note: You must substitute `{main}` with the release name that you used during the installation of Test.

Results

You have successfully copied the third-party application `Jar` files to the folder in Kubernetes.

What to do next

You can configure the API Suite run. See Configuring an API Suite or an API test run on page 1174.

Server extensions

You can run specific tests in Test by enabling the server extensions.

The server extensions are enabled at the time of installation of Test. When the server extensions are enabled, you can perform the following tasks on Test:

- Add repositories that contain the test assets for the HCL AppScan CodeSweep tests, JMeter tests, JUnit tests or Postman collections.
- Configure a test run for the following test types:
    - **HCL AppScan CodeSweep**
    - **JMeter**
    - **JUnit**
    - **Postman**

To learn more about enabling and disabling the server extensions, refer to the following topics:

Disabling server extensions

When you do not want the server extensions in Test to run on the cluster to save server resources, you can disable server extensions.

Before you begin

You must ensure that the server extensions are enabled at the time of server installation by running the following command:

```
kubectl get pods –n devops-system
```

The status of the server extensions that are enabled is displayed as `Running`.

About this task

You must substitute `{{main}}` with the release name that you provided during the installation of Test in the following procedure.

The `devops-system` is the name of the namespace. If you created a namespace by using a different value, then you must use that value in place of `devops-system` in all the instances in this procedure.

1. Log in to the platform that you used to install Test.

   For example, you can log in to the Ubuntu server using an SSH session if you installed Test on Ubuntu.
2. Run the following commands that depend on the server extension you want to disable:

To disable the server extension	Run the command

CodeSweep	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestCodesweepEnabled=false`

To disable the server extension	Run the command

JMeter	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestJMeterEnabled=false`

JUnit	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestJUnitEnabled=false`

Postman	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestPostmanEnabled=false`

All server extensions	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestPostmanEnabled=false \`
	`--set global.hclOneTestJMeterEnabled=false \`
	`--set global.hclOneTestJUnitEnabled=false \`
	`--set global.hclOneTestCodesweepEnabled=false`

3. Run the following command to verify the status of the extensions:

```
kubectl get pods -n devops-system
```

Note: The pod for the server extension that you disabled is not displayed.

Results

You have disabled the required server extensions on Test.

Enabling server extensions

If you find that the server extension is disabled in Test and you want to run the tests supported by the server extension, then you must enable them.

Before you begin

You must ensure that the server extensions are enabled at the time of server installation by running the following command:

```
kubectl get pods -n devops-system
```

The status of the server extensions that are enabled is displayed as `Running`. If the server extension you want to use is not displayed as running, then you must enable the server extension.

About this task

You must substitute `{{main}}` with the release name that you provided during the installation of Test in the following procedure.

The `devops-system` is the name of the namespace. If you created a namespace by using a different value, then you must use that value in place of `devops-system` in all the instances in this procedure.

1. Log in to the platform that you used to install Test.

   For example, you can log in to the Ubuntu server using an SSH session if you installed Test on Ubuntu.

2. Run the following commands that depend on the server extension you want to enable:

To enable the server extension	Run the command

CodeSweep	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestCodesweepEnabled=true`

JMeter	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestJMeterEnabled=true`

JUnit	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestJUnitEnabled=true`

Postman	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestPostmanEnabled=true`

All server extensions	`helm upgrade {{main}} -n devops-system ./hcl-onetest-server \`
	`--reuse-values \`
	`--set global.hclOneTestPostmanEnabled=true \`
	`--set global.hclOneTestJMeterEnabled=true \`
	`--set global.hclOneTestJUnitEnabled=true \`
	`--set global.hclOneTestCodesweepEnabled=true`

3. Run the following command to verify a specific extension or all the extensions are enabled:

   ```
   kubectl get pods –n devops-system
   ```

   Result

   The status of the specific extension or all the extensions in the pod is displayed as `Running`.

Results

You have enabled the required server extensions on Test.

Team space administration

You can find information about team spaces including the initial team space on Test along with the tasks that you can perform to administer a team space.

You can find the following information about team spaces:

- Team space overview on page 742
- Creating a team space on page 745
- Tasks in a team space on page 747
- Tasks in projects in a team space on page 750
- Management of licenses in DevOps Test
- Installation of HCLSoftware Local License Server

Team space overview

Team spaces are logical partitions of Test . Team space is an exclusive, separate, and secure space on Test that enables you to share a single installation among multiple teams.

You can find the following information about team spaces:

- Initial team space on page 742
- Team spaces on page 743
- Migration from earlier releases of Test on page 744

Initial team space

After you install Test and log in for the first time, you enter the **Initial team Space**.

The initial team space is the default logical partition that is created on an instance of Test.

As a server administrator, you must consider the following points:

- After you install Test and log in for the first time, the **Projects** page of the initial team space is displayed.
- You must configure the license server for the initial team space.
- Add or remove users in the team space and assign them different roles in a team space.
- You can assign the role of a *Team Space Owner* to any other member in the initial team space.
- Change the type of the initial team space from the default type of *permissive*.

  The following table describes the type that you can assign to a team space:

Type	Description
Permissive	Specifies that any licensed user of Test can access a team space and get assigned the default roles of a *Project Owner* and *Member* in the team space.
Restrictive	Specifies that all licensed users of Test must request for access to a team space and must be provided access and assigned roles by the *Team Space Owner*. The **Restrictive** type of team space can be either **Public** or **Private**. A **Public** team space is visible in the team spaces dashboard, while a **Private** team space is not visible in the team spaces dashboard.

- You can evaluate the requirement and create team spaces other than the initial team space.

As a licensed user, you must consider the following points:

- When you log in for the first time immediately after the installation of Test, the **Projects** page of the initial team space is displayed.
- After you log in to the initial team space, you are assigned the default roles of *Project Creator* and *Member* of the initial team space.
- On subsequent logins, the **My Projects** page in the initial team space is displayed as the default page.

Team spaces

You can either work with the initial team space or you can create multiple team spaces on Test. The team space facilitates users of the same team space to work together.

Apart from being a container for projects, a team space facilitates the registration of Resource Monitoring agents, designing the system model, and viewing the registered agents, or intercepts.

After you create a team space as a **server administrator**, you must consider the following actions:

Note: You are assigned the default role of a *Team Space Owner* for team spaces that you create.

- Add users in the team space and assign them different roles in a team space.
- Assign the role of a *Team Space Owner* to other team space members, if you want other members to own the team space.

Note: As a *Team Space Owner*, you can remove any member of your team space from the assigned role. The member who is removed from a team space, can send a request and become a member of that team space after the request is accepted.

- If the *Team Space Owner* is no longer a member of a team space, then you as the server administrator can access that team space with the default role of a *Team Space Owner*. You can then assign the role of a *Team Space Owner* to any other member.
- Delete the initial team space or any other team space that you created, if required.

Note: If you delete the initial team space, the users of the initial team space are redirected to the **Team Space Dashboard** page.

You as a server administrator or the *Team Space Owner* must perform the following tasks in a team space before other members can start using the team space:

- Configure the license server.
- Configure the team space type as either *Restrictive* or *Permissive*.
- Configure the SMTP server and add members who can receive notifications about the operations performed in the team space.

As a member of a team space, you must consider the following points:

- When you log in for the first time immediately after the installation of Test, the **Projects** page of the team space is displayed.
- After you log in to the team space, you are assigned the default roles of a *Project Creator*, and *Member* of the team space.
- You can request to become a member of any other team space. After your request is approved, you are assigned the default role of a *Member* of that team space.
- You can become a member of either a **Permissive** or **Restrictive** type of team space.
- On subsequent logins, the **Team Space Dashboard** page is displayed as the default page.

Migration from earlier releases of Test

The initial team space is the only logical partition in Test 10.1.3. If you migrate from an earlier release of Test to 10.2 or later, then all the assets and resources that you created and associated with the initial team space are migrated to associate with the initial team space in Test 10.2 or later.

Note:

The results of migration are as follows:

- All projects are contained in the initial team space.
- If you created a repository in a team space, then you can find the repository in the initial team space in 10.2.
- All agents, and intercepts that you registered with the server are then registered with the initial team space and you can view from the **Agents and Intercepts** page of the initial team space.
- If you configured a resource monitoring agent in any project, then the details of the configured agent are available in the project.
- You can find the details of SMTP configuration on the server. Only you as a server administrator can view the details of SMTP configuration.
- The license server that is configured for the server for earlier release of Test is then configured for the initial team space.
- All users are assigned the role of a *Project Creator* and *Architect* of the initial team space.
- All users with server administrator roles are assigned the default role of a *Team Space Owner* of the initial team space.

Notes:

- All users of earlier releases are migrated to Test 10.2 or later. You can view the list of all migrated users in the application only when they log into the application at least once.
- After you migrate the server data from a previous version to a newer version, the **Project Owner** must log in to Test so that other members of the project can access the test assets in that project.

Default user administration

Creating a team space

To manage projects in the logical containers of Test , you must create team spaces.

Before you begin

You must have been assigned the role of a server administrator of Test.

About this task

As a server administrator, you can create multiple team spaces on Test.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane, and then click **Create Team Space**.
   Result
   The **New Team Space** dialog is displayed.

3. Provide a name to the team space.
   Result
   The **URL alias** field is automatically filled.

   Note: If you modify the name of a team space, the **URL alias** is also modified automatically.

4. **Optional:** Modify the **URL alias** for the team space, if required.

   Note: You must enter the **URL alias** that starts with a letter.

5. Select an option to set the permissions to access the team space. You can select any one of the following options:
   - **Permissive** – When a team space is set as **Permissive**, the new user gets the permissions automatically on sending the request to become a member of that team space.
   - **Restrictive** – When a team space is set as **Restrictive**, the *Team Space Owner* provides permission to the new user who becomes a member of that team space.

     You can set the visibility mode of the **Restrictive** type team space as **Public** or **Private**.
     - The **Public** team space is visible to all users in the **Team Space Dashboard**.
     - The **Private** team space is visible only to the members of that team space in the **Team Space Dashboard**.

     Note: If you select the **Restrictive** type team space, then the default setting of the team space becomes **Public**.

6. Provide a brief description of the team space.
7. Select the owner of the team space from the list of users who accessed the application.

   The selected user is assigned the role of a *Team Space Owner*.

   Note: You can assign the *Team Space Owner* role to only one user when you create a team space.

8. Click **Create**.
   Result
   The dashboard of the team space is displayed.

Results

You have created a team space.

If you are assigned the role of a *Team Space Owner*, then you can view the name of the team space that you created in the navigation pane.

If you assigned any other licensed user with the role of a *Team Space Owner*, then you can view the team space under the **Other Team Spaces** panel.

What to do next

You must configure the license for your team space. See Configuring licenses for team spaces.

Tasks in a team space

You can find information about the tasks that you can perform as a *Member*, *Project Owner*, *Architect*, or *Team Space Owner* in a team space on Test .

The roles assigned in a team space for users are as follows:

Persona	**Initial team space**		**Any team space**	
	Role	**Notes**	**Role**	**Notes**
Server administrator	*Team Space Owner*	Default role assigned	*Team Space Owner*	Default role assigned
Licensed user	*Team Space Owner*	Role assigned by Server administrator	*Team Space Owner*	Role assigned by Server administrator
	Architect	Role assigned by *Team Space Owner*	*Architect*	Role assigned by *Team Space Owner*
	Project Creator	Default role assigned	*Project Creator*	• Default role assigned in a *Permissive* team space. • Role assigned by *Team Space Owner* in a *Restrictive* team space.
	Member	Default role assigned	*Member*	Default role assigned in either a *Permissive* or *Restrictive* team space.

The following table shows the tasks that can be performed by licensed users with their assigned roles in a team space:

Tasks	**Team Space Owner**	**Architect**	**Project Creator**	**Member**
Configuring licenses	✔			
Configuring a Simple Mail Transfer Protocol (SMTP) server to send email notifications.	✔			
Changing the license server configuration	✔			

Tasks	Team Space Owner	Architect	Project Creator	Member
Adding members in a team space	✔			
Assigning different roles to other team space members	✔			
Modifying configuration details of a team space	✔			
Deleting a team space	✔			
Renaming a team space	✔			
Adding or removing the team space repository from a team space	✔	✔		
Designing a system model	✔	✔		
Creating projects in a team space	✔		✔	
Adding agents	✔	✔	✔	✔
Adding, modifying, or removing resource monitoring sources	✔			
Connecting resource monitoring agents	✔			
Adding resource monitoring labels	✔			
Working with projects in a team space	✔	✔	✔	✔

The following table provides the links to the information about the tasks that can be performed by users with different roles in a team space:

Tasks	Roles	More information
Configuring a team space license server	*Team Space Owner*	Configuring licenses for team spaces
Configuring the Named Users	*Team Space Owner*	Adding users to the Named Users list
Modifying the configuration of a team space	*Team Space Owner*	Modifying the configuration of a team space on page 1717

Tasks in projects in a team space

You can find information about the roles that you can assign in a project for members of a team space and the tasks that you can perform in projects in a team space.

Members of a team space with the role of a *Project Creator* can create projects in the team space and become the *Owner* of a project. The owners of projects can add *Members* of the team space to a project and assign them the following roles:

- *Owner*
- *Tester*
- *Viewer*

For the list of actions that members assigned any of the roles can perform, see Managing access to the server projects on page 1735.

All projects are created in a team space. When you open a project, the options that are displayed in the navigation pane are specific to the projects within a team space.

When you are working on a project in a team space and you want to return to the options available to work in the team space, you can click the **Back** icon in the navigation pane.

Note: You must be assigned the role of an *Owner*, a *Tester*, or a *Viewer* of a project.

The following table lists the tasks that members of a team space can perform while working with projects in a team space:

Tasks	More information...
Viewing projects in a team space.	Viewing active projects on page 1733
Adding a project.	Creating a project on page 1728
Adding a repository that contains test assets and resources that you want to run on the server.	Adding repositories to a server project on page 1729
Adding secrets to a classification.	Secrets configuration on page 1732
Encrypting the data set resources.	Managing an encrypted dataset on page 976
Configuring a change management system.	Configuration of a change management on page 1608
Adding members to a project and configuring their roles.	Adding users to a project on page 1732
Selecting the global branch in a project to view the test assets and resources.	Selecting the global branch in a project on page 1748
Adding agents to your project, if you are using remote agents as a location to run certain tests.	Adding a performance agent to a project on page 1076
Reading the considerations that you must take into account before you configure a test run.	Prerequisites to running tests on page 1057
Reading the considerations that you must take into account before you configure a run or start a virtual service.	Prerequisites for running HTTP virtual services on page 1455
Configuring a run of the test assets.	Test run configurations on page 1134
Configuring a run of the virtual service resource.	Configuring a run of a virtual service on page 1462
Viewing the progress of a test run.	Viewing the progress of running test assets on page 1444
Managing a running test.	Management of running tests on page 1440
Viewing the results of a test run after the run is completed.	Test results on page 1499
Reviewing the test results and creating defects for test runs from the **Results** page.	Creating Jira issues for the test results on page 1612

Management of resources

You can find information about managing resources on Test along with the tasks that you can perform to define retention rules and monitor resource usage for test results.

By defining the retention rules, you can prevent the system from running out of resources and ensure only the required data is maintained.

Managing retention rules

You can create, edit, and delete retention rules to automatically manage and clean up outdated or no longer needed test result data. This ensures that outdated or unnecessary results are managed and storage is optimized.

Before you begin

You must have been assigned the Team Space Owner role in Test.

About this task

Retention rules help teams manage storage effectively, especially in large-scale testing environments with frequent or long-running test runs. The retention rule provides an automated way to identify and reclaim resources associated with test results. You can choose to perform the following tasks:

- Delete the entire result, removing it from the system completely
- Delete only the test log and report data, reducing disk usage while keeping result metadata

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Manage > Resources**.
   The **Resources** page is displayed.
3. Click the **Rules** tab.

   The **Rules** page displays the following retention rules for the team space:

   - **Delete Stale Branches**: Deletes test results created on Git branches that no longer exist and are older than 3 days. For example, results from branch edits or Git cleanup.
   - **Delete Old Stub Results**: Deletes results of type APISTUB that are older than 30 days.

   Note: You can disable these default rules if required.

   In the **Rules** tab, you can perform the actions that are listed in the following table:

Task	Action
Enabling or Disabling default retention rule	Perform the following steps: a. Click the **Enabled** button to enable or disable the rules. The **Enable Retention Rule** dialog is displayed. b. Click **Ok** to confirm your action.

Task	Action
Adding retention rule	Perform the following steps: a. Click **Add Rule**. The **New Retention Rule** dialog is displayed. b. Enter a name in the **Rule Name** field. c. Select the conditions from the drop-down list. The condition types are: ▪ **Result age is older than (days)** ▪ **Branch status is** ▪ **Result verdict is one of** ▪ **Result size is greater than (MBs)** ▪ **Result labels contains one of** ▪ **Result labels does NOT contain any of** ▪ **The project is one of** ▪ **The test type is one of** ▪ **Max results per unique test** ▪ **Max results per unique test and verdict** **Note:** You can add multiple conditions to define a retention rule. For example, you can select the condition **The project is one of** and choose a project. You can add another condition **Result verdict is one of** and select the value **Pass**. The **Max results per unique test** and **Max results per unique test and verdict** conditions are not displayed if you have selected any of the following conditions: ▪ **Result age is older than (days)** ▪ **Result verdict is one of** ▪ **Result size is greater than (MBs)** The estimated impact is displayed at the bottom of the window, showing how much data will be freed. d. Select one of the following options:

Task	Action
	▪ **Entire Result**: Removes all traces of the test result. ▪ **Just report/testlog**: Retains metadata such as verdict and stop reason. e. Click **Create** to add a rule.
Editing retention rule	Perform the following steps: a. Click the **Edit** icon next to the rule that you want to modify. The **Edit Rule** dialog is displayed. b. Modify the name in the **Rule Name** field. c. Select the conditions from the drop-down list. The conditions types are: ▪ **Result age is older than (days)** ▪ **Branch status is** ▪ **Result verdict is one of** ▪ **Result size is greater than (MBs)** ▪ **Result labels contains one of** ▪ **Result labels does NOT contain any of** ▪ **The project is one of** ▪ **The test type is one of** ▪ **Max results per unique test** ▪ **Max results per unique test and verdict** **Note:** You can add multiple conditions to define a retention rule. For example, you can select the condition **The project is one of** and choose a project. You can add another condition **Result verdict is one of** and select the value **Pass**. The **Max results per unique test** and **Max results per unique test and verdict** conditions are not displayed if you have selected any of the following conditions: ▪ **Result age is older than (days)** ▪ **Result verdict is one of** ▪ **Result size is greater than (MBs)**

Task	Action
	The estimated impact is displayed at the bottom of the window, showing how much data will be freed. d. Select **Entire Result** to remove all the traces of test result or select **Just report/testlog** to retain the metadata (For example: verdict, stop reason). e. Click **Update** to apply the changes.
Running retention rule	Perform the following steps: a. Click the **Execute retention rule now** icon to run the rule immediately to identify and delete results matching its conditions. The **Confirm Recycle** dialog is displayed. b. Click **Yes** to confirm the action
Deleting retention rule	Perform the following steps: a. Click the **Delete Rule** icon to remove the rule from the team space entirely. The **Delete Rule** dialog is displayed. b. Click **Delete** to confirm the action.

Results

You have successfully created, updated, executed, or deleted retention rules.

Viewing resource usage statistics

You can view statistics about the resource usage to monitor and optimize the retention of results.

Before you begin

You must have been assigned the Team Space Owner role in Test.

About this task

When the server runs low on resources, it is difficult to identify which projects are consuming the most resources. This information is accessible to admins at the team space level to make informed decisions about the projects that can be pruned.

1. Log in to Test.

   The **Projects** page of the initial team space is displayed.

2. Click **Manage > Resources**.

   The **Resources** page is displayed.

3. Click the **Statistics** tab.

   The **Statistics** table is displayed with the following details.

Statistics details	Description
Project	The name of the project.
Archive status	Shows whether the project is currently active or archived.
Users	The number of users associated with the project.
Results	The size of the results stored for the project (For example: KB, MB).
Last Result	The date and time of the most recent test result.
Last Repository Modification	The date and time when the project repository was last modified.

   You can sort the table by any column by clicking the column headers so that you can quickly identify projects that consume the most resources or have the most recent activity.

Results

You have viewed detailed resource usage statistics for projects in the team space.

Configuration of an MCP server endpoint

Test provides a Model Context Protocol (MCP) server endpoint. The configuration of the MCP endpoint enables AI assistants within Visual Studio Code (VS Code) to securely integrate with your testing environment, read the test data, and perform specific actions that are supported by the tools.

When you configure the MCP endpoint in VS Code, the supported AI extension functions as an MCP client that communicates with the MCP server. This connection allows the AI assistant to list projects and test assets, retrieve test result data and summaries, and run tests directly within the development environment.

You can use the following endpoint to connect to the MCP server:

```
https://<server_hostname>/test/mcp
```

MCP tools available in Test

The following table lists the MCP tools that are available in Test for running tests and retrieving test results.

Tools	Description	Input	Output

testhub__get_projects	Retrieves a list of projects available in Test.	None	List of available projects
testhub__list_tests	Retrieves a list of tests in Test for a specific project and branch.	projectId, branch	List of tests for the specified project and branch
testhub__get_results	Retrieves test result summaries for multiple test runs in Test.	projectId, branch	Test result summaries for multiple test runs
testhub__get_result_by_id	Retrieves the test run result and detailed result data.	projectId, resultId	Test run result and detailed data
testhub__run_test	Runs a test in a specific project.	projectId, assetId, branch	Details of the test run, including execution ID

Configuring an MCP server endpoint in VS Code

You can configure an MCP server endpoint that enables an MCP-compliant client, such as VS Code, to access specific server-side tools. The endpoint offers several tools that provide access to teamspace, project, and test asset details, along with the ability to run tests and retrieve test results.

Before you begin

You must have completed the following tasks:

- Obtained the hostname or IP address of Test.
- Logged in to VS Code.

About this task

While configuring the endpoint, you will be prompted to authenticate the connection by entering the credentials. And when you run tests using the tool, you must provide an offline token for authentication.

1. Press `Ctrl+Shift+P` to open the command palette in VS Code.
2. Type `MCP add` and select the **MCP: Add Server...** option from the list.
3. Select the **HTTP (HTTP or Server-Send-Events)** option.
4. Paste the URL of the Test MCP server in the **Enter Server URL** field in the following format:

   `https://<server_hostname>/test/mcp`

   For example, `https://testhubserver.com/test/mcp`
5. Enter a name to identify the server, or accept the default when prompted to enter the server ID in the **Enter Server ID** field.

   For example, `myTestHub_mcp`.
6. Select one of the following workspace options when prompted:
   - **Global**: Ensures the tools are available from all your workspaces.
   - **Workspace**: Ensures the tools are available from only the current workspace.

An `mcp.json` configuration file is created.

7. Open the `mcp.json` file from the explorer.
8. Perform one of the following steps to connect to the server:
    - Click **Start** that is displayed above the server name in the `.JSON` file.
    - Click **Extensions**, right-click the server name, and then select **Start Server**.

   VS Code displays a notification stating that the MCP server requires authentication.
9. Click **Allow**.

   A second notification is displayed asking whether you want to open an external website.
10. Click **Open**.

    Your default browser opens and displays the Test login page.
11. Sign in with your Test credentials.

    A consent screen is displayed requesting access to Test MCP tools.
12. Click **Yes** to approve and complete the connection.

    After successful authentication, VS Code displays the number of available MCP tools.

Note: The MCP server times out after 30 minutes of inactivity. If no tool calls occur during this period, your session will expire and you are prompted to re-authenticate.

Results

You have configured an MCP server endpoint in VS Code.

What to do next

In the VS Code chat window, you can type a prompt that requires data from the server. For example, you can enter `Get the list of projects` or `List the latest failed test runs`. If you enter a prompt such as `Execute the test <test_name>` for running the test, the tool retrieves the test assets details from the server and then displays a prompt to enter the offline token to process the request. You must generate a token, copy it and paste the token in the VS Code chat window for the test run to complete.

Integration of Test with Measure

When you want to export the test results to Measure, you can use the Test plugin to integrate Test with Measure. After you complete the integration, you can run test assets, and then view the metrics on the Measure dashboard.

Prerequisites

You must have completed the following tasks in Measure before proceeding with the tasks to be performed in Test:

1. Added Test integration in Measure. For more information, refer to the Test Hub plugin documentation.
2. Copied the URL that is displayed on the **Integrations** page in Measure and saved it for later use. Here is the URL sample: https://10.0.2.15.nip.io:9443/reporting-consumer/pluginEndpoint/67eaa3c12b5778a2d1332269/onetest/callback.

Steps to perform in Test

You can perform the following tasks when you want to export test results to your dashboard in Measure:

1. Configure a webhook for Measure.
2. Add additional parameters for test runs on page 759.

Adding additional parameters for test runs

When you want to add additional parameters to be included in test results, you can do so by defining the parameters.

Before you begin

You must have completed the following tasks:

- Read and fulfilled the prerequisites that are listed in #unique_1255.
- Configured a webhook for Measure. See #unique_1253.

1. Click **Execution** in the navigation pane.
2. Select the test that you want to run and click in the **Actions** column to open the **Execute test asset** window.
3. Click **Advanced settings**.
4. Enter the following parameters and values in **Additional Configuration Parameters**:

Parameter name	Value
result.property.buildId	Enter the build ID for which you are running the test in the second edit field as the parameter value. For example, 1.13.4.
result.property.buildUrl	Enter the build URL for which you are running the test in the second edit field as the parameter value. For example, `https://10.10.110.112.nip.io/build/tasks/project/build_test123 .`

5. Click **Add** for each parameter.
6. Click **Execute**.

Results

The additional parameter values are captured while your test runs, and the test results are exported to Measure after the test run is complete.

What to do next

You must perform the following tasks to view the test results in the dashboard of Measure:

1. Create a dashboard in the **Insights** section. For more information, refer to Creating dashboards.
2. Add a chart to the newly created dashboard, and when you click **Add charts**, you must select Functional Tests, Unit Tests, API Tests, and Performance Tests from the **Quality** section. For more information, refer to Adding a chart.

Test Author Guide

This guide describes how to create and edit test assets in Test , and then publish test assets to the remote Git repository that you have configured in your project. This guide is intended for testers and test managers.

For an overview of the test creation and management by using Test Editor, click here to watch the video.

Edit branch overview

When you want to create or modify a test resource in Test , you must use an Edit branch. An Edit branch is a temporary branch created from the selected branch in the repository configured within the project, where you can save the created or edited resource.

You must be a *Team Space Owner*, *Project Owner*, or *Member* with a *Tester* role to create or edit a test resource.

When you want to create or edit a test resource, you must first select the branch in the project repository into which you want to add the created resource or the branch that contains the resource you want to edit.

Note: If you create an Edit branch from a read-only repository, a warning is displayed that publishing will fail.

When you create the Edit branch, any project member can use your Edit branch while the branch is available. When you provide a name for the Edit branch, you must adhere to the rules of Git branch naming conventions. For more information, refer to the Git documentation. You can view all the Edit branches from the **Branch** drop-down list when other project members create Edit branches.

Note: If there are too many simultaneous requests for Edit branch creation in a project, Git might take some time to complete the branch creation.

To differentiate the remote branch and Edit branch from the **Branch** drop-down list, an edit icon and the initials of the member who created the Edit branch are shown for the Edit branch. After you create the Edit branch, you can also view the Edit branch by accessing the remote Git repository in a browser.

If you want to save the created or edited resource to the branch in the project repository, publish the changes from the Edit branch to the selected branch. When the project repository is replicated automatically to the remote repository, the created or edited resources are then available in the remote repository in the branch they were published. The Edit branch that you used is automatically deleted after publishing, and it disappears from the **Branch** drop-down list and from the remote Git repository when you perform any of the following actions:

- Publish changes to the remote Git repository
- Discard the changes made in all test assets

Note: After the Edit branch disappears, the **Branch** field is set to the previously selected branch name.

If publishing the changes in edit branch fails due to conflict with remote branch, you can push the edit branch to remote repository by using **Push** option in the **Publish** dialog. Then create a pull request to merge your changes into the target branch by resolving the conflicts manually in Git.

When multiple users use the same edit branch, the modifications, renaming, moving, or deletions made by a user are notified to the other users. The notifications are displayed in the following scenarios:

- A user modifies the test asset. In this scenario, the notification also provides the following options:
  - **Reload**: Refreshes the page with the updated details.
  - **Compare**: Displays the **Compare <asset_name>** pop-up with the last saved version and the current version for comparison. The changes are highlighted.
- A user moves or renames a test asset.
- A user deletes a test asset.
- A user discards the changes on the **Changes** page.

Test Editor overview

You can use the **Test Editor** tab to create and manage test assets such as applications, Web UI tests, test suites, and environments in Test .

You can navigate to the **Test Editor** page and **Suite Editor** page from the **Author > Test Editor** tab in Test.

When you work on individual tests by creating or configuring test assets, the **Test Editor** page streamlines the entire testing process. You can efficiently organize applications, tests, suites, smartshots, environments that you created or modified in your project by using the test navigator panel in **Test Editor**.

Related information

Application management on page 765

Web UI test management on page 769

Test suite management on page 829

Test Editor page on page 763

Suite Editor page on page 764

Test navigator panel

The **Test Editor** page contains a central hub called the test navigator panel. You can use the test navigator panel to manage and organize test assets in multiple folders of your project.

You can right-click a test asset in the Test Navigator panel and select an option from the context menu to perform the following actions:

Actions	Description
Search	You can search for a test asset in a project by entering the name of the test asset in the **Search** field.
New	You can create an application, test, suite, or an environment in a project. See Creating an application on page 766, Recording a Web UI test on page 771, Creating a suite on page 830, and Creating an environment on page 870.
Edit	You can modify application components, Web UI tests, suites, or environments when you want to run a test asset with different values. See Modifying application components on page 767, Editing a Web UI test on page 793, Modifying a suite on page 831, and Modifying an environment on page 872.
Rename	You can change the name of an application, test, suite, environment, or smartshot within a project.
Move	You can change the location of a test, suite, environment, or smartshot and move it under a different application within a project. When moving a single asset, you can choose to include dependencies that are referenced only by the selected asset. If a dependency asset is shared by another asset, you cannot select that dependent asset for moving.
Delete	You can delete an application, test, suite, environment, or smartshot when it is no longer required in a project. When deleting a single asset, you can choose to include dependencies that are referenced only by the selected asset. If a dependency asset is shared by another asset, you cannot select that dependent asset for deletion. See Deleting a test asset on page 827, Deleting a suite on page 845.
Compare	You can view and compare changes made in the edit branch with unpublished changes in the Web UI test, suite or environment. You can select the **Compare** option, which appears when you right-click the test asset.
Save As	You can create a copy of an existing application, test, suite, or an environment with a new name in a project. You can select the **Save As** option, which appears when you right-click the test asset.
Collapse All	You can minimize all expanded test assets in the project view to simplify navigation and focus on top-level items.
Expand All	You can expand all sections or folders in the project view to quickly view the all the test assets.

You can select multiple test assets in the **Test Navigator** by pressing `Ctrl` and clicking individual assets, or by pressing `Shift` and clicking to select a range of assets.

You can use the following options in the test navigator toolbar when you manage and organize tests, applications, and suites across multiple folders of your project.

Icon	Description
	You can use the **Virtual Folder** icon to view folders at different levels. The available options are as follows: • **Root Folders**: Shows virtual folders at the top, followed by the folder structure of the repository. • **Embedded Folders**: Shows the folder structure of the repository first, with files organized into virtual folders. • **None**: Excludes virtual folders entirely, and presents only the original folder structure of the repository.
	You can use the **Link with editor** icon to connect Test Editor tabs to their corresponding locations in the test navigator panel. By using this icon, you can easily navigate and quickly access specific test assets within your project.
	You can apply a filter to view folders by their asset type. You can select one or more of the following asset types and apply the filter: • Datasets • Tests • Environments • Others • Smartshots • Suites
	You can use the **Save All** icon to save all the changes made to multiple test assets or folders within your project.

Test Editor page

The **Test Editor** page consists of two sections: a left pane and a right pane. You can use the left pane to view, edit, and organize the test. You can use the right pane to manage and analyze the test within the project.

You can use the following options in the left pane of the **Test Editor** page:

Options	Actions
View	In the default setup, the test is displayed in the **Visual** view. To view the test in **Code** view, you must click the **Code** option. The view that is selected will be active till you close the test.
Find Step	Enter the name of the test in the **Find Step** to search the test assets in the current test.
	Select the icon to begin the test run.

Options	Actions
Undo	Select the **Undo** icon to undo the recent changes.
Redo	Select the **Redo** icon to redo the recent changes.
Save	Select the **Save** icon to save all the changes made to the test.
Publish	Select the **Publish** icon to publish the test.

You can use the following tabs in the right pane of the **Test Editor** page:

Tabs	Actions
Catalog	Select the **Catalog** tab to add additional steps to the tests. See Adding user actions in a test from smartshots on page 796, New test steps from the General catalog on page 798, and New steps for UI-related actions and user actions in a test from the UI catalog on page 806.
Results	Select the **Results** tab to view the test results. See Running a Web UI test on page 785.
Usage	Select the **Usage** tab to see where the current test is referenced in other tests. You can click the icon to open the referenced tests. If there are no references to the current test, then the tab displays that the current test has no dependants.
Details	Select the **Details** tab to view the Git details such as **Asset ID**, **Repo**, **Path**, **Branch**, and **Commit**.

Related information

Web UI test management on page 769

Suite Editor page

The **Suite Editor** page consists of two sections: a left pane and a right pane. You can use the left pane to view, edit, and organize the suite. You can use the right pane to manage and analyze the suite within the project.

You can use the following options in the left pane of the **Suite Editor** page:

Options	Actions
View	In the default setup, the suite is displayed in the **Visual** view. To view the suite in **Code** view, click the **Code** option. The view that is selected will be active till you close the test.

Options	Actions
Find Step	Enter the name of the suites and tests in the **Find Step** to search suites and tests in the current suite.
	Select the icon to begin the test run.
Undo	Select the **Undo** icon to undo the recent changes.
Redo	Select the **Redo** icon to redo the recent changes.
Save	Select the **Save** icon to save all the changes made to the suite.
Publish	Select the **Publish** icon to publish the suite.

You can use the following tabs in the right pane of the **Suite Editor** page:

Tabs	Actions
Results	Select the **Results** tab to view the test results. See Running a suite sequentially on page 834 and Running a suite concurrently on page 835.
Usage	Select the **Usage** tab to see where the current suite is referenced in other suites. You can click the icon to open the referenced suites. If there are no references to the current suite, then the tab displays that the current suite has no dependants.
Details	Select the **Details** tab to view the Git details such as **Asset ID**, **Repo**, **Path**, **Branch**, and **Commit**.

Application management

When you want to create and manage Web UI tests in Test , you must first create an application within the project.

By creating an application in the project, you can streamline test management by ensuring that the tests are run on the correct application. The application organizes the process by linking each test asset to a specific application. Thereby improving the efficiency of test run.

Components of an application

The components are the key elements in the application that you might want to test. These components include the following details:

- **URL**: The web address where the application is hosted.
- **Description**: A brief explanation or details about the application.
- **Image**: A graphic representation or a logo of the application.

Managing applications primarily consists of two key activities:

- Creating an application on page 766.
- Modifying application components on page 767.

Creating an application

You can create an application within your project in Test and select it to create or record a Web UI test for that specific application.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

When you create an application within your project, you can initiate the test creation process, capture interactions and behaviors on the Web UI, and automate testing workflows.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Navigate to **Author > Test Editor**.
   The **Test Editor** page and test navigator panel are displayed.
4. Perform any of the following actions:
   - Click the **Action Menu** icon and select **Application**.
   - Right-click the project repository in the test navigator panel and select **New Application**.
   - Click **Create Application** on the **Test Editor** page, which is displayed when no applications are created in your project.

The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 6 on page 767.

5. Select your action to either select an existing Edit branch or create an Edit branch:
    - Perform the following steps to select an existing Edit branch:
        a. Select **Use an existing edit branch**.
        b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

        c. Click **Ok**.
    - Perform the following steps to create the Edit branch:
        a. Select **Create new edit branch**.
        b. Enter a name for the Edit branch in the **Branch Name** field.
        c. Click **Save**.
6. Type a unique name in the **Name** field of the **Create Application** dialog.
7. Click **Create**.
   The application is successfully created and it opens in the **Test Editor** for further configuration.
8. Type the web address in the **URL** field.
   Test detects and displays the logo of the website in the **Image** field.
9. Type a brief summary or relevant details about the application in the **Description** field.
10. Click the **Save** icon to save the details.

Results

You have created an application.

What to do next

You can perform the following tasks:

- Record a Web UI test. See Recording a Web UI test on page 771.
- Create a Web UI test. See Creating a Web UI test by using the empty test option on page 777.
- Modify application components. See Modifying application components on page 767.

Modifying application components

You can modify the existing application components within your project in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that your project contains an application.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Navigate to **Author > Test Editor**.
   Result
   The **Test Editor** page and test navigator panel are displayed.
4. Select the **Application** in the test navigator panel and click **Edit**.
   Alternatively, right-click the application in the test navigator panel and click **Edit**.
   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 6 on page 768.
5. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.
6. You can modify the following details of an application in the **Test Editor** page:

- **URL:** Update the web address if the location of the application has changed.
- **Description:** Modify the summary of the application or details to reflect any new information or changes to the application.
- **Image:** Change the logo or graphical representation of the application by clicking the **Edit Icon** in the **Image** field.

7. Click the **Save** icon to save the details.

Results

You have modified the application components.

Web UI test management

You can test your web applications by recording Web UI tests in Test . Test supports industry-standard browsers such as Google Chrome, Microsoft Edge, and Mozilla Firefox to record and play back Web UI tests. After the playback, you can evaluate the test results.

You can perform the following tasks to create and then manage your test assets in Test:

- Recording a Web UI test on page 771
- Creating a Web UI test by using the empty test option on page 777
- Running a Web UI test on page 785
- Viewing step-level results and updating tests on page 789
- Editing a Web UI test on page 793
- Adding user actions in a test from smartshots on page 796
- New test steps from the General catalog on page 798
- New steps for UI-related actions and user actions in a test from the UI catalog on page 806
- Adding conditional logic and redefining the flow in tests from the Flow catalog on page 814
- Creating and assigning test variables on page 847
- Assigning an object property to a test variable on page 849
- #unique_1277
- Configuring timeouts for tests and test steps on page 824
- Deleting a test asset on page 827

Web UI test creation

You can create Web UI tests by using the recording option or the empty test option in the Test . Test automatically enables web browsers and provides DevOps Test Runtime or the recording agent to configure the test environment before you start recording tests for web applications.

You can create tests for the web applications that you have already configured in **Test Editor**. When you create a test, a `.dtx.yaml` file is created and listed in the test navigator panel. Test captures mouse and keyboard actions that the user

performs to interact with the web pages when you record a test. Test supports the following HTML5 controls on the web pages:

- Text box
- Password field
- Text area
- Button
- Checkbox
- Drop-down list
- Date selector
- Radio button
- Slider
- JavaScript popup boxes such as alert, confirm, or prompt dialogs
- Drag-and-drop boxes
- File upload field

Test also supports the use of multiple tabs and windows to record a test.

Application URL management

If you have configured the application with a URL, then Test opens the browser with the configured URL when you record a test for that application. Otherwise, you must enter or paste the URL in the browser when you record a test. When the application contains a URL, Test creates a variable App_<app_name>_URL to store the value of the URL. Otherwise, if you manually enter or paste the URL, then the URL is embedded in the **Open** step.

When you record a test for an application that requires credentials to be supplied in an authorization dialog, before running the test, you must edit the test to modify the URL by adding the credentials as follows:

https://username:password@url

For example, https://test_user:Mypassword!23@sample.com

Also, you must convert any special characters in the username and password by using the URL encoding format.

For example, you can convert Mypassword!23 to Mypassword%2123.

Drag-and-drop boxes

The **Drag** action that is recorded contains two values: From and To. The **From** tab in the **Object Identified By** section displays the identifier of the object that is being dragged, and the **To** tab displays the identifier of the new location for the dragged element.

File upload scenario

You can validate the file upload functionality for a web application by recording and playing back the file upload function. When you record a file upload function, a **Type** step is added with a variable to save the file path and file name. The uploaded file is listed under `blob\Others` in the test navigator panel.

Support for device emulation

You can use the device mode of browsers to record tests, and run tests or suites. Test supports the following device profiles:

Device profile	Default browser
Phone (Small)	Edge
Phone (Medium)	Chrome
Phone (Large)	Edge
Phone (X-Large)	Safari (only on a Mac system)
Tablet (Small)	Edge
Tablet (Medium)	Chrome
Tablet (Large)	Edge
Tablet (X-Large)	Safari (only on a Mac system)

Recording a Web UI test

You can record screens and user actions on the web page of an application to create a Web UI test in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760.
- Ensured that your project contains an application.

About this task

When you choose to create a Web UI test by using the recording option, the installation status of the recording agent is displayed. Initially, when you are recording a test for the first time, the status is displayed as 'Not installed' with the **Download Installer** link to install the recorder agent. The `devops-test-runtime.msi` file is downloaded. You must then double-click the .msi file to install the agent. After the installation is complete, you must click **Verify** to continue with the recording process.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Perform one of the following options:

- Click **Create asset > Create Test** on the **Test Editor** page.
- Click the **Action menu** icon in the test navigator panel to open the menu and click the **Test** option.
- Right-click the application in the test navigator panel, select **New > Test**.

Alternatively, you can create a test by clicking the **Create Test** icon on the application **Details** page if there is an edit branch active.

The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 6 on page 772.

5. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

     Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.
6. **Optional:** Click **Open** in the browser notification that might be displayed for you to confirm the opening of DevOps Test Runtime.

   The browser notification is displayed only when the recording agent is already installed.
7. Perform the following steps in the **Details** tab of the **Create Test** dialog:
   a. Select an application for which you want to create a test from the **Application** drop-down list.

      The application folder is selected as the default location for the test.

   b. **Optional**: Select a folder if there are subfolders in **Location** to save the test assets that you are creating.
   c. Enter a name for the test in **Asset Name**.
8. Click **Next**.

   The **Source** tab is displayed.
9. Select the **By recording** option to record a test in the **Select source** drop-down list.

   Test checks whether the recording agent is installed on your computer.
10. Perform one of the following steps depending on the installation status of the agent:

If...	Then...
The agent is not installed and the screen displays the following options: ◦ Windows (64-bit .msi) ◦ Mac OS (64-bit .zip) ◦ Debian/Ubuntu (64-bit .deb) ◦ RHEL/Fedora/OpenSUSE (64-bit .rpm)	Perform the following steps to install the agent on Windows: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.msi` file is downloaded. b. Double-click the `.msi` file to install the agent. The installation window with the progress bar is displayed. c. Click **Proceed** to accept the download of the proprietary certificate if prompted. d. Click **Verify** to confirm the agent installation. A browser notification might get displayed for you to confirm the opening of the agent. You must click **Open**. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Mac: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.zip` file is downloaded. b. Extract the `.zip` file: unzip devops-test-runtime.zip c. Quarantine the installer: xattr -dr com.apple.quarantine ./* d. Run the installer: ./install.sh e. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Ubuntu: a. Click **Download** to download the recording agent installer. The `devops-test-runtime_11.0.9_amd64.deb` file is downloaded. b. Navigate to the directory where the installer is downloaded: cd <download-directory>

If...	Then...
	c. Run the installer: sudo apt install ./devops-test-runtime_11.0.9_amd64.deb d. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Linux: a. Click **Download** to download the recording agent installer. The `devops-test-runtime-11.0.9-1.x86_64.rpm` file is downloaded. b. Navigate to the directory where the installer is downloaded: cd <download-directory> c. Run the following command: INGRESS_DOMAIN=<domain_name> dnf localinstall ./devops-test-runtime-11.0.9-1.x86_64.rpm d. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
The agent is installed, but not updated, and the screen displays the following options: ◦ Windows (64-bit .msi) ◦ Mac OS (64-bit .zip) ◦ Debian/Ubuntu (64-bit .deb) ◦ RHEL/Fedora/OpenSUSE (64-bit .rpm)	Perform the following steps to update the agent on Windows: a. Click **Upgrade**. The installation screen with the progress bar is displayed. The latest DevOps Test Runtime is installed and configured. b. Click **Proceed** to accept the download of the proprietary certificate if prompted. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Mac: a. Click **Download** to download the recording agent installer. b. Uninstall the existing agent: rm -rf ~/Applications/devops-test-runtime.app c. Extract the downloaded `.zip` file:

If...	Then...
	unzip devops-test-runtime.zip d. Quarantine the installer: xattr -dr com.apple.quarantine ./* e. Run the installer: ./install.sh f. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Ubuntu: a. Click **Download** to download the recording agent installer. b. Uninstall the existing agent: sudo apt remove devops-test-runtime c. Navigate to the directory where the installer is downloaded: cd <download-directory> d. Run the following command: sudo apt install ./devops-test-runtime_11.0.9_amd64.deb e. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
	Perform the following steps to install the agent on Linux: a. Click **Download** to download the recording agent installer. b. Uninstall the existing agent: sudo yum remove devops-test-runtime c. Navigate to the directory where the installer is downloaded: cd <download-directory> d. Run the installer: sudo INGRESS_DOMAIN=<domain_name> dnf localinstall ./devops-test-runtime-11.0.9-1.x86_64.rpm

If...	Then...
	e. Click **Verify** to confirm the agent installation. The additional options for recording are displayed. Go to step 11 on page 776.
The agent is installed.	Go to step 11 on page 776.

11. Select a browser from the **Browser** drop-down list.
    The following browsers are listed:

Operating system	Browsers
Windows, RHEL, or Ubuntu	Chrome, Edge, and Firefox
Mac OS	Chrome, Edge, Firefox, and Safari

    Also, the following device profiles are listed:

Device profile	Default browser
Phone (Small)	Edge
Phone (Medium)	Chrome
Phone (Large)	Edge
Phone (X-Large)	Safari (only on a Mac system)
Tablet (Small)	Edge
Tablet (Medium)	Chrome
Tablet (Large)	Edge
Tablet (X-Large)	Safari (only on a Mac system)

    Note: If you selected the Edge or Firefox browser on a Mac system, you might see the following error: `The recorder encountered a problem: No compatible WebDriver was found or the browser is already running.`

    To resolve this issue, you must check whether the `~/.cache/selenium` folder is password protected, and then change the access permission to make it a regular folder.

12. Select **UI** from the **Interactions** drop-down list.
13. Click **Record**.
    A new browser window is displayed, and the application that you selected for recording opens. If you selected Chrome, Edge, or Firefox, the browser opens in a temporary profile with no cache or cookies. For Safari, when the browser opens, you must manually clear the cache and cookies as required.

Note: If you do not want to continue with the application that is open, you can type or paste the required URL to record the test. Test inserts the **Open** step to capture the new URL that you used for recording the test.

14. Click the UI controls and perform user actions in the application to record test steps.
    You must allow some delay of a few seconds between two user actions to ensure that the UI elements are recognized and registered properly.
15. Close the browser to stop the recording.
    The '`The asset is now ready for your review`' message is displayed in the **Create Asset** dialog.
16. Click **Done**.
    The newly recorded test is displayed in **Test Editor**. The test is displayed in the **Visual** view, which is the default view. You can switch to the **Code** view to view all the step details.

Results

You have recorded a Web UI test.

What to do next

You can perform the following tasks:

- Run the test and view the results. See Running a Web UI test on page 785.
- Edit the test in Test Editor. See Editing a Web UI test on page 793.
- Create variable data for the test. See Test variables on page 846.

Creating a Web UI test by using the empty test option

You can create a Web UI test by selecting the empty test option and then adding the steps and elements either through the catalog in the Visual view or through the written code in the Code view.

Before you begin

You must have completed the following tasks:

- Ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760.
- Ensured that your project contains an application.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Perform one of the following options:
   - Click **Create asset > Create Test** on the **Test Editor** page.
   - Click the **Action menu** icon in the test navigator panel to open the menu and click the **Test** option.
   - Right-click the application in the test navigator panel and select **New > Test**.

   Alternatively, you can create a test by clicking the **Create Test** icon on the application **Details** page if there is an edit branch active.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 6 on page 778.
5. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

     Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.
6. **Optional:** Click **Open** in the browser notification that might be displayed for you to confirm the opening of DevOps Test Runtime.
   The browser notification is displayed only when the recording agent is already installed.
7. Perform the following steps in the **Details** tab of the **Create Test** dialog:
   a. Select an application for which you want to create a test from the **Application** drop-down list.

      The application folder is selected as the default location for the test.

   b. **Optional**: Select a folder if there are subfolders in **Location** to save the test assets that you are creating.
   c. Enter a name for the test in **Asset Name**.
8. Click **Next**.
   The **Source** tab is displayed.

9. Select the **Create an empty test** option in the **Select source** drop-down list.
10. Click **Done**.
    An empty test is displayed in **Test Editor**. The test is displayed in the **Visual** view on the **Test Editor** page. You can also switch to the **Code** view.
11. Choose one of the following options:
    - Add your code to build the test in the **Code** view. Go to step 19 on page 779.
    - Add steps in the **Visual** view. Go to step 12 on page 779.

    Note: You can also copy the steps from an existing test and paste them in the empty test by right-clicking the **Configure settings and data** step.

12. Drag and drop an element from one of the following catalogs to the **Test Editor** page:
    - **General**
    - **UI**
    - **Flow**

    A test step is added.
13. Click the step to add the details.
    The step details pane is displayed and the Smartshot pane does not display any image.
14. Drag and drop a `.jpeg` file to the Smartshots pane from the **shot > Smartshots** folder under the selected application.
15. Select an option from the **UI object** drop-down list.
16. Select a user action in the **Action** drop-down list or enter a value in the **Value** field depending on the type of step you have added from the catalog.
17. Click the **click here to add identifier** link and then in the **Object Identified By** section, specify the condition and value that identifies the UI object.

    Alternatively, you can drag-drop a property that identifies the object from the **Properties** list.
18. **Optional:** Click the **Click here to add relative** to link to define the location and name of the related object.
19. Click the **Save** icon to save the modifications.

Results

You have created a Web UI test by using the empty test option.

What to do next

You can perform the following tasks:

- Run the test and view the results. See Running a Web UI test on page 785.
- Edit the test in Test Editor. See Editing a Web UI test on page 793.
- Create variable data for the test. See Test variables on page 846.

Test creation with Test Genie

Test Genie is an AI-powered capability in Test that automatically translates your natural language instructions into usable test scripts for web applications.

Traditionally, creating automated tests requires manually recording interactions against a live application or writing a test code. Test Genie accelerates this process so that you can define test steps by using plain text prompts. You provide a descriptive prompt, such as adding specific items to a shopping cart and proceeding to checkout, and the AI generates the corresponding test assets.

To improve the accuracy of the generated test steps, Test Genie uses the application context. When you initiate a generation request, the system passes your natural language steps along with the application URL and any application descriptions to the AI model. This context helps the AI understand the target interface and correctly map your instructions to the underlying web elements.

Supported AI providers

Disclaimer:

This release supports Anthropic in Test as a Tech Preview. The Tech Preview is intended for you to view the capability of Anthropic for test generation offered by HCL Test, and to provide your feedback to the product team. You are permitted to use the information only for evaluation purposes and not for use in a production environment. HCL provides the information without obligation of support and "as is" without warranty of any kind.

To use Test Genie, you must configure at least one AI provider in the **Infrastructure > Cloud Credentials** page of Test. Test Genie supports the following AI providers:

- Anthropic - Tech Preview
- OpenAI

For optimal results, you can use OpenAI with the `GPT-5-mini` model.

Capabilities and limitations

Test Genie streamlines the initial creation of test scripts, but it operates within specific boundaries regarding test validation and test modification. The following points describe the scope of Test Genie:

- **Generative scope:** Test Genie generates the navigational and transactional steps of a test, such as clicking buttons, entering text, and navigating between pages. It also provides test generation details, including the model used and token usage metrics.
- **Iterative modifications:** You can use AI prompts to modify or append steps to a test that Test Genie has already generated. To modify the AI-generated steps, you must submit a revised prompt and then generate the test again.
- **Verification points:** The AI does not automatically generate or insert verification points into the test script. You must manually add verification points to the generated steps to validate application behavior and data.
- **Datasets:** Test Genie does not create datasets or automatically link existing dataset files to the generated test. You must configure datasets manually.

Creating a Web UI test with Test Genie

You can use the AI-powered Test Genie to generate test steps for a web application based on your natural language instructions.

Before you begin

You must have completed the following tasks:

- Ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760.
- Ensured that your project contains an application.
- Configured at least one AI provider in the **Cloud Credentials** page. See Adding cloud credentials of AI providers on page 1122.

About this task

Test Genie accelerates test creation by translating your written instructions into a test script. The AI provider uses the application URL and the details in the application description to improve the accuracy of the generated steps.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Perform one of the following options:
   - Click **Create asset > Create Test** on the **Test Editor** page.
   - Click the **Action menu** icon in the test navigator panel to open the menu and click the **Test** option.
   - Right-click the application in the test navigator panel and select **New > Test**.

Alternatively, you can create a test by clicking the **Create Test** icon on the application **Details** page if there is an edit branch active.

The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 6 on page 782.

5. Select an existing edit branch or create a new edit branch.
6. Perform the following steps in the **Details** tab of the **Create Test** dialog:
    a. Select an application for which you want to create a test from the **Application** drop-down list.

       The application folder is selected as the default location for the test.

    b. **Optional**: Select a folder if there are subfolders in **Location** to save the test assets that you are creating.
    c. Enter a name for the test in **Asset Name**.
7. Click **Next**.

   The **Source** tab is displayed.
8. Select the **Create an empty test** option in the **Select source** drop-down list.
9. Enter a set of natural language instructions for your test in the **Steps** text box.

   For example, for testing an e-commerce website, you can enter:

```
Add three sports category items to the cart

Remove one item during the checkout process

Log in with the credentials

Proceed to order
```

10. Click **Done**.

    An empty test is displayed in **Test Editor**.
11. Click the **Test Genie** tab.

    The instructions you entered during the test creation are displayed in the **Steps** text box under the **Test Genie** tab.
12. Review, modify, or add to your natural language instructions in the text box.
13. Click **Generate**.

    The **Generate Test** dialog is displayed.
14. Perform the following steps in the dialog:
    a. Enter or modify the web address of the application under test in the **Start URL** field as required.
    b. Select an AI provider from the configured **AI Provider** list.
15. Click **Generate**.

    The test generation process starts.
16. Click the **Results** tab and then click the **Show in progress page** icon .

    The **Progress** page is displayed. If the page contains many jobs, you must create a filter with the rule **AI Assisted Generation** to filter for AI-assisted jobs.
17. Select **View AI interactions** from the listed actions in the **Actions** column of the AI-assisted job.

    A new tab opens with the console output. You can view the AI interactions and session logs on the progress page by refreshing the view.

18. Switch to the test editor tab after the execution job is complete in the **Progress** page.
    The **Reload** button is displayed with the following warning: `A newer version of this resource is available.`
19. Click **Reload**.
    The AI-generated test steps are displayed.

Results

You have created a Web UI test with Test Genie.

What to do next

You can perform the following steps:

- You can view the execution results, the model used, and the token usage details in the **Test Genie** tab.
- Play back the generated test. See Running a Web UI test on page 785 or Running server test assets on page 1321.

Modifying a Web UI test created by using Test Genie

You can modify the natural language instructions that you provided to generate a test by using the AI-powered Test Genie. After modifying the instructions, you can regenerate the test to update it.

Before you begin

You must have completed the following tasks:

- Ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760.
- Ensured that you have created a Web UI test by using Test Genie. See Creating a Web UI test with Test Genie on page 781.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.yaml` file to open the test.
   The test steps are displayed on the **Test Editor** page.

5. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 784.
6. Select an existing edit branch or create a new edit branch.
7. Click the **Test Genie** tab.

   The instructions you entered during the test creation are displayed in the **Steps** text box under the **Test Genie** tab.
8. Review, modify, or add to your natural language instructions in the text box.
9. Click **Generate**.

   The **Generate Test** dialog is displayed.
10. Perform the following steps in the dialog:
    a. Enter or modify the web address of the application under test in the **Start URL** field as required.
    b. Modify the AI provider from the configured **AI Provider** list if required.
11. Perform one of the steps as required:
    - If you want to first clear the steps that are already generated, retain the selection in the **Reset script before generation** checkbox.
    - If you want to append the new steps after the last step in the generated test, clear the **Reset script before generation** checkbox.
12. Click **Generate**.

    The test generation process starts.
13. Click the **Results** tab and then click the **Show in progress page** icon .

    The **Progress** page is displayed. If the page contains many jobs, you must create a filter with the rule **AI Assisted Generation** to filter for AI-assisted jobs.
14. Select **View AI interactions** from the listed actions in the **Actions** column of the AI-assisted job.

    A new tab opens with the console output. You can view the AI interactions and session logs on the progress page by refreshing the view.
15. Switch to the test editor tab after the execution job is complete in the **Progress** page.

    The **Reload** button is displayed with the following warning: `A newer version of this resource is available.`
16. Click **Reload**.

    The modified test steps are displayed.

Results

You have modified a test that was created by using Test Genie.

What to do next

You can perform the following steps:

- You can view the execution results, the model used, and the token usage details in the **Test Genie** tab.
- Play back the generated test. See Running a Web UI test on page 785 or Running server test assets on page 1321.

Running a Web UI test

You can run a Web UI test in Test after you record the test, and to verify that the web application performs as expected.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensured that your project contains a Web UI test in the test navigator panel.

About this task

When you play back the test, the test runs in the browser that is used to record the test. The progress bar shows the progress of the test, while the three color-coded boxes display the counts of passed steps, failed steps, and errors. You can view the step details of the first failed step or error step by clicking the respective color-coded boxes. As the test runs, you can view checkmarks for the steps that pass and crossmarks for the steps that fail. After the test run is complete, you can view the overall results on the **Results** page.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.yaml` file to open the test.
   The test steps are displayed on the **Test Editor** page.
5. Perform the following steps to specify the browser that you must use for the test run:
   a. Click the **Configure settings and data** step.

      The **Configure settings and data** panel is displayed.

   b. Select one of the following options from the **Browser** drop-down list:
      - Browser
      - Device profile
      - Device from the list of devices for the configured device cloud

      The browser that is used to record the test is selected as the default browser and the browser specified here modifies the default browser.

Note: You must have accepted the license agreements for Google Chrome and Microsoft Edge browsers in the **Third-Party Agreements** section after navigating to **Account** > **Account Settings**. If the third-party agreements are not yet accepted, the list options display links so that you can navigate directly to the agreement and accept the terms.

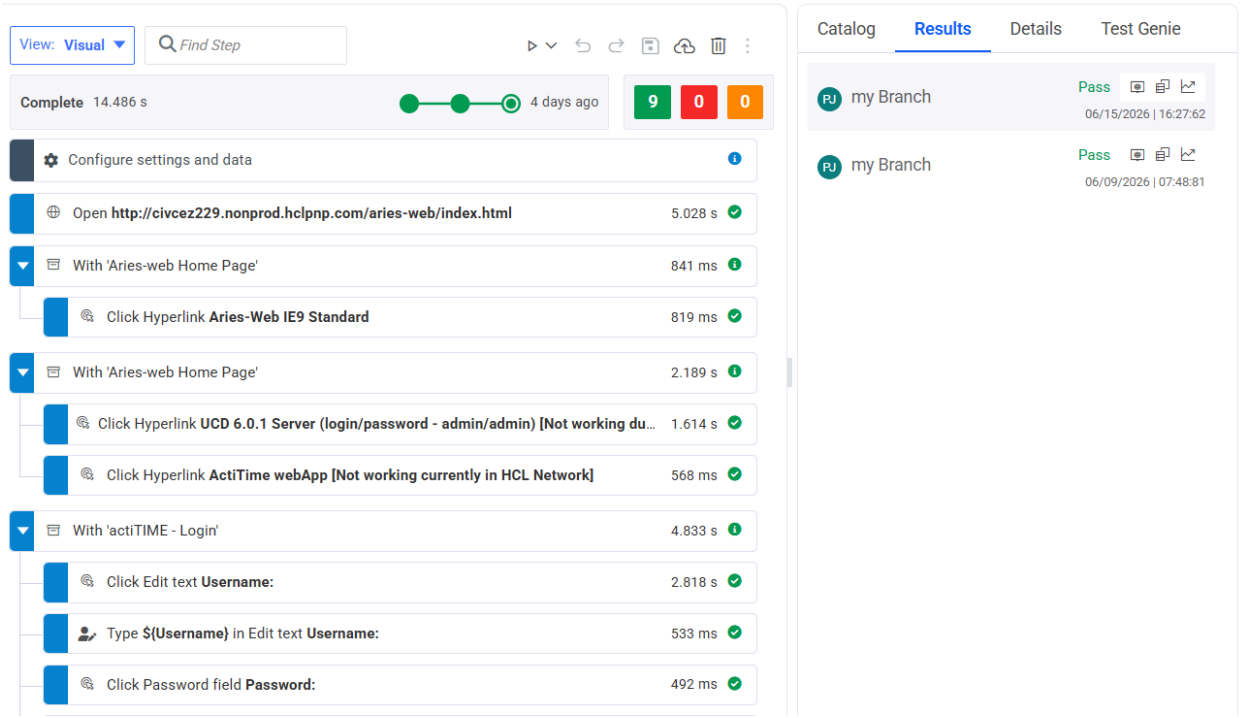
6. Click the icon, and then select the **Run on Default Cluster** option to begin the test run.

   You can also select the **Run on Personal Agent** option if the personal agent is in the ready state.

   You can view the following stages during the test run:
   - **In transition**: The test setup is in progress.
   - **Running**: The test run is active.
   - **Complete**: The test run is completed. This section also displays the time taken for test run.
   - During the **Running** phase, the following step result indicators are displayed with the time taken to process each step:
     - A checkmark appears for the passed step.
     - An error mark appears for the steps with an error.
     - A crossmark appears for the failed step.
     - An info icon appears for the **With** step that indicates a new screen or window.
   - The **Results** tab displays the test as **In Progress** during the test run.
   - After the test run is completed, the **Results** tab displays the test as **Pass** or **Fail**.

   The **Result** page supports selecting individual items from the list. When a row is selected, the corresponding high-level information is displayed in the top banner of the Test Editor.

Figure 3. Running a Web UI test



7. Click to open the **Results** page, where you can view the results, reports, and logs of the completed test run.

Results

You have run a Web UI test.

What to do next

You can view the following information:

- The console output, which includes error messages and logs. See Accessing console output on page 787.
- The results, reports, and logs on the **Results** page after the test completes the run.
- The summary of the test run, which includes passed or failed status, count of passed or failed tests or test steps, and the verification points in the functional report. See Viewing a Functional Report on page 1511.

Related information

Viewing the progress of running test assets on page 1444

Accessing the console output

When you run tests, you can access the console output that provides information such as error messages, logs, and the test verdict. You can then use this output to troubleshoot issues by reviewing details, such as session IDs and error messages.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensure that your project contains a test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.yaml` file to open the test.
   The test steps are displayed on the **Test Editor** page.
5. Click the **Console** tab at the bottom of the **Test Editor** page.

   Alternatively, you can click the expand icon .

   The **Console** output view is displayed.
6. Review the console output to identify the error messages and logs.
7. Perform the following actions to manage the console output:

Action	Description
Search a keyword in the console output	Enter a keyword in the **Search console** field, and the corresponding word is highlighted in the console output.
Select all console content	Right-click the console output area and, then select the **Select All** option to select all content.
Copy the selected content	Right-click the selected content and choose **Copy** to copy the content.
Expand console output view	Click the up arrow to expand the console output view for more details.
Restore console output view	Click the down arrow to return the console output page to its original size.
Close console output view	Click the drop-down icon to close the console output view.

Results

You have accessed the console output content.

What to do next

You can perform any of the following tasks:

- Decide on the actions that you might want to take based on the logs.
- Rerun the test asset.

Viewing step-level results and updating tests

You can view the step-level results of each step after running a Web UI test. You can edit and update the steps in test scripts by replacing smartshots.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a Project Owner or Tester in the project. See Managing access to the server projects on page 1735.
- Ensured that you have run the Web UI test.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.

About this task

Test collects the UI data during the test run and smartshots that are captured during the test run can be used to update the failed step. If an object is not identified during the test run, then the step fails. The test steps are indicated in different colors to specify the status of each test step. For the failed step, you can replace the smartshot with the latest one from the last test run. Also, you can update a step by replacing the smartshot and selecting a target element.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click Tests to view the list of tests recorded for the selected application.
5. Click the `.yaml` file to open the test.
   The test steps are displayed on the **Test Editor** page.

   Note: If you have just run the test and the edit branch is not published, then you can click the color-coded step result indicators that are displayed for each step to view the result details.

6. Click any test step for which you want to view the result details.
   The step details pane is displayed.

7. Click the **Show Result** toggle button in the upper-right corner of the step details pane to view the outcome of the step.

   The **Result** section displays the following details:

   - Step run status, such as **Completed step** or **Failure**, along with the **Duration** is displayed. The failure reason is displayed when the step fails.
   - **Start Time** and **End Time**, which you can view by clicking the **Expand view** icon .
   - Overall step outcome, such as **PASS** or **FAIL**.

   Note: The **Show Result** option can be enabled only if the test has already been run. You can disable this option and navigate to the **Test Editor** page.

8. Click the **Fullscreen** icon to view the details with smartshot and other configuration details in full-screen mode for better visibility.

   Note: The **Fullscreen** icon is displayed only after you click the **Expand view** icon.

9. Click the **Exit fullscreen** icon to close the full-screen view.

   Note: The **Exit fullscreen** icon is displayed only when fullscreen mode is enabled.

10. Click the **Previous Step** icon and the **Next Step** icon to navigate between the previous and next test steps.
11. Perform the following actions to update the step by replacing the smartshot for the step:
    You can update both passed and failed steps.

    a. Click the **Replace Smartshot** icon that is displayed if the edit branch is active.

       The **Replace Smartshot** pop-up window is displayed with a list of smartshots under two different sections: **Result Smartshots** and **Application Smartshots**. The **Result Smartshots** displays the smartshots from the last test run, and the **Application Smartshots** displays all the available smartshots captured earlier for the application. You can hover over an image and click the zoom icon or to view the enlarged image. The image is displayed with the controls to rotate right, rotate left, zoom in, and zoom out.

Note: If the test is run as part of the test suite, then the **Replace Smartshot** icon is disabled even when the edit branch is active. You can click the Open button that is displayed to open the test for editing.

b. Select a smartshot, and then click **Replace** if you want to replace the smartshot for the step.

12. Click the **Save** icon to save the modifications.

Results

You have viewed the step-level result and updated the test.

What to do next

You can perform the following tasks:

- Run the test and view the results. See Running a Web UI test on page 785.
- View the Functional Report to verify the test steps with the variable assignment. See Viewing a Functional Report on page 1511.

Related information

Modification of Web UI tests on page 792

Stopping a test run

You can stop a test run when issues occur or if you decide to stop the run before completion.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Initiated a test run from the **Test Editor** page.

About this task

You can stop a running test from the **Test Editor** page if the test run is in the **In transition** or **Running** state.

1. Go to the **Test Editor** page.
2. Click the **Stop playback** icon .
   The status of the test is displayed as **Inconclusive** on the **Results** tab and **Stopped by User** on the progress bar.

Results

You have stopped a test run.

What to do next

You can re-initiate the test run from the **Test Editor** page.

Modification of Web UI tests

With **Test Editor**, you can view and customize a Web UI test that is created in Test.

The **Test Editor** page displays the test scripts. The test script lists user actions and UI elements recorded as chronological sequence of events during the recording session. Actions are presented in the natural language and you can modify the test manually.

The **Test Editor** also displays the following sections:

- **Catalog** tab: Displays the catalog elements that can be dragged and dropped to an existing script as steps. The catalog elements are categorized as **General**, **UI**, and **Flow**. For more information on the usage of catalog elements, see New test steps from the General catalog on page 798, New steps for UI-related actions and user actions in a test from the UI catalog on page 806, and Adding conditional logic and redefining the flow in tests from the Flow catalog on page 814.

  Note: If you want to drag and drop a catalog element to a test when you use Chrome or Edge on a Ubuntu virtual machine, you must directly connect to the machine instead of connecting through a desktop sharing system such as VNC.

- **Results** tab: Displays the status of the test run when it is in progress, and the verdict of the previous test runs with a link to the **Results** page to view reports.
- **Variables** pane: Displays the defined variables and provides options to add or edit variables.

When you click a test step, the step details pane that is expandable is displayed with different sections as follows:

- **Smartshot**: Displays screen captures with UI objects from the web application under test. You can select a UI object, and add or modify an action related to the object. This section provides **Zoom in**, **Zoom out**, **Pan**, **Fit to available space**, and **Replace Smartshot** controls to work with images.

  The **Zoom in** icon increases the magnification of the smartshot image by 10%. The **Zoom out** icon decreases the magnification of the smartshot image by 10%. By using the **Focus on object** icon, you can move the smartshot within the available viewing area by dragging the image. While the **Focus on object** mode is enabled, smartshot interactions such as drag-and-drop and context menu actions are disabled.

  The **Full screen**

- **Details**: Displays the object type and the associated value or action depending on the step type. This section also displays values that identify the object. You can use any of the following conditions while defining the target to identify the object: Includes, Ends with, Matches regex, Starts with, Equals, Doesn't equal, Doesn't match regex, Doesn't include, Doesn't start with, Doesn't end with.

  For the XPath that identifies the object, you can also provide a relative XPath when you select **xpath** in the drop-down list of properties in the **Object Identified** section. The element for which you provided an XPath is highlighted in the **Smartshot** view.
- **Advanced**: Displays options to define a timeout for the step and disable the step.
- **Elements**: Displays the elements available on the web page that are captured in the smartshot.
- **Properties**: Displays the properties such as aria label, class, content, exists, href, id, label, name, placeholder, tagName, type, value, and XPath of the object. The displayed properties are the properties that are captured while recording and they are required to identify the objects during the playback.

The step details pane displays information about the currently selected step and provides options to modify the step. See Editing a Web UI test on page 793.

Editing a Web UI test

You can edit a Web UI test to add new steps, remove the existing steps, or update the step details.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the application for which you recorded a test in the test navigator panel.
   The assets created for the application are displayed.
5. Click Tests to view the list of tests recorded for the selected application.
6. Click the `.yaml` file to open the test.
   The test steps are displayed on the **Test Editor** page.

Note:

The top-level steps and first-level child steps are automatically expanded to provide better visibility.

7. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 9 on page 794.
8. Select an existing edit branch or create a new edit branch.
9. Select a step to view the details.
   The step details pane is displayed. If the step has a user action, then the **Smartshot**, **UI Object** type, **Action**, and **Object Identified By** details are displayed.
10. Perform any of the following actions to modify the step details as required:

Action	Description
Edit the object and action for the step	Perform the following steps: a. Hover over the UI elements in the **Smartshot** view, right-click the required UI element, and then select **Use this element as a step target** to change the object assigned for the step. The values in the **Object Identified By** field are updated based on the selected UI object. You can also select a different UI object from the list if required. b. You can use the available filter options in the **Smartshot** view to filter the displayed UI objects: i. **Filter by HTML**: Displays the identified UI objects based on HTML elements. ii. **Filter by Window**: Displays the identified UI objects based on the application window. iii. **Filter by jQuery UI**: Displays supported jQuery UI controls identified during recording. Supported controls include Button, Radio Button, Checkbox, Menu, Menu Item, Date Picker, Tabs, and Accordion.

Action	Description
	c. Modify the value from the **UI Object** drop-down list if required. d. Select a user action from the **Action** drop-down list. e. **Optional**: Click the **Click here to add relative to** link, specify the relative location in the **Location** field, and specify the relative object in the **UI Object** field. f. **Optional**: Click the **Click here to add alternative identifier** link, and select a target object from the list in the **Target 2** field. Alternatively, you can drag and drop an element from the **Smartshot** view.
Open the test that is embedded in the **Run** step	Right-click the **Run** step and click **Open**. The embedded test is displayed in **Test Editor**.
Select a step or a set of steps	Right-click a step and click **Select**. Checkboxes are displayed for each step to select the required steps. When you right-click a selected step, the **Extract Steps** and **Deselect All** options are displayed.
Disable the step	Click the **Advanced** tab and select the **Disable** checkbox. Alternatively, you can right-click the step and click **Disable**. The option changes to **Enable** for the disabled step.
Copy the step	Right-click the step and click **Copy**.
Paste the step	Right-click a step, and then click **Paste**. The copied step is pasted after the selected step.
Delete the step	Right-click the step, and then click **Delete**.

11. Click to close the step details pane.
12. Click the **Save** icon to save the modifications.

Results

You have edited a Web UI test.

What to do next

You can perform the following tasks:

- Run the test and view the results. See Running a Web UI test on page 785.
- Add additional steps from the catalog. See New test steps from the General catalog on page 798, New steps for UI-related actions and user actions in a test from the UI catalog on page 806, and Adding conditional logic and redefining the flow in tests from the Flow catalog on page 814.
- Create and use variables in the test. See Creating and assigning test variables on page 847.

Adding user actions in a test from smartshots

When you want to add user actions as steps in an existing Web UI test, you can add such steps from smartshots associated with the test. You can select a graphical element in the smartshot and add a user action for that element.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

About this task

The **Test Editor** page displays a hierarchical view of the steps in a test. The step details pane displays the object properties with the associated smartshot. You can add a step as a node and add further actions as sub-steps by selecting any of the widgets in the **Smartshot** view.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 796.
2. Select an existing branch or create a new branch.
3. Drag and drop one of the following element from the **UI** catalog in the **Catalog** tab after the required step.

- Click
- Select
- Type
- Verify
- Assign

A test step is added.

4. Click the newly added step.
   The step details pane is displayed.
5. Select one of the panes and perform the following actions:

Name of the pane	Action
Smartshot	Hover over a UI element in the **Smartshot** view, right-click, and then select one of the following options: ◦ **Use this element as a step target** ◦ **Create user action for this element**: **Click, Select, Type, Drag & Drop, Verify, Assign** Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object Identified By** section.
Elements	Perform the following actions: a. Expand the list of elements in **Elements**. b. Select an element, right-click, and then select one of the following options: ▪ **Use this element as a step target** ▪ **Create user action for this element**: **Click, Select, Type, Drag & Drop, Verify, Assign**
Properties	Perform the following actions: a. Click any of the UI elements in the **Smartshot** view. b. Select a property from the **Properties** list, right-click, and then select one of the following options: ▪ **Add property to step target** ▪ **Create user action with this property**: **Click, Select, Type, Drag & Drop, Verify, Assign** If the target object is already defined, then you can use the **Replace property in step target** option to replace the identifier.

If you selected the **Use this element as a step target** option, the action or condition is assigned to the selected element. Else, if you selected the **Create user action for this element** option with one of the listed actions, a step is added just before the selected step.

The step details pane is displayed with the **Smartshot**, **UI Object** type, **Action**, and **Object Identified By** details. The values displayed are dependent on the object selected.

Alternatively, you can select the **Code** checkbox, and then enter a JavaScript code that returns the target object for the selected action.

6. **Optional:** Click the **Click here to add relative to** link, specify the relative location in the **Location** field, and then specify the relative object in the **UI Object** field.
7. **Optional:** Click the **Click here to add alternative identifier** link, and select a target object from the list in the **Target 2** field.
8. Click the **Save** icon to save the modifications.

Results

You have added user actions as steps from smartshots in a Web UI test.

What to do next

You can perform the following tasks:

- Run the test and view the results. See Running a Web UI test on page 785.
- Add additional steps from the catalog. See New test steps from the General catalog on page 798, New steps for UI-related actions and user actions in a test from the UI catalog on page 806, and Adding conditional logic and redefining the flow in tests from the Flow catalog on page 814.
- Create and use variables in the test. See Creating and assigning test variables on page 847.

New test steps from the General catalog

When you want to add a log statement, validation, variable assignment, or pause the test for a specific duration, you can add the corresponding steps from the **General** catalog.

You can add the following steps from the **General** catalog in the **Catalog** tab to update the test:

Catalog element	Description	Reference
Assign	You can assign a value to an existing variable or a new variable.	Adding an Assign step on page 799
Log	You can insert a custom log statement in a test as a step. The inserted log statement is printed in the **Console** window and the Functional report.	Adding a Log step on page 802

Catalog element	Description	Reference
	For example, you can add a custom statement to demarcate the test steps related to order generation, user creation, or report generation in an application or you can use a log statement to display the value of a variable.	
Pause	You can add Pause as a step in the recorded test for a specified duration. You can specify the pause duration in milliseconds, seconds, minutes, or hours.	Adding a Wait step on page 802
Verify	You can verify the values assigned to a variable. You can compare the values of two variables.	Adding a Verify step on page 803

Adding an Assign step

You can use the **Assign** step to assign values from datasets to test variables or store values extracted from UI elements in variables during a test run.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.
- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.

About this task

You can use the **Assign** step to assign values to variables during a test run. You can assign values from datasets to support data-driven testing or extract values from UI elements and store them in variables. The assigned values can then be used in subsequent test steps to perform flexible data-driven testing across multiple scenarios

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 3 on page 800.

2. Select an existing branch or create a new branch.
3. Drag the **Assign** statement from the **Catalog > General** pane and drop it under a test step as required.
   The **Assign** step is inserted.

   Note:

   You can also use the **Assign** step within a **while** or **do-while** step, so that the **Assign** step retrieves the values from a dataset to process each row of the dataset iteratively and assign the retrieved values to the test variables.

4. Click the **Assign** step.

   The step details pane opens with the **Details** tab which was the default selection.

5. Select the required mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.

6. Click **Yes**.

   Note:
   - The default mode depends on where the **Assign** step is added. When the **Assign** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.
   - You can switch between the available modes by selecting a different option from the **Mode** list.
   - If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.

7. You can perform the actions that are listed in the following table to configure assign during a test run:

Mode	Action
General	Perform the following steps: a. Select an existing dataset in the **Dataset** field. b. Click **Add** to add a variable and assign the value from dataset. c. Select an existing variable from the **Select a variable to assign** drop down. **Note:** You can also select **Create variable** from the list to create a new variable and assign the value from the dataset. The variable is displayed in the **Variables** section. d. Select the column in the dataset from which you want to assign the values during test run. e. Click the **Close** icon to close the run details pane.
UI	Perform the following steps: a. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**. Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section. The **UI Object** type is identified. b. Enter a property name such as Content, Id, or XPath of the object that must be used for variable assignment in **UI Property**. If you entered the property name correctly, the value of the property is displayed under **Extracted Value**. c. Select an existing variable, or Select **Add new variable**, enter a name for the variable, and then click **Add**.

8. Click the **Save** icon to save the modifications.

Results

You can configured the **Assign** step to assign values to test variables during a test run. Based on the selected mode, the Assign step assigns values from a dataset to variables or stores values extracted from UI elements in variables.

What to do next

You can run the test in **Test Editor** and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785.

Adding a Log step

You can insert a custom **Log** statement in a test as a step. The inserted **Log** statement is printed in the **Console** window and the Functional report. For example, you can add a custom statement to demarcate the test steps related to order generation, user creation, or report generation in an application or you can use a **Log** statement to display the value of a variable.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 802.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Log** element under any test step as required from the **General** catalog in the **Catalog** tab.
4. Click the **Log** step.
   The step details pane is displayed.
5. Enter a custom message in the **Log statement** text box.
6. Click the **Save** icon to save the modifications.

Results

You have added a custom message in the test by using the **Log** step from the **General** catalog.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Wait step

You can add **Wait** as a step in the recorded test for a specified duration. You can specify the wait time in milliseconds, seconds, minutes, or hours. Adding a **Wait** step gives the application the required time to load the UI elements and update the screen.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 803.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Wait** element under any test step as required from the **General** catalog in the **Catalog** tab.
4. Click the **Wait** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Specify the amount of time that the step must pause in **Duration**.
   b. Select the unit of time for the timeout in **Unit**.
   c. Alternatively, you can select the **Code** checkbox to enter the time and unit in the **Duration** text box.
   d. **Optional**: Enter a message to indicate the reason for the pause in the **Note** text box.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Wait** step to pause the test for a specific duration from the **General** catalog.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Verify step

You can use the **Verify** step to validate expected conditions during Web UI test run. The Verify step checks whether the application under test behaves as expected by comparing actual runtime values with expected values defined in the test. If the verification fails, the step is marked as failed in the test run results. After you add the **Verify** step from the **General** section of the catalog, you can choose the type of verification to perform by selecting a mode in the step details pane.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 804.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Verify** element under any test step as required from the **General** catalog in the **Catalog** tab.
4. Click the **Verify** step.
   The step details pane is displayed.
5. Select the required verification mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **Verify** step is added. When the **Verify** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.
6. Click **Yes**.

Note:

- The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.
- You can switch between the available modes by selecting a different option from the **Mode** list.
- If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.

7. You can perform the actions that are listed in the following table to configure verification in a **Verify** step during a test run:

Mode	Action
General: You can use **General** mode to verify variables, expressions, and business logic conditions during a test run. This mode validates runtime data instead of UI elements.	Perform the following steps: a. Type or select a variable name in the first column. b. In the operator field, select an option to indicate the basis of comparison of the two operands. The available operators are as follows: ▪ Equals ▪ Not Equals ▪ Greater Than ▪ Greater Than Equals ▪ Less Than ▪ Less Than Equals ▪ Strict Equals ▪ Strict Not Equals ▪ Includes ▪ Not Includes c. In the third column, type or select the name of the variable to be compared with the value of the selected variable in the first column. Additionally, you can add, duplicate or delete rows for verification. Also, you can switch to the JS code view to create or modify the comparison statement.
UI: You can use **UI** mode to verify UI elements and their properties in the application under test during a test run. This mode ensures that UI components are displayed correctly and match expected values.	Perform the following steps: a. Select an object to be verified by dragging and dropping an element from **Smartshot** view, an element from **Elements** list, or a property-value pair from the **Properties** list.

Mode	Action
	Alternatively, you can select an object to be verified from the list in **UI Object**, and then select an identifier such as Class, Content, Label, XPath, or Id of the object from the list. If you follow this method, you must ensure that the object is highlighted in the **Smartshot** view after you enter the values. b. Click **click here to add a row** to provide values to be verified under **Verification Points**. c. Enter the property name and value to be verified in the newly added row. d. **Optional**: Click the **Click here to add relative to** link, specify the relative location in the **Location** field, and specify the relative object in the **UI Object** field. e. **Optional**: Click the **Click here to add alternative identifier** link, and select a target object from the list in the **Target 2** field. Alternatively, you can drag and drop an element from the **Smartshot** view. f. **Optional**: Select the **Override Timeout** checkbox in the **Advanced** tab and increase the timeout value in **Duration** for the object verification.

8. Click the **Save** icon to save the modifications.

Results

You have added a **Verify** step to validate conditions in a Web UI test during a test run.

What to do next

You can run the test in **Test Editor** and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785.

New steps for UI-related actions and user actions in a test from the UI catalog

When you want to add UI-related actions and user actions to update a test, you can add those steps from the UI catalog. UI-related actions are actions such as opening a new page and adding a new section in the test. User actions are actions such as click, select, type, and key press for user inputs.

You can add the following UI-related actions and user actions from the **UI** catalog in the **Catalog** tab to update the test:

Catalog element	Description	Reference
With	You can add a container for a new page, section, or tab on the web page.	Adding a With step on page 807
Open	You can add a step to open a URL.	Adding an Open step on page 808
Click	You can add a click action as a step.	Adding a Click step on page 809
Select	You can add a select action as a step.	Adding a Select step on page 810
Type	You can add a type action for entering the text in a text box as a step.	Adding a Type step on page 811
Press	You can add a press action for window controls or supported keys as a step. For example, you can add a step to minimize a window or press Ctrl + M.	Adding a Press step on page 812

When you insert a step after a **With** or **Open** step by using the catalog elements such as **Assign**, **Click**, **Press**, **Select**, **Type**, and **Verify** from the **UI** catalog, the step is added without a smartshot. You must drag a smartshot to the pane or click the **click here to add smartshot** link to select a smartshot from the **Add Smartshot** pop-up. You also can hover over an image and click the zoom icon to view the enlarged image. The image displays with the controls to rotate right, rotate left, zoom in, and zoom out.

Adding a With step

You can add a container for a new page, section, or tab on the web page by using the **With** step from the **UI** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 3 on page 808.

2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **With** element under any test step as required from the **UI** catalog in the **Catalog** tab.
4. Click the **With** step.

   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Enter a description of the container in the **Note** text box.
   b. Enter a title to identify the container in the **Context** text box.
6. Click the **Save** icon to save the modifications.

Results

You have added a **With** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding an Open step

You can add a step to open a URL that is required for any test step by using the **Open** step from the **UI** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 3 on page 808.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Open** element under any test step as required from the **UI** catalog in the **Catalog** tab.

4. Click the **Open** step.
   The step details pane is displayed.
5. Perform the following steps in the **Details** tab of the step details pane:
   a. Enter the URL of the page to be opened in the **URL** text box.
   b. Select **Attach** to open the URL in a new tab or window.
   c. Enter a title to identify the container in the **Context** text box.
   d. Enter a description about the container in the **Note** text box.
6. Click the **Advanced** tab.
7. **Optional:** Select the **Disable** checkbox if you want to disable the step.
   The selected step is greyed out.
8. **Optional:** Perform the following steps to set the timeout value:
   a. Select the **Override Timeout** checkbox.
   b. Specify the duration of time that Test must wait for the step to be completed in **Duration**.
   c. Select the unit of time for the timeout in **Unit**.

   Alternatively, you can select the **Code** checkbox and enter the timeout and unit in **Duration**.
9. Close the step details pane.
10. Click the **Save** icon to save the modifications.

Results

You have added an **Open** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Click step

You can add a click action as a step by using the **Click** step from the **UI** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 810.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Click** element under any test step as required from the **UI** catalog in the **Catalog** tab.
4. Click the **Click** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Right-click a UI object in the **Smartshot** pane and select **Use this element as step target**.

      The **UI Object** type, **Click** action, and values for **Object identified by** are displayed. Optionally, you can modify the values that identifies the object.

   b. **Optional**: Select the **Click here to add alternative identifier** link to select one more object that works as an alternative target if the first object was not found.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Click** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Select step

You can add a select action as a step by using the **Select** step from the **UI** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 811.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Select** element under any test step as required from the **UI** catalog in the **Catalog** tab.
4. Click the **Select** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Right-click a UI object in the **Smartshot** pane and select **Use this element as step target**.

      The **UI Object** type, **Value**, and values for **Object identified by** are displayed. Optionally, you can modify the values that identifies the object by using one of the following methods:
      - Enter the values in the **Object identified by** fields.
      - Drag and drop an element from the **Elements** section or a Property-Value pair from the **Properties** section.

   b. **Optional**: Select the **Click here to add alternative identifier** link to select one more object that works as an alternative target if the first object was not found.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Select** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Type step

You can add a type action for entering the text in a text box as a step by using the **Type** step from the **UI** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.

- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 812.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Type** element under any test step as required from the **UI** catalog in the **Catalog** tab.
4. Click the **Type** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Right-click a UI object such as text box that is suitable for entering text in the **Smartshot** pane and select **Use this element as step target**.

      The **UI Object** type, **Value**, and values for **Object identified by** are displayed. Optionally, you can modify the values that identifies the object by using one of the following methods:
      - Enter the values in the **Object identified by** fields.
      - Drag and drop an element from the **Smartshot** view or the **Elements** section, or drag and drop a Property-Value pair from the **Properties** section.

   b. **Optional**: Enter a value to be captured as a user input in the **Value** field.
   c. **Optional**: Select the **Click here to add alternative identifier** link to select one more object that works as an alternative target if the first object was not found.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Type** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Press step

You can add a press action for window controls or supported keys as a step by using the **Press** step from the **UI** catalog. For example, you can add a step to minimize a window or press `Ctrl + M`.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 813.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Press** element under any test step as required from the **UI** catalog in the **Catalog** tab.
4. Click the **Press** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Select an option from the **Press** list.

      The **Press** list displays the Back, Close, Enter, Forward, Keyboard, Maximize, Minimize, Refresh, Reset, Restore, and Tab options. If you selected the keyboard option, then the Modifiers and Key fields are displayed.

   b. Select one or more modifier keys such as Cmd (only for Mac), Ctrl, Shift, Alt in **Modifier**.
   c. Enter a name of the key to be used in combination with the modifier or independently in **Key**. For example, you can use Ctrl + Home or Home.
   d. Select the **Native System Input** checkbox to simulate the input keys or special key actions at the screen level on the active window.

      This option is used to handle non-HTML windows such as file browse dialogs. To interact with file browse dialogs, you must keep your machine unlocked and the browser dialog must be in the foreground.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Press** step from the **UI** catalog to add user actions in a Web UI test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding conditional logic and redefining the flow in tests from the Flow catalog

When you want to add conditional logic and redefine the flow to update a test, you can add such steps from the **Flow** catalog. You can add a test inside the test as a step and abort the test after marking it as failed. Also, you can insert the `If`, `While`, and `Do-While` conditions in the test to make a set of steps run only if a specific condition is met.

You can add conditional logic and redefine the flow by adding the following steps from the **Flow** catalog in the **Catalog** tab to update the test:

Catalog element	Description	Reference
Run	You can embed tests within a test and run them. You can add a test after any step within the test.	Adding a Run step on page 814
Fail	You can abort the test and mark the test as failed. For example, you can add this element as a resulting step after checking a condition by using the `If` statement.	Adding a Fail step on page 815
If	You can insert the `If` logic in a test to make a set of steps run only if a specific condition is met.	Adding an If step on page 816
While	You can insert the `While` logic in a test to make a set of steps run in a loop only if a specific condition is met.	Adding a While step on page 818
Do-While	You can insert the `Do-While` logic in a test to make a set of steps run in a loop only if a specific condition is met after the first iteration.	Adding a Do-While step on page 821

Adding a Run step

When you want to add a test inside the test as a step, you can use the **Run** step from the **Flow** catalog.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.

- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 815.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Run** element under any test step as required from the **Flow** catalog in the **Catalog** tab.
4. Click the **Run** step.
   The step details pane is displayed.
5. Perform the following steps in the step details pane:
   a. Select a test from the list in **Path** or drag and drop the `.yaml` file in the designated field.
   b. **Optional**: Select a dataset from the list in **Dataset** or drag and drop the `.csv` file in the designated field.
6. Click the **Save** icon to save the modifications.
7. **Optional:** Click the expand icon to view the embedded test steps.
   The embedded test steps are displayed in greyed-out mode indicating that you can only view the steps. You can click any step to view the step details. If you want to edit the embedded test, you must right-click the **Run** step and click **Open**. The embedded test is displayed in a new tab in **Test Editor**. When you run the test, the step result indicators are displayed for an embedded test as well.

Results

You have added a **Run** step from the **Flow** catalog to embed a test inside another test.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Fail step

You can abort the test and mark the test as failed. For example, you can add the **Fail** element as a resulting step after checking a condition by using the `If` statement.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 816.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Fail** element under any test step as required from the **Flow** catalog in the **Catalog** tab.
4. Click the **Fail** step.
   The step details pane is displayed.
5. Enter a custom message in the **Fail statement** text box.
6. Click the **Save** icon to save the modifications.

Results

You have added a **Fail** step from the **Flow** catalog to mark the test as failed.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding an If step

You can insert the `If` logic in a test to make a set of steps run only if a specific condition is met.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 3 on page 817.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **If** element under any test step as required from the **Flow** catalog in the **Catalog** tab.
4. Click the **If** step.

   The step details pane is displayed.
5. Select the required mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.
6. Click **Yes**.

   Note:
   - The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.
   - You can switch between the available modes by selecting a different option from the **Mode** list.
   - If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.
7. You can perform the actions that are listed in the following table to configure an **If** step during a test run:

Mode	Action
General	Perform the following steps: a. Select a variable in the **Value 1** list. b. In the **Operator** field, indicate the basis of comparison of the two operands. Note that the two operands are strings. The available operators are as follows: ▪ Equals ▪ Greater Than ▪ Greater Than Equals

Mode	Action
	▪ Equals variable ▪ Less Than ▪ Less Than Equals ▪ Strict Equals c. Enter a value to be compared with the value of the selected variable in the **Value 2** list.
UI	Perform the following steps: a. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**. Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section. The **UI Object** type is identified. b. Enter a property name such as Content, Id, or XPath of the object in the **UI Property** field. If you entered the property name correctly, the value of the property is displayed under **Extracted Value**. You can select the **Code** checkbox to enter the If statement in the text box. This allows you to write the condition in the text box in the JS mode.

8. Click the **Save** icon to save the modifications.

Results

You have configured the **If** step to evaluate a condition during a test run. The steps within the If block are run only when the specified condition is met.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a While step

You can insert the `While` logic in a test to make a set of steps run in a loop only if a specific condition is met after the first iteration. The test results display iteration details such as the iteration number, status, and test run time. The test tree displays information from the latest iteration, while the results panel displays either the last successful iteration or the first failed iteration, depending on the test run outcome.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.

- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 819.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **While** element under any test step as required from the **Flow** catalog in the **Catalog** tab.
4. Click the **While** step.
   The step details pane is displayed.
5. Select the required mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **While** step is added. When the **While** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.
6. Click **Yes**.

   Note:
   - The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.
   - You can switch between the available modes by selecting a different option from the **Mode** list.
   - If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.

7. You can perform the actions that are listed in the following table to configure a **While** step during a test run:

Mode	Action
General	Perform the following steps:

Mode	Action
	a. Select a variable in the **Value 1** list. b. In the **Operator** field, indicate the basis of comparison of the two operands. Note that the two operands are strings. The available operators are as follows: ▪ Equals ▪ Greater Than ▪ Greater Than Equals ▪ Equals variable ▪ Less Than ▪ Less Than Equals ▪ Strict Equals c. Enter a value to be compared with the value of the selected variable in the **Value 2** list.
UI	Perform the following steps: a. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**. Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section. The **UI Object** type is identified. b. Enter a property name such as Content, Id, or XPath of the object in the **UI Property** field. If you entered the property name correctly, the value of the property is displayed under **Extracted Value**. You can select the **Code** checkbox to enter the If statement in the text box. This allows you to write the condition in the text box in the JS mode.

8. Click the **Save** icon to save the modifications.

Results

You have added a **While** step that checks whether a specific condition is met in the test from the **Flow** catalog.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a Do-While step

You can insert the `Do-While` logic in a test to make a set of steps run in a loop only if a specific condition is met after the first iteration. The test results display iteration details such as the iteration number, status, and test run time. The test tree displays information from the latest iteration, while the results panel displays either the last successful iteration or the first failed iteration, depending on the test run outcome.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

About this task

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 821.
2. Select an existing edit branch or create a new edit branch.
3. Drag and drop the **Do While** element under any test step as required from the **Flow** catalog in the **Catalog** tab.
4. Click the **Do While** step.
   The step details pane is displayed.
5. Select the required mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **Do While** step is added. When the **Do While** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.
6. Click **Yes**.

Note:

- You can switch between the available modes by selecting a different option from the **Mode** list.
- If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.

7. You can perform the actions that are listed in the following table to configure a **Do While** step during a test run:

Mode	Action
General	Perform the following steps: a. Select a variable in the **Value 1** list. b. In the **Operator** field, indicate the basis of comparison of the two operands. Note that the two operands are strings. The available operators are as follows: ▪ Equals ▪ Greater Than ▪ Greater Than Equals ▪ Equals variable ▪ Less Than ▪ Less Than Equals ▪ Strict Equals c. Enter a value to be compared with the value of the selected variable in the **Value 2** list.
UI	Perform the following steps: a. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**. Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section. The **UI Object** type is identified. b. Enter a property name such as Content, Id, or XPath of the object in the **UI Property** field. If you entered the property name correctly, the value of the property is displayed under **Extracted Value**. You can select the **Code** checkbox to enter the do while condition in the text box in the JS mode.

8. Click the **Save** icon to save the modifications.

Results

You have configured the **Do While** step to evaluate a condition during a test run. The steps within the **Do While** block run at least once and continue to run as long as the specified condition evaluates to true.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Adding a drag-and-drop action in a test from a smartshot

When you want to manually add the drag-and-drop action in a Web UI test, you can do so by editing the recorded test and then add the drag-and-drop action by using a smartshot.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 823.
2. Select an existing branch or create a new branch.
3. Click the test step before which you want to add a drag-and-drop step.
   The step details pane is displayed.
4. Select an element that you want to drag to the new location from one of the following options:
   - The **Smartshot** view
   - The **Elements** list
   - A property-value pair from the **Properties** list
5. Right-click the element and select the **Drag & Drop** option.
   The **Details** tab displays the values in the **UI Object** and **Action** fields. Also, the **Object Identified By** section displays the **From** and **To** tabs. The **From** tab displays the identified target element.
6. Switch to the **To** tab in the **Object Identified By** section.

7. Select the destination element on which you want to drop the previously selected element from one of the following options:
    - The **Smartshot** view
    - The **Elements** list
8. Right-click the element and select the **Use this element as step target (To)** option.
   The details of the target element are populated.
9. Save the test.

Results

You manually added the drag-and-drop action in a Web UI test by using a smartshot.

What to do next

You can run the test and view the results. See Running a Web UI test on page 785.

Configuring timeouts for tests and test steps

You can configure timeouts for tests and individual steps to define the duration of the time that the system should wait before marking an action as failed due to timeout.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

About this task

You can configure timeouts at two levels:

- Test level: You can set a global timeout for the entire test by using the **Configure settings and data** step.
- Step level: You can override the global timeout for individual steps directly within the step settings.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 3 on page 825.

2. Select an existing edit branch or create a new edit branch.
3. Perform any of the following actions:

Action	Description
Configure timeout for the test	Click the **Configure settings and data** step in **Test Editor** The timeout details are displayed with **Duration** and **Unit** fields. By default, the timeout is set to 30 seconds. You can select the **Override Timeout** checkbox to modify this value.
Configure timeout for a test step	Select a step and select the **Advanced** tab. The **Timeout Details** section including the **Duration** and **Unit** fields, is displayed.

4. Select the **Override Timeout** checkbox.
5. Specify the duration of time that Test must wait for the step to be completed in **Duration**.
6. Select the unit of time for the timeout in **Unit**.
7. **Optional:** Select the **Code** checkbox to enter the timeout and unit.
8. Close the step details pane.
9. Click the **Save** icon to save the modifications.

Results

You have configured timeout settings for your test or individual test steps.

Copying test steps from one test to another

When a set of steps in a test is required in another test, you can copy them and paste them into an existing test or an empty test. You can select the required steps from a test to copy, although they are not in a sequence. If there are any variables associated with the selected step, they are also copied with the step.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 826.
2. Select an existing edit branch or create a new edit branch.
3. Right-click a step or a container and click **Select**.
   Checkboxes are displayed for each step.
4. Select the checkboxes to select any step or a container with multiple steps.
5. Right-click a selected step and click **Copy**.
6. Perform one of the following steps:
   - Open a test, right-click a step where the copied steps are required, and then select **Paste**.
   - Open an empty test, right-click the **Configure settings and data** step, and then select **Paste**.
7. Click the **Save** icon to save the modifications.

Results

You have copied a set of steps from a Web UI test to another test.

Running a Web UI test on page 785

Renaming a test asset

You can rename test assets such as tests, suites, smartshots, and applications in your project by using the **Rename** option.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a Project Owner or Tester in the project. See Managing access to the server projects on page 1735.
- Ensured that your project contains test assets.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.

1. Log in to Test Hub.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.

3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Right-click a test asset that you want to rename from the test navigator panel and select **Rename**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 6 on page 827.
5. Select an existing edit branch or create a new edit branch.
6. Enter a unique name in the **Rename Asset** dialog.
7. Click **Rename**.
   A success message is displayed.

Results

You have renamed a test asset in your project.

Deleting a test asset

You can delete an application, test, suite, or smartshot when it is no longer required in your project. If the test asset that is selected for deletion is referenced in another test or a test suite, or if the selected smartshot is referenced in a test, a warning is displayed.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a Project Owner or Tester in the project. See Managing access to the server projects on page 1735.
- Ensured that your project contains test assets.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.

1. Log in to Test Hub.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Select a test or a smarshot that you want to delete from the test navigator panel.
5. Click the

button, displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 7 on page 828.

6. Select an existing branch or create a new branch.
7. Click the **Delete** icon .
   Alternatively, right-click a test, suite, smarshot, or an application in the test navigator panel, and then click **Delete**.
   Result
   The **Delete Asset** dialog is displayed. This dialog provides information if the selected asset is referenced by the other test asset.
8. Click the **Delete** button to delete the test asset.

Results

You have deleted a test asset from your project.

Creating a test module from an existing set of steps

When a set of steps are repeated and required in multiple tests, you can create a test module for such repeatable steps. You can select the required steps that are in sequence from an existing test and extract them to create a new test module. After extraction, the selected steps are replaced by the **Run** step and the new test module is listed in the test navigator panel.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

About this task

When you extract a set of steps, the resulting asset might be one of the following types:

- A test with the application or page URL details in the **Open** step. You can play back this type of test.
- A module without the application or page URL. You must add the required URL by adding the details in the **Configure settings and data** step or **Open** step.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 829.
2. Select an existing edit branch or create a new edit branch.
3. Right-click a step or a container and click **Select**.
   Checkboxes are displayed for each step.
4. Select the checkboxes to select a set of steps or a container with multiple steps in sequence.
5. Right-click a selected step and click **Extract Steps**.
   The **Create Test from Steps** dialog is displayed. The **Extracted Content** text box displays the list of selected steps and the **Application** field displays the application for which you create the test.
6. Enter a name for the test in **Asset Name**.
7. Select an existing folder from the list in **Location** to save the test assets that you are creating.
   Alternatively, click **New Folder** to create a folder to save the test assets.
8. Click **Create**.
   The selected steps are replaced by the **Run** step for the new test module and the newly created test module is listed in the test navigator panel.

   Note: When you save the test under a different application by using the **Save As** option, on clicking the step, the step details pane displays the `Error loading smartshot` message for all test steps. To resolve this error, you can either manually insert a suitable smartshot from the new application by using the **Replace Smartshot** option in the step details pane, or you can play back the test and save the required smartshots directly from the test results.

Results

You have created a test module by extracting a set of steps from the existing test.

Test suite management

A suite is a collection of the tests and other suites. You can combine the multiple tests and suites into a single workflow and organize them into a suite.

As part of the test suite management, you can create, edit, run, and delete the suites. When you create a suite, a `.dts.yaml` file is created and listed under the **Suites** folder in the test navigator panel.

You can run the suite either sequentially or in parallel. In a sequential run, the tests and suites within the suite are run sequentially, one after the other. In a parallel run, the tests and suites within the suite are run concurrently. Setting the maximum concurrency value limits how many test instances can run at the same time. When a suite is running, you can click the Show in progress icon to monitor execution and the page displays active test suite instances up to your specified concurrency limit. For example, if a suite contains three tests and the concurrency value is set to two, the progress page will display two instances running simultaneously.

When you run a suite, each child test within the suite generates an individual result. You can open the test from the suite by right-clicking the test and selecting **Open**, and the results of the child test are displayed in the **Results** tab along with the details of the suite that includes this test.

You can rerun the failed tests and suites instead of rerunning the suite. When you run the test suite, you can access the console output to troubleshoot the issues.

Creating a suite

You can create a suite within your project in Test . You can add multiple tests and suites into a single suite for a test run.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the suite assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Perform any of the following actions:
   - Click **Create Asset > Create Suite** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Suite**.
   - Right-click the application in the test navigator panel and select **New > Suite**.

The **Edit Branch** dialog is displayed if there is no edit branch active. Otherwise, go to step 6 on page 831.

5. Select your action to either select an existing Edit branch or create an Edit branch:
    - Perform the following steps to select an existing Edit branch:
        a. Select **Use an existing edit branch**.
        b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

        c. Click **Ok**.
    - Perform the following steps to create the Edit branch:
        a. Select **Create new edit branch**.
        b. Enter a name for the Edit branch in the **Branch Name** field.
        c. Click **Save**.
6. Perform the following steps in the **Create Suite** dialog to create a suite:
    a. Enter a name for the suite in the **Asset Name** field.
    b. Select an existing application to save the suite asset you create.
    c. Click **Done**.
7. Perform any of the following actions to add the tests and suites to the existing suite:
    - Drag the tests and suites from the test navigator panel to **Suite Editor**.
    - Click the **Click to add** option to add the tests and suites in **Suite Editor**.
8. (Optional) To add the tests and suites to the existing suite from other application, drag the test or suite from other application on the test navigator panel to **Suite Editor**.
9. Click the **Save** icon to save the suite.

Results

You have created a suite.

What to do next

You can perform the following tasks:

- Run the test suite and view the results. See Running a suite sequentially on page 834 and Running a suite concurrently on page 835.
- Modify the suite. See Modifying a suite on page 831.

Modifying a suite

You can modify the existing suite within your project in Test by adding, removing, or rearranging the tests and suites in a suite.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that your project contains a suite.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the suite assets.
   The **Overview** page of the project is displayed.
3. Navigate to **Author > Test Editor**.
   The test navigator panel is displayed.
4. Select the suite that you want to modify from the test navigator panel.
   Result
   The suite opens in **Suite Editor**.
5. Click the

button, displayed on the **Suite Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the suite in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed if there is no edit branch active. Otherwise, go to step 7 on page 833.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:

a. Select **Create new edit branch**.
b. Enter a name for the Edit branch in the **Branch Name** field.
c. Click **Save**.

7. Perform any of the following actions to modify the suite in **Suite Editor**:

Action	Description
Add the test or suite	Perform any of the following actions to add the test or suite to the suite: ◦ Drag the test or suite from the test navigator panel to **Suite Editor**. ◦ Click the **Click to add** option to add the test or suite in **Suite Editor**. The test or suite are added to the existing suite.
Open the test or suite	Right-click the test or suite, and then click **Open**. The test opens in **Test Editor** and the suite opens in **Suite Editor**. Alternatively, click any test step for which you want to view the result details. The step details pane is displayed. Click **Open** to open the test in the **Test Editor** for further review or editing. **Note:** If a step has not been run, results are not available for that step in the **Results** view, and the **Open** option is disabled.
Arrange the test or suite	Drag and drop the test or suite. The test or suite are arranged in the order of your preference.
Copy the test or suite	Right-click the test or suite you want to copy, and then click **Copy**. The test or suite are copied to the clipboard.
Paste the test or suite	Right-click anywhere in **Suite Editor**, and then click **Paste**. The test or suite are added to the end of the workflow.
Remove the test or suite	Right-click the test or suite you want to remove from the suite, and then click **Delete**. The test or suite are removed from the existing suite.

8. Click the **Save** icon to save the changes.

Results

You have modified the suite in your project.

What to do next

You can run the test suite and view the results. See Running a suite sequentially on page 834 and Running a suite concurrently on page 835.

Running a suite sequentially

When you want tests to run one after the other, you can run a suite sequentially that maintains the correct order and accuracy of the test results.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensured that a suite is available in your project.
- Added tests or other suites to the suite.

About this task

During the playback, you can run all tests or only the failed tests. The **Continue on Fail** option ensures that the suite continues to run even if a test fails.

As the test runs, the three color-coded boxes display the counts of passed steps, failed steps, and errors. You can view the step details of the first failed step or error step by clicking the respective color-coded boxes. Also, you can view checkmarks for the steps that pass and crossmarks for the steps that fail.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.dts.yaml` file in the list of Suites to open the suite.
   The tests or suites are displayed on the **Suite Editor** page.
5. Click the **Configure settings and data** step.
   The **Settings** pane is displayed.
6. Ensure that the **Run in Parallel** option is unchecked to run the test in sequence.

   Note: If **Run in Parallel** is selected, tests will execute simultaneously rather than sequentially.

7. Verify that the **Continue on Fail** option is selected as the default setting, under the **Options** tab.

Note: If you clear the **Continue on Fail** checkbox, the suite stops when the first test fails.

8. Click the icon, and then select the **Run all > Run all on Default Cluster** option.

   You can also select the **Run all on Personal Agent** option if the personal agent is in a ready state.

   You can view the following stages on the progress bar during the test run:
   - **In transition**: The test setup is in progress.
   - **Running**: The test is actively running.
   - **Complete**: The test run is completed. This section also displays the time taken for test run.
   - During the **Running** phase, you can view the following details:
     - A checkmark after each test or suite that passes, and a crossmark for any failed test or suite.
     - The **Results** tab displays the test as **In Progress** during the test run.
   - After the test run is completed, you can view the following results:
     - The **Results** tab displays the test as **Pass** or **Fail**.
9. Click to open the **Results** page, where you can view the results, reports, and logs of the completed test run.

Results

You have run a suite sequentially.

What to do next

You can view the following information:

- The details of the suites and individual test results from the **Run Details** tab.
- The console output, which includes error messages and logs. See Accessing console output on page 787.
- The test results, reports, and logs from the **Results** page after the test completes the run.
- The summary of the test run, which includes passed or failed status, count of passed or failed tests or test steps, and the verification points in the functional report. See Viewing a Functional Report on page 1511.

Related information

Viewing the progress of running test assets on page 1444

Running a suite concurrently

You can run a suite to run multiple tests and other suites in parallel to expedite the testing process.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensured that a suite is available in your project.
- Added tests or other suites to the suite.

About this task

You can run a suite concurrently to run multiple suites and tests simultaneously across several pods. You can set up the maximum number of concurrent pods, which defines how many suites or test assets can run in parallel. In the default set up, suites run their child assets sequentially on a single pod, with only one test asset running at a time.

When you select the **Run in Parallel** option, the **Continue on Fail** checkbox is disabled. Whether a test passes or fails, all test assets run independently and concurrently across the available pods.

Restriction: To run server suite assets on the Safari browser, you must use DevOps Test Runtime agents. When you use Safari, the tests in the suite run sequentially even when you selected the **Run in Parallel** option.

As the test runs, the three color-coded boxes display the counts of passed steps, failed steps, and errors. You can view the step details of the first failed step or error step by clicking the respective color-coded boxes. Also, you can view checkmarks for the steps that pass and crossmarks for the steps that fail.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.dts.yaml` file in the list of Suites to open the suite.
   The tests or suites are displayed on the **Suite Editor** page.
5. Click the **Configure settings and data** step.
   The **Settings** pane is displayed.
6. Select the **Run in parallel** checkbox to enable multiple tests to run at the same time.
   The **Continue on Fail** option gets disabled.
7. Enter the value in the **Maximum Concurrent Pods** field.

   Note:

   The **Maximum Concurrent Pods** setting defines the number of test assets from a suite that can run in parallel and the minimum value must be two. A lower value reduces server resource usage but increases run time, and a higher value speeds up the run time at the cost of higher resource consumption.

8. Click the icon, and then select the **Run all > Run all on Default Cluster** option.

You can also select the **Run all on Personal Agent** option if the personal agent is in a ready state.

You can view the following stages on the progress bar during the test run:

- **In transition**: The test setup is in progress.
- **Running**: The test is actively running.
- **Complete**: The test run is completed. This section also displays the time taken for test run.
- During the **Running** phase, you can view the following details:
  - A checkmark after each test or suite that passes, and a crossmark for any failed test or suite.
  - The **Results** tab displays the test as **In Progress** during the test run.
- After the test run is completed, you can view the following results:
  - The **Results** tab displays the test as **Pass** or **Fail**.

9. Click **Analyze** to open the **Results** page, where you can view the results, reports, and logs of the completed test run, and perform the following steps:
   a. Verify that a **secondary** label appears for the secondary executions.
   b. Click on secondary and main/primary execution.
   c. Verify that the **Test Log** and **Functional Report** options are displayed only for the main/primary execution and does not display for the secondary executions.

Results

You have run a suite concurrently.

What to do next

You can view the following information:

- The details of the suites and individual test results from the **Run Details** tab.
- The console output, which includes error messages and logs. See Accessing console output on page 787.
- The test results, reports, and logs from the **Results** page after the test completes the run.
- The summary of the test run, which includes passed or failed status, count of passed or failed tests or test steps, and the verification points in the functional report. See Viewing a Functional Report on page 1511.

Running multiple suites or tests by using the wildcard pattern

When you want to enable a single suite to run multiple tests and suites based on their name, you can use a **Run** step to refer to tests and suites by using wildcard patterns. You can also use these patterns to specify the suites that must be excluded.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Test suite management on page 829 and Creating a suite on page 830.
- Ensured that there are multiple suites available in your project.

About this task

Within a **Run** step, wildcard patterns can be used to reference tests and suites. The following two wildcards are supported:

- **Single Asterisk (`*`)**: Matches zero or more characters within a single folder and it does not match the `/` character.
- **Double Asterisk (`**`)**: Matches zero or more characters including the `/` character. It can be used to match across multiple folder.

You can only match files located in the same folder as the test suite, or within its subfolders. You cannot use patterns to match files located in a different folder for a different application.

The following table lists the sample patterns:

Pattern	What it matches
*.dtx.yaml	All tests located in the same folder as the test suite.
a*.dtx.yaml	All tests starting with the letter "a" in the same folder as the suite.
**/*.dtx.yaml	All tests in subfolders under the folder containing the suite.
**/abc/*	All tests and suites located in any subfolder that is named ‘abc’ under the folder containing the suite.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Perform one of the following actions:
   - Create a new suite, open the suite, and then add a test or suite.
   - Open a suite from the list of Suites.

   The contents are displayed on the **Suite Editor** page.
5. Click a **Run** step.
   The step details pane is displayed.
6. Enter a wildcard pattern in **Path** to specify the tests or suites to be included in the test run.
7. Click **+Add Exclusion** if you want to exclude some of the suites.

A new text box is displayed.

8. Perform one of the following actions to specify the suite or test to be excluded from the test run:
   - Enter the file name.
   - Click the button to browse and select the suite, and then click **Add**.
   - Drag a suite or test from the test navigator panel to **Suite Editor**.
   - Enter a wildcard pattern.
9. Click to close the step details pane.
10. **Optional:** Perform the following steps to enable multiple tests to run at the same time:
    a. Click the **Configure settings and data** step, and then select the **Run in parallel** checkbox.
    b. Enter a value ≥ 2 in the **Maximum Concurrent Pods** field.

    Note: Tests that are resolved by a wildcard pattern run in parallel only if the suite contains a single run step. That is, the only step defined in the suite must be the test with the wildcard expression.

11. Click to save the changes.
12. Click the icon, and then select the **Run all > Run all on Default Cluster** option.

    You can also select the **Run all on Personal Agent** option if the personal agent is in a ready state.

    The **Results** tab displays the progress of the test run. After the test run is complete, the tab displays the verdict, and links to view the functional report, test log, and results page.

Results

You have run multiple suites or tests.

What to do next

You can view the following information:

- The test results, reports, and logs from the **Results** page after the test completes the run.
- The summary of the test run, which includes passed or failed status, count of passed or failed tests or test steps, and the verification points in the functional report. See Viewing a Functional Report on page 1511.

Running suites on multiple browsers and devices

You can now configure a test suite to run across multiple web browsers and supported devices in one consolidated run. Instead of managing separate test runs for each browser and device, you can define all of your target browsers and devices within the configuration of the test suite. This simplifies cross-browser validation, saves time, and provides comprehensive report.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensured that a suite is available in your project.
- Added tests or other suites to the suite.

About this task

You can select the following browsers that are supported for cross-browser testing:

- Chrome
- Firefox
- Edge
- Safari

Also, you can select the following device profiles that are supported:

Device profile	Default browser
Phone (Small)	Edge
Phone (Medium)	Chrome
Phone (Large)	Edge
Phone (X-Large)	Chrome
Tablet (Small)	Edge
Tablet (Medium)	Chrome
Tablet (Large)	Edge
Tablet (X-Large)	Chrome

When the suite runs, all the tests in the suite run sequentially for each selected browser or device.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Double-click the `.dts.yaml` file in the list of Suites to open the suite.
   The tests or suites are displayed on the **Suite Editor** page.
5. Click the

button, displayed on the **Suite Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

Alternatively, right-click the suite in the test navigator panel and select **Edit**.

The **Edit branch** dialog is displayed if there is no edit branch active. Otherwise, go to step .

6. Select your action to either select an existing Edit branch or create an Edit branch:
    - Perform the following steps to select an existing Edit branch:
        a. Select **Use an existing edit branch**.
        b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

        c. Click **Ok**.
    - Perform the following steps to create the Edit branch:
        a. Select **Create new edit branch**.
        b. Enter a name for the Edit branch in the **Branch Name** field.
        c. Click **Save**.
7. Click the **Configure settings and data** step 7 on page 841.
   The **Settings** pane is displayed.
8. Select the required browser and device profiles from the **Profile** drop-down list.
9. Click to close the step details pane.
10. Click to save the changes.
11. Click the icon, and then select the **Run all > Run all on Default Cluster** option.

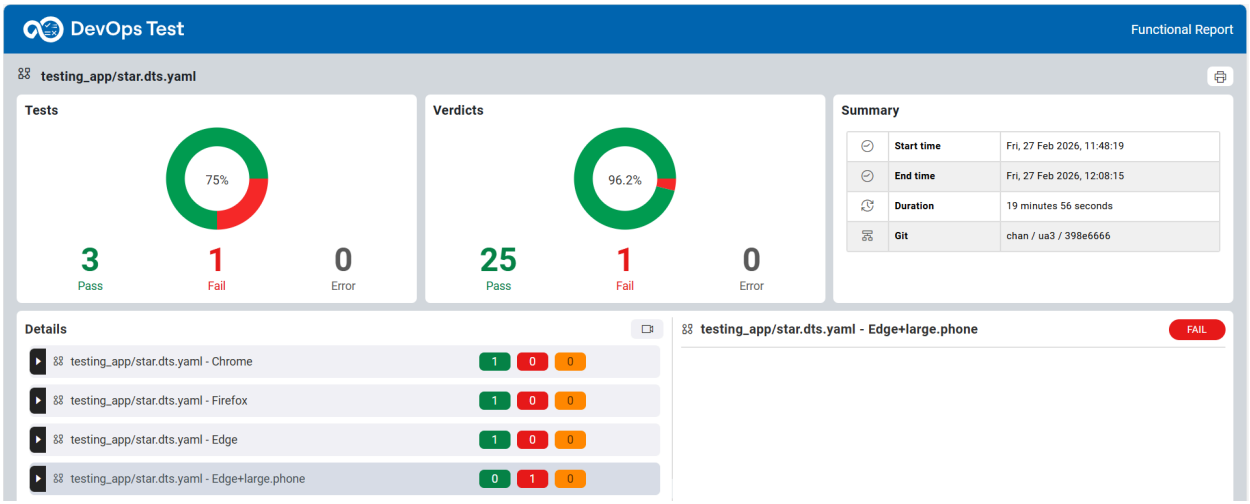
    You can also select the **Run all on Personal Agent** option if the personal agent is in a ready state.

    The **Results** tab displays the progress of the test run. After the test run is complete, the tab displays the verdict and links to view the functional report, test log, and results page.

    Alternatively, you can select the **Run with** option to choose specific browsers. You can select one or multiple browsers. The suite runs only on the selected browser for that run.

12. Click the **Functional Report** icon to open the report in a separate window.

The functional report displays the results of the test run for each configured browser.



Results

You have run the test suite on multiple browsers and devices.

Accessing the console output

When you run suites, you can access the console output that provides information such as error messages, logs, and the test verdict. You can then use this output to troubleshoot issues by reviewing details, such as session IDs and error messages.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensure that your project contains a test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.yaml` file in the list of Suites to open the suite.
   The test steps are displayed on the **Suite Editor** page.
5. Click the **Console** tab at the bottom of the **Test Editor** page.

   Alternatively, you can click the expand icon .

   The **Console** output view is displayed.

6. Review the console output to identify the error messages and logs.
7. Perform the following actions to manage the console output:

Action	Description
Search a keyword in the console output	Enter a keyword in the **Search console** field, and the corresponding word is highlighted in the console output.
Select all console content	Right-click the console output area and, then select the **Select All** option to select all content.
Copy the selected content	Right-click the selected content and choose **Copy** to copy the content.
Expand console output view	Click the up arrow to expand the console output view for more details.
Restore console output view	Click the down arrow to return the console output page to its original size.
Close console output view	Click the drop-down icon to close the console output view.

Results

You have accessed the console output content.

What to do next

You can perform any of the following tasks:

- Decide on the actions that you might want to take based on the logs.
- Rerun the test asset.

Stopping test runs within a suite

You can stop the tests that run within a suite when issues occur or if you decide to stop the run before completion.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Initiated a test run from the **Suite Editor** page.

About this task

You can stop multiple running tests from the **Suite Editor** page if the test run is in **In transition** or **Running** state.

1. Go to the **Suite Editor** page.
2. Click the **Stop playback** icon .
   The status of the tests is displayed as **Inconclusive** on the **Results** tab and **Stopped by User** on the progress bar.

Results

You have stopped test runs within a suite.

What to do next

You can re-initiate the test runs from the **Suite Editor** page.

Rerunning failed tests in a suite

When you run tests in a suite, a few tests might fail. You can rerun the failed tests instead of rerunning the suite.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Ensured that a suite is available in your project.

About this task

The **Run only failed** option is available only if the suite ran previously and contained failed tests. When the **Run only failed** option is available, you can select it to rerun the tests that failed.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the `.dts.yaml` file in the list of Suites to open the suite.
   The tests, suites or both are displayed on the **Suite Editor** page.
5. Click the icon, and then select the **Run failed tests > Default Cluster** option.

   You can also select the **Personal Agent** option if the personal agent is in a ready state.

   You can view the following stages on the progress bar during the test run:

- **In transition**: The test setup is in progress.
- **Running**: The test is actively running.
- **Complete**: The test run is completed.
- During the **Running** phase, you can view the following details:
  - A checkmark after each test or suite that passes, and a crossmark for any failed test or suite.
  - The **Results** tab displays the test as **In Progress** during the test run.
- After the test run is completed, you can view the following results:
  - The **Results** tab displays the test as **Pass** or **Fail**.

6. Click to open the **Results** page, where you can view the results, reports, and logs of the completed test run.

Results

You have rerun the failed tests in a suite.

What to do next

You can view the following information:

- The details of the suites and individual test results from the **Run Details** tab.
- The console output, which includes error messages and logs. See Accessing console output on page 787.
- The test results, reports, and logs from the **Results** page after the test completes the run.

Deleting a suite

You can delete a suite when it is no longer required in your project.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource. See Managing access to the server projects on page 1735.
- Ensured that your project contains a suite.

1. Log in to Test Hub.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the suite assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The test navigator panel is displayed.
4. Select the suite that you want to delete from the test navigator panel.
   Result
   The suite opens in **Suite Editor**.

5. Click the button displayed on the **Suite Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   The **Edit branch** dialog is displayed if there is no edit branch active. Otherwise, go to step 7 on page 846.
6. Select an existing branch or create a new branch.
7. Click the **Delete** icon .

   Alternatively, right-click the suite in the test navigator panel and select **Delete**.

   Result

   The **Delete Asset** dialog is displayed.
8. Click **Delete**.

Results

You have deleted a suite from your project.

Suite Editor page on page 764

Test variables

A test variable is a user-defined, name-value pair that stores and refers to information throughout a test. You can assign the value of a variable to a test element or assign the value of a UI object property to a test variable.

When you record a test, the URL of the application is stored in the default variable, APP_APP1_URL. You can create variables by using the following options:

- By using the **Add** option in the **Configure settings and data** pane.
- By using the **Add new variable** option when you assign the property of an object to a variable in the **Assign** step.
- By adding var_name: var_value under vars: section in the **Code** view of the test script in **Test Editor**.

You can use the variables for substitution. To substitute data from a test variable, you can use the **Details** section of the step details pane. You can perform the following actions with test variables:

- Provide a default value to the variable during variable creation.
- Change the value of a UI object by replacing the value with a variable. The UI object assumes the value of the variable when the test is run.
- Change the value of the variable using the 'Assign' statement. You can assign an object property to a variable.
- Modify the value of a variable by using the values extracted through RegEx patterns.

Types of variables

Variables are classified as input, local, or output variables based on their purpose and scope.

- **Input variables** : Provide a way to receive values from calling tests or configurations. Use them to pass data into a test or module at runtime.
- **Local variables** : Define values that are used within a test or a suite. These variables remain internal and are not accessible outside the test or suite in which they are declared.
- **Output variables** : These variables are used to return values to the calling test or a suite. You can map these variables to existing or new variables to capture the returned data.

Random number generation

You can generate random numbers and assign the value to a variable by defining a random expression. For example, you can define `${Math.floor(Math.random()*100)}` and assign it to a variable, `${value}`.

You can use a random expression in the following ways:

- Create a new variable in the **Configure settings and data** step, and assign the random expression to the variable.
- Create a new variable in the test, and insert an **Assign** step before any step where the random number is needed. Then, in the **Assign** step details, you can assign the random expression to the variable.

Assigning the random expression to the variable allows the random number to be stored in the variable and referenced throughout the test run.

Creating and assigning test variables

You can create a variable and initialize it to an alphanumeric value. Then, within the test, you can assign the value of the variable to a test element.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 848.
2. Select an existing branch or create a new branch.
3. Click the **Configure settings and data** step in **Test Editor**.
   The **Configure settings and data** pane is displayed.
4. Click **Add** icon

in the **Variables** section.
5. Enter a name for the variable in **Name**.
   The name must start with an alphabet, $, or _ and the name must not be a reserved keyword or contain a space.
6. Enter a value for the variable.
   The newly created variable is listed in the **Variables** section.
   The default variable type is **Input**.
7. **Optional:** Click the variable icon to change the type to **Output** or **Local**.
8. Perform the following steps to assign a variable to a test element:

   a. Select a **Type** or **Select** step for which you want to replace the value with the value of a variable.
      The step details pane is displayed.

   b. Enter the variable name in the **Value** field for the selected **UI Object** in the following format:
      ${variable_name}

      For example, you can replace the text that is saved in the text field for `username` with the value of the variable, `user_name`.

   c. Close the step details pane.
      The test step is updated with the variable that you chose.

9. Click the **Save** icon to save the modifications.

Results

You have created a variable and assigned the value of the variable to a test element.

Note: The variables that you created in **Test Editor** are listed in the **Variables** section of the **Configure settings and data** pane as test variables.

What to do next

- Run the test in **Test Editor** and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785.
- Start the test run from the **Execution** page, and in the **Execute test asset** dialog, navigate to the **Configure settings and data** option on the **Test Editor** page to view the Test variables defined in the test. See Configuring a run of a Web UI test on page 1309 and Variables on page 1317.

Related information

Viewing a Functional Report on page 1511

Assigning an object property to a test variable

You can use the value of a UI object property and assign the value to a test variable in the Web UI tests. The process of assigning a variable to an object property is called a variable assignment.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

About this task

You can modify the value that is being assigned to the variable by using a regular expression. You can extract a substring from the content of an object property by using a regular expression, and then assign the substring to a variable. For example, you can extract *User Documentation* from the Content property of a hyperlink, and then assign the string to the *trimVar* variable. Further, you can include *trimVar* in the subsequent steps and run the test. You can view the variable value *User Documentation* in the Functional Report.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 850.
2. Select an existing branch or create a new branch.

3. Drag the **Assign** statement from the **Catalog > UI** pane and drop it under a test step as required.
   The **Assign** step is inserted.
4. Click the **Assign** step.
   The step details pane is displayed.
5. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**.
   Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section.

   The **UI Object** type is identified.
6. Enter a property name such as Content, Id, or XPath of the object that must be used for variable assignment in **UI Property**.
   If you entered the property name correctly, the value of the property is displayed under **Extracted Value**.
7. Select one of the following options from the **Assign to** list:
   - Select an existing variable.
   - Select **Add new variable**, enter a name for the variable, and then click **Add**.
8. **Optional:** Select the **Modify value** checkbox.
   The **Regex** field is displayed.
9. **Optional:** Enter a regular expression to extract a substring from the value of the object property in **Regex**.
   For example, if you want to extract the last 3 digits from `560064`, which is a Zip code, and assign it to the variable `'zipCode_3'`, you can use the expression `[0-9]{3}`.
10. Close the step details pane.
11. Click the **Save** icon to save the modifications.

Results

You have assigned the value of a UI object property to a test variable in the Web UI test.

Note: The variables that you created in **Test Editor** are listed in the **Variables** section of the **Configure settings and data** pane as test variables.

What to do next

You can perform the following tasks:

- Run the test in **Test Editor** and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785.
- Start the test run from the **Execution** page, and in the **Execute test asset** dialog, navigate to the **Configure settings and data** option on the **Test Editor** page to view the Test variables defined in the test. See Configuring a run of a Web UI test on page 1309 and Variables on page 1317.

Related information

Viewing a Functional Report on page 1511

Adding an Assign step

You can use the **Assign** step to assign values from datasets to test variables or store values extracted from UI elements in variables during a test run.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.
- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.

About this task

You can use the **Assign** step to assign values to variables during a test run. You can assign values from datasets to support data-driven testing or extract values from UI elements and store them in variables. The assigned values can then be used in subsequent test steps to perform flexible data-driven testing across multiple scenarios

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 3 on page 851.
2. Select an existing branch or create a new branch.
3. Drag the **Assign** statement from the **Catalog > General** pane and drop it under a test step as required.
   The **Assign** step is inserted.

   Note:

   You can also use the **Assign** step within a **while** or **do-while** step, so that the **Assign** step retrieves the values from a dataset to process each row of the dataset iteratively and assign the retrieved values to the test variables.

4. Click the **Assign** step.

   The step details pane opens with the **Details** tab which was the default selection.

5. Select the required mode from the **Mode** list:
   - **UI**
   - **General**

   Note: The default mode depends on where the **If** step is added. When the **If** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.

   A confirmation dialog is displayed, indicating that switching modes clears the current step configuration.
6. Click **Yes**.

   Note:
   - The default mode depends on where the **Assign** step is added. When the **Assign** step is added within a **With** step, it opens in **UI** mode. When it is added outside a **With** step, it opens in **General** mode.
   - You can switch between the available modes by selecting a different option from the **Mode** list.
   - If you switch modes after configuring the step, select the required mode and then click **Yes** in the confirmation dialog. The existing configuration is cleared and the step opens in the selected mode.

7. You can perform the actions that are listed in the following table to configure assign during a test run:

Mode	Action
General	Perform the following steps: a. Select an existing dataset in the **Dataset** field. b. Click **Add** to add a variable and assign the value from dataset. c. Select an existing variable from the **Select a variable to assign** drop down. **Note:** You can also select **Create variable** from the list to create a new variable and assign the value from the dataset. The variable is displayed in the **Variables** section. d. Select the column in the dataset from which you want to assign the values during test run. e. Click the **Close** icon to close the run details pane.
UI	Perform the following steps: a. Hover over a UI element in the **Smartshot** view, right-click, and then select **Use this element as a step target**. Alternatively, you can drag and drop a UI element from the **Smartshot** view to the **Object identified by** section. The **UI Object** type is identified.

Mode	Action
	b. Enter a property name such as Content, Id, or XPath of the object that must be used for variable assignment in **UI Property**. If you entered the property name correctly, the value of the property is displayed under **Extracted Value**. c. Select an existing variable, or Select **Add new variable**, enter a name for the variable, and then click **Add**.

8. Click the **Save** icon to save the modifications.

Results

You can configured the **Assign** step to assign values to test variables during a test run. Based on the selected mode, the Assign step assigns values from a dataset to variables or stores values extracted from UI elements in variables.

What to do next

You can run the test in **Test Editor** and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785.

Assigning test variable values from a dataset by using the Run step

You can assign values from a dataset to test variables by using the **Run** step. This supports dynamic data substitution during test execution, allowing subsequent steps to use unique and data-driven values.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.
- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.

About this task

You can create datasets in Test and assign their values to variables in a test or suite. This process helps you to run data-driven tests consistently with parameters and reduces the need to repeat steps. Dataset values are mapped to variables in a test or suite, to perform flexible data-driven testing across multiple scenarios.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test or suite in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 3 on page 854.
2. Select an existing branch or create a new branch.
3. Click the **Run** step to assign the dataset columns to variables.

   The run details pane opens with the **Details** tab which was the default selection. The variables in the test and suite are displayed in the **Inputs** section.
4. Select an existing dataset in the **Dataset** field.
5. Click the drop-down icon in the variable.

   Result

   The variables in the parent test and column names in the selected datasets are listed.
6. Select the column in the dataset from which you want to assign the values during test run.
7. Click Close icon to close the run details pane.
8. Click the **Save** icon to save the modifications.

Results

You have assigned the dataset to test variables in a test or suite by using the **Run** step.

What to do next

You can run the test or suite in **Test Editor** sequentially or concurrently and view the Functional Report to verify the test steps with the variable assignment. See Running a Web UI test on page 785, Running a suite sequentially on page 834, or Running a suite concurrently on page 835.

Configuring test variables in the Run step of a test or suite

You can configure input and output variables in a **Run** step to pass values into and out of a test during test run.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.

- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.

About this task

When configuring input and output variables in a Run step, the following tooltips help indicate the status of each variable:

- **Using default variable**: The variable uses a predefined default value from the called test.
- **Value expected**: No value or mapping has been provided, and the variable does not have a default value. A value must be provided at runtime.
- **Value provided**: A value has been successfully assigned, either through direct input, variable mapping, or hard coding.
- **Using variable**: The variable is mapped to an existing variable in the parent test.
- **Value ignored**: The variable is configured as an output, but its returned value is not used or mapped in the calling test.
- **Value extracted**: The variable is configured as an output, and its value will be captured from the called test

These tooltips guide you in ensuring that all required values are correctly configured before running the test.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** is not displayed, then go to step 3 on page 855.
2. Select an existing branch or create a new branch.
3. Click the **Run** step in the **Test Editor**.

   The run details pane opens with the **Details** tab selected by default. The variables in the test or suite are displayed in the **Inputs** and **Outputs** section.
4. You can perform following tasks to configure variables:

Task	Action
Define a value	Perform following steps: a. Click **Define variable** icon . b. Type the value in the **Value** field. c. Click **Add**. The tooltip is updated as **Value provided**, and the define variable icon is disabled.

Task	Action
Add a new variable in the suite	Perform the following steps: a. Select the drop-down icon under the variable. b. Select **Add new variable**. The **Add Variable** dialog is displayed. c. Type the name of the variable in the **Name** field. d. Type the value in the **Variable** field. e. Click **Add**. A new variable is created and mapped to the selected variable.
Link the new variable to the parent variable	Perform the following steps: a. Click the drop-down icon under the variable. b. Select an existing variable from the parent test. The tooltip is updated as **Value provided**, and the define variable icon is disabled.
Change the value of a variable	Type the new value directly under the variable name. The tooltip is updated as **Value provided**, and the define variable icon is disabled.
Map output variables	Perform the following steps: a. Click the drop-down icon under the variable. b. Select an existing variable from the child test to capture the output value. The tooltip is updated as **Value extracted**, and the define variable icon is disabled. If no mapping is done, the tooltip is displayed as **Value ignored**.

5. Click the **Close** icon to close the run details pane.
6. Click the **Save** icon to save the modifications.

Results

You have configured input and output variables in the **Run** step of a test or suite.

What to do next

You can run the suite in **Test Editor** sequentially or concurrently and view the Functional Report to verify the test steps with the variable assignment. See Running a suite sequentially on page 834 or Running a suite concurrently on page 835.

Creating a dataset by using test variables

When you want to create a dataset by using variables that are configured in a test or a suite, you can do so in Test Editor. In the dataset, each variable gets displayed as a column, and you can update it by adding values to the columns.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Opened the test in **Test Editor**. See Editing a Web UI test on page 793.

1. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** dialog is not displayed, then go to step 3 on page 857.
2. Select an existing branch or create a new branch.
3. Click the **Configure settings and data** step in **Test Editor**.
   The **Configure settings and data** pane is displayed. If the test contains the configured variables, then they are listed under the **Data** section.
4. Click **+ Create Dataset** in the **Data** section.
   The **Create dataset** dialog is displayed.
5. Perform the following steps in the **Create dataset** dialog:
   a. Select an application for which you want to create a dataset from the **Application** drop-down list.
   b. Select an existing folder in **Location** to save the new dataset.
   c. Enter a name for the dataset in **Name**.
6. Click **Next**.

   All the variables available in the test are listed with a checkbox, and only the **Input** variables are selected.
7. Select the variables to be part of the dataset.

8. Click **Create**.
   A success message is displayed. The dataset created is listed under the logical folder `Datasets` within the selected application.

Results

You have created a dataset by using the variables configured in a test.

What to do next

You can view the dataset and add values to it. See Editing a dataset on page 962.

Related information

Adding an Assign step on page 799

Assigning test variable values from a dataset by using the Run step on page 853

Editing a dataset in Test Editor

You can now create and edit a dataset in **Test Editor** either through the catalog in the **Visual** view or through the written code in the **Code** view. However, for encrypted datasets, switching to the **Code** view is disabled to ensure data confidentiality.

Before you begin

1. Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
2. Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
3. Ensured that you have created a dataset or configured a repository that contains the dataset.

About this task

If you are a project **Owner** or **Tester** in Test , you can perform basic tasks in datasets by right-clicking any row, column, or cell in the dataset to organize your data more efficiently. For example, you can cut, copy, paste, insert, or delete rows or columns, show encrypted data, encrypt column data, or rename column names.

After you edit the dataset, you can save the changes made to the dataset, and then you can publish the dataset to the Git repository. If you save and close the edited dataset, the **Changes** page lists the edited dataset, and later you can publish it to the Git repository for other members to use.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.

4. Select the branch that contains your project with the datasets that you want to edit.

   The projects in the selected branch are displayed in the Test Editor navigator panel. The datasets are listed under the folder you created to contain the dataset within a logical folder named `Datasets`.

5. Click the dataset in the Test Editor navigator panel.

   The dataset opens in the right pane.

   The dataset is displayed in the **Visual** view, where you can add, modify, remove, import, or export data by using the toolbar actions or the right-click menu. If needed, you can switch to the **Code** view to edit the dataset in code form.

   Note: For encrypted columns, switching to the **Code** view is not allowed.

6. Click **Edit**.

   Alternatively, right-click the dataset in the Test Editor navigator panel, and then click **Edit**.

   The **Edit Branch** dialog is displayed.

   If the **Edit Branch** dialog is not displayed, then go to step 8 on page 859.

7. Select an existing branch or create a new branch.
8. Perform the following actions to use the top-level editing controls available in the toolbar:

Editing Options	Actions
Find and Replace	To find: a. Click the **Find and Replace** icon. b. Enter the content that you want to search for in the **Find** field. c. Select any of the following options to refine your search content: ▪ Select the **Case sensitive** icon Aa to search the content that matches the exact letter case entered in the **Find** field. ▪ Select the **Match entire cell contents** icon ab to search for cells that contain only the characters that you have entered in the **Find** field. ▪ Select the **Search using regular expression** icon .* to search the pattern that matches strings. For example, to search a cell that contains any number between 0 to 9, do the following: i. Enter *\d* in the **Find** field. ii. Select the **Search using regular expression** checkbox. iii. Click **Find**.

Editing Options	Actions
	d. Click the **Find** icon. If the text is found, the cell containing that text is selected. e. Click the **Find** icon again to find further instances of the search text. To find and replace: a. Click the **Find and Replace** icon. b. Enter the content that you want to search for in the **Find** field. c. Enter the content that you want to replace in the **Replace** field. d. Select any or all of the following options to find and replace the content more effectively: ▪ Select the **Case sensitive** icon to find the content that is the exact letter case of the content entered in the **Find** field. ▪ Select the **Match entire cell contents** icon to find and replace for cells that contain only the characters that you have entered in the **Find** and **Replace** fields. ▪ Select the **Search using regular expression** icon to find and replace the pattern that matches strings. e. Click the **Replace** icon to replace the individual instances. f. Click the **Replace All** icon to replace every instance of the content throughout the dataset.
Undo	a. Click the **Undo** icon. b. From the list, click the change that you want to undo. The **Undo** option reverts the change you made in the dataset.
Redo	a. Click the **Redo** icon. b. From the list, click the change that you want to redo.
Import	You can import variable data into a dataset from the following sources: ◦ When there is a large amount of data stored in a CSV file ◦ When you use the data fabrication feature to generate test data ◦ When you import data by using a database query **Importing data from a CSV file** a. Click the **Import** icon. b. Select **Import a CSV file** from the drop-down list.

Editing Options	Actions
	c. Click **Select file**, and choose the CSV file that contains variable data to import into the dataset. d. Enable the **First row contains headers** if your CSV file contains the header. e. Select one of the following import options to append or overwrite data in the dataset: ▪ Enable **Overwrite existing data** to add the rows and columns from the beginning of the dataset. ▪ Enable **Append existing data** to add rows and columns to the end of the dataset. f. Click **Import**. **Importing data by using data fabrication** a. Click the **Import** icon . b. Select **Fabricate data** from the drop-down list. c. Select a data definition from the drop-down list. d. Enter the number of rows that you want to generate in the **Number of Rows** field. e. Enter a seed value in the **Seed (optional)** field. f. Enable **Fabricate headers** if your schema contains the headers. g. Select one of the following options to append or overwrite data in the dataset: ▪ Enable **Overwrite existing data** to add the rows and columns from the beginning of the dataset. ▪ Enable **Append existing data** to add rows and columns to the end of the dataset. h. Click **Import**. **Importing data by using a database query** a. Click the **Import** icon . b. Select **Import a Database Query** from the drop-down list. c. Select a database query from the drop-down list.

Editing Options	Actions
	d. Enter the number of rows that you want to generate in the **Number of Rows** field. e. Select one of the following options to append or overwrite data in the dataset: ▪ Enable **Overwrite existing data** to add the rows and columns from the beginning of the dataset. ▪ Enable **Append existing data** to add rows and columns to the end of the dataset.
Export	You can export variable data from a dataset to a CSV file to reuse the data in future tests. You must open the dataset from which you want to export the data. Click the **Export** icon to download the dataset as a CSV file.
Configure	You can configure the dataset by clicking the **Menu** icon , and then selecting **Configure**. In the **Configure Dataset** dialog, you can change the row and column settings and configure the string values in the dataset that contain variable data for tests to use when they run. ◦ Select any of the separator values that you used in the CSV file. The available options are **Comma**, **Semicolon**, **Space**, **Tab**, and **Other**. If the CSV file uses any separator characters that are not listed, select **Other**, and then you can specify the character. For example, if the data in the CSV file is separated by a character #, then select the **Other** option and enter # in the field. ◦ Configure the following options to change the row and column settings: ▪ **Column header** - Use an up-down control button to increment or decrement the value of the column header. ▪ **Data start point** - Use an up-down control button to increment or decrement the value of the data starting pointer. ▪ **Current row** - Use an up-down control button to increment or decrement the value of the current row. ◦ Configure the following options to change the string values in the dataset:

Editing Options	Actions
	▪ **Treat as null** - Enter a string value that is to be treated as null when running the test. ▪ **Treat as empty** - Enter a string value that is to be treated as empty when running the test. For example, when you run the test, and the data *123* in the dataset is to be treated as empty, then you must specify *123* in the **Treat as empty** field. ▪ **Treat empty text as null** - Select this field when you want the dataset that contains any blank cells, and the value of those blank cells to be interpreted as null. ◦ Click **Update** to apply the changes.
Discard	Click the **Menu** icon and select **Discard** to discard the changes made to the dataset.

9. Perform the following actions using the editing options available in the column header:

Editing Options	Actions
Rename column	Hover over the column header and click the **Rename column** icon to update the column name.
Delete column	Hover over the column header and click the **Delete column** icon to delete the column.

10. Perform the following actions to use the cell-level editing options available in the right-click context menu.

Option	Actions
Cut	Right-click the cell and click the **Cut** icon to remove the content from the selected cell and paste it into another cell.
Copy	Right-click the cell and click the **Copy** icon to copy the content.
Paste	Right-click the cell and click the **Paste** icon to insert the copied or cut content.
Insert row above	Right-click the row and click **Insert row above** to add a new row above.
Insert row below	Right-click the row and click **Insert row below** to add a new row below.

Option	Actions
Insert column left	Right-click the column and click **Insert column left** to add a column on the left.
Insert column right	Right-click the column and click **Insert column right** to add a column on the right.
Delete row(s)	Right-click the selected row and click **Delete row(s)**.
Delete column(s)	Right-click the selected column and click **Delete column(s)**.
Show encrypted data	Right-click the encrypted column and click the **Show encrypted data** icon to view the encrypted data. Right-click the decrypted column and select **Hide encrypted data** to encrypt the data again. **Important:** The **Show encrypted data** option is available only when you have added the encrypted dataset to the respective classification. For more information about adding an encrypted dataset to a classification, see Adding an encrypted dataset to a classification on page 977.
Encrypt column data	Perform the following steps to encrypt the column data: a. Right-click any cell in a column that you want to encrypt and select the **Encrypt column data** icon . The **Encrypt Column** window is displayed. b. Enter an encryption key in the **Encryption Key** field to encrypt the data in the column. **Remember:** When you have already encrypted other columns in the dataset, you must enter the same encryption key that you used previously. You can use only one encryption key to encrypt columns in a dataset. **Important:** The encryption keys that you use to encrypt data in a dataset are not stored on the server, nor they can be retrieved from the server. Therefore, you must remember to store the encryption keys in a secure location. You must use the same encryption keys to perform the following operations:

Option	Actions
	 ▪ View the encrypted values ▪ Decrypt data ▪ Enable the use of the encrypted dataset during test runs c. Click **Encrypt Column**. Asterisks are displayed instead of actual data for the encrypted column.
Decrypt column data	Perform the following steps to decrypt the column data: a. Right-click the encrypted cells that display the contents with asterisks, and then select the **Decrypt column data** icon . The **Decrypt Column** window is displayed. b. Enter an encryption key in the **Encryption Key** field to decrypt the data in the column. c. Click **Decrypt Column**. Asterisks are replaced with the actual data in the decrypted column. When you run a test that uses a dataset that contains decrypted data, the variable data is substituted for the original data in the recorded test without prompting for the encryption.
Set as current row	During the test run, if you want variable data to be selected from the current row instead of the first row in a dataset, right-click any cell in a row and select the **Set as current row** icon . **When rows are deleted:** If you delete any row between row 1 and the current row, the current row data is taken from the next row. For example, when you set the current row as 6, and then you delete any row between row 1 to row 6, the current row remains at row 6, but the content of row 7 is moved to row 6. **When rows are inserted:** If you insert any new row between row 1 to the current row, the current row data is taken from the previous row. For example, when you set the current row as 6, and then you insert any row between row 1 to row 6, the current row remains at row 6, but the content of row 5 is moved to row 6.

11. Click the **Save** icon to save the changes made to the dataset or the **Save All** icon in the Test Editor navigator panel to save all changes made to different datasets by using the same Edit branch.
12. Click the **Publish** icon to publish the dataset to the Git repository.

Results

You have edited the dataset in the **Test Editor**.

Multiple datasets in tests and test suites

You can configure multiple datasets in tests or test suites to provide additional data for variables during a test run. You can combine data from multiple datasets which supports flexible data-driven testing across different scenarios.

Overview

When working with datasets in a test or test suite, you can use a primary dataset along with additional datasets to provide values for variables.

The primary dataset is used as the main data source. Additional datasets provide supporting values when required. Therefore, you can use data from multiple datasets without duplicating test logic.

In **Test Editor**, you can add additional datasets when configuring tests and test suites.

You can configure multiple datasets in **Test Editor** as follows:

- Select a dataset as the primary dataset.
- Add one or more additional datasets, which are displayed indented under the primary dataset.
- Add additional datasets only after selecting the primary dataset.

Note: You cannot select the same dataset more than once.

Dataset behavior

The following behavior applies when you assign values to variables:

- Columns from both primary and additional datasets are available for mapping to variables.
- If a column name exists in multiple datasets, the value from the first matching dataset is used for mapping to variables. Datasets are considered in the configured order, and the primary dataset is considered first.
- If the same column exists in multiple datasets, the value from the first matching dataset is used.
- Additional datasets are used to provide values that are not available in the primary dataset.

Assigning test variable values from multiple datasets by using the Assign step

You can assign test variable values from multiple datasets to retrieve values from more than one dataset. This capability supports flexible data-driven testing across different scenarios and reduces the need to repeat test steps.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test.
- Ensured that the required variables have been created and are included in your Web UI test.
- Ensured that your project contains a dataset.

1. Open the required test in **Test Editor**.
2. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.
   If the **Edit branch** is not displayed, then go to step 4 on page 867.
3. Select an existing branch or create a new branch.
4. Drag the **Assign** statement from the **Catalog > General** pane and drop it under a test step as required.
   The **Assign** step is inserted.

   Note:

   You can also use the **Assign** step within a **while** or **do-while** step, so that the **Assign** step retrieves the values from a dataset to process each row of the dataset iteratively and assign the retrieved values to the test variables.

5. Click the **Assign** step.

   The step details pane opens with the **Details** tab.
6. Perform the following steps to add multiple datasets:

   a. Select an existing dataset in the **Dataset** field.
      This dataset acts as the primary dataset. The **Add Dataset** option is enabled.

   b. Click **Add Dataset** and select additional datasets.

      You can add multiple datasets as required.

      If you want to remove a dataset, you can click **Remove Dataset** from the dataset list.

7. Click **Add Variable** to add a variable and assign the value from the dataset.

8. Select an existing variable from the **Select a variable to assign** drop down.

   Result

   The variable is displayed in the **Variables** section.
9. Click the drop-down icon for the variable.

   Note: You can also select **Create variable** from the list to create a new variable and assign the value from the dataset.

   Result

   The variables in the test and column names in the selected datasets are listed.
10. Select the column in the dataset from which you want to assign the values during test run.
11. Click the **Close** icon to close the step details pane.
12. Click the **Save** icon to save the modifications.

Results

You have assigned multiple datasets to test variables in a test by using the **Assign** step.

Assigning test variable values from multiple datasets by using the Run step

You can assign or modify test variable values from multiple datasets to retrieve values from more than one dataset. This capability supports flexible data-driven testing across different scenarios and reduces the need to repeat test steps.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.
- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.

1. Open the required test or suite in **Test Editor**.
2. Click the

button displayed on the **Test Editor** page.

   The **Edit** button appears only when no active edit branch is selected.

   Alternatively, right-click the test in the test navigator panel and select **Edit**.

   The **Edit branch** dialog is displayed.

If the **Edit branch** is not displayed, then go to step 4 on page 869.

3. Select an existing branch or create a new branch.
4. Click the **Run** step to assign the dataset columns to variables.

   The step details pane opens with the **Details** tab. The variables in the test and suite are displayed in the **Inputs** section.

5. Perform the following steps to add multiple datasets:

   a. Select an existing dataset in the **Dataset** field. This dataset acts as the primary dataset.
   This dataset acts as the primary dataset. The **Add Dataset** option is enabled.

   b. Click **Add Dataset** and select additional datasets. You can add multiple datasets as required.

   If you want to remove a dataset, you can click **Remove Dataset** from the dataset list.

6. Locate the variable in the **Inputs** variable section for which you want to assign a value.
7. Hover over the variable value field.

   A drop-down icon is displayed next to the field.

8. Click the drop-down icon for the variable.
   Result
   The variables in the test and column names in the selected datasets are listed.
9. Select the column in the dataset from which you want to assign the values during the test run.
10. Click the **Close** icon to close the run details pane.
11. Click the **Save** icon to save the modifications.

Results

You have assigned multiple datasets to test variables in a test or suite by using the **Run** step.

Test environments

You can define custom environments to manage sets of variables such as application URLs and user credentials, and to configure profile overrides. When you run a test, the variables and override rules defined in the environment dynamically replace the values within your test script. You can easily change testing targets without modifying your test script by using environments because the environment-level configurations take precedence over the default values defined in the script.

You can create, edit, copy, move, and delete the environments. When you create an environment, a `.dte.yaml` file is created and listed under the **Environments** folder for the selected application in the test navigator panel.

Environments that you defined for an application are available for selection in the **ENVIRONMENT** tab of the **Execute test asset** dialog when you initiate a test run.

Profile overrides

In addition to managing variables, you can use environments to configure profile overrides. By using profile overrides, you can substitute a default profile, such as a specific browser or emulated device, with a different target profile, such as a cloud-native device or alternative browser, when you run tests.

In the **Execute test asset** dialog, you can either specify an **Environment** that carries override rules or select a browser or device profile in the **Browser** field. If you specify values in both the **Environment** and **Browser** fields, then the value in the **Browser** field takes priority.

Related information

Test navigator panel on page 761

Creating an environment

You can create an environment to define custom variables that override the variables defined in the test when you run a test or suite. You can also configure profile overrides so that cloud-native devices can replace the default browsers or device profiles when you run a test or suite.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

About this task

You can use environments such as Dev, QA, or Staging to manage a set of variables and profiles with different values. When you run a test, the environment variables dynamically replace the matching variable values, and profile overrides replace the browser or device profiles defined in the test.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Navigate to **Author > Test Editor**.
   The **Test Editor** page and test navigator panel are displayed.
4. Perform any of the following actions:

- Click the **Action Menu** icon and select **Environment**.
- Right-click the application folder in the test navigator panel and select **New > Environment**.

The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 6 on page 871.

5. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.
6. Perform the following steps to configure the environment details in the **Create Environment** dialog.
   a. Select a target application from the **Application** drop-down list.
   b. Enter a unique name for your environment in the **Name** field.
7. Click **Done**.

   Result

   The new environment is created, and it opens in the **Test Editor** for further configuration.
8. Perform the following steps to add specific variables in the **Variables** section:
   a. Click **+ Create Variable**.
   b. Enter the name of the variable in the **Name** column.
      For example, `App_URL`, `username`, or `password`.
   c. Enter the corresponding value for the variable in the **Value** column.
   d. Repeat these substeps to add all necessary variables for this environment.
9. Perform the following steps to define overrides for the default profiles in the **Profiles** section:
   a. Click **+ Add Override**.
   b. Select the name of the default browser or device profile from the **Profile** drop-down list.
      For example, select `Phone (Small)` or `Chrome`.

c. Select a device from the list of devices for the configured device cloud from the **Override** drop-down list.

d. Repeat these substeps to add all necessary overrides for this environment.

10. Click the **Save** icon to save the details.

Results

You have created an environment.

What to do next

You can perform the following tasks:

- Run a server test asset. See Running server test assets on page 1321 or Running server test assets on an agent on page 1324.
- Run a server test suite asset. See Running server suite assets on page 1329.

Modifying an environment

You can add, update, or remove variables and profile overrides that are part of the configured environments.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that your project contains an environment.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Navigate to **Author > Test Editor**.
   Result
   The **Test Editor** page and test navigator panel are displayed.
4. Double-click the environment that you want to modify in the test navigator panel, and then click **Edit**.
   Alternatively, right-click the environment in the test navigator panel and click **Edit**.
   The **Edit branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 6 on page 873.

5. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.
6. Perform any of the following steps to modify your variables in the **Variables** section of the environment editor:

Action	Steps
Add a new variable	Click **+ Create Variable**, then enter the new variable name and value.
Edit an existing variable	Click inside the **Name** or **Value** field of the specific variable and type your updates.
Delete a variable	Click the **Delete** icon next to the variable row that you want to remove.

7. Perform any of the following steps to modify overrides in the **Profiles** section of the environment editor:

Action	Steps
Add an override	Click **+ Add Override**, select the name of the default browser or device profile from **Profile**, and then select a device in the configured device cloud from **Override**.
Edit an existing override	Select different values from the **Profile** or **Override** field.
Delete an override	Click the **Delete** icon next to the override row that you want to remove.

8. Click the **Save** icon to save the details.

Results

You have modified the existing environment.

Catalog management

You can use the data catalog in Test to browse and manage data generators used in test data creation. The catalog section provides access to built-in generators, allows you to create custom generators tailored to specific needs, and group them using custom categories.

You can access the data catalog for a project from **Author > Catalog** tab in the Test. The catalog includes:

- **Basic Generators**: You can select any generator from the available generators listed in the **Catalog** tab of a data definition. The generators in turn contain different options and fields that generate data by using a built-in database in Test Hub. See Basic generators on page 874.

  Note: You must add at least one generator as a field in the data definition to generate test data.

- **Custom Generators**: Custom generators are modifications of the built-in generators that you modify any or all the fields in a generator to suit your specific requirements of your test data. The modified generator cannot be saved to the built-in generator and hence, you must save them as custom generators by providing a name to identify the custom generator. See Management of custom generators on page 923.
- **Custom Categories:** You can create a custom category in the catalog to contain the custom generators that you create. See Management of custom categories on page 930.

Basic generators

You can use the built-in basic generators in Data definitions with or without modifying the default configurations of the generators.

The Data fabrication feature of Test contains a collection of built-in data generators available in the **Basic** category on the **Catalog** tab of a Data definition.

Basic generators are the built-in generators of the Data fabrication feature of Test that you can use to generate diverse test data. These generators provide commonly used data types and patterns that you can select and configure in a Data definition to generate realistic test data.

The basic generators that you can use in Test are as follows:

- Address
- Boolean
- Dataset
- DateTime
- Enumerator
- Function
- Name
- Number
- Phone
- Regex

- String
- Text
- UUID

Every basic generator has unique parameters with default features. When you click a basic generator that is added as a field in the Data definition, the corresponding unique parameters with their default configuration are displayed in a new dialog. The new dialog is named after the generator that you select.

You can change the default configurations of any basic generator only when it is added as a field in a Data definition. You can use the changed configurations for any basic generator in the Data definition by saving the Data definition. The changed configuration is applicable only in the Data definition that contains it and is not available for use from the **Catalog** tab.

If you want to save the modified generators, you can create them as custom generators and save them in a custom category in the **Catalog** tab.

You can find details about the parameters in each of the basic generators along with their default configuration and the configurations that you can change or modify. The parameters of the basic generators are as follows:

- Parameters of the Address generator on page 875
- Parameters of the Boolean generator on page 880
- Parameters of the Dataset generator on page 883
- Parameters of the DateTime generator on page 885
- Parameters of the Enumerator generator on page 889
- Parameters of the Function generator on page 893
- Parameters of the Name generator on page 899
- Parameters of the Number generator on page 903
- Parameters of the Phone generator on page 907
- Parameters of the Regex generator on page 911
- Parameters of the String generator on page 914
- Parameters of the Text generator on page 919
- Parameters of the UUID generator on page 922

Parameters of the Address generator

After you add the Address generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Address generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Address generator that contains the existing configuration details for that field are displayed in the **Address** dialog.

The following table provides the list of UI elements of the **Address** dialog with their description, default features, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Address**.	The field is not editable.	NA
The **Distribution** field	Determines whether the addresses are randomly generated in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the addresses to follow a random distribution when generated in the test data. • Clear the **Random** option if you want the addresses to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for addresses using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains addresses with the postal codes and `70%` to another configuration that contains the address with no postal codes, then the address column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines whether duplicate or unique addresses are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated addresses to include duplicate entries. This means that some addresses might appear more than once in the generated data.

UI element	Description	Default feature	Action
			• Clear the **Allowed** option if you want to ensure unique addresses with no duplicates. This will prevent any duplicate addresses from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank addresses in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the secondary addresses fields in the generated data will be empty or blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated addresses when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of addresses to be generated. For example, if you enter `50`, the generated data will display the address column with a 50% occurrence rate.
The **First Line** option	Determines whether the generated addresses include the first line of the address.	The **First Line** option is selected.	• Do not perform any action if you want the generated addresses to include the first line of the address. • Clear the **Allowed** option if you want to exclude the first line from the generated addresses.
The **Second Line** option	Determines whether the generated addresses include the second line of the address.	The **Second Line** option is selected.	• Do not perform any action if you want the generated addresses to include the second line of the address. • Clear the **Allowed** option if you want to exclude the second line from the generated addresses.

UI element	Description	Default feature	Action
The **City** option	Determines whether the generated addresses include the city name.	The **City** option is selected.	• Do not perform any action if you want the generated addresses to include the name of the city. • Clear the **Allowed** option if you want to exclude the name of the city from the generated addresses.
The **Zip Code** option	Determines whether the generated addresses include the postal code.	The **Zip Code** option is selected.	• Do not perform any action if you want the generated addresses to include the postal code. • Clear the **Allowed** option if you want to exclude the postal code from the generated addresses.
The **Country** option	Determines whether the generated addresses include the country name.	The **Country** option is selected.	• Do not perform any action if you want the generated addresses to include the name of the country. • Clear the **Allowed** option if you want to exclude the name of the country from the generated addresses.
The **Add new configuration** tab	You can add additional address configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the	Click the tab to create additional address configurations. For example, you can have one configuration for addresses with the postal code, and another configuration for addresses with no postal code. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		Random option is not selected. • The selected options from the previous configuration remain selected, and the unselected options remain unselected for the following elements: ◦ First Line ◦ Second Line ◦ City ◦ Zip Code ◦ Country	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Address** generator is complete, you can use the **Address** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon to save the new generator with a unique name in the catalog. You can reuse the same configuration at a later time in different scenarios without having to set it up again. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Address** generator dialog.

Parameters of the Boolean generator

After you add the Boolean generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Boolean generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Boolean generator that contains the existing configuration details for that field are displayed in the **Boolean** dialog.

The following table provides the list of UI elements of the **Boolean** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Boolean**.	The name is not editable.	NA
The **Distribution** field	Determines if the Boolean values are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the Boolean values, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the Boolean to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the Boolean values using the **Percentage** field. For example, if you set the percentage distribution of `100%` and provide a value as `True`, then all the generated Boolean values in the corresponding column will be true. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Blank perce**	Determines the frequency of blank values in the corresponding column of the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`.

UI element	Description	Default feature	Action
ntage field			For example, if you enter `10`, approximately 10% of the Boolean values in the corresponding column of the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated Boolean values when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of the Boolean values to be generated. For example, if you enter `50`, the generated data will display the Boolean column with a 50% occurrence rate.
The **Format** section	Determines the additional details about the format of the generated Boolean values for the selected configuration.	NA	Provide information about the format of the Boolean values for the selected configuration. For more details about the section, see The Format section on page 882.
The **Add new configuration** tab	You can add additional configurations for boolean values with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the **Random** option is not selected.	Click the tab to create additional configurations for Boolean values. This is useful when you need different sets of Boolean values in your synthetic data. For example, you can have one configuration for `Is married` with a fixed distribution, and another configuration for `Has children` with a random distribution. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		• The **Value** and **Distribution** fields display the same values that were provided in the previous configuration.	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Boolean** generator is complete, you can use the **Boolean** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Boolean** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Dataset** generator should be equal to `100`.

The Format section

You can add additional details about the format of the generated Boolean values for a selected configuration in the **Format** section of the **Boolean** dialog. The following table provides the list of UI elements of the section with their description, default features, and actions that you can perform in the section to customize the configuration:

UI element	Description	Default feature	Action
The **Value** fields	Contains two editable fields.	Displays `Yes` in the first field and `No` in the second field.	You can modify the default values to any other suitable Boolean values.
The **Distribution** fields	Contains two editable fields. The field determines the proportion of the entered values when you do not select the **Random** option.	Editable when **Random** is not selected. Displays 60% and 40% as default values.	If you did not select the **Random** option, enter a number from `0` to `100` in the **Distribution** field for both values. Note: The total percentage of the distribution corresponding to both values must be equal to 100.
The **Random** option	Determines if the Boolean values are randomly generated or not.	The option is selected.	• Do not perform any action if you want the Boolean values, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the Boolean values to follow a fixed distribution and to be non-random.

Parameters of the Dataset generator

After you add the Dataset generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Dataset generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Dataset generator that contains the existing configuration details for that field are displayed in the **Dataset** dialog.

The following table provides the list of UI elements of the **Dataset** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Dataset**.	The name is not editable.	NA
The **Blank**	Determines the frequency of blank datasets in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`.

UI element	Description	Default feature	Action
percentage field			For example, if you enter `10`, approximately 10% of the fields corresponding to datasets in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated rows with datasets.	Editable.	Enter a number from `0` to `100` in the field to set the percentage of rows with datasets to be generated. For example, if you enter `50`, the generated data will display the datasets column with a 50% occurrence rate.
The **Dataset** field	Allows you to browse and select a dataset file from the system.	NA	Click the **Browse** option to select a dataset file from your system. The selected dataset value is displayed in the **Dataset** field.
The **Column** list	Allows you to select the desired column from the dataset for data generation.	NA	Click the list to select the column from the dataset.
The **Add new configuration** tab	You can add additional dataset configurations with specific dataset and column selections, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable. • The **Dataset** and **Column** fields display the	Click the tab to create additional dataset configurations, and then add the required components for the additional dataset configuration. For example, if the previous configuration included a dataset with the Address column, you can add a new dataset in another configuration to include another dataset with the Email column.

UI element	Description	Default feature	Action
		same values that were provided in the previous configuration.	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Dataset** generator is complete, you can use the **Dataset** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Dataset** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Dataset** generator should be equal to `100`.

Parameters of the DateTime generator

After you add the DateTime generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the DateTime generator of a specific field in the Data definition in the Edit branch, the unique parameters of the DateTime generator that contains the existing configuration details for that field are displayed in the **DateTime** dialog.

The following table provides the list of UI elements of the **DateTime** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **DateTime**.	The name is not editable.	NA
The **Distribution** field	Determines if the date and time are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the date and time, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the date and time to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the date and time using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains the dates of weekdays with a fixed time range and `70%` to another configuration that contains the dates of weekends with a different time range, then the enumerator column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique date and time are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated date and time to include duplicate entries. This means that some of the date and time values might appear more than once in the generated data.

UI element	Description	Default feature	Action
			• Clear the **Allowed** option if you want to ensure a unique date and time with no duplicates. This will prevent any duplicate date and time from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank date and time values in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the date and time values in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated date and time values when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of the date and time values to be generated. For example, if you enter `50`, the generated data will display the column corresponding to the date and time values with a 50% occurrence rate.
The **Pattern** list	Allows you to select the date pattern for data generation.	The default pattern is **mm/dd/yyyy**.	Select the required date pattern from the list of available options.

UI element	Description	Default feature	Action
The **Limit dates** section	Allows you to define limitations on the generated dates.	NA	• Either enter the dates in the **From** and **To** fields in the format of dd/mm/yyyy or select the dates from the corresponding calendar icons to reflect in the fields. • Select the days of the week (S, M, T, W, T, F, S) in the **Exclude** section to exclude those days from the **From** and **To** date fields. • Enter multiple dates in the **Specific dates to exclude** field, separated by commas, to exclude specific dates from the generation.
The **Limit times** section	Allows you to define limitations on the generated times.	NA	Enter the times in the **From** and **To** fields in the AM and PM format.
The **Add new configuration** tab	You can add additional date and time configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the **Random** option is not selected. • The following sections display	Click the tab and then add the required components for the additional date and time configuration. For example, you can have one configuration for weekdays with a fixed time range, and another configuration for weekends with a different time range. **Note:** You can click the delete icon to delete any additional configuration that you do not need.

UI element	Description	Default feature	Action
		the same values that were provided in the previous configuration: ◦ Limit dates ◦ Limit times	
The **Save to catalog** option	After the customization of the **DateTime** generator is complete, you can use the **DateTime** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon . You can reuse the same configuration at a later time in different scenarios without having to set it up again from scratch. See Creating custom generators and categories from Data definitions on page 925.
The close icon	NA	NA	Click the icon to exit the **DateTime** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **DateTime** generator should be equal to `100`.

Parameters of the Enumerator generator

After you add the Enumerator generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Enumerator generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Enumerator generator that contains the existing configuration details for that field are displayed in the **Enumerator** dialog.

The following table provides the list of UI elements of the **Enumerator** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Enumerator**.	The name is not editable.	NA
The **Distribution** field	Determines if the enumerator values are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the enumerator values, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the enumerator values to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the enumerator values using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains the names of colors and `70%` to another configuration that contains the names of shapes, then the enumerator column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Blank perc**	Determines the frequency of blank enumerator values in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the enumerator values in the generated data will be blank.

UI element	Description	Default feature	Action
entage field			
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated enumerated values when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of enumerator values to be generated. For example, if you enter `50`, the generated data will display the enumerator column with a 50% occurrence rate.
The **Format** section	Determines the additional details about the format of the generated enumerator values for the selected configuration.	NA	Provide information about the format of the enumerator values for the selected configuration. For more details about the section, see The Format section on page 892.
The **Add new configuration** tab	You can add additional enumerator value configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage**	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for colors with a fixed distribution, and another configuration for shapes with a random distribution. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		field is editable when the **Random** option is not selected. • The **Value** and **Distribution** fields display the same values that were provided in the previous configuration.	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Enumerator** generator is complete, you can use the **Enumerator** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from scratch. See Creating custom generators and categories from Data definitions on page 925.
The close icon	NA	NA	Click the icon to exit the **Enumerator** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Enumerator** generator should be equal to `100`.

The Format section

You can add additional details about the format of the generated enumerator values for a selected configuration in the **Format** section of the **Enumerator** dialog. The following table provides the list of UI elements of the section with their description, default features, and actions that you can perform in the section to customize the configuration:

UI element	Description	Default feature	Action
The **Value** fields	You can add multiple editable fields and provide desired values.	Displays three editable fields with `RED`, `GREEN`, and `BLUE` as the corresponding values.	You can modify the default values to any other suitable enumerator values or add additional values.
The **Distribution** fields	You can add multiple editable fields. The field determines the proportion of the entered values when you do not select the **Random** option.	Editable when **Random** is not selected. Displays 20%, 30%, and 50% as default values.	If you did not select the **Random** option, enter a number from `0` to `100` in the **Distribution** fields for all the values. **Note:** The total percentage of distribution corresponding to both values must be equal to 100.
The **Random** option	Determines if the enumerator values are randomly generated or not.	The option is selected.	• Do not perform any action if you want the enumerator values, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the enumerator values to follow a fixed distribution and to be non-random.

Parameters of the Function generator

After you add the Function generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Function generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Function generator that contains the existing configuration details for that field are displayed in the **Function** dialog.

The following table provides the list of UI elements of the **Function** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Gene**	Displays the name of the selected generator, that is, **Function**.	The name is not editable.	NA

UI element	Description	Default feature	Action
rator field			
The **Distribution** field	Determines if the values are randomly generated or not in the function column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the values, when generated in the function column, to follow a random distribution. • Clear the **Random** option if you want the function values to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the Function values using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains the names in uppercase and `70%` to another configuration that contains the names in lowercase, then the Function column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique function values are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated function values to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique function values with no duplicates. This will prevent any duplicate values from appearing in the function column.

UI element	Description	Default feature	Action
The **Blank percentage** field	Determines the frequency of blank function values in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the function values in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated function values when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of function values to be generated. For example, if you enter `50`, the generated data will display the function column with a 50% occurrence rate.
The **Function** section	Determines the additional details about the function for the selected configuration.	NA	Provide information about the function for the selected configuration. For more details about the section, see The Function section on page 897.
The **Add new configuration** tab	You can add additional function configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage**	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for uppercase names with a 30% distribution and another configuration for lowercase names with a 70% distribution. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		field is editable when the **Random** option is not selected. • The **Function** field displays the same values that were provided in the previous configuration.	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Function** generator is complete, you can use the **Function** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Function** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Function** generator should be equal to `100`.

The Function section

You can add additional details about the function for a selected configuration in the **Function** section of the **Function** dialog. The following table provides the list of UI elements of the section with their description, default features, and actions that you can perform in the section to customize the configuration:

UI element	Description	Default feature	Action
The **Function** field	Combines the built-in methods and the Data definition fields to create custom functions.	Empty	You can either enter a function or select values from the **Fields** and **Methods** scroll areas to create a function.
The **Items for function** field	Finds matching results in both the **Methods** and **Fields** scroll areas based on the entered text.	NA	You can type a few letters in the **Items for function** field, and matching results from both the **Methods** and **Fields** scroll areas will be displayed.
The **Methods** scroll area	Displays predefined Java methods that you can use to perform specific operations on entity fields within the function.	NA	When you double-click on an available method, the corresponding parameter is added to the **Function** field. When you hover over a method in the scroll area, the corresponding function, description, and example are displayed. The Data fabrication feature of Test supports a variety of built-in methods. See The supported built-in methods on page 897.
The **Fields** scroll area	Displays the names of all the fields used in the Data definition. You can double-click a field to add it to the **Function** field and incorporate it into the custom function.	NA	When you double-click an item in the **Fields** scroll area, the corresponding parameter is added to the **Function** field.

The supported built-in methods

The Data fabrication feature of Test supports a variety of built-in methods. The following table provides the list of built-in methods, their description, and relevant examples that you can use as functions:

Method	Description	Example
`replace(oldString, newString)`	Replaces all occurrences of the old string with the new string	`F$address.replace('road', 'street')`
`format(formatString, args)`	Returns a formatted string using format string and arguments	`String.format('Hello %s', F$name)`
`split(matchString)`	Splits the string around the given matching string	`F$name.split(" ")[0].concat('@gmail.com')`. In this example, the name is split where a white space is present and only the first part of the split is considered. Also, the first part of the split is appended with `@gmail.com`. If the input name is `Amy Smith`, then the result of the function is `Amy@gmail.com`.
`join(delimiter, stringElements)`	Joins string elements by a delimiter.	`String.join(',', F$id, F$name)`
`length()`	Returns the length of the string	`F$name.length`
`isBlank()`	Returns True only if the string has zero length or contains only white spaces	`F$address.isBlank`
`trim()`	Removes leading and trailing spaces of the string	`F$phone.trim`
`toUpperCase()`	Converts all characters into uppercase	`F$name.toUpperCase`
`toLowerCase()`	Converts all characters into lowercase	`F$name.toLowerCase`

Method	Description	Example
`concat`	Concatenates the specified string to the end of the selected string	`'Hello '.concat(F$name)`

Parameters of the Name generator

After you add the Name generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Name generator of a specific field in the Data definition in the edit branch, the unique parameters of the Name generator that contains the existing configuration details for that field are displayed in the **Name** dialog.

The following table provides the list of UI elements of the **Name** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Name**.	The name is not editable.	NA
The **Distribution** field	Determines if the names are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the names, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the names to follow a fixed distribution and to be non-random, when you add a new configuration. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.

UI element	Description	Default feature	Action
The **Duplicates** field	Determines if duplicate or unique names are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated names to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique names with no duplicates. This will prevent any duplicate names from appearing in the generated data. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the names using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains the names with titles and `70%` to another configuration that does not contain the title, then the names column of the generated data displays the values accordingly.
The **Blank percentage** field	Determines the frequency of blank names in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the names in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percent**	Determines the proportion of the generated names when	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the

UI element	Description	Default feature	Action
age field	you do not select the **Random** option.		**Percentage** field to set the percentage of names to be generated. For example, if you enter `50`, the generated data will display the names column with a 50% occurrence rate.
The **Title** option	Determines whether the generated names include the title.	The **Title** option is selected.	• Do not perform any action if you want the generated names to include the title. • Clear the **Allowed** option if you want to exclude the title from the generated names.
The **First Name** option	Determines whether the generated names include the first name.	The **First Name** option is selected.	• Do not perform any action if you want the generated names to include the first name. • Clear the **Allowed** option if you want to exclude the first name from the generated names.
The **Last Name** option	Determines whether the generated names include the last name.	The **Last Name** option is selected.	• Do not perform any action if you want the generated names to include the last name. • Clear the **Allowed** option if you want to exclude the last name from the generated names.
The **Add new configuration** tab	You can add additional name configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for names with titles and another configuration for names without titles. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		Random option is not selected. • The selected options from the previous configuration remain selected, and the unselected options remain unselected for the following elements: ◦ Title ◦ First Name ◦ Last Name	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Name** generator is complete, you can use the **Name** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Name** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Name** generator should be equal to `100`.

Parameters of the Number generator

After you add the Number generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Number generator of a specific field in the Data definition in the Edit branch, the unique parameters of the Number generator that contains the existing configuration details for that field are displayed in the **Number** dialog.

The following table provides the list of UI elements of the **Number** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	**Description**	**Default feature**	**Action**
The **Generator** field	Displays the name of the selected generator, that is, **Number**.	The name is not editable.	NA
The **Distribution** field	Determines if the numbers are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the numbers, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the numbers to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the numbers using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains numbers with 2 decimal values and `70%` to another configuration that contains numbers with no decimal values, then the number column of the generated data displays the values accordingly.

UI element	Description	Default feature	Action
			The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique numbers are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated numbers to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique numbers with no duplicates. This will prevent any duplicate numbers from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank numbers in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the numbers in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated numbers when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of numbers to be generated. For example, if you enter `50`, the generated data will display the number column with a 50% occurrence rate.

UI element	Description	Default feature	Action
The **Numbers** section	Determines either the range of numbers or the number of digits that appear in the generated data. You can select either the **Range** or **# of Digits** button and then enter the corresponding values in the **Min** and **Max** fields.	The **# of Digits** button is selected with a minimum digit of **1** and a maximum digit of **10**.	• Enter numeric values in the **Min** and **Max** fields to set the minimum and maximum number of digits respectively. The **# of Digits** button is selected as the default feature. • Click the **Range** button to switch to range-based number generation and then enter numeric values in the **Min** and **Max** fields to set the minimum and maximum range of numbers.
The **Decimal places** section	Determines the range of decimal places that are displayed in the generated numbers.	The **Min** and **Max** fields in the section are blank.	Enter numeric values in the **Min** and **Max** fields to set the minimum and maximum number of decimal places, respectively, in the generated numbers.
The **Add new configuration** tab	You can add additional configurations for numbers with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage**	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for numbers with fixed decimal places and another configuration with no decimal places. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		field is editable when the **Random** option is not selected. • The fields or options in the following sections display the same values that were provided in the previous configuration: ◦ Numbers ◦ Decimal places	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Number** generator is complete, you can use the **Number** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close	NA	NA	Click the icon to exit the **Number** generator dialog.

UI element	Description	Default feature	Action
icon			

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Number** generator should be equal to `100`.

Parameters of the Phone generator

After you add the Phone generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Phone generator of a specific field in the Data definition in the edit branch, the unique parameters of the Phone generator that contains the existing configuration details for that field are displayed in the **Phone** dialog.

The following table provides the list of UI elements of the **Phone** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Phone**.	The name is not editable.	NA
The **Distribution** field	Determines if the phone numbers are randomly generated in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the phone numbers, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the phone numbers to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the phone numbers using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that

UI element	Description	Default feature	Action
			contains a specific pattern with the UK as the country and `70%` to another configuration that contains another pattern with France as the country, then the column of the phone number of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique phone numbers are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated phone numbers to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique phone numbers with no duplicates. This will prevent any duplicate phone numbers from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank phone numbers in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the phone numbers in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percent**	Determines the proportion of the generated phone numbers when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of phone numbers to be generated.

UI element	Description	Default feature	Action
age field			For example, if you enter `50`, the generated data will display the phone numbers column with a 50% occurrence rate.
The **Format** list	Determines the desired format for the generated phone numbers.	NA	Select a specific format from the list.
The **Country** list	Determines the country for which you want to generate phone numbers. <Not sure why this list is provided. Selecting or not selecting from this list has no changes in the generated data - Need to confirm with the team>	NA	Select a specific country name from the list.
The **Add new configuration** tab	You can add additional phone number configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable.	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for colors with a fixed distribution, and another configuration for shapes with a random distribution. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		• The **Percentage** field is editable when the **Random** option is not selected. • The **Format** and **Country** fields display the same values that were provided in the previous configuration.	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Phone** generator is complete, you can use the **Phone** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.

UI element	Description	Default feature	Action
The close icon	NA	NA	Click the icon to exit the **Phone** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Phone** generator should be equal to `100`.

Parameters of the Regex generator

After you add the Regex generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Regex generator of a specific field in the Data definition in the edit branch, the unique parameters of the Regex generator that contains the existing configuration details for that field are displayed in the **Regex** dialog.

The following table provides the list of UI elements of the **Regex** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Regex**.	The name is not editable.	NA
The **Distribution** field	Determines if the Regex values are randomly generated in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the Regex values, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the Regex values to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the Regex values using the **Percentage** field.

UI element	Description	Default feature	Action
			For example, if you set the percentage distribution of `30%` to a configuration that contains Regex values of ten numeric values and `70%` to another configuration that contains Regex values of five alphabets, then the Regex column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique Regex values are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated Regex values to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique Regex values with no duplicates. This will prevent any duplicate Regex values from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank Regex values in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the Regex values in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated Regex values when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of the Regex values to be generated.

UI element	Description	Default feature	Action
			For example, if you enter `50`, the generated data will display the column of the Regex values with a 50% occurrence rate.
The **Regex** field	Determines the custom regular expression pattern to generate data that matches the given pattern.	Displays **[a-z]{4}**.	• Edit the default Regex pattern and enter the desired custom Regex pattern. • Perform the following actions to use the helper, if you are not sure of the required Regex format: ◦ Click the **Helper** option. The **Regex helper** dialog appears. ◦ Enter the sample texts in the fields provided, and then click the **Create regex** option. The Regex format is displayed in the **Regex generated** field. ◦ Click **Save** to close the dialog and display the Regex value in the **Regex** field of the generator dialog.
The **Add new configuration** tab	You can add additional configurations of the Regex values with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the **Random** option is not selected. • The **Regex** fields display	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration that contains ten numerals, and another configuration that contains five alphabets. You can similarly customize the values, distribution, and percentage as required. You can click the delete icon to delete any additional configuration that you do not need.

UI element	Description	Default feature	Action
		the same values that were provided in the previous configuration.	
The **Save to catalog** option	After the customization of the **Regex** generator is complete, you can use the **Regex** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Regex** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Regex** generator should be equal to `100`.

Parameters of the String generator

After you add the String generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the String generator of a specific field in the Data definition in the Edit branch, the unique parameters of the String generator that contains the existing configuration details for that field are displayed in the **String** dialog.

The following table provides the list of UI elements of the **String** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **String**.	The name is not editable.	NA
The **Distribution** field	Determines if the strings are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the strings, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the strings to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the strings using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains strings with special characters and `70%` to another configuration that contains strings with no special characters, then the string column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique strings are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated strings to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique strings with no duplicates. This will prevent any duplicate strings from appearing in the generated data.

UI element	Description	Default feature	Action
The **Blank percentage** field	Determines the frequency of blank strings in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the strings in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated strings when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of strings to be generated. For example, if you enter `50`, the generated data will display the string column with a 50% occurrence rate.
The **Minimum characters** field	Determines the minimum number of digits for the string in the generated data.	Displays `10`.	Edit the default number and enter the custom minimum value, if required.
The **Maximum characters** field	Determines the maximum number of digits for the string in the generated data.	Displays `1,000`.	Edit the default number and enter the custom maximum value, if required.
The **Include special characters** option	Determines whether special characters must be included in the string.	The option is not selected.	Select the option if you want to include special characters in the string.

UI element	Description	Default feature	Action
The **Include digits** option	Determines whether digits must be included in the string.	The option is not selected.	Select the option if you want to include digits in the string.
The **Add new configuration** tab	You can add additional string configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for strings with special characters and another configuration for strings with no special characters. You can similarly customize the values, distribution, and percentage as required.

UI element	Description	Default feature	Action
		Random option is not selected. • The fields or options in the following sections display the same values that were provided in the previous configuration: ◦ Minimum characters ◦ Maximum characters ◦ Include special characters ◦ Include digits	**Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **String** generator is complete, you can use the **String** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.

UI element	Description	Default feature	Action
The close icon	NA	NA	Click the icon to exit the **String** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **String** generator should be equal to `100`.

Parameters of the Text generator

After you add the Text generator in a field of a Data definition, you can customize the existing configurations of the field.

When you click the Text generator of a specific field in the Data definition in the edit branch, the unique parameters of the Text generator that contains the existing configuration details for that field are displayed in the **Text** dialog.

The following table provides the list of UI elements of the **Text** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **Text**.	The name is not editable.	NA
The **Distribution** field	Determines if the texts are randomly generated or not in the corresponding column of the test data. Contains the **Random** option.	The **Random** option is selected.	• Do not perform any action if you want the texts, when generated in the test data, to follow a random distribution. • Clear the **Random** option if you want the texts to follow a fixed distribution and to be non-random. When you clear the option, the **Percentage** fields of all the existing configurations become editable. You can set a fixed distribution for the enumerator values using the **Percentage** field. For example, if you set the percentage distribution of `30%` to a configuration that contains words with a count of 10 and `70%` to another configuration that

UI element	Description	Default feature	Action
			contains words with a count of 5, then the text column of the generated data displays the values accordingly. The percentage for each configuration is automatically rebalanced preserving the allocation in the existing configurations, when you add a configuration subsequently.
The **Duplicates** field	Determines if duplicate or unique texts are present in the generated data. Contains the **Allowed** option.	The **Allowed** option is selected.	• Do not perform any action if you want the generated texts to include duplicate entries. • Clear the **Allowed** option if you want to ensure unique texts with no duplicates. This will prevent any duplicate texts from appearing in the generated data.
The **Blank percentage** field	Determines the frequency of blank texts in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the texts in the generated data will be blank.
The **Name** field	Displays the custom name of the selected configuration.	Displays `Default` and is editable.	Enter an identifiable name to the selected configuration, if required.
The **Percentage** field	Determines the proportion of the generated texts when you do not select the **Random** option.	Editable when **Random** is not selected.	If you did not select the **Random** option for distribution, enter a number from `0` to `100` in the **Percentage** field to set the percentage of texts to be generated. For example, if you enter `50`, the generated data will display the text column with a 50% occurrence rate.
The **Text**	Determines the desired text type for the generated texts.	The **Words** option is selected.	Select a specific text type from the list. The available options are as follows:

UI element	Description	Default feature	Action
type list			• Words • Sentences • Paragraphs
The **Count** field	Determines the count with respect to the selected text type.	Displays `10`.	Edit the default count to enter the custom count of the selected text type.
The **Add new configuration** tab	You can add additional text configurations with specific components and settings, if required.	• The **Name** field displays `Configuration-1` and is editable. • The **Percentage** field is editable when the **Random** option is not selected. • The **Text type** and **Count** lists display the same values that were provided in the previous configuration.	Click the tab and then add the required components for the additional configuration. For example, you can have one configuration for words with a count of 10, and another configuration for words with a count of 5. You can similarly customize the values, distribution, and percentage as required. **Note:** You can click the delete icon to delete any additional configuration that you do not need.
The **Save to catalog** option	After the customization of the **Text** generator is complete, you can use the **Text** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon. You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.

UI element	Description	Default feature	Action
The preview icon	The preview icon is available for each configuration of a generator.	NA	Click the preview icon to view the sample test data for the selected configuration of a generator.
The close icon	NA	NA	Click the icon to exit the **Text** generator dialog.

Note: The total percentage displayed in the **Percentage** fields of all the configurations in the **Text** generator should be equal to `100`.

Parameters of the UUID generator

After you add the UUID (Universal Unique Identifier) generator in a field of a data definition, you can customize the existing configurations of the field.

When you click the UUID generator of a specific field in the Data definition in the edit branch, the unique parameters of the UUID generator that contains the existing configuration details for that field are displayed in the **UUID** dialog.

The following table provides the list of UI elements of the **UUID** dialog with their default parameters, and the actions that you can perform in the dialog to customize the parameters for the selected field:

UI element	Description	Default feature	Action
The **Generator** field	Displays the name of the selected generator, that is, **UUID**.	The name is not editable.	NA
The **Blank percentage** field	Determines the frequency of the unique identifiers in the generated data.	Displays `0` and is editable.	Enter a number from `0` to `100`. For example, if you enter `10`, approximately 10% of the unique identifiers in the generated data will be blank.

UI element	Description	Default feature	Action
The **Save to catalog** option	After the customization of the **UUID** generator is complete, you can use the **UUID** generator as the base generator to create a new custom generator.	NA	Click the **Save to catalog** icon . You can reuse the same configuration at a later time in different scenarios without having to set it up again from the scratch. See Creating custom generators and categories from Data definitions on page 925.
The close icon	NA	NA	Click the icon to exit the **UUID** generator dialog.

Management of custom generators

Test provides flexibility to create, modify, and delete custom generators. You can access and modify custom generators to suit your specific data requirements in the **Catalog** page.

You can use the built-in Basic generators as the base to create custom generators that closely mimic the real-world data patterns and distributions. You can customize the parameters of the Base generators and save them as new custom generators to use them for future uses.

The creation, modification, and deletion of custom generators are restricted to the edit branch only. Also, only those members with either owner or tester roles within the project are authorized to create, modify, or delete these generators. This security measure can help to maintain data integrity and consistency while preventing unauthorized changes in Test. After all the modifications are published, other project members can view the changes and updated assets.

Creating a custom generator

You can create custom generators in addition to the existing generators in the Test catalog. You can customize the existing generators and save them as new custom generators to help you create complex real-world scenarios for synthetic data generation. Additionally, custom generators enable the generation of data for specialized fields or domains that may not be readily available in standard datasets.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Read information about the built-in basic generators. See Basic generators on page 874.
- Read about the parameters of the basic generators. See Basic generators on page 874.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Catalog**.
   The **Catalog** page is displayed.
4. Select the branch where you want to store the data generator from the **Branch** list.
5. Perform one of the following actions to open the **Add new generator** dialog:
   - Perform the following actions to use the base generator:
     a. Click a generator from the **Basic** category that you want to use as the base generator.

        The *Generator* dialog is displayed.
     b. Click the **Customize** icon .
   - Click the icon in the **Catalog** page, and then click **Add new generator**.

   Based on the selected **Branch**, the following dialog is displayed:
   - **Edit Branch**: If you selected a branch other than the Edit branch.
   - **Add new generator**: If you selected the Edit branch.
6. Perform one of the following actions in the **Edit branch** dialog, if you selected a branch other than the Edit branch:

Action	Steps	Result
Select an Edit branch	a. Select an Edit branch from the **Select branch** list if the Edit branch already exists. b. Click **Ok**.	The **Add new generator** dialog is displayed.
Create an Edit branch	a. Select **Create new branch**. b. Enter a name for the Edit branch. c. Click **Save**.	The **Add new generator** dialog is displayed.

7. Enter a unique name for the generator in the **Name** field of the **Add new generator** dialog.
8. Select a built-in generator from the **Base generator** list.
   Test displays only the built-in Basic generators as the base generator.
9. Perform one of the following actions to select the category of the new generator in the **Category** list:
   - To select an existing category, go to step 10 on page 924.
   - To add a new category, go to step 11 on page 925.
10. Perform the following steps to select an existing category:

a. Select an existing category, if any, that is displayed in the **Category** list.

Note: You cannot create a new generator in the **Basic** category. Therefore, the **Basic** category is not displayed in the **Category** list.

b. Click **Create**.

The new generator is added under the existing category of the **Catalog** page.

11. Perform the following steps to add a new category:
    a. Click **Add new category** in the **Category** list, and then click **Next**.

    The **Add new category** dialog displays a new set of fields to capture more details about the new category.

    b. Enter a unique name in the **Category name** field where the new generator will be saved in the catalog of Test.
    c. Select a color from the available range of colors so that you can identify the new category easily.
    d. Select the location to create the new category in the selected folder.

    For example, if you entered `MyFolder/MyCategory` in the **Category name** field, and then selected `Location` as the location to create the category in the folder, then the category is created under the `Location/MyFolder/MyCategory` path.

    e. Click **Create**.

    The new generator is added in the newly created category and is displayed in the **Catalog** page.

Results

You have created a custom generator in addition to the existing generators of the Test catalog.

What to do next

You can perform any of the following tasks:

- Publish the custom generators to the project repository so that other members of the project can use the custom generator. See Publishing all changes in an Edit branch on page 1023.
- Modify the parameters of custom generators. See Modifying custom generators on page 927.
- Delete custom generators. See Deleting custom generators on page 929.

Creating custom generators and categories from Data definitions

You can create custom generators and categories from existing Data definitions in Test . After you add an existing generator in a field of a Data definition, you can customize the generator parameters that are displayed for the field. You can then save the customized parameters in the Data fabrication catalog as a new generator. You can also save the new generator either in an existing category or save in a new category.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.
- Read about the parameters of the basic generators. See Basic generators on page 874.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Open a Data definition in the Edit branch.
5. Click a generator in the **Generator** column of a field where you want to customize the configuration.
6. Perform any modification in the *Generator* dialog to customize the existing configuration of the selected field.
7. Click **Save to catalog** to save the customized parameters in the catalog of the Data fabrication feature as a new generator.
   The **Add new generator** dialog is displayed.
8. Enter a unique name for the new generator in the **Name** field.
   Test uses the existing generator as the base generator. Therefore, the **Base generator** list is not editable.
9. Perform one of the following actions to select the category of the new generator:
   - To select an existing category, go to step 10 on page 926.
   - To add a new category, go to step 11 on page 926.
10. Perform the following steps to select an existing category:
    a. Select an existing category that is displayed in the **Category** list.
    b. Click **Create**.

       The new generator is added in the existing category and is displayed in the **Catalog** panel of the data definition.
11. Perform the following steps to add a new category:
    a. Click **Add new category** in the **Category** list, and then click **Next**.

       The **Add new generator** dialog displays a new set of fields to capture more details about the new category.
    b. Enter a unique name in the **Category name** field where the new generator will be saved in the catalog of Test.
    c. Select a color from the available range of colors so that you can identify the new category easily.
    d. Select the location to create the new category in the selected folder.

       For example, if you entered `MyFolder/MyCategory` in the **Category name** field, and then selected `Location` as the location to create the category in the folder, then the category is created under the `Location/MyFolder/MyCategory` path.

e. Click **Create**.

The new generator is added in the newly created category and is displayed in the **Catalog** panel of the data definition.

Results

You have created a custom generator using an existing generator from a Data definition. Also, you have learned to create a new category and save the custom generator under the category.

What to do next

You can save and publish the Data definition to the Git repository so that other members of the project can use the Data definition. See Publishing all changes in an Edit branch on page 1023.

Modifying custom generators

You can modify the parameters of custom generators from the Catalog page of Test . You can make modifications to precisely align the test data that uses the custom generators with the desired dataset.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a custom generator. See Creating a custom generator on page 923.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Catalog**.
   The **Catalog** page is displayed.
4. Select the branch that contains the custom generator for modification from the **Branch** list.
5. Select the custom generator for modification.

   The selected *Generator* dialog that contains the following tabs is displayed:

Element	Description
The **Configuration** tab	Displays all the existing parameters of the selected custom generator.
The **Details** tab	Provides following details about the selected custom generator and its associated Git details: ◦ Name of the branch that contains the generator ◦ Description for the generator, if any

Element	Description
	◦ Git-related details for the generator as follows: ▪ Asset ID: The ID uniquely identifies the generator. You also have the option to copy the ID for easy reference or use. ▪ Repo: The repository name and path where the generator is stored. ▪ Path: The exact location of the generator within the repository. ▪ Commit: The Git commit message, the name of the member who performed the changes, and the date and time of the commit. ▪ The copy button: You can click the button to copy the complete SHA commit ID for the generator. ▪ The commit ID button: You can click the button to view the changes that were made in the commit directly within Git. ▪ The browse button: You can click the button to view the specific location in the Git history where the commit was performed for the generator.
The **Usage** tab	Displays a list of all the Data definitions along with their location in the project that currently use the selected generator.

6. Perform one of the following actions in the **Generator** dialog:
   ◦ Perform the required modifications to the existing configurations in the **Configuration** tab, if you are in the edit branch.
   ◦ Perform the following actions, if you are in a branch other than the Edit branch:

      a. Click the **Edit** icon .

         The **Edit branch** dialog is displayed.

      b. Perform one of the following actions in the dialog:

Action	Steps	Result
Select an Edit branch	i. Select an Edit branch from the **Select branch** list if the Edit branch already exists. ii. Click **Ok**.	The **Catalog** page is displayed in the Edit branch. You can open the custom generator and perform modifications to the existing generator configurations in the **Configuration** tab of the *Generator* dialog.
Create an Edit branch	i. Select **Create new branch**. ii. Enter a name for the Edit branch. iii. Click **Save**.	The **Catalog** page is displayed in the Edit branch. You can open the custom generator and perform modifications to

Action	Steps	Result
		the existing generator configurations in the **Configuration** tab of the *Generator* dialog.

7. Click the save icon in the *Generator* dialog to save the modified custom generator.

Note: If you want to continue using the modified generator to generate test data without publishing it, you must save the changes. However, if you want to collaborate with other members of your project, you must publish the changes.

Results

You have modified the parameters of a custom generator.

What to do next

You can perform any of the following tasks:

- Publish the custom generators to the project repository so that other members of the project can use the custom generator. See Publishing all changes in an Edit branch on page 1023.
- Delete custom generators. See Deleting custom generators on page 929.

Deleting custom generators

You can delete custom generators to remove them when custom generators are outdated or no longer relevant to the current project. Additionally, when custom generators contain errors or inaccuracies that can lead to misleading or incorrect fabricated data, then you might need to remove them. This ensures that the project remains clutter-free, optimizes the performance of Test , and reduces storage requirements.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a custom generator. See Creating a custom generator on page 923.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Catalog**.
   The **Catalog** page is displayed.

4. Select the branch that contains the custom generator to delete from the **Branch** list.
5. Select the custom generator for deletion.
   The selected *Generator* dialog is displayed.
6. Click the **Delete** icon .

Results

You deleted a custom generator from your project.

What to do next

You can publish the changes performed to the custom generator (that is, deletion of the custom generator) to the Git repository so that other members of the project do not see the deleted custom generator. See Publishing all changes in an Edit branch on page 1023.

Management of custom categories

Test provides flexibility to create and delete custom categories in the **Catalog** page. The **Catalog** page displays both the basic and custom categories of generators in a project.

The basic category consists of all the built-in basic generators to simplify the access when you work with Data definitions. When you create custom generators that are tailored to specific use cases, then you can save them under the custom categories and organize them in a way that aligns with the project requirements. You can locate and use the custom generators when you need.

The creation and deletion of custom categories are restricted to the Edit branch only. Also, only those members with either owner or tester roles within the project are authorized to create or delete these categories. This security measure can help to maintain data integrity and consistency while preventing unauthorized changes in Test. After all the modifications are published, other project members can view the changes and updated assets.

Creating a new custom category

You can create custom categories in addition to the existing Basic category in the Test catalog. You can save the custom generators under various custom categories with unique names.

Before you begin

You must be a member of the project with the **Owner** or **Tester** role.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Catalog**.
   The **Catalog** page is displayed.
4. Select the branch where you want to store the custom category from the **Branch** list.

5. Click the icon in the **Catalog** page, and then click **Add new category**.
   Based on the selected **Branch**, the following dialog is displayed:
   - **Edit Branch**: If you selected a branch other than the Edit branch.
   - **Add new category**: If you selected the Edit branch.
6. Perform one of the following actions in the **Edit branch** dialog, if you selected a branch other than the Edit branch:

Action	Steps	Result
Select an Edit branch	a. Select an Edit branch from the **Select branch** list if the Edit branch already exists. b. Click **Ok**.	The **Add new category** dialog is displayed.
Create an Edit branch	a. Select **Create new branch**. b. Enter a name for the Edit branch. c. Click **Save**.	The **Add new category** dialog is displayed.

7. Perform the following steps in the **Add new category** dialog:
   a. Enter a unique name in the **Category name** field.
   b. Select a color from the available range of colors so that you can identify the new category easily.
   c. Select the location to create the new category in the selected folder.

      For example, if you entered `MyFolder/MyCategory` in the **Category name** field, and then selected `Location` as the location to create the category in the folder, then the category is created under the `Location/MyFolder/MyCategory` path.

   d. Click **Create**.

   The new category is added in the **Catalog** page.

Results

You created a custom category in the **Catalog** page.

What to do next

You can perform the following tasks:

- Add custom generators to the new category. See Creating a custom generator on page 923.
- Publish the changes to the Git repository so that other members of the project can use the new custom category. See Publishing all changes in an Edit branch on page 1023.

Deleting custom categories

You can delete custom categories to remove them when custom categories are outdated or no longer relevant to the current project. Additionally, when custom categories contain inaccuracies that can lead to misleading or incorrect fabricated data,

then you might need to remove them. This ensures that the project remains clutter-free, optimizes the performance of Test , and reduces storage requirements.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a custom category. See Creating a new custom category on page 930.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Catalog**.
   The **Catalog** page is displayed.
4. Select the branch that contains the custom category that you want to delete from the **Branch** list.
5. Click the **Delete** icon beside the category tab to delete the custom category.
   Based on the selected **Branch**, the following dialog is displayed:
   - **Edit Branch**: If you selected a branch other than the Edit branch.
   - **Delete category**: If you selected the Edit branch.
6. Perform one of the following actions in the **Edit branch** dialog, if you selected a branch other than the Edit branch:

Action	Steps	Result
Select an Edit branch	◦ Select an Edit branch from the **Select branch** list if the Edit branch already exists. ◦ Click **Ok**.	The **Delete category** dialog is displayed.
Create an Edit branch	◦ Select **Create new branch**. ◦ Enter a name for the Edit branch. ◦ Click **Save**.	The **Delete category** dialog is displayed.

7. Click **Delete** in the **Delete category** dialog.

Results

You deleted a custom category from your project.

What to do next

You can publish the changes performed to the custom category (that is, deletion of the custom category) to the Git repository so that other members of the project do not see the deleted category. See Publishing all changes in an Edit branch on page 1023.

Data management

Effective data management is at the core of robust application testing. In Test , you can manage test data by using the **Data** tab, which provides a centralized workspace for handling various types of data. Whether you work with fabricated data, retrieve information from databases, or define structured schemas, this interface supports both creating new data and reusing existing assets across your testing requirements.

The **Data** tab contains the following core components:

- **Data Definition**: Data definitions represent the data structures that are composed of one or more generators. Test provides you the interface to create and manage data definitions so that you can design data structures that closely resemble the real-world scenarios. You can configure generators, define rules, set restrictions and distributions if required, and generate test data using a data definition. You can generate realistic and diverse test data for comprehensive testing scenarios. See Management of data definition on page 979 and Catalog management on page 874.
- **Dataset**: Datasets provide tests with variable data during a test run. The test that uses a dataset at the run time replaces a value in the recorded test with variable test data that is stored in the dataset. In Test, you can create a dataset and use its values during the run time to test various scenarios. See Management of datasets on page 954.
- **Database Query**: A database query is a request for data or information from a database. You can run queries on integrated databases to examine existing data structures and retrieve records. Then, use the information to guide the design of schemas or enhance your data definitions. See Management of database query on page 947.
- **Schema**: Schemas define how data objects relate to each other. In Test Hub, schemas provide a visual and configurable way to design relational data environments that closely mirror real-world systems. See Management of schemas on page 999.

Generating fabricated test data on page 1012

Prerequisites for working with datasets and data definitions

You can find information about the tasks that you need to perform before you work with datasets and data definitions in Test .

Management of classifications

You can create a classification and provide access only for the required members of a project in Test. You can add the encrypted datasets, restricted database connections, or API secrets that you create in a project to the classification and

ensure that it can be accessed and used only by the members who have access to the classification. See Management of classifications on page 934.

Management of database connections

You can import the data that you have in an external database that can be used to create the test assets such as datasets and Data definitions in Test.

You can establish and manage connections with the following external databases in **Test Hub**:

- Oracle
- PostgreSQL
- IBM DB2

See Management of database connections on page 938.

Management of database queries

You can create a database query to import the data that is present in an external database, after you establish a connection with the external database. You can query the required data from a database when you create a database query to import the useful data present in your existing databases to create the test assets. See Management of database query on page 947.

Management of classifications

You can find information about creating, editing, deleting, and granting access to a classification in Test .

You can find the following information about managing the classifications:

- Creating a classification on page 934
- Editing a classification on page 935
- Deleting a classification on page 935
- Granting access to classification on page 936

Creating a classification

As a project *Project Owner* or *Tester*, you must create a classification to organize encrypted datasets, external database connections, and API secrets so that project members can use them efficiently..

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created a project in Test. See Managing DevOps Test projects on page 1724.
- Configured the repository that contains the test assets in your project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click **Create Classification** and enter a name for the classification.
5. Click **Create**.
   The classification is added to the **Classification** list.

What to do next

You can grant access to other project members to use the encrypted dataset. See Granting access to classification on page 936.

Editing a classification

You might want to change the name of a classification that you created, you can do so by editing the classification.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created a classification. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification that you want to edit from the list under **Classification**.
5. Click the **Edit** icon in line with the classification.
   The **Edit classification** dialog is displayed.
6. Edit the name of the classification, and then click **Save**.

Results

You edited the name for a classification in your project.

Deleting a classification

After you create a classification, you can delete a classification when it is not required in your test environment.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created at least one dataset and encrypted the dataset with an encryption key. See Dataset encryption on page 969.
- Created at least two classifications. See Creating a classification on page 934.

About this task

You can delete a classification from your project any time after you create a classification. For example, you might want to delete the classification if the classification that was created earlier is not required.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification that you want to delete from the list under **Classification**.

   Note: Before deleting a classification associated with encrypted datasets, you must remove or move the encrypted datasets under it to another classification so that the delete icon is enabled.

5. Click the **Delete** icon .
   The **Delete Classification** dialog is displayed.
6. Click **Delete** to confirm the deletion of the classification.

Results

You deleted a classification.

Granting access to classification

You can grant or revoke access to the classification in your project to individual members with different roles or all members with a specific role. Without access to the classification, members cannot view, create, edit, delete, or use the classification.

Before you begin

You must be a *Project Owner* and have completed the following tasks:

- Created a project in Test. See Managing DevOps Test projects on page 1724.
- Added one or more users to your project. See Adding users to a project on page 1732.
- Created at least one classification. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification in the list under **Classification** for which you want to grant the access.
5. Choose any of the following methods to grant access to a member:
   Choose from:

   - Select the checkbox for the specific role under **Grant Read Only Access to roles** to grant read-only access to the members of a specific role. For example, if you select **Tester** then all members in the project with a tester role are granted read-only access to the selected classification. You can select any role or all the roles listed.
   - To grant read/write access to specific members, perform the following steps:
     a. Click **Add Members** under **Members with Read/Write Access**.

        The **Additional Members** dialog is displayed.

     b. Enter the name or email ID to search the user or navigate through the list and select the member you want to grant access. You can select multiple members in the list.

        Important:

        Irrespective of the role that the member (**Owner**, **Tester**, or **Viewer**) was assigned in the project, access to the classification has to be specifically granted to the members from the **Security** page.

     c. Click **Add Members.**

        You granted read/write access to the added members.
6. Choose any of the following methods to revoke access to a member:
   Choose from:

- Clear the checkbox for the specific role under **Grant Read Only Access to roles,** to revoke read-only access to the members of a specific role. For example, if you clear the **Tester** checkbox then access for all members in the project with a tester role is revoked for the selected classification. You can select any role or all the roles listed.
- Click the **Delete** icon in line with the member name that you want to remove the specific members from the **Members with Read/Write Access** list.

Notes:

- Any member with access to the classification can remove access to other members specifically added or of all members with a specific role.
- Members with access to the classification can remove themselves from the access list provided that there is at least one member in the list. After removing themselves, members cannot add themselves back to the access list and must be added by any of the other members in the list.

Results

You have granted or revoked the classification access to project members.

Management of database connections

You can add a database connection to a project and import the data from an external database in Test .

You can also restrict the database connection when you add it to a project and then add it to a classification to grant or restrict access for other members of the project. After you add a database connection you can create the database query that can be used to create test assets.

You can find the following information about adding the database connection and managing them in Test:

- Adding a database connection on page 938
- Adding a database connection to a classification on page 941
- Removing a database connection from a classification on page 942
- Editing a database connection on page 943
- Duplicating a database connection on page 944
- Deleting a database connection on page 946

Adding a database connection

You can add a database connection to your project in Test to import the data from an external database and create the test assets. You can restrict the project members from using this database connection by adding it to a Classification and providing permission only to the required members.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Ensured that you have a valid Java Database Connectivity (JDBC) URL and credentials for the database.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Infrastructure > Database Connections**.
   Result
   The **Database Connections** page is displayed.
4. Click **New Connection**.
   Result
   The **New Connection** dialog is displayed.
5. Perform the following actions in the **Details** tab:

   a. Enter a name for the database connection in the **Name** field.

   b. Select the database from the **Driver** list.
      The following are the supported databases:
      - Oracle
      - PostgreSQL
      - IBM DB2

   c. Enter the URL for the database in the **URL** field.

   d. Enter the username for the database in the **Username** field.

   e. Enter the password for the database in the **Password** field.

   f. Enter the schema name for the database in the **Schema** field.

   g. Add a description for the database connection in the **Description** field.

6. Select the **Restrict access using Classifications** checkbox if you want to restrict other members of the project from using this database connection.

   Later you can grant access to the required members by adding the connection to a classification.

   Note: The option, **Restrict access using Classifications** is not selected. This is the default selection.

7. Perform the following steps to add the SSL certificate for encrypting the data exchanged between Test and the database.

a. Click the **SSL** tab.

b. Click **Select File** and browse to the location on your computer where you have the Java Keystore File.

c. Select the file, and then click **Open**.

Result

The selected file name is displayed.

d. Enter the password for the Java Keystore File in the **Password** field.

8. Click **Test** to test the connection with the database.

Result

A message is displayed that confirms the connection with database.

9. Click **Save** to save the database.

A message is displayed that confirms database connection is added.

You can view the following details of the database connection on the **Database Connections** page:

Column header	Description	
Name	Displays the name of the database connection that you added.	
URL	Displays the URL of the database connection that you added.	
User	Displays the name of the user who added the database connection.	
Description	Displays the description that you entered when you created the database connection.	
Actions	or	Click the lock icon to go to the **Security** page. You can grant access to the database connection by adding it to a classification. **Note:** The unlock icon is displayed to indicate that the database connection is not restricted for other members of the project, and they can use database connection to create the test assets.
		Click the edit icon to edit the database connection. See Editing a database connection on page 943.
		Click the duplicate icon to duplicate the database connection. See Duplicating a database connection on page 944.
		Click the delete icon to delete the database connection. See Deleting a database connection on page 946.

Results

You have added a database connection to your project.

What to do next

You can add the database to a classification to provide access to other members of the project, if you have restricted it when you created the database connection. See Adding a database connection to a classification on page 941.

You can create a database query using the database connection that you added to your project. See Creating a database query on page 947.

Adding a database connection to a classification

You can add the database connection to a classification to grant access to the classification for other project members in Test . After the access is provided, they can use the database connection to create the database query and import the data from the database.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one database connection and restricted the access to other members of the project. See Adding a database connection on page 938
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created at least one classification. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   Result
   The **Security** page is displayed.
4. Click a classification for which you want to add the database connection in the list under **Classification**.
5. Click the **Add Connection** icon to select the database that you want to add to the classification.
   Result
   The **Add Connection** dialog is displayed.
6. Click the **Database Connection** field to view the available database connection in the project.
7. Identify and select the database connection that you want to add to the classification.
8. Enter the password that you use to connect to the database in the **Password** field.

Tip: You can click the view icon to view the entered password and ensure that you entered the correct password.

9. Click **Add**.
   Result
   The database connection that is added to the classification is displayed.

Results

You have added a database connection to the classification.

What to do next

You can create a database query by using the database connection that you added to your project. See Creating a database query on page 947.

Removing a database connection from a classification

You can remove a database connection from a classification when you are no longer required to provide access to other members of your project.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one restricted database connection to a classification. See Adding a database connection to a classification on page 941.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   Result
   The **Security** page is displayed.
4. Click a classification in the list under **Classification** from which you want to delete the database connection.
5. Click the **Delete** icon in line with the database connection that you want to delete from the classification.
   Result
   The **Remove database connection** dialog is displayed.

6. Click **Remove**.

Note: Removing the database connection from the classification also removes the password stored in Test for that database. You must enter the password again to gain access to the database connection while adding it to a different classification.

Results

You have removed the database connection from a classification.

Editing a database connection

You can edit the database connection, when you want to change the database details that you added earlier or if you want to update the SSL certificate file.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one database connection. See Adding a database connection on page 938
- Ensured that you have credentials for the database that you want to edit in a Test project.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Infrastructure > Database Connections**.
   Result
   The **Database Connections** page is displayed.
4. Click the Edit icon inline with the database that you want to edit.
   Result
   The **Edit connection** dialog is displayed.
5. Perform the following actions in the **Details** tab:

   a. Edit the details of the connection.

   b. Enter the password for the database in the **Password** field.

   c. Select the **Restrict access using Classifications** checkbox if you want to restrict other members of the project from using this database connection.

Later you can grant access to the required members by adding the connection to a classification.

Note: The option, **Restrict access using Classifications** is not select. This is the default selection.

6. Perform the following steps to change or add the SSL certificate and encrypt the data exchanged through the database.
    a. Click the **SSL** tab.
    b. Click the **x** icon to remove the existing Java Keystore file.
    c. Click **Select File** and browse to the location on your computer where you have the Java Keystore File.
    d. Select the file, and then click **Open**.
    Result
    The selected file name is displayed.
    e. Enter the password for the Java Keystore File in the **Password** field.
7. Click **Test** to test the connection with the database.
    Result
    A message is displayed that confirms the connection with database.
8. Click **Save** to save the database connection.

    A message is displayed that confirms database connection is modified and the edited database connection is displayed on the **Database Connections** page.

Results

You have edited the database connection in your project.

Duplicating a database connection

When you want create a similar database connection with different user credentials, to create the similar database connection and restrict or unrestricted it, or to create a similar database connection by encrypting the data exchanged between Test and database, you can create a new database connection using an existing database connection.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one database connection. See Adding a database connection on page 938.
- Ensured that you have a valid URL and credentials for the database that you want to add or duplicate in a Test project.

About this task

You can duplicate database connection and create a new one in the following scenarios:

- Creating the same database connection with or without restricting the access to other members of the project.
- Adding the same database connection to a different classification which consists of different datasets, secrets and have access to different group of people.
- Adding the same database with different user credentials.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Infrastructure > Database Connections**.
   Result
   The **Database Connections** page is displayed.
4. Click the **Duplicate** icon inline with the database connection that you want to duplicate.
   Result

   The **Duplicate connection** dialog is displayed.

   The value in the **URL** field, and the selections in the **Driver** field and the **Restrict access using Classifications** checkbox are auto-populated with the current values and selections in the database connection that you duplicate.
5. Perform the following actions in the **Details** tab:

   a. Enter a different name for the database connection in the **Name** field.

   b. Enter the username for the database in the **Username** field.

   c. Enter the password for the database in the **Password** field.

   d. Select the **Restrict access using Classifications** checkbox if you want to restrict other members of the project from using this database connection.

      Later you can grant access to the required members by adding the connection to a classification.

      Note: The option, **Restrict access using Classifications** is not select. This is the default selection.
6. Perform the following steps to change or add the SSL certificate for encrypting the data exchanged through the database.

   a. Click the **SSL** tab.

   b. Click the **x** icon to remove the existing Java Keystore file.

   c. Click **Select File** and browse to the location on your computer where you have the Java Keystore File.

d. Select the file, and then click **Open**.
Result
The selected file name is displayed.

e. Enter the password for the Java Keystore File in the **Password** field.

7. Click **Test** to test the connection with the database.
Result
A message is displayed that confirms the connection with database.
8. Click **Save** to save the database connection.
Result

A message is displayed that confirms database connection is added and the new database connection created by using the existing database connection is displayed on the **Database Connections** page.

Results
You have created a new database connection by using the existing database connection in your project.

Deleting a database connection

You can delete the database connection from a project when it is no longer required.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one database connection. See Adding a database connection on page 938.

1. Log in to Test.
The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

The **Overview** page of the project is displayed.

3. Click **Infrastructure > Database Connections**.
Result
The **Database Connections** page is displayed.
4. Click the **Delete** icon inline with the database connection that you want to delete.
Result
The **Delete Connection** dialog is displayed.
5. Click **Ok** to confirm the deletion.
Result
The **Connection deleted successfully** message is displayed.

Results

You have deleted a database connection from your project.

Management of database query

You can find information about creating, editing, duplicating, and deleting the database query in Test .

You can find the following information about creating and managing the database queries:

- Creating a database query on page 947
- Editing a database query on page 949
- Duplicating a database query on page 951
- Deleting a database query on page 952
- Publishing all changes in an Edit branch

Creating a database query

When you have the data that is useful for creating the test assets is stored in a database, you can import the data from the database and create a database Query in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Added at least one database connection. See Adding a database connection on page 938
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Database Query** on the **Test Editor** page.

- Click the **Action Menu** icon and select **Database Query**.
- Right-click the application in the Data navigator panel, select **New > Database Query**.

The **Edit Branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 7 on page 948.

6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

   Result

   The **Create database query** dialog is displayed.
7. In the **Create database query** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a dataset.
   b. Select **Location** from the drop-down list to store the dataset.
   c. Type a name for the database query.
   d. Click **Save**.

   Result

   The database query is created and displayed on the **Data** page. The database query created is listed under the `Database Queries` container within the selected application.
8. Perform the following steps in the **Data** page to select the table and query the data from the database:
   a. Select the database from the **Connection** list.
   b. Select the table in the selected database from the **Table** list.

      Result

      The data from the selected table is displayed.
   c. Select the required column of the table from which you want to import the data.
   d. Click **View** to switch between the **Visual** and **Code** view.

Note: Note: The default view is **Visual** view. In the **Code** view you can type the query to get data from the database.

e. Click the **Preview** icon to view the queried data from the database in tabular format in the bottom window.

f. Click **Save** icon to save the queried data from the database.

Results

You have created a database query in your project.

What to do next

Publish the database query to the Git repository so that other members of the project can use the database query. See Publishing all changes in an Edit branch.

You can create a dataset using the database query. See Creating a dataset by using a database query on page 960

You can create a Data definition using the database query. See Creating a data definition by importing fields from a database query on page 986.

Editing a database query

You can edit the database query when you want to query different data from the database or if you want to query the data from a different database.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created at least one database query. See Creating a database query on page 947.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.

5. Navigate to the **Database Queries** container, then right-click the database query you want to edit and select **Edit**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 950.

6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

7. Perform the following steps on the **Data** page to select a different table or query the different data from the same database or different database:

   a. Select a different table, modify the query, or different connection.

   b. Click **View** to switch between the **Visual** and **Code** view.

      Note: The default view is **Visual** view. In the **Code** view you can type the query to get data from the database.

   c. Click the **Preview** icon to view the queried data from the database in tabular format in the bottom window.

   d. Click the **Save** icon to save the queried data from the database.

Results

You have edited a database query in your project.

What to do next

You can publish the database query to the Git repository so that other members of the project can use the database query. See Publishing all changes in an Edit branch.

Duplicating a database query

You can create a new database query by using the existing database query, when you want the same database query with a different name or only slight modification required in the existing database query.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created at least one database query. See Creating a database query on page 947.

About this task

When you want to create a database query by using the existing database query, you must have an Edit branch. You can create the Edit branch during the creation of the database query. All your dataset resides in the Edit branch until you publish or discard the changes.

After you create a database query using the existing database query, you can either publish your changes to a remote Git repository or you can discard the changes made to the database query. The Edit branch automatically disappears from the **Branch** list as well as from the remote Git repository and sets the global branch to the previously selected branch in the following conditions:

- When you publish changes to the remote Git repository.
- When you discard the changes made in the dataset.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Navigate to the logical folder **Datasets** in the Data navigator, right click the database query that you want to save with a different name, and then click **Save As**.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

7. Enter a different name for the database query in the **Name** field.
8. Select a folder in the **Location** field.
9. Click **Save**.
   Result

   A message is displayed that confirms database query is created.

   The database query is displayed on the **Data** page. The dataset created is listed under the logical folder `Datasets` under the selected physical folder that you selected. The name of the database query is suffixed with the `.dtd.yaml` file extension.
10. Make any required changes to the existing query, and then click **Save** icon to save the queried data from the database.

Results
You have created a database query using the existing database query in your project.

What to do next

You can publish the database query to the Git repository so that other members of the project can use the database query. See Publishing all changes in an Edit branch.

Deleting a database query

You can delete a database query when it is no longer required.

Before you begin
You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created at least one database query. See Creating a database query on page 947.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.

3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.

4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.

5. Perform one of the following actions:
   a. Select the database query to open it on the **Data** page. Click the **Delete** icon .
   b. Right-click the database query you want delete and select **Delete**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 953.

6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

   Result

   The **Delete database query** dialog is displayed.

7. Click **Delete** to confirm the deletion.

   Result

   A message is displayed that confirms database query is deleted.

Results

You have deleted the selected database query from your project repository.

What to do next

You can publish the database query to the Git repository so that other members of the project can use the database query. See Publishing all changes in an Edit branch.

Management of datasets

You can find information about creating datasets in Test , applying a dataset classification, editing datasets, and managing datasets that are in your project repository.

A dataset contains variable data that are used by a test at test run time. You create the datasets and associate them with your tests in the desktop products. You can decide whether you want to use the dataset associated with the test to be used at run time or override that associated dataset with another dataset at run time. You can create datasets in the desktop products itself and select the datasets as overrides in the desktop products.

When you want to run those tests from Test and you want the tests to use a different set of variable data, you can create datasets in Test. You can then select them to override the dataset associated with the tests that are in the project repository.

You can create a dataset in Test by using any of the following methods:

- Creating an empty dataset. See Creating a dataset on page 954.
- Importing data from a CSV file. See Creating a dataset by using a CSV file on page 956.
- Creating a dataset with fabricated data. See Creating a dataset by using a Data definition on page 958.

When you want to edit the data in a dataset, you must open it for editing. See Editing a dataset on page 962.

After you edit the dataset, you must publish the changes, so that the dataset is added to the project repository. See Publishing changes in datasets.

If the data in your dataset contains sensitive information, you can encrypt the dataset columns. See Encrypting a dataset column on page 969.

If a dataset has encrypted columns and you want to view an encrypted dataset, see Viewing an encrypted dataset on page 975.

When you want to remove the encryption for dataset columns, you can decrypt the dataset column. See Decrypting a dataset column on page 971.

You can assign a classification for encrypted datasets. See Managing an encrypted dataset on page 976.

You can change the classification of an encrypted dataset. See Changing classification for an encrypted dataset on page 976.

Creating a dataset

You can create datasets in Test to replace the values of existing dataset with the values of new dataset during a test or schedule run.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Dataset** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Dataset**.
   - Right-click the application in the data navigator panel, select **New > Dataset**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to 7 on page 956.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

Result

The **Create dataset** dialog is displayed.

7. In **Step 1** of the **Create dataset** dialog, perform the following tasks:
    a. Select the **Application** for which you want to create a dataset.
    b. Select **Location** from the drop-down list to store the dataset.
    c. Type a name for the dataset.
    d. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create dataset** dialog, perform the following tasks:
    a. Select **Source** as **Create an Empty dataset**.
    b. Click **Create**.

    Result

    The dataset is displayed on the **Data** page. The dataset created is listed under the logical folder `Datasets` within the selected application.
9. Enter the variable data in the table to match the data that you want to use in tests.
10. Click the **Save** icon to save the dataset.

Results

You created a dataset in your project.

What to do next

You can perform the following tasks:

- Add, modify, or remove data in the dataset. See Editing a dataset on page 962.
- Publish the dataset to the Git repository so that other members of the project can use the dataset. See Publishing changes in datasets.

Creating a dataset by using a Data definition on page 958

Creating a dataset by using a CSV file

When you use variable data that is contained in a CSV file, you can import the data from the CSV file and create a dataset in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Saved a CSV file that contains variable data on your computer.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Dataset** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Dataset**.
   - Right-click the application in the data navigator panel, select **New > Dataset**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 958.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

Result

The **Create dataset** dialog is displayed.

7. In **Step 1** of the **Create dataset** dialog, perform the following tasks:
    a. Select the **Application** for which you want to create a dataset.
    b. Select **Location** from the drop-down list to store the dataset.
    c. Type a name for the dataset.
    d. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create dataset** dialog, perform the following tasks:
    a. Select **Source** as **Import a CSV file**.
    b. Click **Select File** and choose the CSV file that contains variable data to import into the dataset.
    c. **Toggle on** the **First row contains headers** option if your CSV file includes column headers.
    d. Click **Create**.

Results

You have created the dataset by using the CSV file in your project.

What to do next

You can perform the following tasks:

- Add, modify, or remove data in the dataset. See Editing a dataset on page 962.
- Publish the dataset to the Git repository so that other members of the project can use the dataset. See Publishing changes in datasets.

Creating a dataset on page 954

Creating a dataset by using a Data definition on page 958

Creating a dataset by using a Data definition

When you created a Data definition in Test to fabricate test data, you can create a dataset by using the Data definition.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

- Created a data definition. See Creating an empty data definition on page 980.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Dataset** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Dataset**.
   - Right-click the application in the data navigator panel, select **New > Dataset**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 959.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

   Result

   The **Create dataset** dialog is displayed.
7. In **Step 1** of the **Create dataset** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a dataset.
   b. Select **Location** from the drop-down list to store the dataset.

c. Type a name for the dataset.
d. Click **Next** to proceed to Step 2.

8. In **Step 2** of the **Create dataset** dialog, perform the following tasks:
   a. Select **Source** as **Fabricate data**.
   b. Select the Data definition to use from the **Select Data Definition** list.
   c. Enter the number of rows in the **Number of Rows** field.
   d. Enter a seed value in the **Seed** field.
   e. Click the **Fabricate headers** toggle to generate a header row.
   f. Click **Create**.

Results

You have created the dataset by using a Data definition in your project.

What to do next

You can perform the following tasks:

- Add, modify, or remove data in the dataset. See Editing a dataset on page 962.
- Publish the dataset to the Git repository so that other members of the project can use the dataset. See Publishing changes in datasets.

Creating a dataset by using a database query

When you use variable data that is contained in a database, you can create a database query to import the required data from a database and use the data that is present in the database query to create a dataset in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created at least one database query. See Creating a database query on page 947.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Dataset** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Dataset**.
   - Right-click the application in the data navigator panel, select **New > Dataset**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 961.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

   Result

   The **Create dataset** dialog is displayed.
7. In **Step 1** of the **Create dataset** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a dataset.
   b. Select **Location** from the drop-down list to store the dataset.
   c. Type a name for the dataset.
   d. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create dataset** dialog, perform the following tasks:

a. Select **Source** as **Use a Database Query**.
b. Select the database query to use from the **Select Database Query** list.
c. Enter the number of rows in the **Number of Rows** field.
d. Enter a seed value in the **Seed** field.
e. Click **Create**.

Results

You have created the dataset by using a database query in your project.

What to do next

You can perform the following tasks:

- Add, modify, or remove data in the dataset. See Editing a dataset on page 962.
- Publish the dataset to the Git repository so that other members of the project can use the dataset. See Publishing changes in datasets.

Related information

Creating a dataset on page 954

Creating a dataset by using a CSV file on page 956

Editing a dataset

You can add, modify, remove, import, or export data from a dataset.

Before you begin

You must have created a dataset or configured a repository that contains the dataset.

About this task

If you are a project **Owner** or **Tester** in Test , you can perform basic tasks in the datasets by right-clicking any row, column, or cell in the dataset to organize your data in a better way. For example, you can perform tasks such as updating data in a cell, inserting or deleting rows and columns, or renaming column names.

After you edit the dataset, you can save the changes made to the dataset, and then you can publish the dataset to the Git repository. If you save and close the edited dataset, the **Changes** page lists the edited dataset and later you can publish it to the Git repository for other members to use.

When you have a CSV file that has data separated from a character, then you can import that CSV file into the dataset. You can select any of the following separator characters from the **Configure Dataset** window, and the selection can be the separator character that you used in the CSV file:

- Comma
- Semicolon
- Space
- Tab
- Other

Consider that you have the data in the CSV file in the following format:

Name;CCNum
John;1234 5678 1234 5678
Bob;1122 3344 5566 7788
Amy;2233 4455 6677 8899

When you import the CSV file in the dataset, and then select the separator value as **Semicolon**, the data in the dataset is displayed as follows:

	Name	CCNum
1	John	1234 5678 1234 5678
2	Bob	1122 3344 5566 7788
3	Amy	2233 4455 6677 8899

If you want the data in its original format, that is, a semicolon (;) character to separate the data, then you can choose any other separator value from the **Configure Dataset** dialog.

Note: The default separator value is **Comma**.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch that contains your project with the dataset that you want to edit.

   The projects in the selected branch are displayed in the Data navigator panel. The dataset are listed under the folder you created to contain the dataset within a logical folder named `Datasets`.

5. Click the dataset in the data navigator.

   The dataset opens in the right pane.

6. Click **Edit**.

   Alternatively, right-click the datset in the data navigator panel, and then click **Edit**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 8 on page 964.

7. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

     Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

8. Perform the following actions to use the options available for editing:

Options	Actions
Find and Replace	To find: a. Click the **Find and Replace** icon. b. Enter the content that you want to search in the **Find** field. c. Select any or all the following options to find the search content more effectively: ▪ Select the **Case sensitive** icon to search the content that is the exact letter case of the content entered in the **Find** field. ▪ Select the **Match entire cell contents** icon to search for cells that contain only the characters that you have entered in the **Find** field. ▪ Select the **Search using regular expression** icon to search the pattern that matches strings. For example, to search a cell that contains any number between 0 to 9, do the following:

Options	Actions
	i. Enter \d in the **Find** field. ii. Select the **Search using regular expression** checkbox. iii. Click **Find**. d. Click the **Find** icon. If the text is found, the cell containing that text is selected. e. Click the **Find** icon again to find further instances of the search text. To find and replace: a. Click the **Find and Replace** icon. b. Enter the content that you want to search in the **Find** field. c. Enter the content that you want to replace in the **Replace** field. d. Select any or all the following options to find and replace the content more effectively: ▪ Select the **Case sensitive** icon to find the content that is the exact letter case of the content entered in the **Find** field. ▪ Select the **Match entire cell contents** icon to find and replace for cells that contain only the characters that you have entered in the **Find** and **Replace** fields. ▪ Select the **Search using regular expression** icon to find and replace the pattern that matches strings. e. Click the **Replace** icon to replace the individual instances. f. Click the **Replace All** icon to replace every instance of the content throughout the dataset.
Undo	a. Click the **Undo** icon. b. Select the recent changes from the list that you want to undo, and then click the list. The **Undo** option reverts the change you made in the dataset.
Redo	a. Click the **Redo** icon. b. Select the recent changes from the list that you want to redo, and then click the list.
Import	You can import variable data into a dataset from the following sources: ◦ When there is a large amount of data stored in a CSV file. ◦ When you use the data fabrication feature to generate test data. **Importing data from a CSV file**

Options	Actions
	a. Click the **Import** icon . b. Select **Import a CSV file** from the drop-down list. c. Click **Select file** and choose the CSV file that contains variable data to import into the dataset. d. Enable the **First row contains headers** by using the toggle icon if your CSV file contains the header. e. Select one of the following options to append or overwrite data in the dataset: ▪ Enable **Overwrite existing data** by using the toggle icon to add the rows and columns from the beginning of the dataset. ▪ Enable **Append existing data** by using the toggle icon to add rows and columns to the end of the dataset. f. Click **Import**. **Importing data by using data fabrication** a. Click the **Import** icon . b. Select **Fabricate data** from the drop-down list. c. Select a Data definition from the drop-down list. d. Enter the number of rows that you want to generate in the **Number of Rows** field. e. Enter a seed value in the **Seed (optional)** field. f. Enable **Fabricate headers** by using the toggle icon if your schema contains the headers. g. Select one of the following options to append or overwrite data in the dataset: ▪ Enable **Overwrite existing data** by using the toggle icon to add the rows and columns from the beginning of the dataset. ▪ Enable **Append existing data** by using the toggle icon to add rows and columns to the end of the dataset. h. Click **Import**.
Export	You can export variable data from the dataset into a CSV file to reuse in future tests when required. You must have opened a dataset from which you want to export the data.

Options	Actions
	Click the **Export** icon to download the dataset as a CSV file.
Set as current row	During the test run, if you want variable data to be selected from a current row instead of the first row in a dataset, right-click any cell in a row and select **Set as current row**. **When rows are deleted:** If you delete any row between row 1 and the current row, the current row data is taken from the next row. For example, when you set the current row as 6, and then you delete any row between row 1 to row 6, the current row remains at row 6, but the content of row 7 is moved to row 6. **When rows are inserted:** If you insert any new row between row 1 to the current row, the current row data is taken from the previous row. For example, when you set the current row as 6, and then you insert any row between row 1 to row 6, the current row remains at row 6, but the content of row 5 is moved to row 6.
Dataset Configuration	You can configure the dataset by clicking the **Menu** icon, and then selecting **Configure**. In the **Configure Dataset** dialog, you can change the row and column settings and configure the string values in the dataset that contains variable data for tests to use when they run. ◦ Select any of the separator values that you used in the CSV file. The available options are **Comma**, **Semicolon**, **Space**, **Tab**, and **Other**. In the CSV file, if you have any other separator characters other than the available options, then you can select the **Other** option, and then can specify a value. For example, if the data in the CSV file is separated by a character #, then select the **Other** option and enter # in the field. ◦ Configure the following options to change the row and column settings: ▪ **Column header** - Use an up-down control button to increment or decrement the value of the column header. ▪ **Data start point** - Use an up-down control button to increment or decrement the value of the data starting pointer. ▪ **Current row** - Use an up-down control button to increment or decrement the value of the current row. ◦ Configure the following options to change the string values in the dataset:

Options	Actions
	▪ **Treat as null** - Enter a string value that is to be treated as null when running the test. ▪ **Treat as empty** - Enter a string value that is to be treated as empty when running the test. For example, when you run the test and the data *123* in the dataset is to be treated as empty, then you must specify *123* in the **Treat as empty** field. ▪ **Treat empty text as null** - Select this field when you want the dataset that contains any blank cells, and the value of those blank cells to be interpreted as null. ◦ Click **Update** to apply the changes.
Discard	Click the **Menu** icon and select **Discard** to discard the changes made to the dataset.

9. Click the **Save** icon to save the changes made to the dataset or the **Save All** icon in the Data navigator panel to save all changes made to different datasets by using the same Edit branch.

Note: When editing multiple assets (such as datasets, data definitions or schemas) simultaneously, right-click a test asset in the Data page to manage open tabs using the following options:

To...	Do this...
Keep your current file open and close the open files on the right.	Right-click, and then click the **Close Tabs to right** option.
Keep your current file open and close the open files on the left.	Right-click, and then click the **Close Tabs to left** option.
Keep your current file open and close all the other open files.	Right-click, and then click the **Close Others** option.
Close all open file tabs.	Right-click, and then click the **Close All Tabs** option.

10. Click the **Publish** icon to publish the dataset to the Git repository.

Results

You have edited the dataset.

Dataset encryption

Encrypted datasets are useful when you want to run tests that contain confidential information such as a set of passwords or account numbers.

When you run a test in Test that uses an encrypted dataset, then you must provide an encryption key for decrypting the encrypted data in columns so that the data can be used in the test. If the test uses data from the multiple encrypted dataset columns, you must enter the same encryption key for every encrypted dataset column that the test uses.

When you run the test that uses the dataset with the encrypted column, the value of the column is decrypted at a run time. The data in the column is sent as a clear-text string in requests to the server. The actual values of the encrypted dataset variables are not displayed in the test log. The test log displays asterisks for the encrypted dataset variables.

You can use only one encryption key to encrypt data in the columns in any dataset.

You can set the dataset classification (encrypted password) for a dataset. The dataset classification that you set is applied for the dataset if it is saved in different branches of the project repository and you need not set a password for the dataset in each branch. If you want to use different passwords, then you can create a different dataset by cloning the dataset that you want.

Important:

The encryption keys that you use to encrypt data in a dataset are not stored on the server, nor they can be retrieved from the server. Therefore, you must remember to store the encryption keys in a secure location. You must use the same encryption keys to perform the following operations:

- View the encrypted values
- Decrypt data
- Enable the use of the encrypted dataset during test runs

Encrypting a dataset column

To secure test data, you must encrypt datasets in Test . You can encrypt data in the columns of a dataset by using an encryption key. When you run a test that utilizes a dataset with encrypted variables, you must enter the encryption key for the encrypted column that the test uses.

Before you begin

You must have created a dataset. See Creating a dataset on page 954.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

The **Overview** page of the project is displayed.

3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.

4. Select the branch that contains your project with the dataset that you want to edit.

   The projects in the selected branch are displayed in the Data navigator panel. The dataset are listed under the folder you created to contain the dataset within a logical folder named `Datasets`.

5. Click the dataset in the data navigator.

   The dataset opens in the right pane.

6. Click **Edit**.

   Alternatively, right-click the datset in the data navigator panel, and then click **Edit**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 8 on page 964.

7. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

8. Right-click any cell in a column that you want to encrypt and select **Encrypt column data**.
   Result
   The **Encrypt Column** window is displayed.
9. Enter an encryption key in the **Encryption Key** field to encrypt the data in the column.

   Remember: When you have already encrypted other columns in the dataset, you must enter the same encryption key that you used previously. You can use only one encryption key to encrypt columns in a dataset.

   Important:

The encryption keys that you use to encrypt data in a dataset are not stored on the server, nor they can be retrieved from the server. Therefore, you must remember to store the encryption keys in a secure location. You must use the same encryption keys to perform the following operations:

- View the encrypted values
- Decrypt data
- Enable the use of the encrypted dataset during test runs

10. Click **Encrypt Column**.
    Result
    Asterisks are displayed instead of actual data for the encrypted column.
11. Click the **Save** icon to save the changes to the dataset.

Results

You have encrypted the dataset column in your project.

What to do next

You can publish the dataset to the Git repository so that other members of the project can use the dataset by clicking the **Publish** icon. See Publishing changes in datasets.

Decrypting a dataset column

To view the content of an encrypted dataset in Test , you can decrypt the dataset column. Removing encryption from a dataset revokes the protection offered to the test data.

Before you begin

You must have created at least one dataset and encrypted the dataset with an encryption key. See Creating a dataset on page 954 and Encrypting a dataset column on page 969.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch that contains your project with the dataset that you want to edit.

   The projects in the selected branch are displayed in the Data navigator panel. The dataset are listed under the folder you created to contain the dataset within a logical folder named `Datasets`.
5. Click the dataset in the data navigator.

The dataset opens in the right pane.

6. Click **Edit**.

   Alternatively, right-click the datset in the data navigator panel, and then click **Edit**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 8 on page 964.

7. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

8. Right-click encrypted cells that display the contents with asterisks, and then select **Decrypt column data**.
   Result
   The **Decrypt Column** window is displayed.
9. Enter the encryption key that you used to encrypt the data in the column in the **Encryption Key** field.
10. Click **Decrypt Column**.
    Result
    Asterisks are replaced with the actual data in the decrypted column.
11. Click the **Save** icon to save the changes to the dataset.

Results

The encryption is removed from the selected column in the dataset. When you run a test that uses a dataset that contains decrypted data, the variable data is substituted for the original data in the recorded test without prompting for the encryption.

What to do next

You can publish the dataset to the Git repository so that other members of the project can use the dataset by clicking the **Publish** icon. See Publishing changes in datasets.

Viewing a dataset

When test assets includes datasets, you can view the contents of a dataset from Test . The datasets residing in the Git repository are listed in the **Datasets** page.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created or joined a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created at least one dataset and encrypted the dataset with an encryption key. See Creating a dataset on page 954 and Encrypting a dataset column on page 969.
- Created a classification for an encrypted dataset. See Managing an encrypted dataset on page 976.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch that contains your project with the dataset that you want to edit.

   The projects in the selected branch are displayed in the Data navigator panel. The dataset are listed under the folder you created to contain the dataset within a logical folder named `Datasets`.
5. Click the dataset in the data navigator.

   The dataset opens in the right pane.

Results

You have viewed the contents of the dataset.

Deleting a dataset

You can delete the dataset when it is not required in your test environment.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created at least one dataset in your Git repository that you have configured.

About this task

You can delete datasets in Test in the following scenarios:

- Datasets that you created in the desktop clients and that are cloned to the repository in your project on Test.
- Datasets that you created in Test and that are published to the repository in your project.
- Datasets that are in the `.csv` file format.

You cannot delete the following datasets:

- Datasets that you created or edited in Test and that are not published to the repository in your project.
- Datasets that are in the `.sit` file format.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch that contains your project with the datasets that you want to edit.

   The projects in the selected branch are displayed in the Data navigator panel. The datasets are listed under the folder you created to contain the dataset within a logical folder named as `Datasets`.
5. Right-click the dataset in the data navigator, and then click the **Delete** option.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 975.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

◦ Perform the following steps to create the Edit branch:

a. Select **Create new edit branch**.

b. Enter a name for the Edit branch in the **Branch Name** field.

c. Click **Save**.

7. Perform the following steps in the **Delete <Dataset>** dialog that is displayed, where *<Dataset>* displays the name of the selected dataset.

a. Select the option to publish the deletion from the edit branch to the main branch.

b. Click **Delete**.

The selected dataset is deleted and the deletion is published from the edit branch to the main branch.

Results

You deleted a dataset.

Viewing an encrypted dataset

You can use the **Dataset** page to view the contents of an encrypted dataset from Test .

Before you begin

You must have opened the dataset to view the contents.

1. Perform the following steps, if you have created a classification but yet to add the encrypted dataset to it:

a. Find the encrypted dataset that you are interested in, and then right-click it.

b. Click the **Security** option in the menu.
The **Change the classification for the dataset** dialog is displayed.

c. Select a classification from the list and enter the encryption key set for the dataset.

d. Click **Save** to save the classification details.

2. Right-click the encrypted column and click **Show encrypted data**.
You can right-click the decrypted column and select **Hide encrypted data** to encrypt the data again.

Important: The **Show encrypted data** option is available only when you have added the encrypted dataset to the respective classification.

Results

You have viewed the contents of an encrypted dataset.

Changing classification for an encrypted dataset

To move the encrypted dataset from one classification to another dataset in Test , you can change the classification for an encrypted dataset.

Before you begin

You must have created at least two or more classifications. See Creating a classification on page 934.

1. Go to the **Datasets** page and find an encrypted dataset for which you want to change the classification.
2. Click the **Lock** icon from the **Actions** column of a dataset.
3. In the **Change the classification for the Dataset** window:
    a. Choose the classification from the list.
    b. Enter the encryption key for the dataset that was set while encrypting the dataset column.
    c. **Save** the classification details.

Remember: You can perform this task only if you know the encryption key set for the dataset while encrypting the dataset column.

Results

You have changed the classification for an encrypted dataset.

Related information

Creating a classification on page 934

Managing an encrypted dataset

You can use encrypted datasets to limit access to confidential information such as account number or passwords. You can arrange data by an appropriate category so that project members can use datasets more effectively in certain tests and protect them.

About this task

A dataset can contain classified information that other members can access with permission. As a project owner, you can group encrypted datasets into different classifications and enable project members to view and edit datasets and run tests associated with the encrypted datasets. After you created a classification, you can change the classification for a dataset. You can also delete a classification if you do not require it in your test environment.

Notes:

- You must grant access and provide an encryption key of an encrypted dataset to other members of the project to work with the encrypted dataset.
- A project member who has been added as a *Tester* role can work with the encrypted dataset.

Adding an encrypted dataset to a classification

As a project *Project Owner* or *Tester*, you can organize encrypted datasets by adding it to a classification so that project members can use and protect datasets more efficiently.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created a project in Test. See Managing DevOps Test projects on page 1724.
- Configured the repository that contains the test assets in your project. See Adding repositories to a server project on page 1729.
- Created at least one dataset and encrypted the dataset with an encryption key. See Dataset encryption on page 969.
- Created at least one classification. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click **Add Dataset** to select the encrypted dataset to become part of the classification.
   The **Add Dataset** dialog is displayed.
5. Perform the following steps:
   a. Click the **Encrypted dataset** field to view the encrypted dataset.
   b. Identify and select the encrypted dataset that you wanted to add to the classification.
   c. Enter the encryption key that you used to encrypt the dataset in the **Password** field.

      Tip: You can click the view icon to view the entered encryption key and ensure that you entered the correct key.

   d. Click **Add**.

      The encrypted dataset that is added to the classification is displayed.

   e. You can add other encrypted datasets to the same classification, if required.

What to do next

You can grant access to other project members to use the encrypted dataset. See Granting access to classification on page 936.

Moving an encrypted dataset to another classification

When you add many encrypted datasets to the same classification, you can move some of them to another classification or when you want to delete a classification but you want to retain the encrypted datasets associated with it, you can move them to different classification before deleting the classification.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created at least one dataset and encrypted the dataset with an encryption key. See Dataset encryption on page 969
- Created at least two classifications. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification from the list under **Classification** from which you want to move the encrypted dataset.
5. Click the **Edit** icon inline with the encrypted dataset that you want to move to another classification.
   The **Change the classification for the dataset** dialog is displayed.
6. Click a classification from the list under **Classification** to which you want to move the encrypted dataset.
7. Enter the encryption key that you used to encrypt the dataset in the **Password** field.
8. Click **Save**.

   The encrypted dataset is moved to the classification that you selected and the same is displayed on the **Security** page.

Results

You have moved the encrypted dataset from one classification to another.

Removing a dataset from the classification

You can remove a dataset from a classification when it is no longer required.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Viewer*, *Tester*, or *Project Owner* in the project.
- Created at least one dataset and encrypted the dataset with an encryption key. See Dataset encryption on page 969
- Created a classification and added the encrypted dataset to it. See Creating a classification on page 934.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Manage > Security**.
   The **Security** page is displayed.
4. Click a classification from the list under **Classification** from which you want to delete the encrypted dataset.
5. Click the **Delete** icon in line with the encrypted dataset that you want to delete from the classification.
   The **Remove Dataset** dialog is displayed.
6. Click **Remove**.

Note: Removing dataset from the classification also removes the password stored in Test for encrypted data. You must provide the password again while adding it to a different classification.

Results

You have removed the datasets from a classification.

Management of data definition

You can find information about creating, editing, and managing data definitions in Test , to support realistic and reusable test data generation.

You can create a data definition in Test by using any of the following methods:

- Creating an empty data definition. See Creating an empty data definition on page 980.
- Importing data from a CSV file. See Creating a data definition by importing fields from a CSV file on page 982.
- Creating a data definition from a dataset. See Creating a data definition by importing fields from a dataset on page 984
- Creating a data definition from a database query. See Creating a data definition by importing fields from a database query on page 986.

When you want to edit the data in a data definition, you must open it for editing. See Modifying a data definition on page 991.

After you edit the data fefinition, you must publish the changes, so that the data definition is added to the project repository. See Publishing changes in datasets.

Creating an empty data definition

You can create an empty data definition in Test as the first step to create a data definition. After you save the empty data definition within the selected application in your project repository, you can edit the data definition to add the different generators.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Read information about using data definitions to fabricate test data. See Overview of data fabrication.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:

   - Click the **Open action menu** icon in the Data navigator, and then click **Data definition**.
   - Click **Add files** in the right panel, and then click **Data definition**.
   - Right-click the application in the data navigator panel, select **New > Data definition**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 981.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

7. In **Step 1** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a data definition.
   b. Select **Location** from the drop-down list to store the dataset.
   c. Type a **Name** for the data definition.
   d. Add a description about the data definition in the **Description** field.
   e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select **Source** as **Create an empty data definition**.
   b. Click **Create**.

The new data definition opens in the **Data** page in the editing mode. The data definition created is listed under the logical folder `Data definitions` under the application selected.

Results

You created an empty data definition in your project.

What to do next

You can perform the following tasks:

- Add basic generators with their default settings to the data definition. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their default settings on page 988.
- Add basic generators to the data definition, and then modify the configuration of the generators. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their modified settings on page 990.

Creating a dataset by using a Data definition on page 958

Creating a data definition by importing fields from a CSV file

When you want to create a data definition in Test with specific fields for the test data, you can import a CSV file that defines the specific fields. After you import fields to the data definition, you can edit the data definition and add generators for the specific fields before you generate the test data.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that a CSV file is available on your computer, from which you want to import data.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:

   - Click the **Open action menu** icon in the data navigator, and then click **Data definition**.
   - Click **Add files** in the right panel, and then click **Data definition**.
   - Right-click the application in the data navigator panel, select **New > Data definition**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 983.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

7. In **Step 1** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a data definition.
   b. Select **Location** from the drop-down list to store the dataset.
   c. Type a **Name** for the data definition.
   d. Add a description about the data definition in the **Description** field.
   e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select **Source** as **Imports fields from a CSV file**.
   b. Click **Select file** and browse to the location on your computer where you have the CSV file.
   c. Click **Create**.

The new data definition opens in the **Data** page in the editing mode. The data definition created is listed under the logical folder `Data definitions` under the application selected.

Results

You created a data definition in your project, which has the fields from the CSV added as the fields of the new data definition but no generators are added.

What to do next

You can perform the following tasks:

- Add basic generators with their default settings to the data definition. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their default settings on page 988.
- Add basic generators to the data definition, and then modify the configuration of the generators. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their modified settings on page 990.

Creating a data definition by importing fields from a dataset

When you want to create a data definition in Test with specific fields for the test data, you can import the fields from a dataset. After you import fields to the Data definition, you can edit the data definition and add generators for the specific fields before you generate the test data.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that a dataset is available in your project repository, from which you want to import data.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:

   - Click the **Open action menu** icon in the Data navigator, and then click **Data definition**.
   - Click **Add files** in the right panel, and then click **Data definition**.
   - Right-click the application in the data navigator panel, select **New > Data definition**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 985.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

7. In **Step 1** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a data definition.
   b. Select **Location** from the drop-down list to store the dataset.
   c. Type a **Name** for the data definition.
   d. Add a description about the data definition in the **Description** field.
   e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create Data Definition** dialog, perform the following tasks:
   a. Select **Source** as **Import fields from a dataset**.
   b. Search for the dataset in your project repository by entering the file name in the **Dataset** field.

      Alternatively, browse to the location in your project repository, and then select the file.

   c. Click **Create**.

The new data definition opens in the **Data** page in the editing mode. The headers in the dataset file are added as the fields of the new data definition but no generators are added.The data definition created is listed under the logical folder `Data definitions` under the application selected.

Results

You created a data definition in your project, which has the fields from the dataset added as the fields of the new data definition but no generators are added.

What to do next

You can perform the following tasks:

- Add basic generators with their default settings to the data definition. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their default settings on page 988.
- Add basic generators to the data definition, and then modify the configuration of the generators. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their modified settings on page 990.

Creating an empty data definition on page 980

Creating a dataset by using a Data definition on page 958

Creating a data definition by importing fields from a database query

You can create data definition to generate a random test data that is required to run a test in Test using the specific database fields.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.
- Created at least one database query. See Creating a database query on page 947.

About this task

You must first create a database query and then create a data definition using the database query to import the specific fields from the database query. After you import fields to the data definition, you can edit the data definition and add generators for the specific fields before you generate the test data.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click the **Open action menu** icon in the data navigator, and then click **Data definition**.
   - Click **Add files** in the right panel, and then click **Data definition**.
   - Right-click the application in the data navigator panel, select **New > Data definition**.

The **Edit Branch** dialog is displayed.

If the **Edit branch** dialog is not displayed, then go to step 7 on page 987.

6. Select your action to either select an existing Edit branch or create an Edit branch:
    - Perform the following steps to select an existing Edit branch:
        a. Select **Use an existing edit branch**.
        b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

        c. Click **Ok**.
    - Perform the following steps to create the Edit branch:
        a. Select **Create new edit branch**.
        b. Enter a name for the Edit branch in the **Branch Name** field.
        c. Click **Save**.
7. In **Step 1** of the **Create Data Definition** dialog, perform the following tasks:
    a. Select the **Application** for which you want to create a data definition.
    b. Select **Location** from the drop-down list to store the dataset.
    c. Type a **Name** for the data definition.
    d. Add a description about the data definition in the **Description** field.
    e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create Data Definition** dialog, perform the following tasks:
    a. Select **Source** as **Import fields from a database query**.
    b. Select the required database query file in your project.
    c. Click **Create**.

The new data definition opens in the **Data** page in the editing mode. The columns in the database query are added as the fields of the new Data definition but no generators are added. The data definition created is listed under the logical folder `Data definitions` under the application selected..

Results

You have created a data definition in your project by importing fields from a database query.

What to do next

You can perform the following tasks:

- Add basic generators with their default settings to the data definition. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their default settings on page 988.
- Add basic generators to the data definition, and then modify the configuration of the generators. You can then save and publish the data definition. See Saving a data definition by adding basic generators with their modified settings on page 990.

Related information

Creating an empty data definition on page 980

Creating a dataset by using a Data definition on page 958

Saving a data definition by adding basic generators with their default settings

After you create a data definition in Test , you must add the basic generators with their default settings and save the data definition before you can generate test data.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an empty data definition that is opened for editing.

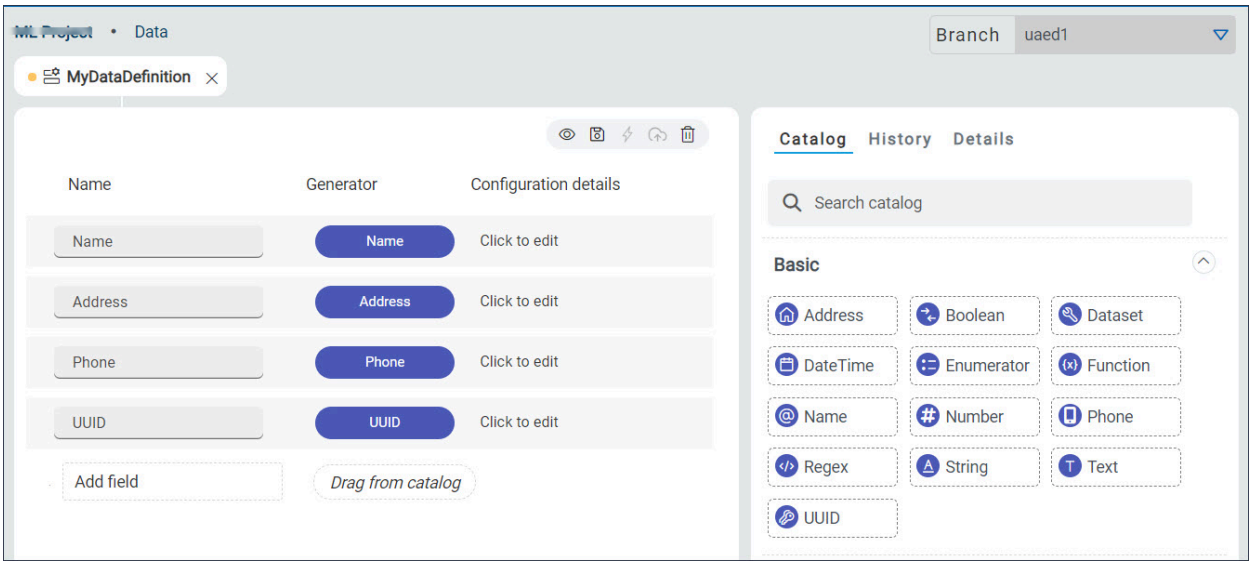
1. Drag a basic generator from the **Catalog** panel to the data definition.

   The basic generator is added as a field in the data definition.

2. Drag other basic generators from the **Catalog** panel to the data definition to complete the data structure that you want in the fabricated data.

   Do not change any of the fields in the data definition or the configuration of the basic generators.

   For example, if you want to fabricate data about persons with their name, address, phone number, and a unique ID for each name or record, you can drag the **Name**, **Address**, **Phone**, and **UUID** generators to the data definition, without making any changes to any of the fields in the data definition or in the basic generators.



3. Click the **Save** icon to save the changes made to the Data definition or the **Save All** icon to save all changes made to different Data definitions by using the same Edit branch.

Note: When you edit different files that include datasets or Data definitions simultaneously, you can select your action from the following options:

To...	Do this...
Keep your current file open and close the open files on the right.	Right-click, and then click the **Close Tabs to right** option.
Keep your current file open and close the open files on the left.	Right-click, and then click the **Close Tabs to left** option.
Keep your current file open and close all the other open files.	Right-click, and then click the **Close Others** option.
Close all open file tabs.	Right-click, and then click the **Close All Tabs** option.

Note: The changes you made are only visible and available to you in the Edit branch. You must publish the changes in the Edit branch to the branch in the project repository for the changes to be visible to the other members of the project.

4. Click the **Publish** icon to publish the changes made to the data definition to the branch in the project repository.

Results

You edited and saved a data definition after adding basic generators with their default settings.

What to do next

You can perform any of the following tasks:

- Preview the test data generated by using the generators added as fields in the data definition by clicking the **Preview** icon .
- Generate the test data by using the generators added as fields in the data definition by clicking the **Generate** icon .

Saving a data definition by adding basic generators with their modified settings

After you create an empty data definition in Test , you must add the basic generators with their modified settings, and save the data definition before you can generate test data.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an empty data definition that is opened for editing.

1. Drag a basic generator from the **Catalog** panel to the data definition.

   The basic generator is added as a field in the data definition.
2. Drag other basic generators from the **Catalog** panel to the data definition to complete the data structure that you want in the fabricated data.
3. Perform the following steps to modify the parameter configurations of a basic generator in a field of the data definition:

   a. Click a generator in the **Generator** column of a field where you want to customize the configuration.
   The parameters of the generator are displayed in the **Generator** dialog.

   b. Change the parameter settings in the **Generator** dialog to customize the generator.

   c. Close the **Generator** dialog.
   The changes in the generator configuration are automatically saved.
4. Click the **Save** icon to save the changes made to the Data definition or the **Save All** icon to save all changes made to different Data definitions by using the same Edit branch.

Note: When you edit different files that include datasets or Data definitions simultaneously, you can select your action from the following options:

To...	Do this...
Keep your current file open and close the open files on the right.	Right-click, and then click the **Close Tabs to right** option.
Keep your current file open and close the open files on the left.	Right-click, and then click the **Close Tabs to left** option.
Keep your current file open and close all the other open files.	Right-click, and then click the **Close Others** option.
Close all open file tabs.	Right-click, and then click the **Close All Tabs** option.

Note: The changes you made are only visible and available to you in the Edit branch. You must publish the changes in the Edit branch to the branch in the project repository for the changes to be visible to the other members of the project.

5. Click the **Publish** icon to publish the changes made to the data definition to the branch in the project repository.

Results

You edited and saved a data definition after adding basic generators and then modifying the configuration of the generators.

What to do next

You can perform any of the following tasks:

- Preview the test data generated by using the generators added as fields in the data definition by clicking the **Preview** icon .
- Generate the test data by using the generators added as fields in the data definition by clicking the **Generate** icon .

Modifying a data definition

After you create and publish a data definition in Test , you can modify the fields or the configuration of the generators in an existing data definition when you want to change the structure of the test data.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Click the data definition that you want to edit in the data navigator panel.

   Alternatively, right-click the data definition in the data navigator panel, and then click **Edit**.

   The selected data definition opens in the **Data** page.
5. Perform the actions that are listed in the following table to modify the data definition:

Modification	Action
Addition of new fields	Click the **Add field** option, and then enter a name for the field in the **Name** column. **Note:** A new row with an empty field is automatically displayed below the row that you edit.
Addition of generators in fields	Drag a generator from the **Catalog** panel into a field under the **Generator** column. **Note:** You can use the **Search catalog** field in the **Catalog** panel to find the required generator.
Replacement of generators in fields	Drag a generator from the **Catalog** panel into an existing generator field under the **Generator** column. The existing generator in the field is automatically replaced by the generator.
Modification of generator configurations	Click a generator in the **Generator** column. The generator configurations are displayed. Modify the options and settings in the generator configuration.

Modification	Action
	Note: If you modify the configurations of a basic generator, the changes are applicable only when the generator is used as field in a Data definition. The basic generator that is available in the catalog is not modified nor saved.
Inclusion of additional configuration details	Click the **Add new configuration** tab. Provide a name, and enter or select the other settings as an additional configuration to the generator.
Arrangement of fields	Drag and drop the field rows in the Data definition panel to rearrange the fields in the order you want.
Deletion of fields	Click the delete icon in the row of a field to remove the field from the Data definition.
Deletion of Data definition	Click the **Delete** icon in the Data definition panel to delete the Data definition from the existing location.

6. Click the **Save** icon to save the changes made to the Data definition or the **Save All** icon in the Data navigator panel to save all changes made to different Data definitions by using the same Edit branch.

Note: When editing multiple assets (such as datasets, data definitions or schemas) simultaneously, right-click a test asset in the Data page to manage open tabs using the following options:

To...	Do this...
Keep your current file open and close the open files on the right.	Right-click, and then click the **Close Tabs to right** option.
Keep your current file open and close the open files on the left.	Right-click, and then click the **Close Tabs to left** option.
Keep your current file open and close all the other open files.	Right-click, and then click the **Close Others** option.

To...	Do this...
Close all open file tabs.	Right-click, and then click the **Close All Tabs** option.

Note: The changes you made are only visible and available to you in the Edit branch. You must publish the changes in the Edit branch to the branch in the project repository for the changes to be visible to the other members of the project.

7. Click the **Publish** icon to publish the changes made to the data definition to the branch in the project repository.

Results

You modified an existing data definition in your project.

What to do next

You can generate test data by using the modified Data definition. See Generating fabricated test data on page 1012.

Viewing a data definition and its details

You can view the contents of a data definition on the Data page in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch from the **Branch** list.
   The navigation panel displays all the existing projects in the selected branch.
5. Find the data definition that you want to view, and then click it.

   You can either enter the name of the data definition in the **Search** field or expand the project and manually search in the data navigator panel.

The selected data definition opens in the **Data** page and the following elements are displayed:

Element	Description
The **Name** column	A list of fields and their custom names that exist in the Data definition is displayed in the column.
The **Generator** column	The generator that is selected for the corresponding field is displayed in the column. **Note:** If any of the fields does not have a corresponding generator, then you cannot preview or generate the test data for the Data definition.
The **Configuration details** column	The configuration details of each field are displayed in the column. **Note:** The column displays details only when additional configuration is added for the field. Also, if you have added three or more additional configurations, then the ellipses icon ... is displayed. You can hover over the icon to view the list of additional configuration names along with their distribution values. You can also click the column of a field to view the existing configuration details for the field in the corresponding *Generator* dialog.
Initials of members	The colored avatars, that represent the initials of the project members who are currently editing the data definition, are displayed in the page. You can hover over an avatar to view the name of the member and the branch that they are currently editing. This information can facilitate collaboration and communication among team members who are working on the same Data definition simultaneously. To understand how you can resolve conflicting edits, see Modifying a data definition on page 991.
The **Preview** icon	You can click the icon to preview the test data in the preview dialog of the **Data** page. The preview dialog contains the generate icon and the close icon. **Notes:**

Element	Description
	◦ If you are in an Edit branch, then you can access the **Generate** icon in the preview dialog only if the Data definition is saved. ◦ If you modify the Data definition but not save it, you can still preview the corresponding test data. However, you can generate the test data only after you save the Data definition.
The **Save** icon	You can click the icon to save the Data definition. If you modified the Data definition and you want to continue using the modified Data definition to generate test data without publishing it, you must save the changes. However, if you want to collaborate with other members of your project, you must publish the Data definition.
The **Generate** icon	You can click the icon to generate the test data in the CSV format. See Generating standard test data by using data definitions and exporting it to a .zip file on page 1014.
The **Delete** icon	You can click the icon to delete the Data definition. See Deleting a data definition on page 998.
The **Catalog** tab	Provides a structured overview of the available built-in and custom generators for the selected project.
The **History** tab	Provides an overview of all the previously generated test data. The following information about the history of the generated data is displayed: ◦ The month, date, and year of the generated test data. ◦ The status of the download that indicates whether the data generation was successful or failed. ◦ The number of rows in the generated test data. ◦ The initials of the project member who downloaded the generated test data. You can also use the following options to work with the past data: ◦ You can click the preview icon to review the already generated data before taking any further actions. ◦ You can click the generate icon to regenerate the same test data, if required. See Generating test data by using data definition history on page 1017. ◦ You can click the delete icon to delete specific test data history. You get a clutter-free view of the most relevant data and maintain your data generation history effectively.
The **Details** tab	Provides following details about the Data definition and its associated Git details:

Element	Description
	◦ Name of the branch that contains the data definition. ◦ Description for the Data definition, if any. ◦ Git-related details for the Data definition as follows: ▪ Asset ID: The ID uniquely identifies the data definition. You also have the option to copy the ID for easy reference or use. ▪ Repo: The repository name and path where the Data definition is stored is displayed. ▪ Path: The exact location of the data definition within the repository is displayed. ▪ Commit: The Git commit message, the name of the member who performed the changes, and the date and time of the commit are displayed. ▪ The copy button: You can click the button to copy the complete SHA commit ID for the data definition. ▪ The commit ID button: You can click the button to view the changes that were made in the commit directly within Git. ▪ The browse button: You can click the button to view the specific location in the Git history where the commit was performed for the data definition.
The Data definition tabs	When you open a Data definition, the name of the currently opened Data definition is displayed as a tab in the **Data** page. Beside this tab, additional tabs with the names of all other data definitions that are currently open on the **Data** page are also displayed. You can use these tabs to navigate between different Data definitions easily. Also, when you hover over the tab of a Data definition, a tooltip is displayed that provides the location and repository details where the Data definition is stored.
The **Branch** list	The list displays the name of the branch where you currently opened the Data definition. You can also use the list to choose and select a different branch from the available options, if required. You can switch between branches easily.

Note: The **Save** icon and the **Delete** icon are displayed in the Data definition page only if you are in an Edit branch. If you are in a branch other than the Edit branch, then an **Edit** icon is displayed in the Data definition. You can click the **Edit** icon to perform any modification to the Data definition. Also, if you do not have either the owner or the tester role for the Data definition, you cannot save, modify, or delete the Data definition.

Results

You have viewed the contents of the data definition in your project.

What to do next

You can perform any of the following tasks:

- Modify the data definition. See Modifying a data definition on page 991.

Deleting a data definition

You can delete a data definition when it is outdated or no longer relevant to your project. Additionally, when data definitions contain errors or inaccuracies that can lead to misleading or incorrect fabricated data, then you might want to remove them. This ensures that the project remains clutter-free, optimizes the performance of Test , and reduces storage requirements.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the data definition in the data navigator panel.
   Result
   The data dedfinition is displayed in the **Data** page
5. Click the **Delete** icon to delete the data definition.

   Alternatively, right-click the data definition in the data navigator panel, and then click **Delete**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 999.
6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

7. Click the **Delete** button in the **Delete Data definition** dialog.

Results

You have deleted a data definition from your project.

What to do next

You can publish the changes performed to the data definition (that is, deletion of the data definition) to the Git repository so that other members of the project do not see the deleted data definition. See Publishing all changes in an Edit branch on page 1023.

Management of schemas

A schema, also known as a database schema, defines how data is structured, organized, and managed in a database management system (DBMS). It outlines the format, storage, processing, security, and data access across various structural schema elements such as tables, views, and logical constraints.

The following sections provide an overview of how schema concepts are applied within Test Hub to support efficient data management and test design:

- Using schema in Test Hub on page 999
- Key benefits of schema in Test Hub on page 1000
- Primary key on page 1000
- Foreign key on page 1000

Using schema in Test Hub

- You can create a new schema either as an empty structure or by connecting it to an existing database, allowing you to visualize how data is structured and related in real environments. See Creating an empty schema on page 1000 and Creating a schema by using a database connection on page 1002.
- After the schema is created, two separate tabs are displayed based on the database connection:
  - **Database View**
  - **Schema View**
- You can add data definitions and establish relationships between their fields in a schema.

Key benefits of schema in Test Hub

The schema in Test offers the following advantages:

- It defines how data is stored and related within the database, making it easier to understand, manage, and maintain.
- You can group similar data to reuse it across different scenarios, even when it serves different purposes.
- You can enhance data integrity by using logical constraints such as tables, primary keys, and relationships that helps maintain data consistency and accuracy while reducing errors.

To use schema in Test, you must be aware of the terms and concepts that are used to link database tables.

Primary key

A primary key is one or more columns in a database table that uniquely identify each record in that table. The primary key enforces data integrity by ensuring that no two rows have the same value(s) in the key column(s) and that these values are never null. Database systems use the primary key to efficiently retrieve, update, or relate records across multiple tables in a relational database.

Foreign key

A foreign key is a link between two tables that ensures the data in one table corresponds with the data in another table, thereby maintaining uniformity of the database information.

Creating an empty schema

You can create an empty schema to define a structured data storage. Initially, the schema is not connected to any database.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.

4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.

5. Perform any of the following actions:
   - Click **Add files** and select **Schema** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Schema**.
   - Right-click the application in the data navigator panel, go to **New**, and select **Schema**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 1001.

6. Select your action to either select an existing Edit branch or create an Edit branch:

   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

        Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

     c. Click **Ok**.
   - Perform the following steps to create the Edit branch:
     a. Select **Create new edit branch**.
     b. Enter a name for the Edit branch in the **Branch Name** field.
     c. Click **Save**.

   Result

   The **Create a Schema** dialog is displayed.

7. In **Step 1** of the **Create a Schema** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a schema.
   b. Select **Location** from the drop-down list to store the schema.
   c. Type a unique **Name** for the schema.
   d. Type a brief description of the schema in the **Description** field.
   e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create a Schema** dialog, perform the following tasks:
   a. Select **Source** as **Create an Empty Schema**.
   b. Click **Create**.

Results

You have created an empty schema.

What to do next

You can add a database connection to an empty schema. See Adding a database connection to the schema on page 1002.

Adding a database connection to the schema

You can add a database connection to link a schema to a database for data generation and management.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Added a database connection in your project. See Adding a database connection on page 938.
- Created an empty schema in your project. See Creating an empty schema on page 1000.

About this task

When you create an empty schema, it is not linked to any database. In the **Database View** tab, a message is displayed that indicates that the schema is empty and requires a database connection.

1. Select the **Schema** in the data navigator panel that is not connected to any database.
   Result
   The selected schema is displayed on the **Data** page.
2. Navigate to the **Database View** tab.
   If the schema is not connected to any database, a message appears `This schema is not linked to any database.`
3. Click **Add DB Connection**.
   The **Add a Database Connection** dialog is displayed.
4. Select a database from the **Select a Database Connection** list.
5. Click **Done**.

Results

You have added a database connection to the schema.

Related information

Creating a schema by using a database connection on page 1002

Creating a schema by using a database connection

When your tests require data that reflects existing database models, you can create a schema by connecting to an existing database. You can retrieve and manage live data structures that help your test data reflect production schema complexity and relationships more accurately.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Read information about using the schema. See Management of schemas on page 999.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Created an application in your project. See Creating an application on page 766.
- Added a database connection in your project. See Adding a database connection on page 938.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch in the project repository from the **Branch** list.

   The assets and resources in the selected branch are displayed in the data navigator panel.
5. Perform any of the following actions:
   - Click **Add files** and select **Schema** on the **Test Editor** page.
   - Click the **Action Menu** icon and select **Schema**.
   - Right-click the application in the data navigator panel, select **New > Schema**.

   The **Edit Branch** dialog is displayed.

   If the **Edit branch** dialog is not displayed, then go to step 7 on page 1004.
6. Select your action to either select an existing Edit branch or create an Edit branch:
   - Perform the following steps to select an existing Edit branch:
     a. Select **Use an existing edit branch**.
     b. Select an Edit branch from the **Select branch** list if Edit branches already exist for your repository.

Note: A warning message is displayed if the Edit branch, which you selected, is behind the source branch. To update the selected edit branch and maintain synchronization with the source branch, you can select the **Update branch option when switching** checkbox.

c. Click **Ok**.

- Perform the following steps to create the Edit branch:
  a. Select **Create new edit branch**.
  b. Enter a name for the Edit branch in the **Branch Name** field.
  c. Click **Save**.

Result

The **Create a Schema** dialog is displayed.

7. In **Step 1** of the **Create a Schema** dialog, perform the following tasks:
   a. Select the **Application** for which you want to create a schema.
   b. Select **Location** from the drop-down list to store the schema.
   c. Type a unique **Name** for the schema.
   d. Type a brief description of the schema in the **Description** field.
   e. Click **Next** to proceed to Step 2.
8. In **Step 2** of the **Create a Schema** dialog, perform the following tasks:
   a. Select **Source** as **Select a Database Connection**.
   b. Select a database from the **Select a Database Connection** list.
   c. Click **Create**.

Results

You have created a schema by using an existing database connection.

Managing data definitions in a schema on page 1004

Managing data definitions in a schema

You can manage and organize data definitions within a schema to support consistent and accurate test data generation.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that your project contains a schema.

About this task

You can access a schema in your project and perform actions such as creating or importing data definitions, linking fields, modifying generator settings, and saving schema changes. You can design data relationships by using the **Schema View**, or use the **Database View** to align data definitions with your database structure.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.
   The **Data** page and the data navigator panel are displayed.
4. Select the schema that you want to edit in the data navigator panel.

   The selected schema opens in the **Data** page.
5. You can perform the actions that are listed in the following table to modify data definitions in a **Schema View**:

Task	**Action**
Create an inline data definition	Perform the following steps: a. Click **Add Data Definition**. b. Type a name in the **Name** field under the **Create Inline Data Definition** section. c. Click **Add**. A table with an empty field is displayed in the schema view.
Import existing data definitions	Perform the following steps: a. Click the **Add Data Definition**. b. Select the data defintions from the **Available Data Definitions** section. c. Click **Add**. **Note:** You can use the **Search** field in the **Add Data Definition** dialog to find the required data definition.
Add a relationship between fields	Perform the following steps: a. Hover over the field line until the **Drag to connect to a field** tooltip appears. b. Drag to the destination field in another data definition

Task	Action
	Note: The data type of the source field and the destination field must be the same.
Define the relationship ratio	Perform the following steps: a. Click the **Destination** field. b. Enter the distribution ratio (For example: One-to-One or One-to-Many) in the **Relationship configuration** dialog.
Convert between Referenced and Inline DDFs	Perform the following steps: a. Click the **Actions-menu** icon on the data definition. ▪ Select **Convert to Referenced**, if the data definition is **inline** ▪ Select **Convert to Inline**, if the data definition is referenced.
Rename inline data definition	Perform the following steps: a. Click the **Actions-menu** icon on the data definition. b. Select **Rename**. c. Type a new name in the **Rename Data Definition** dialog. d. Click **Rename**.
Add new fields	Perform the following steps: a. Click the **Add field** icon . b. Type a field name in the **Name** column. An empty row is automatically inserted below the current row for your next entry.
Add generators in fields	Drag a generator from the **Catalog** panel into a field under the **Generator** column. **Note:** You can use the **Search Catalog** field in the **Catalog** panel to find the required generator.
Replace generators in fields	Drag a generator from the **Catalog** panel into an existing generator field under the **Generator** column. The existing generator in the field is automatically replaced by the generator.
Modify generator configurations	Perform the following steps:

Task	Action
	a. Click a generator in the **Generator** column. b. Update the configuration settings in the panel. **Note:** If you modify the configurations of a basic generator, the changes are applicable only when the generator is used as a field in a data definition. The basic generator that is available in the catalog is not modified or saved.
View sample data for a generator in Schema View	Perform the following steps: a. Click the generator label next to a field in the table in **Schema View**. The properties of the generator is displayed. b. Click the **View sample data**. A list of five sample records is displayed, fetched from the source database. c. **Optional**: Click the **Reload Sample Data** icon to refresh the data from the source.
Include additional configuration details	Perform the following steps: a. Click the **Add new configuration** tab. b. Type a name and set other settings as an additional configuration to the generator.
Reorder fields	Drag and drop rows in the table to rearrange the fields.
Delete fields	Click the **Delete** icon in the field row to remove the field.
Remove one or more data definitions from Schema View	Perform the following steps: a. Click the **Actions-menu** icon on the data definition. b. Select **Remove from schema**. The data definition is removed from the schema. Alternatively, select the data definition and click **Remove (1)**. c. Select the data definitions or that you want to remove and click **Remove (#)**. The number in parentheses indicates the number of data definitions that are currently selected. For example, **Remove (2)** or **Remove (5)**. To remove all the data definitions from the Schema View, perform the following steps:

Task	Action
	a. Select the data definitions in the Schema View by pressing **Ctrl+A** to select all, or by pressing **Ctrl** and clicking on each DDF that you want to select. b. Click **Remove All** to remove all the data definition from the schema. The **Remove All Data Definitions** dialog box is displayed. c. Click **Yes** to confirm. **Note:** You cannot undo this action after the data definitions are removed.
Update data definitions in Schema View	Perform the following steps: a. Click the **Update** icon to update the default row counts and default distribution ratios for the data definitions within the schema. The **Update Schema** dialog box is displayed, with the **Default row counts** and **Default distribution ratios** selected. b. Click **Update**.

6. You can perform the actions that are listed in the following table to modify data definitions in a **Database View**:

Task	Action
Export a data definition to a schema	Perform the following steps: a. Click the **Actions-menu** icon on the data definition. b. Select **Add table to schema**. **Note:** The exported data definition changes to green color.
Select the linked data definitions	Perform the following steps: a. Click the **Actions-menu** icon on the data definition. b. Select **Select linked tables**. **Note:** The linked data definitions are changed to blue color.
Add missing columns	Perform the following steps: a. Select the data definition exported to schema.

Task	Action
	b. Click the **Actions-menu** icon on the data definition. c. Select **Add missing columns to schema**.
Remove unnecessary fields	Perform the following steps: a. Select the data definition exported to schema. b. Click the **Actions-menu** icon on the data definition. c. Select **Remove unnecessary fields**.

7. Click the **Save** icon to save the changes made to the schema.

Results

You have updated the data definition within a schema.

Auto-assigning generators and AI-provided data configurations to data definitions in the Schema View

You can use AI assistance to automatically assign generators and AI-provided data configurations to the fields in data definitions within the Schema View.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.
- Ensured that your project contains a Web UI test or suite.
- Ensured that the required variables have been created and are included in your Web UI test or suite.
- Ensured that your project contains a dataset.
- Ensured that you have configured the required AI provider credentials. For more information, see Adding cloud credentials of AI providers. on page 1122

About this task

When a schema contains multiple data definitions and fields, manually assigning generators and configuring them can be time-consuming. AI-based inference analyzes the available field information and recommends suitable generators and data configurations for the selected data definitions.

Note: Existing generators remain unchanged unless you select the option to overwrite them.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.
   The **Data** page and the data navigator panel are displayed.
4. Select the schema that you want to edit in the data navigator panel.

   The selected schema opens in the **Data** page.
5. Click the **Update** icon .
6. Select the **Assign generators to fields** checkbox.

   The **AI Provider** option is displayed.
7. Select the configured **AI Provider** from the drop-down list.

   Note: When you select an **AI provider**, sample data from the selected tables is shared with the AI service to configure generators.
8. **Optional:** Select the **Overwrite existing generators** checkbox to overwrite the existing generators.
9. Click **Update**.

   Note: Verify the AI-provided generator configurations to ensure their accuracy, as AI-produced data might contain errors.

Results

You have automatically assigned generators and AI-provided data configurations to the fields in the selected data definitions.

Deleting a schema

You can delete a schema when it is outdated or no longer relevant to your project. Additionally, if a schema contains errors or inaccuracies that might lead to the generation of misleading or incorrect fabricated data, then you might want to remove them. By removing such shemas, you can maintain a clean and organized workspace, optimize the performance of Test , and reduce unnecessary storage usage.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735
- Ensured that your project contains a schema.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the schema that you want to delete from the data navigator panel.

   The selected schema opens on the **Data** page.
5. Click the **Delete** icon .

   Alternatively, right-click the schema in the data navigator panel, and then click **Delete**.

   The **Delete Schema** dialog is displayed.
6. Click **Delete**.

Results

You have deleted a schema from your project repository.

Publishing changes in data definitions, datasets, or schemas

After creating or modifying a data definition, dataset, or schema in Test , you can publish changes from an Edit branch to the source branch in the project repository. After you publish the changes, other members of the project can view and work with the updated datasets.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created or modified a schema, dataset, or data definition.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.

3. Go to **Author > Data**.

   Result

   The **Data** page and data navigator panel are displayed.

4. Select the data asset (schema, data definition, or dataset) you want to publish from the data navigator panel.

   Result

   The selected data asset is displayed on the **Data** page.

5. Click the **Save** icon to save changes.

6. Click the **Publish** icon .

   The **Publish** dialog is displayed.

7. Type the description in the **Description of change** field.

8. Click **Publish**.

   Alternatively, you can publish the changes from the **Changes** tab.

   If the publish succeeds, the Edit branch is automatically deleted and removed from the **Branch** list and the changes are merged into the previously selected remote branch.

   If the publish fails due to a conflict with the remote branch, click **Push** in the **Publish** dialog to push the edit branch to the remote repository. Then, you can create a pull request and resolve the conflicts manually in Git before you merge the changes into the target branch.

Results

You have published the changes in an Edit branch to the remote branch in the project repository.

Publishing all changes in an Edit branch on page 1023

Generating fabricated test data

You can generate fabricated test data in Test to support a wide range of test scenarios. The generated data is saved as a CSV file on your system and can be used to override existing datasets during test execution.

Data fabrication is the process of creating synthetic test data that mimics real-world information without exposing actual user or production data. You can simulate various testing scenarios using structured, configurable, and reusable datasets. In Test , this process involves defining data structures, applying data generation logic through built-in or custom generators, and producing test-ready datasets that enhance both test coverage and data privacy.

By combining datasets, data definitions, database query and schemas, Test Hub helps you to create realistic, privacy-compliant, and reusable test datasets that improve test coverage and accuracy.

You can generate fabricated test data in the following ways:

- Generating test data by using data definitions and exporting it to a `.zip` file.
- Generation of test data using Data definition history.
- Generation of schema based test data and exporting it as a `.zip` file.
- Generating test data by using data definitions or schema and exporting it to a database.

Generating test data by using data definitions and exporting it to a `.zip` file

You can create a data definition, add fields, and configure generators to produce realistic test data. Before generating, you can preview the data to ensure it meets your expectations. If the fields have no generators, you can still save the definition, but preview and generation are only available after at least one generator is configured.

Note: While configuring the generator parameters for a field in a Data definition, you must use the **Allowed** option of the **Duplicates** field of the generator with caution, particularly when you configure the data generator with a narrow criteria for data generation. If you enable the **Allowed** option in scenarios where duplications are not feasible within the defined criteria, then the preview or generation of test data might not be successful.

Also, the data distribution in a generated test data closely aligns with the configured weightage that you provide in the **Distribution** field of the generator. Therefore, the accuracy of the test data improves as more number of records are generated. See Basic generators on page 874.

See Generating standard test data by using data definitions and exporting it to a .zip file on page 1014.

Generation of test data using Data definition history

You can use the **History** tab in Test to view all previously generated test data for a Data definition. From this tab, you can select and regenerate any earlier version of test data without reconfiguring the Data definition. This helps ensure consistency during repeated test runs, simplifies troubleshooting, and supports better collaboration when multiple team members need access to the same test dataset.

See Generating test data by using data definition history on page 1017.

Generation of schema based test data and exporting it as a `.zip` file

You can generate test data based on a schema in Test and export it as a `.zip` file containing CSV datasets. This allows you to use the fabricated data outside Test Hub or share it across different environments.

See Generating and exporting schema-based test data to a .zip file on page 1019.

Generating test data by using data definitions or schema and exporting it to a database

You can generate test data from a schema in Test and export it directly to a connected database. This enables seamless population of test environments with realistic, structured data for end-to-end testing.

See Generating test data by using data definitions or schema and exporting it to a database on page 1020.

Generating standard test data by using data definitions and exporting it to a `.zip` file

You can generate synthetic standard test data by using data definitions in Test to simulate realistic test scenarios, preview data, and export it for use in your testing workflows.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch from the **Branch** list.
   The navigation panel displays all the existing projects in the selected branch.
5. Find the data definition that you want to view, and then click it.

   Note: You can either enter the name of the data definition in the **Search** field or expand the project and manually search in the Data navigator panel.

   Result
   The selected data definition opens in the **Data** page.
6. Click the **Preview** icon to preview the test data that you want to generate.

   The test data is generated in the preview dialog.

   Note: You can preview a test data to ensure whether the data is in the expected format. You can have a glimpse of the generated test data that can help you to identify any potential issues, inconsistencies, or errors in the Data definitions. If you modify the data definition but not save it, you can still preview the corresponding test data. However, you can generate the test data only after you save the data definition.

7. Click the **Standard** tab in the preview section to view the generated standard test data.
8. Click the **Generate** icon either from the **Data** page or from the preview page.
   The **Generate data** dialog is displayed.

Note: If you are in an Edit branch, then you can access the **Generate** icon from the preview dialog only if the data definition is saved.

9. Perform the following actions in the **Generate data** dialog:
    a. Enter a name in the **Name** field to identify the test data when generated.
    b. Enter the number of rows that you want to generate in the **Number of Rows** field.
    c. **Optional**: Enter the seed value in the **Seed** field.

    Whenever you generate test data to perform application testing, the generated data is different. You can produce the same set of data multiple times by setting the seed value.

    For example, assume that you have used the seed value as `1` to generate test data from a data definition. When you want to create another test data with the same set of values, then you can provide the seed value as `1` during the creation of the test data.

    d. Clear the **Include headers** option if you do not want to include headers in the generated test data.
    e. Click the **Download** option to initiate the generation of the test data.

Results

The generated test data is downloaded into your local file system as a Comma Separated Values (CSV) file.

Note: You can use other applications that support viewing or editing of the CSV files. You must ensure to apply the relevant formats to the fields to view the correct format of the generated test data.

What to do next

You can view the information about the history of the generated data in the **History** tab of the **Data** page.

Generating negative test data for a data definition

You can generate synthetic negative test data for a data definition in Test to simulate invalid and boundary test scenarios for application forms.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

The **Overview** page of the project is displayed.

3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.

4. Select the branch from the **Branch** list.
   The navigation panel displays all the existing projects in the selected branch.
5. Find the data definition that you want to view, and then click it.

   Note: You can either enter the name of the data definition in the **Search** field or expand the project and manually search in the Data navigator panel.

   Result
   The selected data definition opens in the **Data** page.
6. Click the **Preview** icon to preview the test data that you want to generate.

   The negative test data is generated in the preview dialog.

   Note: You can preview test data to ensure that the data is in the expected format. You can have a glimpse of the generated test data that can help you to identify any potential issues, inconsistencies, or errors in the Data definitions. If you modify the data definition and do not save it, you can still preview the corresponding test data. However, you can generate the test data only after you save the data definition.

7. Click the **Negative** tab in the preview section to view the generated negative test data.
8. Click the **Generate** icon either from the **Data** page or from the preview page.
   The **Generate data** dialog is displayed.

   Note: If you are in an Edit branch, then you can access the **Generate** icon from the preview dialog only if the data definition is saved.

9. Perform the following actions in the **Generate Data** dialog:
   a. Enter a name in the **Name** field to identify the test data when generated.
   b. Enter the number of rows that you want to generate in the **Number of Rows** field.
   c. **Optional**: Enter the seed value in the **Seed** field.

      Whenever you generate test data to perform application testing, the generated data is different. You can produce the same set of data multiple times by setting the seed value.

      For example, assume that you have used the seed value as `1` to generate test data from a data definition. When you want to create another test data with the same set of values, then you can provide the seed value as `1` during the creation of the test data.

d. **Optional**: Select the following options as required:
   - **Include Headers** - Includes column headers in the generated output.
   - **One per Row** - Generates one invalid value per row while keeping the remaining field values valid.
   - **Include Metadata** - Includes metadata information in the generated output, such as the column that contains the negative data and the property used to generate the negative data.

e. Click the **Download** option to initiate the generation of the test data.

Results

The generated test data is downloaded into your local file system as a Comma-Separated Values (CSV) file.

Note: You can use other applications that support viewing or editing of the CSV files. You must ensure to apply the relevant formats to the fields to view the correct format of the generated test data.

What to do next

You can view the information about the history of the generated data in the **History** tab of the **Data** page.

Generating test data by using data definition history

You can generate fabricated test data in Test by using the history of existing data definitions. This approach supports better collaboration by allowing multiple team members to work with consistent test data at different stages of the project.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a data definition. See Creating an empty data definition on page 980.
- Generated test data by using a data definition. See Generating standard test data by using data definitions and exporting it to a .zip file on page 1014.

Note: If a project member has generated a test data from a data definition, then the other project members can view the generated test data only when the changes are pushed to the repository.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch from the **Branch** list.

The navigation panel displays all the existing projects in the selected branch.

5. Find the data definition that you want to use for regenerating test data, and then click it.

   Note: You can either enter the name of the data definition in the **Search** field or expand the project and manually search in the data navigator panel.

   Result

   The selected data definition opens in the **Data** page.

6. Click the **History** tab.

   A list of all the previously generated test data are displayed, along with the following information:

   - The month, date, and year of the generated test data.
   - The status of the download action that indicates whether the data generation was successful or failed.
   - The number of rows in the generated test data.
   - The initials of the project member who downloaded the generated test data.

7. Perform the following actions in the **History** tab:

   a. Find the required test data.

   b. **Optional**: Click the **Preview** icon to preview the test data before regeneration.

      The test data is generated in the preview dialog.

      Note: You can preview the previosuly generated test data to ensure whether the data is in the expected format. You can have a glimpse of the regenerated test data that can help you to identify any potential issues, inconsistencies, or errors in the data definitions.

   c. Click the **Generate** icon .

      The **Generate data** dialog is displayed.

      Note: If you are in an Edit branch, then you can access the **Generate** icon from the preview dialog only if the data definition is saved.

8. Perform the following actions in the **Generate data** dialog:

   a. Enter a name in the **Name** field to identify the test data when generated.

   b. Enter the number of rows that you want to generate in the **Number of Rows** field.

   c. **Optional**: Enter the seed value in the **Seed** field.

      Whenever you generate test data to perform application testing, the generated data is different. You can produce the same set of data multiple times by setting the seed value.

For example, assume that you have used the seed value as `1` to generate test data from a data definition. When you want to create another test data with the same set of values, then you can provide the seed value as `1` during the creation of the test data.

d. Clear the **Include headers** option if you do not want to include headers in the generated test data.
e. Click the **Download** option to initiate the generation of the test data.

Results

The generated test data is downloaded into your local file system as a Comma Separated Values (CSV) file.

Note: You can use other applications that support viewing or editing of the CSV files. You must ensure to apply the relevant formats to the fields to view the correct format of the generated test data.

Generating and exporting schema-based test data to a `.zip` file

You can generate schema-based test data and export it as a `.zip` file that contains `.csv` files. The exported data remains consistent with the schema structure, which supports accurate testing, data validation, and you can use this data to perform data-driven testing across multiple scenarios in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that your project contains a schema.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch from the **Branch** list.
   The navigation panel displays all the existing projects in the selected branch.
5. Select the schema from which you want to generate and export test data in the data navigator panel.

   The selected schema is displayed in the **Data** page.

Note: You can either enter the name of the Schema in the **Search** field or expand the project and manually search in the data navigator panel.

6. Click the **Preview** icon to preview the test data that you want to generate.

   The test data is generated in the preview dialog.

   Note: You can preview test data to ensure whether the data is in the expected format. You can review the generated test data that can help you to identify any potential issues, inconsistencies, or errors in the schema. If you modify the schema and do not save it, you can still preview the corresponding test data. However, you can generate the test data only after you save the schema.

7. Click the **Generate** icon from the **Data** page.
   The **Generate data** dialog is displayed.
8. Select **Download as a zip file** from the **Select destination** list.
9. Type the file name in **File Name** field.
10. **Optional**: Enter the seed value in the **Seed** field.
    For example, consider that you have used the seed value of `1` to generate data from a schema. When you want to create another data with the same set of values, then you can provide the seed value as `1` during the creation of the test data.
11. Enter the number of rows that you want to generate in the **Generate** column.
12. **Optional**: Enter a value in the **Target** field to customize the number of rows to be generated in the tables.
    The default value in the **Target** field is set to 100%.

    For example, if a table in the database contains 10 rows and if you set the **Target** field to 200%, then the generated data displays 20 rows.

13. Click **Download** to initiate the generation of the data.
    Result
    The generated data is downloaded into your local file system as a `.zip` file.

Results

You have generated realistic and schema-aligned test data and exported it as a `.zip` file that contains `.csv` files.

What to do next

You can create a dataset by using the downloaded `.csv` files. See Creating a dataset by using a CSV file on page 956.

Generating test data by using data definitions or schema and exporting it to a database

You can generate test data by using data defintions or and schema, and export it directly to a connected database in Test . This process supports populating or updating database tables with realistic and schema-aligned test data used in development, testing, or validation workflows.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Ensured that your project contains data definition or schema.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **Author > Data**.

   The **Data** page and the data navigator panel are displayed.
4. Select the branch from the **Branch** list.
   The navigation panel displays all the existing projects in the selected branch.
5. Select the data definition or schema from which you want to generate and export test data in the data navigator panel.

   The selected data definition or schema is displayed in the **Data** page.

   Note: You can either enter the name of the data definition or schema in the **Search** field or expand the project and manually search in the data navigator panel.

6. Click the **Preview** icon to preview the test data that you want to generate.

   The test data is generated in the preview dialog.

   Note: You can preview test data to ensure whether the data is in the expected format. If you modify the data definition or schema and do not save it, you can still preview the corresponding test data. However, you can generate the test data only after you save.

7. Click the **Generate** icon on the **Data** page.
   The **Generate data** dialog is displayed.
8. Perform the following steps to generate test data by using data definitions:
   a. Select the appropriate database from the **Select a Database Connection** list.

   b. Select a table from the **Table** dropdown.

      The selected table name appears in the **Table** field.

If the selected table structure does not match the data definition for data generation, a **Mismatch** indicator is displayed next to the table name, and the **Export** button is disabled.

The **Current Contents** field displays the existing number of rows in the selected table.

c. Enter the number of rows you want to generate in the **Number of Rows** field.

9. Perform the following steps to generate schema based test data:
   a. Select the appropriate database from the **Select a Database Connection** list.

      The **Tables** column lists the available tables from the schema.

      The **Current** column displays the number of existing rows in each table.

   b. Enter the number of rows to generate for each table in the **Generate** column.

      If there is a mismatch between the selected table and the schema used for data generation, a **Schema mismatch** indicator is dispalyed, and you cannot generate data for that table.

   c. Enter a value in the **Target** field to customize the number of rows to be generated in the tables.

      The default value in the Target field is set to 100%.

      For example, if a table in the database contains 10 rows and if you set the Target field to 200%, then the generated data displays 20 rows.

10. **Optional**: Enter the seed value in the **Seed** field.
    Whenever you generate data to perform application testing, the generated data is different. You can produce the same set of data multiple times by setting the seed value.
    For example, consider that you have used the seed value of `1` to generate data from a data defintion or schema. When you want to create another data with the same set of values, then you can provide the seed value as `1` during the creation of the test data.
11. **Optional**: Select the **Overwrite** checkbox to overwrite the rows in the tables for generating data.
    This option is not selected initially.
    For example, if a table in the database contains 10 rows and if you select the **Overwrite** checkbox, then the generated data replaces the existing 10 rows with new data generated.
12. Click the **Export** option to initiate the generation of the test data.
    The generated data is exported to the database.

Results

You have generated the test data by using data definition or schema and exported it to directly to the connected database.

What to do next

You can create a dataset by using the database query. See Creating a dataset by using a database query on page 960.

Publishing all changes in an Edit branch

After you create or modify any data or test assets in an Edit branch of a project in Test , you can publish all the changes that are in an Edit branch to the source branch in the project repository. After publishing, other members in the project can view and use the resources.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created or modified a test or data asset.
- Read and understood the information in Edit branch overview on page 760 and Create or select an Edit branch on page 772.

About this task

When you create or modify multiple assets in a project, the **Changes** page lists all the changed assets in the selected branch. In this scenario, you cannot publish or discard a single change. You must either publish or discard all changes that are made to all the listed assets.

When you review assets on the **Changes** page before publishing, each executable asset displays a colored status indicator in the parent row as follows:

- **Green** – The most recent run passed.
- **Red** – The most recent run failed.
- **Orange** – The most recent run resulted in an error.
- **Grey** – No run result is available for this revision.

The indicator helps you view the most recent run result for that specific asset revision. The colored bar on the left side of the parent row represents the most recent run result.

When you review assets on the **Changes** page before publishing, each executable asset displays a coloured status indicator in the parent row. The indicator helps you understand the most recent run result for that specific revision of the asset. The coloured bar on the left side of the parent row represents the latest run result:

- **Green** – The most recent run passed.
- **Red** – The most recent run failed.
- **Orange** – The most recent run resulted in an error.
- **Grey** – No run result is available for this revision.

The **Changes** page also provides you with information about the number of commits that the selected branch is ahead and behind. After you publish an asset to the Git repository, all the other project members who have access to that asset can view the updated asset. You can perform the following actions in the **Changes** page:

Options	Actions
Edit	Click **Edit** to make any updates to the asset before publishing.
Discard	Click **Discard** to remove the changes that you made to the asset.
Save as	Click **Save as** to save a copy of the asset. **Note:** When you try to publish a modified asset with conflicting edits, an error about conflicting changes is displayed. However, you can use the **Save as** option to save a copy of the asset edits under a new asset name. You must discard the edits that you made to the original asset. For example, consider a scenario when Amy Smith and John Doe edit the same Data definition, and Amy Smith edits and publishes the Data definition. On the **Changes** page, a message that indicates the number of commits ahead and behind in the branch is displayed when John Doe tries to publish the same Data definition. You can then use the **Save as** option to resolve this issue.
Compare	Click **Compare** to view the differences between the asset on the edit branch and the asset on the main branch.
Update	Click **Update** to merge the changes from remote branch that are not in your Edit branch.
Details	Click **Details** to see the changes.
Reset	Click **Reset** to discard the changes
Push	Click **Push** to upload the edit branch to remote repository when a conflict prevents publishing.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Go to **Author > Changes**.
4. Select the Edit branch from the **Branch** list.
   All the updated assets that are present in the selected branch are displayed in the **Changes** page.
5. Click **Publish**.
   The **Publish** dialog is displayed.

6. Enter a description for the changes that you performed to the asset, and then click **Publish**.
   If the publish succeeds, the Edit branch is automatically deleted and removed from the **Branch** list and the changes are merged into the previously selected remote branch.
   If the publish fails due to a conflict with the remote branch, click **Push** in the **Publish** dialog to push the edit branch to the remote repository. Then, you can create a pull request and resolve the conflicts manually in Git before you merge the changes into the target branch.

Results

You have published all the changes in an Edit branch to the remote branch in the project repository.

Test Execution Specialist Guide

This guide describes tasks that you must complete before you can configure and run tests in Test . You can find information about configuring runs for the different test types that are supported. You can also find information about other tasks that you can perform on the Resource Monitoring Service, Virtualization, and Integrations with third-party applications. This guide is intended for testers or test execution specialists.

System modeling

You can use the system model feature on Test to create a model that simulates an application or system under test. You can define components to represent the actual components in the system under test, define their relationships and then view the components in a system under test as a diagrammatic representation.

Introduction to a system model

A system model is a logical presentation of the components contained in a system under test and the relationships between components. You can create a system model when you want to visualize the different components and their relationships as a diagrammatic representation.

You can create only one system model within a team space on Test. A team space repository is required to contain the system model that you create. Before you can create a system model, you must add a team space repository. The system model that is created or edited is stored in the team space repository. All projects within a team space share the same system model. All members of a team space can create, edit, and view the system model.

After you log in to Test, you can go to the **System Model** page to create a system model for your team space. Alternatively, you can go to any of the projects in your team space and create a system model from the **System Model** page within a project. The system model is accessible from all the projects in your team space.

Components in a system model

Components are the basic building blocks that are used to represent a piece of software in an application.

You can model a system by using components. You can create components that represent the type of asset or resource used by the system or application under test and can be of the following types:

Component type	Description
Database	The component type represents the database resource. You can select this component type when you want to represent a database asset or resource in the system model.
Service	The component type represents the virtual service resource. You can select this component type in the system model to represent a virtual service in the team space repository or associate a virtual service resource that is in the project repository.
UI	The component type represents the user interface (UI) resource. You can select this component type when you want to represent the UI resource in the system model.

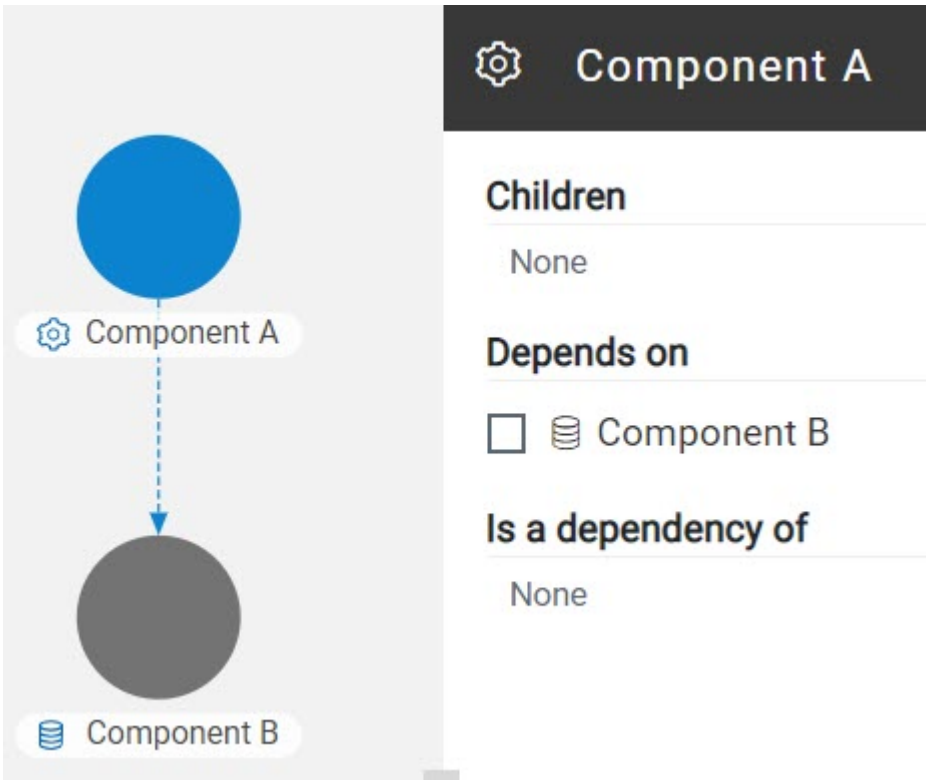
Component relationships

You can create multiple components to depict the different resources in the system or application under test. You can create a component as a *child* component of a *parent* component. You can also create multiple components as children components of the same parent component.

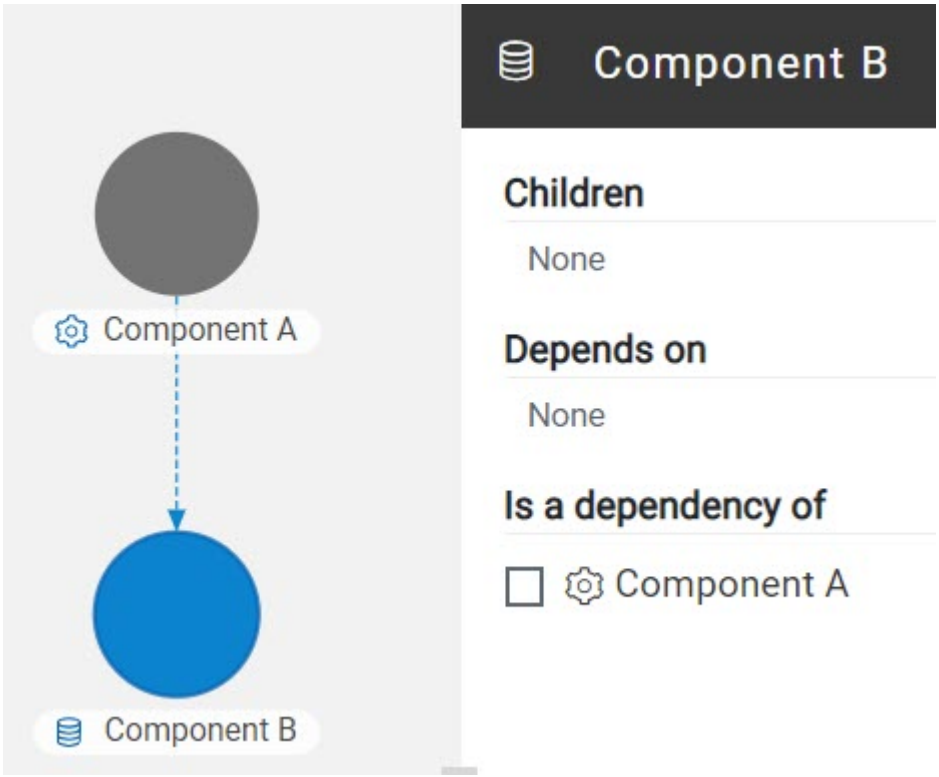
You can define the relationship between components if one component depends on another or if a component has a dependency of another component. The **Depends on** or **Is a dependency of** relationship depends on the component that you select in the system model after you define the relation.

For example, if you define *Component A* to depends on *Component B*, then the relationship is displayed with a line arrow from *Component A* to *Component B*, and the arrow points to *Component B*.

When you click the *Component A* in the system model page, you can view that the *Component B* is listed under the **Depends on** section for *Component A* in the right pane.



When you click the *Component B* in the system model, you can view that the *Component A* is listed under the **Is a dependency of** section for *Component B* in the right pane.



Component associations

When you work with the system model from your project in a team space, you can associate test resources that are in your project repository with components in the system model. You can associate all types of test resources such as Suites or tests, and virtual service resources with the components.

After associating test resources, you can view them when you select the component with which they are associated. You can select the associated test resources to start a run of the Suites or tests or start an instance of the virtual services resource.

Using the system model UI

The following table lists the icons used in a system model and the icons that are displayed on the **System Model** page:

Icon	Description
	Represents a system model.
	Represents Suites and tests in a repository.
	Represents a database resource. The component name is prefixed with this icon when you select the component type as database.
	Represents a service resource. The component name is prefixed with this icon when you select the component type as service.
	Represents a user interface (UI) resource. The component name is prefixed with this icon when you select the component type as UI.
	Represents the virtual services.
	Represents the dependency between the components.
	Represents the inherited dependencies.

The following table lists the icon that you can use to perform different actions in the system model:

Icon	Used for...
	Adding components, child components, or dependent components.
	Searching for components in the system model.
	Publishing the changes made to the system model, changes made to components, or changes made to component associations. The changes are published to the team space repository.

You can perform the following operations when you view the model that is displayed on the **System Model** page:

Operation	Action
Pan the view of the model	1. Click the area of the model that you want to pan and move the area by keeping the left mouse button pressed. 2. Release the left mouse button to stay on the view that you panned.
Zoom in the view of the model	1. Click the **Zoom-in** icon . The view is enlarged or zoomed in. **Note:** You can repeatedly click the **Zoom-in** icon to further enlarge the view. Alternatively, you can use the scroll button on the mouse or device to zoom in the view.
Zoom out the view of the model	1. Click the **Zoom-out** icon . The view is diminished or zoomed out. **Note:** You can repeatedly click the **Zoom-out** icon to further diminish the view. Alternatively, you can use the scroll button on the mouse or device to zoom out the view.
Reset the view	1. Click the **Menu** icon on the **System Model** page. 2. Select **Reset Zoom**. The view is reset to the default view without any zoom applied. If the view was zoomed in or zoomed out, the view is reset to 100% of the size.
Position the model view	1. Click the **Menu** icon on the **System Model** page. 2. Select from the following options: ◦ **Center**: Select this option to align the view of the model to the center of the pane. ◦ **Fit to View**: Select this option to fit the view of the model in the pane on the **System Model** page.

Tasks in system modeling

When you want to model the system under test for the first time after you install the server software, you must first add the team space repository. See Adding a repository to a team space on page 1031.

After a repository is configured as the team space repository, you can work with the system model. See Tasks for working with a system model on page 1030.

When you want to change, update or delete the repository, you can work with the team space repository. See Tasks for working with the team space repository on page 1031.

Task flows for working with a system model

You can find information about the tasks that you can perform when you want to create a system model, components, associate the components, create linkages among the components, and then publish the system model to the team space repository. You can also find information about the tasks that you must perform when you want to modify an existing system model.

Tasks for working with a system model

You can find the tasks when you want to create a system model for the application under test in your team space.

Tasks	Go to...

Adding a repository to a team space

You must add a repository to the team space in Test when you want to create, modify, or store a system model.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* or an *Architect* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you obtained valid credentials to access the Git repository that you want to add.

About this task

As a *Team Space Owner* or an *Architect*, you can add a repository to the team space. You can add a repository to the team space in any of the following methods:

- Add an existing repository that can contain test assets, which are created in the desktop products.
- Add a bare repository.

Attention: The repository that you want to add must not contain any projects or `.project` files under the root directory.

You can add a Git repository using SSH. When you add a repository, the Git repository is cloned to the team space. While you add a repository, you must provide the necessary authentication credentials that are set for the Git repository. If the authentication type is SSH, then you must provide the Git URL, a deploy key, and a passphrase.

For example:

- `git@github.com:account/testRepo.git`
- `ssh://git@10.111.111.333:2222/~/account/project.git`

Important: You can add only one repository to the team space. After you add a repository to the team space, the option to add another repository is not available. You must delete an existing repository before you can add a different repository.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **Manage > Configuration**.
   Result
   The **Configuration** page of the team space is displayed
4. Click **Add Repository**.
   Result
   The **Add Repository** dialog is displayed.
5. Perform the action based on the selected repository type:
   The following table describes the actions required for each repository type:

Repository type	Action
Remote Repository	a. Enter the URL of the Git repository that you want to add to the team space in the **Git URL** field. The required fields are displayed based on the type of Git URL that you entered. b. Enter the required credentials based on any of the following authentication methods configured in the repository. To gain access to the repository, you must use any one of the following authentication methods:

Repository type	Action
	▪ SSH: Deploy key and passphrase ▪ HTTPS: Username and password ▪ HTTP: Username and password **Note:** ▪ You must have defined the authentication type and set the authentication credentials in the Git repository. ▪ If you use SSH to connect to your remote repository and Test displays an `Auth Fail` exception while using the deliver changes option, you can resolve this exception error by regenerating your SSH keys by using the -m PEM option.
Local Repository	Enter a unique repository name in the **Repository Name** field. Optional: Modify the default branch name in the **Default Branch Name** field. By default, the branch name is `main`. **Note:** ◦ You cannot change the Local repository names after creation. ◦ You can create and edit branches, create and edit assets, and publish changes locally in a local repository. ◦ You can later push a local repository to a supported remote repository provider. ◦ Ensure that the branch you are pushing from your local repository does not already exist in the remote repository. This helps avoid merge conflicts.

6. Click **Add**.

Results

The Git repository is added to the team space on Test.

Note: The time to clone the repository can take a few to several minutes and depends on the size of the repository.

What to do next

You can perform the following actions on the repository that you added:

- Update the authentication credentials if they are changed in the Git repository configuration. See Updating the authentication credentials of the repository on page 1745.
- Refresh a repository to fetch and synchronize changes from the remote repository. See Refreshing repositories manually on page 1746.
- Configure a webhook to notify the server if there is a push event in the remote repository. See Creating webhooks on page 1749.
- Add a system model to the repository. See Creating a system model on page 1034.
- Delete a repository that is added to the team space, if it is no longer required. See Deleting a repository from a team space on page 1056.

Managing repositories on page 1741

Creating a system model

Before you can create components in a system model in Test , you must create an empty system model and publish the system model to the team space repository.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Added a repository to the team space. See Adding a repository to a team space on page 1031.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space for which you want to create a system model.
3. Select an option to create a system model based on your role in the team space or in a project in the team space:

- If you are a *Team space owner* or an *Architect*, go to Step 4 on page 1035.
- If you are not a *Team space owner* or an *Architect* but a project *Owner* or *Tester*, go to Step 5 on page 1035.

4. Perform the following steps, if you are a *Team space owner* or an *Architect*:
   a. Click **System Model** in the left navigation pane.

      The **System Model** page is displayed.

   b. Click the **Add system model** icon .

      An empty system model is created.

   c. Go to Step 6 on page 1035.

5. Perform the following steps, if you are not a *Team space owner* or an *Architect* but a *Project owner*:
   a. Open your project that is displayed under **My projects** tab.

      The **Overview** page of the project is displayed.

   b. Click **System Model** in the left navigation pane.

      The **System Model** page is displayed.

   c. Click the **Add system model** icon .

      An empty system model is created.

   d. Go to Step 6 on page 1035.

6. Click the icon, and then click the **Publish** option.

   Note: If you do not want to commit the changes that you made to the system model, you can select the **Discard** option.

7. Enter a commit message in the **Description of change** field, and then click **Publish**.

   The empty system model is committed and published to the team space repository. When the system model is published to the team space repository, other members of the team space can work with the same system model from any of their projects in the team space.

Results

You have created an empty system model and published it to the team space repository.

What to do next

You can perform any of the following tasks:

- Create components in the system model. See Creating components on page 1036.
- Create child components for the components that you added to the system model. See Creating child components on page 1037.

Creating components

After you create an empty system model in the team space in Test , you can create components that represent components of the system under test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Added a repository to the team space. See Adding a repository to a team space on page 1031.
- Created and published the system model. See Creating a system model on page 1034.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Perform the following steps to add a component to the system model:

   a. Click the **Add component** icon in the **Components** row on the right pane.

      The **Add a component** dialog is displayed.

   b. Enter a name for the component in the **Name** field.

   c. Select the type of component that you want to add from the following options displayed in the **Type** field.

      - **Service**
      - **Database**
      - **UI**

   d. Click **Add**.

The component is displayed as a circular block on the system model pane with the icon and name of the component below the block. The added component is also displayed under the **Components** list on the right pane.

You can create components of other types or the same type in the system model by following the preceding steps.

Results

You have created components in the system model.

What to do next

You can perform any of the following tasks:

- Publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.
- Create child components for the components that you added to the system model. See Creating child components on page 1037.
- Create linkages between components in the system model. See Creating linkages between components on page 1039.

Creating child components

You can create child components in the system model in Test when you want to represent the sub-components of a component in a system under test.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.

About this task

You can create multiple components in your system model and multiple child components under any component in the system model. After you create a child for a component, the child is represented as a circular block within the circular component block in the system model.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed with the existing components.
4. Create child components by using any of the following options:
   - To create child components from the left pane on the **System Model** page, go to Step 5 on page 1038.
   - To create child components from the right pane on the **System Model** page, go to Step 6 on page 1038.
5. Perform the following steps to create child components from the left pane:
   a. Click the component under which you want to create child components.

      The details of the component are displayed in the right pane.

   b. Click the **Add child** icon in the **Children** row on the right pane.

      The **Add a child to...** dialog is displayed.

   c. Enter a name for the component in the **Name** field.

   d. Select the type of component that you want to add from the following options displayed in the **Type** field.

      - **Service**
      - **Database**
      - **UI**

   e. Click **Add**.

      The child component is displayed as a circular block within the circular block of the parent component on the system model pane. The added child component is also displayed under the **Children** list under the component on the right pane.

      You can create child components of other types or the same type for the same or other components in the system model by following the preceding steps.
6. Perform the following steps to create child components from the right pane of the stem model page:
   a. Click the component name listed under the **Components** in the right pane.

   b. Click the **Add child** icon in the **Children** row on the right pane.

      The **Add a child to...** dialog is displayed.

   c. Enter a name for the component in the **Name** field.

   d. Select the type of component that you want to add from the following options displayed in the **Type** field.

- **Service**
- **Database**
- **UI**

e. Click **Add**.

The child component is displayed as a circular block within the circular block of the parent component on the system model pane. The added child component is also displayed under the **Children** list under the component on the right pane.

You can create child components of other types or the same type for the same or other components in the system model by following the preceding steps.

Results

A component is created and it is associated as a child with the selected component and the name of the child is displayed under the **Children** section on the right pane.

What to do next

You can perform any of the following tasks:

- Publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.
- Create linkages between components in the system model. See Creating linkages between components on page 1039.

Creating linkages between components

You can create linkages between components in Test to display the relationship between them. The linkages can be between components or between child components of the same or different parent components.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Created child components. See Creating child components on page 1037.

About this task

You can create multiple components in your system model. You can also create multiple child components under any component in the system model. You can specify the dependency among the components.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Perform the following steps to create a relationship between the components in the system model:

   a. Click the component that you want.

      The details of the component are displayed on the right pane.

   b. Perform the actions in the following table to create dependencies between the components:

Option	Action
Depends on	Perform the following steps, if the component that you selected is dependent on another component: i. Click the **Add dependency** icon in the **Depends on** row on the right pane. The **Add dependency** dialog is displayed. ii. Select the component from the list of components displayed under **Depends on**. iii. Click **Add**. The components linked are listed under the **Depends on** section on the right pane. The linkage between the first to the second component that you selected is shown with an arrow that starts from the first and ends in the second component.
Is a dependency of	Perform the following steps, if the component that you selected has a dependency on another component: i. Click the **Add dependent** icon in the **Is a dependency of** row on the right pane. The **Add dependent** dialog is displayed.

Option	Action
	ii. Select the component from the list of components displayed under the **Is a dependency of** section. iii. Click **Add**. The components linked are listed under **Is a dependency of** section on the right pane. The linkage between the first to the second component that you selected is shown with an arrow that starts from the second and ends in the first component.

Results

You have created linkages between components in the system model.

What to do next

You can publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.

Deleting linkages between components

When you do not want to retain the linkages between components that you created in the system model in Test , you can delete the linkages.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Created child components. See Creating child components on page 1037.
- Created linkages between components in the system model. See Creating linkages between components on page 1039.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.

4. Perform the following steps to delete a relationship between the components in the system model:

    a. Click the component that you want.

    The details of the component are displayed on the right pane.

    b. Select from the following types of relationships that you want to delete:

When...	Action
The component depends on another component.	Perform the following steps, if the component that you selected is dependent on another component: i. Select the component from the list of components that are displayed under the **Depends on** section on the right pane. ii. Click the **Delete selected** icon inline with the **Depends on** row. The **Delete relationship** dialog is displayed with the details of the component and the dependent component. iii. Click **Delete**. The component linkage is removed from the system model pane.
The component has a dependency on another component.	Perform the following steps, if the component that you selected has a dependency on another component: i. Select the component from the list of components that are displayed under the **Is a dependency of** section on the right pane. ii. Click the **Delete selected** icon inline with the **Is a dependency of** row. The **Delete relationship** dialog is displayed with the details of the component and the component dependency. iii. Click **Delete**. The component linkage is removed from the system model pane.

Results

You have created linkages between components in the system model.

What to do next

You can publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.

Modifying components

At any point in time, after you create a component in Test , you can modify and update the details of the components such as the component type, and the relationships with other components.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Created child components. See Creating child components on page 1037.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Click the component that you want to edit.

   The component details are displayed on the right pane.
5. Perform the actions for the task to modify components as listed in the following table:

Task	Action
Change the component type.	Perform the following steps: a. Identify the component that you want to modify from the components listed under **Components** on the right pane. b. Click the component checkbox. The **Edit selected** icon is enabled. c. Click the **Edit** icon. The **Edit component** dialog box is displayed. d. Select the component type. e. Click **Modify** The type of the component is modified.

Task	Action
Change the name of a component.	Perform the following steps: a. Identify the component that you want to modify from the components listed under **Components** on the right pane. b. Click the component checkbox. The **Edit selected** icon is enabled. c. Click the **Edit** icon. The **Edit component** dialog box is displayed. d. Edit the component name in the **Name** field. e. Click **Modify**. The name of the component is modified.
Change the parent of a component.	Perform the following steps: a. Identify the component that you want to modify from the components listed under **Components** on the right pane. b. Click the component checkbox. The **Change parent** icon is enabled. c. Click the **Change parent** icon. The **Change parent** dialog box is displayed. d. Select another parent for the selected components from those that are listed under the **Parent** list. e. Click **Change**. The parent of the component is changed.

Results

You have edited components and updated the details successfully.

What to do next

You can publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.

Deleting components

When you do not require a component in Test , you can delete the component from the system model.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Click the component that you want to delete.

   The component details are displayed on the right pane.
5. Click the **Delete component** icon in the row of the component name.

   The **Delete component** dialog is displayed.
6. Click **Delete**.

Results

You have deleted a component from the system model.

What to do next

You can perform any of the following tasks:

- Publish the changes that you made to the system model. See Publishing changes to the system model on page 1045.
- Create components in the system model. See Creating components on page 1036.

Publishing changes to the system model

When you create, delete, or modify components in a system model in Test , the changes are saved locally and are not visible to the other project members or team space members. You must publish the system model changes to the team space repository to make your changes visible to all users of the team space.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as an *Architect* in the team space, a *Project Owner* or a *Tester* in the project. See Managing members and their roles in a team space on page 1721 or Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Created child components. See Creating child components on page 1037.
- Created linkages between components in the system model. See Creating linkages between components on page 1039.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Click the icon, and then click the **Publish** option.

   Note: If you do not want to commit the changes that you made to the system model, you can select the **Discard** option.
5. Enter a commit message in the **Description of change** field, and then click **Publish**.

Results

You have published the changes that you made in the system model to the team space repository. Other members of the team space can view and use the system model.

Associating resources with components

After creating components in the system model in Test , you can navigate to a project in the team space to associate the Suites, tests, or virtual service resources in the project repositories with components in the system model.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
4. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
5. Click the component that you want to associate with the Suites, Tests, or virtual service resources.

   The component details are displayed in the right pane.
6. Click the **Associate** tab, and then perform the following steps:

   a. Click **Add**.

   b. Select the type of resource that you want to associate with the component from the following options:

      - Suites and Tests
      - Virtual services

      Note: You can select either of the options or both the options.

      The **Edit branch** dialog is displayed.

   c. Select your action that depends on the existence of an *Edit* branch from the following options:

      - Select an existing *Edit* branch that you created previously from the list of branches listed in the **Select branch** field, and then click **Save**.
      - Click **Create new branch**, enter a name for the branch, and then click **Save**, if you want to create a new branch.

      The **Associate Assets** dialog is displayed. The resources that are contained in the branch of the project repository are listed. The name of the component and the branch are also displayed.

      The **Suites and Tests** option is selected and the assets are listed if you selected the **Suites and Tests** option.

      The **Virtual services** option is selected and the virtual service resources are listed if you selected the **Virtual services** option.

      If you selected both the types of resources, then assets and virtual services in the branch are listed.

   d. Identify the assets or virtual resources that you want to associate with the component in the system model by performing any of the following actions:

- Search for the resource by entering the asset name in the **Search** field.
- Find the assets by scrolling through the list of assets.

e. Select the resources, and then click **Add**.

The selected resources are associated with the component.

You can view the associated resources that are displayed in the **Associate** tab and the **Overview** tab. The test assets are listed under the **Suites and Tests** section and the virtual service resources are listed under the **Virtual services** section.

If you want to associate other resources to the same component, you can add them by clicking the **Add association** icon in the resource row on the right pane. You can then select the resource and add the resource to the selected component.

Results

You have associated Suites, tests, or virtual service resources with a component in the system model.

What to do next

You can perform any of the following tasks:

- Publish the changes made in the system model for associating resources with components. See Publishing changes to the system model on page 1045.

Viewing resources that are associated with components

After you associate Suites, tests, or virtual services resources with components in the system model in Test , you can view the associated resources from the **System Model** page. You can opt to run an instance of the associated resource or stop a running instance of the associated resource.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Associated resources in a project with components in the system model. See Associating resources with components on page 1046.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.

2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
4. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
5. Click the component that you associated with the resources in the project repository.

   The resources associated with the component are displayed under the resource type in the **Associate** tab.
6. Click the **Overview** tab, if it is not already displayed.

   The resources that are associated with the component are displayed under the **Suites and Tests** or **Virtual Services** section.
7. View and perform the actions for the resource type that you want from the following options:
   - For **Suites and Tests** resources, go to 8 on page 1049.
   - For **Virtual Services** resources, go to 9 on page 1050.
8. Identify the test resource from those that are listed under the **Suites and Tests** section, and perform the action that you want as described in the following table:

Task	Description	Action
Collapse icon	You can hide the resource sections by clicking the **Collapse** icon. **Note:** When the section is hidden, you can view the number that is displayed of the resources that are associated.	Click the icon to toggle the display to show or hide the resource list in the **Suites and Tests** section.
Type	You can view the type of Suite or test.	Hover over the Suites and Tests icon under the **Type** column to view the type of Suite or test.
Name	You can view the name of the associated Suite or test and the path in the repository.	There is no action to perform.
Status	You can view the details of the test runs.	Click each of the squares to view the details of the specific test run. For example, if the status of a test run is represented as shown in the image , then it indicates that the

Task	Description	Action
		Suite or test has run only two times. After you click any colored square, the **Results** page is displayed.
Action	You can start the execution of the Suite or test from the **Execution** page when you click the **Show in execution page** icon.	Click the **Show in execution page** icon to view the Suite or test on the **Execution** page. The Suite or test is displayed on the **Execution** page.

9. Identify the virtual service resource from those that are listed under the **Virtual Services** section, and perform the action that you want as described in the following table:

Field	Description	Action
Collapse icon	You can hide the resource sections by clicking the **Collapse** icon. **Note:** When the section is hidden, you can view the number that is displayed of the resources that are associated.	Click the icon to toggle the display to show or hide the resource list in the **Virtual Services** section.
Show all icon	You can opt to view the virtual services that are associated with the component either on the **Resources** or **Instances** page. You can start an instance of the virtual service from the **Resources** page while you can stop a running instance from the **Instances** page.	Perform the following steps: a. Click the **Show all** icon. b. Select any of the following actions: ▪ To start an instance of the virtual service: i. Select **Show all in resources page** to go to the **Resources** page. ii. Click the **Execute** icon in the row of the virtual service. iii. Configure the settings for the run of the virtual service, if you want to change any of the settings, else click **Execute.** The virtual service starts to run. ▪ To stop a running instance of the virtual service:

Field	Description	Action
		i. Select **Show all in instances page** to go to the **Instances** page. ii. Identify the instance that you want to stop and click the **Stop** icon in the **Actions** column of the selected virtual service instance. iii. Click **Ok** in the **Stop virtual service instance** dialog that is displayed. The running virtual service instance is stopped.
Name	You can view the name of the associated virtual service and the path in the repository.	There is no action to perform.
Instances	You can view the state of the running instance of the virtual service resource. The state is displayed as `Running` only if the instance is running.	There is no action to perform.
Action	You can go to the **Resources** page to view the virtual service resource when you click the **Show resource** icon . You can start an instance of the virtual service from the **Resources** page.	Click the **Show resource** icon to view the virtual service on the **Resources** page. The virtual service resource is displayed on the **Resources** page.
Expand icon	You can expand the virtual service card only if the virtual service is a running instance. In the expanded card, you can view the details such as the Environment, the total number of requests received by the virtual service, and the relative time	Perform the following steps: a. Expand the virtual service card for a running instance. You can view the details of the instance. b. Click the **Show instance** icon to go to the **Instances** page to view the running instance of the virtual service. The running instance of the virtual service is displayed on the **Instances** page.

Field	Description	Action
	from when the virtual service had started. You can stop a running instance of the virtual service from the **Instances** page.	

Results

You have viewed the resources that are associated with a component from the **System Model** page.

Removing resources that are associated with components

When you do not want to retain the resource that you associated with a component in Test , you can delete the resource association from the system model.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Associated resources in a project with components in the system model. See Associating resources with components on page 1046.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
4. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
5. Click the component that you associated with the resources in the project repository.

   The resources associated with the component are displayed under the resource type in the **Associate** tab.
6. Select the resource that you want to remove from the component by clicking the checkbox of the resource.

   You can select any or all resources for removal.

7. Click the **Delete selected** icon in the row of the resource type.

   The **Disassociate...** dialog is displayed for the type of resource that you selected. For example, the **Disassociate Suites and Tests** dialog is displayed when you selected the test assets.

8. Click **Delete**.

   The **Edit branch** dialog is displayed.

9. Select your action that depends on the existence of an *Edit* branch from the following options:

   - Select an existing *Edit* branch that you created previously from the list of branches listed in the **Select branch** field, and then click **Save**.
   - Click **Create new branch**, enter a name for the branch, and then click **Save**, if you want to create a new branch.

   The dialog that is displayed depends on the type of resource you selected and can be any of the following types:
   - The **Dissociate suites and tests** dialog is displayed, if you selected Suites or tests as the resources to dissociate.
   - The **Dissociate virtual services** dialog is displayed, if you selected the virtual services as the resources to dissociate.

10. Click **Delete**.

Results

You have removed resources that were associated with components in the system model.

What to do next

You must publish the dissociation changes in the system model to the project repository if you want the changes to be reflected in the system model for all members of the project. See Publishing changes of associating or dissociating resources with components on page 1053.

Publishing changes of associating or dissociating resources with components

After you associate or dissociate resources in a project with a component in the system model in Test , you must publish the changes made to the branch in the project repository so that the association changes are visible to the other members of the project.

Before you begin

You must have completed the following tasks:

- Created and published the system model. See Creating a system model on page 1034.
- Created components in the system model. See Creating components on page 1036.
- Associated resources in a project with components in the system model. See Associating resources with components on page 1046.
- Dissociated resources from components in the system model. See Removing resources that are associated with components on page 1052.

1. Log in to Test.

   Result

   The **Projects** page of the initial team space is displayed.
2. Click **My projects > *project_name*** to open the project that contains the test assets.

   The **Overview** page of the project is displayed.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Click the icon.

   You can view the options for unpublished changes made to the components and associations in the system model. The options available for association changes are as follows:
   - See unpublished commits
   - Discard
   - Publish
5. Perform any of the following actions to publish the association or dissociation changes:

   - Review the unpublished changes before you publish them. Go to Step 6 on page 1054.
   - Publish the changes. Go to Step 7 on page 1055.
6. Perform the following steps to review the unpublished changes:

   a. Select the **See unpublished commits** option.

      The **Your system model changes** page is displayed. You can find the following information about the changes that you made to the system model when you associated resources with components or deleted the association:
      - The *Edit* branch that you selected to contain the changes is displayed in the **Branch** field. You can select the *Edit* branch that you used before associating resources to components, if it is not already displayed as selected.
      - The projects that contained the resources, which you associated with components in the system model are listed under the **Asset name** column.
      - The type of change is listed under the **Changes** column.
      - The name of the member who made the change is displayed under the **Last changed by** column.
      - The relative time when the change was made is displayed under the **Last updated** column.
      - The number of changes that the *Edit* branch is ahead of from the project repository branch is indicated by the **commits ahead** option. You can view the details by clicking the **commits ahead** option and in the dialog that displays, you can discard the pending commits by clicking the **Reset** option.
      - The number of changes that the *Edit* branch is behind from the project repository branch is indicated by the **commits behind** option. The *Edit* branch can be behind the project repository branch if another member has published or committed other changes in the system model to the same project

repository branch. You can view the details by clicking the **commits behind** option. You can merge all the changes to your *Edit* branch so that the *Edit* branch is updated with all the changes made in the project repository branch.

b. Click **Publish**.

c. Enter a commit message in the **Description of change** field, and then click **Publish**.

Note: If you do not want to commit the changes that you made to the system model, you can select the **Discard** option.

7. Perform the following steps to publish the unpublished changes:

a. Click the **Publish changes** option.

b. Enter a commit message in the **Description of change** field, and then click **Publish**.

Note: If you do not want to commit the changes that you made to the system model, you can select the **Discard** option.

Results

You have published the association changes that you made in the system model to the repository in the project. Other members of the team space can view the association changes and use the system model.

Viewing the system model

You can view an existing system model that is in a team space in Test .

Before you begin

You must be a licensed user of Test and a member of a team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.

Results

You viewed an existing system model in the team space from the **System Model** page.

Deleting a system model

When you want to create a new system model in Test , you must first delete the existing system model, as only one system model is supported per team space.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **System Model** in the left navigation pane.

   The **System Model** page is displayed.
4. Click the **Delete** icon .

   The **Delete system model** dialog is displayed.
5. Click **Delete**.

Results
You deleted a system model.

What to do next
You must publish the changes to the team space repository. See Publishing changes to the system model on page 1045.

Deleting a repository from a team space

You can delete a repository from a team space in Test when you do not want to use a team space repository.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* or an *Architect* in the team space. See Managing members and their roles in a team space on page 1721.
- Added a repository to the team space. See Adding a repository to a team space on page 1031.

1. Log in to Test.
   Result
   The **Projects** page of the initial team space is displayed.
2. Click the **Switch Team Space** icon from the left navigation pane. Then, use the **Switch to** option to open the team space to which a team space respository is added.
3. Click **Manage > Configuration**.
   Result
   The **Configuration** page of the team space is displayed.

4. Click the **Delete** icon in the action menu list.

   The **Delete repository** dialog is displayed.

5. Select the **I understand...** checkbox, and then click **Delete**.

Results

You have deleted the team space repository.

Restriction: When you delete the team space repository, the system model if it exists is also deleted, and you or other members of the team space cannot add a system model.

Prerequisites to running tests

Before you can run a test asset in a project on Test , you must read the information about the different tests assets. You can add a remote static agent, or Kubernetes cluster to the project and then select it as an alternate location to run the test assets.

You can find the following information about the prerequisite tasks:

- Test run considerations for AFT Suites or Functional tests on page 1057
- Test run considerations for API Suites or API tests on page 1059
- Test run considerations for browser-based Web UI tests on page 1061
- Test run considerations for JMeter tests on page 1061
- Test run considerations for JUnit tests on page 1063
- Test run considerations for Postman tests on page 1066
- Test run considerations for schedules on page 1067
- Test run considerations for Selenium tests on page 1068
- Test run considerations for using mobile device clouds on page 1069
- Management of agents on page 1071
  - Test run considerations for running tests on remote performance agents on page 1073
- Management of remote Kubernetes clusters on page 1101
  - Considerations for using a remote Kubernetes cluster on page 1101
- Management of cloud credentials on page 1115

Related information

Test run configurations on page 1134

Test run considerations for AFT Suites or Functional tests

Before you configure an AFT Suite or a Functional test run in Test , you must first read the considerations that you need to take into account.

When you want to run an AFT Suite or Functional test in a project on Test, you can check if the AFT Suite or Functional test meets any of the following conditions:

If...	Then...
The AFT Suite or Functional test uses the settings configured in an `AFT XML` file for a remote agent	You must ensure that you have configured the location element in the `AFT XML` to point to a remote agent. For more information about setting the location element, refer to Using an XML file to run multiple Web UI tests and Compound Tests simultaneously.
You want to run an AFT Suite or Functional test on a remote agent	You must run the test on the remote agent before you commit the test asset to the remote repository. When you run the test on the remote agent, the following events occur: • The agent is added as the location in the `AFT XML` file, on which the test is to be run. • The agent is displayed as the agent on which the test is to be run, under the **Host** column within the **Location** tab in the **Execute test asset** dialog.
You commit the test asset to the remote repository without running the test on the remote agent	The agent is not displayed under the **Host** column within the **Location** tab in the **Execute test asset** dialog.

Before you configure the run for an AFT Suite or a Functional test, you must complete the following tasks, if they are applicable:

- Add the remote agents, on which the test is to be run, to the project on Test. See Adding a performance agent to a project on page 1076.
- After you add the agent, you can select the agent configured in the `AFT XML` file as the location for the test run or select the remote agents that you add to the project, when you configure a run for an AFT Suite.

  The remote agents are shown as the agents available for selection under the **Override** column within the **Location** tab in the **Execute test asset** dialog.

  You can then select the remote agent as the location to run the AFT Suite or Functional test when you are configuring the test run. Alternatively, you can enter the argument `-swaplocation <configured_agent_location>:<overriding_agent_location>` in the **Program Arguments** field in the **Advanced Setting** dialog when you are configuring the test run.

For running an AFT Suite, see Configuring an AFT Suite run on page 1141.

Related information

Test run configurations on page 1134

Test run considerations for API Suites or API tests

Before you configure an API Suite or API test run, you must first read the considerations that you need to take into account.

You can find the following information about API Suites:

- Important information about API Suites or tests on page 1059
- Important information about report configuration in API Suites or tests on page 1061

Important information about API Suites or tests

When you want to run an API Suite or test from a project on Test and the test asset in HCL DevOps Test Integrations and APIs (Test Integrations and APIs) meets any of the following conditions:

- The Suite or test refers to local stubs that use a transport other than HTTP or MQ.
- The Suite or test refers to local stubs that use the HTTP transport.
- The transport used in the tests or Suite is configured with the hostname set to *localhost* for the HTTP/TCP proxy.
- The Suite or test has tests that use a transport and the transport requires third-party application `Jar` files for a successful run.

You must then refer to the following table for the next steps:

If...	Then...
The test asset refers to local stubs that use a transport other than HTTP or MQ.	You must perform any of the following actions before you commit the test asset to the remote repository: • Remove the reference to the local stub from the test asset. • Publish the stubs to Test Virtualization Control Panel. To publish and edit stubs, see Publishing stubs.
The tests refer to local stubs that use the HTTP transport.	You must perform the following actions before you commit the test asset to the remote repository:

If...	Then...
	1. Create a test or test Suite that contains the stub and tests that run on the stub. 2. Configure the physical HTTP transport with the following parameters in the **Client** tab in the **Physical View**: ◦ Set the `hostname or IP address of the HTTP Proxy server` in the **Proxy Host** field. ◦ Set *3128* as the proxy server port in the **Proxy Port** field. 3. Set the reference to the stub for the tests in the test suite scenario from the **Scenario Editor** dialog from the **Test Factory** view by selecting the *Live system* option in the **Satisfied by** column to run the stubs on the HTTP proxy registered with Test. 4. Save the project.
The transport used in the Suite or tests is configured with the hostname set to *localhost* for the HTTP/TCP proxy.	You must replace the hostname with *fully-qualified-domain-name* or *IPAddress* of the proxy host in the tests before you commit the test asset to the remote repository.
You plan to run the API Suite or test on the computer where Test is installed and the API Suite or test that use a transport from any of the following third-party applications: • Camel • CentraSite • CICS • Coherence • Database • IMS • Integra • JMS • SAP RFC • Software AG Universal Messaging • TIBCO EMS • TIBCO Rendezvous • TIBCO SmartSockets	You must complete the following tasks: 1. Identify the location of the third-party application JAR files. You can use Library Manager to know the location where the third-party application JAR files are saved. 2. Copy the third-party application JAR files to the computer where Test is installed. See Copying third-party application Jars to Kubernetes on page 736.

If...	Then...
• WebSphere Application Server Service Integration Bus (SiBus) • WebLogic • Software AG webMethods • WebSphere MQ	

Important information about report configuration in API Suites or tests

You must configure test Suites or tests in Test Integrations and APIs to use a results database so that the details of the test results can be captured and displayed in the Test API results reports. See Configuring the project results database.

If your server projects use either a Microsoft SQL Server, MYSQL, or both as a project results database, you must copy the Microsoft SQL Server and MySQL database JAR files to the JDBC folder in the path `/data/JDBC` on Test. See Copying third-party application Jars to Kubernetes on page 736.

The database JAR files that you need are based on the version of Microsoft SQL Server or MQSQL that you use with Test Integrations and APIs. See Adding Microsoft SQL Server and MySQL drivers.

To run an API Suite, see Configuring an API Suite or an API test run on page 1174.

Test run considerations for browser-based Web UI tests

Before you configure a Web UI test or a Compound Test that contains Web UI tests, which use either the Chrome or Edge browsers, you must first read the considerations that you need to take into account.

When you want to run a Web UI test or a Compound Test that contains Web UI tests, which use either the Chrome or Edge browser from Test , you must consider the following conditions:

- You must perform any of the following actions:
  - Accept the license agreement of the built-in Chrome and Edge browsers at the time of signing in or logging in to Test.
  - Accept the license agreement of the built-in Chrome and Edge browsers, if it is not accepted at the time of signing in or logging in. See Management of third-party licenses on page 731.

Test run considerations for JMeter tests

Before you can run JMeter tests on Test , you must read the considerations that you must take into account and complete the tasks indicated.

Before you run JMeter tests that you create in JMeter, you must have completed the following tasks:

- You must ensure that the JMeter extension on Test is enabled. You must enable the JMeter extension either at the time of installation of Test or before you add the repository that contains JMeter tests to the server project. See Enabling server extensions on page 740.
- You must have committed the following JMeter assets or resources as a JMeter project to a remote Git repository:

Note: You must have created a project directory and added the associated tests or assets in sub directories, that might be required for the JMeter tests to run successfully.

- The `jmeterRoot.jprj` project file in the project directory.
- The JMeter tests in a sub directory with a name you provide within the project directory.
- Optionally, the Java Key Store that is required at test run time in the `certs` sub directory.
- Optionally, the JMeter properties files that are required at test run time in the `properties` sub directory.
- Optionally, the library jar files that are required at test run time in the `lib` sub directory.
- Optionally, the test dependencies that are required at test run time in the `deps` sub directory.

For example, the project directory can be *myproject* that contains the `jmeterRoot.jprj` project file. In the project directory, you can create the following sub directories:

- The `mytests` sub directory that contains the JMeter tests.
- Optionally, the `certs` sub directory that contains the Java Key Store.

  For example, the path to the key store can be specified in the `system.properties` file as follows:

  ```
  javax.net.ssl.trustStore=$(deploy.home)/certs/simpleStore.jks
  ```

  Where <*simpleStore.jks*> is the Java Key Store and the <*deploy.home*> is the keyword to access the key store at the test run time.
- Optionally, the `properties` sub directory that contains properties files such as `system.properties`, `jmeter.properties`, `reportGenerator.properties`, or `user.properties`.
- Optionally, the `lib` sub directory that contains the **lib** and **lib/ext** content to be used at test run time. For example, the **amq client** and the **plugins** required to parse the **jmx** that contains **amqp** calls.
- Optionally, the `deps` sub directory that contains the test dependencies.

The resulting project directory can be as follows:

```
myproject (that contains the jmeterRoot.jprj)
myproject/mytests
myproject/certs
myproject/properties
myproject/lib
myproject/deps
```

- You must ensure that you use a relative path when JMeter tests refer to other test assets. For example, if the JMeter test that is in the `myproject/mytests` folder refers to a `mycsv.csv` file that is in the `myproject/deps` folder, then the `mycsv.csv` is referred as follows: `../deps/mycsv.csv` in the JMeter test.
- You can create the JMeter project file named as `jmeterRoot.jprj`.

  The project file is a java properties file. The JMeter project file is required so that Test can identify the asset as a JMeter project. You can specify additional information in the project file. You can specify the names of the sub directories created and through keywords you can specify the path in the properties files whether they are relative to the root directory or to the tests sub directory.

For example, if you have created the following sub directories in the project directory called *myproject* that contains the `jmeterRoot.jprj` project file:

- `myproject/mytests`
- `myproject/properties`

If the JMeter tests are contained in the following path: `myproject/mytests/testplan/test1.jmx`, and some dependencies that are also required to be deployed at test run time exists in the following path: `myproject/mytests/testplan/localdir`. You must specify these file paths in the project file as follows:

```
testDir.localtest.sub.dir=localdir
aSecondRootDir.sub.dir=dir2
athirdRootDir.sub.dir=dir3
```

Test run considerations for JUnit tests

Before you can run JUnit tests on Test , you must read the considerations that you must take into account and complete the tasks indicated.

Before you run JUnit tests, you must have completed the following tasks:

- You must ensure that the JUnit extension on Test is enabled. You must enable the JUnit extension at the time of installation of the server software or before you add the repository that contains the JUnit tests to the server project. See Enabling server extensions on page 740.
- You must have created the JUnit tests that use JDK 8, as part of a Maven V3.6.3 project. The Maven project must contain the Maven Surefire plugin, which is required to run the JUnit tests contained in the Maven project. The Maven project as a `pom.xml` must be committed to the remote repository.

Note: If you create the JUnit tests on other versions of JDK, you must copy the JDK version to the `userlibs` pod under the `/data/junit-ext/jdks` directory. See Copying third-party application Jars to Kubernetes on page 736.

Test run considerations for using Machine learning capabilities

Before you configure a Performance Test or Schedule run to use Machine learning (ML) capabilities, you must first read the considerations that you need to take into account.

When you want Test to analyze Performance tests or Schedules by using ML capabilities, you must ensure that Performance tests or Schedules conform to the following criteria:

- Must contain HTML tests.
- Must contain stress or performance user profiles.
- Must contain the following minimum stress test requirements:
  - 20 users or more.
  - A minimum of three different user groups and each group has an activity of more than two minutes.
  - Stages that have a reasonably high number of samples within each stage.
  - Stages do not have an increasing number of users.
  - Tests run for longer durations so that a trend can be observed.

You can refer to the following table to view the criteria for analysis of the parameters:

Parameter analyzed	Criteria for analysis
Response Time Lock-Step Pattern	The analyzer identifies the **Response Time Lock-Step Pattern** parameter in the overall page response time observed against the user count based on the following criteria: • Tests have a minimum of 20 users. • Tests run for longer durations for a trend to be observed. • Tests contain a minimum of three different user groups and each group has an activity of more than two minutes.
Response Time Standard Deviation Pattern	The analyzer attempts to detect the response time of pages that are more than thrice the value of the standard deviation calculated for the page response time as the **Response Time Standard Deviation Pattern** parameter.
Throughput Drop Pattern	The analyzer attempts to detect sudden drops in network throughput as the **Throughput Drop Pattern** parameter that is based on the following criteria: **Note:** Sudden drops in throughput might be related to the performance tool itself, issues with network connectivity, or issues with signal-scalability of the system under test. • Tests have a minimum of 20 users. • Tests have stages with a reasonably high number of samples within a stage. • The length and intensity of the throughput drops that are less than 20% of the median observed within a stage are considered by the analyzer. When no

Parameter analyzed	Criteria for analysis
	throughput is received within 60 seconds, such drops are considered in the analysis. Short shark-tooth patterns in drops are not considered by the analyzer. • Parts of the stage with increasing users are not considered for analysis. For example, when the test adds one user every minute and the user range is between one user to 500 users, the **Throughput Drop Pattern** parameter is not analyzed.
Performance Agent Health	The analyzer inspects the health of agents that are participating in a performance execution and identifies potential configuration issues based on the following criteria: • **Minimum requirements** ◦ At least 10 users ◦ At least 10-minute run time ◦ Requires schedule with at least 1 static agent (Performance Agent Health insight is not generated if you are running the test on local host) • **Blocking threads** ◦ Considered as Blocking threads when 90% of available threads are used for 20% of the run time • **Pegged CPU** ◦ Considered as Pegged CPU when 90% of CPU is utilized for 10% of the run time • **Pegged CPU for interval** ◦ Considered as Pegged CPU for interval when there are intervals of high CPU utilization greater than 95% For example, above 95% of CPU utilized for 50% of a 10-minute interval or 98% of CPU utilized over a shorter interval. ◦ Considered as Pegged CPU for interval when there are spikes in CPU utilization during long test runs The agents that are not configured properly can distort performance assessments of the system under test. The analyzer can provide multiple insight types. The insight recommendation texts are parametrized and they provide specific recommendations such as identifying the agents with issues. You can view the following insights: • Pegged CPU for run insight • Pegged CPU for interval insight • Blocked thread insight

Test run configurations on page 1134

Test run considerations for Postman tests

Before you can run Postman tests on Test , you must read the considerations that you must take into account and complete the tasks indicated.

Before you run Postman tests that you create in Postman, you must have completed the following tasks:

- You must ensure that the Postman extension on Test is enabled. You must enable the Postman extension at the time of installation of the server software or before you add the repository that contains Postman collections to the server project. See Enabling server extensions on page 740.

  Restriction: If you add a Git repository with Postman collections to a server project before you enable the Postman microservice, the Postman collections might not be displayed in the **Execution** page for you.

- You must have exported the following resources from Postman and saved the resources on your computer:
  - Collections and their associated variables and environments from Postman in which all collections are exported as a single file.

    Note: You can export as many collections as you want.

    For more information, refer to Exporting a collection from Postman and Exporting data dumps.
  - Environments configured in Postman, if you are exporting only the environments as separate JSON files.

    For more information, refer to Exporting environments from Postman.
- You must have committed the following Postman assets or resources to the remote repository:
  - Collections and their associated variables and environments that you exported. You can export all resources that are in your workspace in Postman. You can also export the collections along with the variables as a single file and the environments separately as another file.

    For example, you can save the exported file as `MyCollectionsVarEnv.json` that contains the collections, variables, and environments or you can export only the collections and variables as `MyCollectionsVar.json`.
  - Environments that you exported, if you are exporting only the environments as separate JSON files. For example, you can save the exported file as `MyEnv.json`.
  - An empty text file with the `.postman` extension that is contained in the same directory as the other Postman resources, so that the contents in the directory are attributed as Postman resources. For example, you can create `MyProject.postman`.

Note: The `.postman` file enables Test to identify the test resources as Postman resources.

For example, if you have saved the Postman resources that you downloaded from Postman as follows:

- `MyCollectionsVarEnv.json` or `MyCollectionsVar.json` that contains the Postman collections.
- `MyEnv.json` that contains the environments associated with the Postman collection.

The project directory can be as follows:

```
/Project
/Project/MyProject.postman
/Project/MyCollectionsVarEnv.json
```

Alternatively, the directory can be as follows:

```
/Project
/Project/MyProject.postman
/Project/MyCollectionsVar.json
/Project/MyEnv.json
```

Test run considerations for schedules

Before you configure a Rate Schedule or VU Schedule run, you must first read the considerations that you need to take into account.

Important information about JMeter tests in schedules

When you want to run JMeter tests as part of the VU Schedule or Rate Schedule on Test , you must have completed the following tasks:

- Installed the HCL DevOps Test Performance Agent on a computer.
- Installed the JMeter application on the computer where you have installed the HCL DevOps Test Performance Agent.
- Set the environment variable **JMETER_HOME** that points to the JMeter installation directory.

Important information about Resource Monitoring sources in schedules

When you want to run schedules on Test, you must have completed the following tasks in Test Performance:

- Created a performance schedule of **Rate** or **VU** type.
- Added Resource Monitoring sources, or the labels of Resource Monitoring sources to a schedule. Refer to Adding resource monitoring sources to a performance schedule by using labels.

Before you configure a run of a Schedule, you must complete the following tasks in Test:

- Add Resource Monitoring sources to your project in Test. See Monitoring an NGINX server on page 1566.
- Enable Test as Resource Monitoring service only if you want to replace Resource Monitoring labels set in Test Performance with the labels that you created in Test. See Controlling resource monitoring sources in a schedule on page 1595.
- Perform the following steps when you want to override the Resource Monitoring labels in the test asset with the Resource Monitoring labels that you create in Test:
    1. Click the **Resource Monitoring** tab.

        Note:

        The **Resource Monitoring** tab displays only if you enabled the **Resource Monitoring from Service** option in Test Performance when you created the test asset.

    2. Click , and press the `Ctrl` + `Space bar` keys, or enter the initial letter of a label to select a label in the list.

        Note:

        You can select or add labels only if you added the labels in the **Resource Monitoring Sources** page in Test.

For running a Rate Schedule or VU Schedule, see Configuring a run of a Rate Schedule or VU Schedule on page 1404.

Test run considerations for Selenium tests

Before you can run Selenium tests on Test , you must read the considerations that you must take into account and complete the tasks indicated.

Before you run Selenium tests, you must have completed the following tasks:

- You must ensure that the JUnit extension on Test is enabled. You must enable the JUnit extension at the time of installation of the server software or before you add the repository that contains the Selenium tests to the server project. See Enabling server extensions on page 740.
- You must have created the Selenium tests that use JDK 8, as part of a Maven V3.6.3 project. The Maven project must contain the Maven Surefire plugin, which is required to run the Selenium tests contained in the Maven project. The Maven project as a `pom.xml` must be committed to a remote Git repository.

  Note: If you create the Selenium tests on other versions of JDK, you must copy the JDK version to the `userlibs` pod under the `/data/junit-ext/jdks` directory. See Copying third-party application Jars to Kubernetes on page 736.

- You must ensure that the following flags are configured in the Selenium test:
  - Firefox is configured as the web browser to run the test.
  - Firefox is enabled to accept all certificates (secured and unsecured).
  - Firefox is configured to not display alerting messages when the test runs in the Firefox browser.
- You must set the system property to point to the Firefox driver (`linux_x64_geckodriver`) that is provided along with the JUnit server extension and is available in the `/tmp` folder.

  For example,

```
System.setProperty("webdriver.gecko.driver", "/tmp/linux_x64_geckodriver")
```

Test run considerations for using mobile device clouds

Before you configure runs of tests that use mobile device clouds as the location, you must first read the considerations that you need to take into account.

Before you can use mobile devices that are connected to a mobile device cloud from Test , you must complete the following tasks:

- Create any of the following types of tests that are supported to be run from Test.

Test type	Description
AFT Suite	The AFT Suite must specify the path to the tests, device names, and the device cloud location to run the tests.

Test type	Description
	AFT Suites that specify multiple tests or devices on the same device cloud are supported. **Restriction:** AFT Suites that specify a single test on multiple devices or multiple tests on multiple devices when the devices are connected to multiple device clouds are not supported.
Compound Tests that contain mobile tests or Web UI tests that use a device cloud	The Compound Tests must specify multiple mobile tests or multiple Web UI tests that run on a device connected to a single device cloud. **Restriction:** Compound Tests that specify tests on single or multiple devices that are connected to multiple device clouds are not supported.
Individual mobile test or Web UI test that use a device cloud	The individual test must be either a mobile test or a Web UI test that runs on a device connected to a single device cloud.

- Ensure that you have valid credentials for the mobile device clouds, which are supported to be connected from Test. You must have the details as listed in the following table for the mobile device cloud that you want to connect and use:

Attribute	Description	Mobile device cloud				
		BitBar Cloud	**BrowserStack Cloud**	**LambdaTest Cloud**	**pCloudy Cloud**	**Perfecto Mobile Cloud**
Host	The hostname of the mobile device cloud instance.	Required	Required	Required	Required	Required
API key	The API key of your cloud account to authenticate the connection.	Required	Required	Required	Required	Not applicable
Security token	The token used to authenticate the connection.	Not applicable	Not applicable	Not applicable	Not applicable	Required
Project	The project name to use on the mobile device cloud.	Required	Required	Required	Not applicable	Not applicable

Attribute	Description	Mobile device cloud				
		BitBar Cloud	**BrowserStack Cloud**	**LambdaTest Cloud**	**pCloudy Cloud**	**Perfecto Mobile Cloud**
Username	The username of your cloud account.	Not applicable	Required	Required	Required	Not applicable

- Complete the following prerequisite tasks to enable the devices on the mobile device cloud for testing mobile apps or mobile web browsers:

Device cloud	Testing on Android OS	Testing on iOS
BitBar Cloud BrowserStack Cloud Perfecto Mobile Cloud	◦ Uploaded the `.apk` file of the Android application that you want to test. ◦ Installed the Android application that you want to test on the Android device.	◦ Installed the `.ipa` or `.app` file of the iOS application that you want to test. ◦ Installed the iOS application that you want to test on the iOS device.
pCloudy Cloud LambdaTest Cloud	◦ Uploaded the `.apk` file of the Android application that you want to test. ◦ Installed the Android application that you want to test on the Android device. ◦ Verified that the device you want to test is available and in the *Released* state on the cloud platform.	◦ Uploaded the `.ipa` file of the iOS application that you want to test. ◦ Installed the iOS application that you want to test on the iOS device. ◦ Verified that the device you want to test is available and in the *Released* state on the cloud platform.

- Ensure that as a *Project Owner* or *Tester*, you are an authorized user of the cloud credential in your team space. See Viewing details of cloud credentials on page 1126.
- Ensure that you create a variables file that contains the details of the agent or device cloud, if you do not want to use the cloud credentials on the server.

Management of agents

You can find information about managing agents that you install on remote computers and then configure the remote agents to register with Test . After the agents are registered, you can add them to your projects and then select them as locations to run tests or virtual services.

When you plan to run any of the tests from a project on Test on a remote performance agent, see Management of performance agents on page 1072.

When you plan to run any of the supported virtual services from a project on Test on a remote API agent, see Management of API agents on page 1080.

When you plan to run Web UI tests that are created in Test on a remote agent. See Running server test assets on an agent on page 1324.

Management of performance agents

You can manage the performance agents that you want to use as locations to run tests from Test . When you install the agents by using your offline user token, the agents are registered with the team space in Test. You can view the registered agents before you add them to your projects. You can then select them as locations to run tests.

When you plan to run any of the tests on a remote performance agent from a project in Test, you must have completed the following tasks:

- Installed the performance agent of the same version as the version of Test. Refer to Installing DevOps Test Performance Agent.
- Configured the performance agent with your offline user token so that the performance agent can register with Test.

  Note: When you configure the performance agent by using your offline user token, Test considers you as the owner of the performance agent.

- Verified that you have write permissions to the `majordomo.config` file so that certain transactions can be written by Test to the `majordomo.config` file.

  Note: You can verify if you have the *Read* and *Write* permissions by checking the properties of the `majordomo.config` file.

- Viewed the performance agents that are registered with Test. See Viewing performance agents that are registered with DevOps Test on page 1074.
- Added the remote performance agents that are registered with Test to your project on Test. See Adding a performance agent to a project on page 1076.
- After you add the remote performance agents to your project, Test determines the capabilities that are provided by the remote performance agent and displays the details and capabilities of the performance agent on the **Agents and Intercepts** page. You can also define the capabilities that you want to add, and then view, edit, or delete the capabilities that you defined for the performance agents in your project. See Working with the capabilities of a performance agent on page 1078.

Connecting a Docker performance agent to Test

You can run a Performance agent in Docker container and connect it to Test.

Before you begin

You must have the following details to connect the Docker performance agent to Test Hub:

- `TESTHUB_SERVER`: Server host name.
- `TESTHUB_TOKEN`: Offline user token that is obtained in following context.
- `TESTHUB_PORT`: `443`
- `TESTHUB_TEAM_SPACE`: `Initial`
- `TESTHUB_PATH_CONTEXT`: Server API context path.
- `Docker_Image`: Download the `HCL_DT_AGENT_<version_number>_DOCKER_IMG.zip` file from My HCLSoftware and refer to README document in the zip file to load the docker image `hcl-devops-test-performance-<version_number>.tar`.

1. Log in to Test.
2. Click the **User** icon , and select the **Create Token** option.

   Result

   The token is generated automatically and displayed in the **Create Offline User Token** dialog.
3. Click **Copy** to copy the token and save it in a secure location.
4. Run the following command where the Docker image of the performance agent is located:

```
TESTHUB_SERVER=<server_url>
TESTHUB_TOKEN=<access_token>
TESTHUB_PORT=443
TESTHUB_TEAM_SPACE=Initial
TESTHUB_PATH_CONTEXT="/test"
docker run --detach --name Test_performance_agent_docker \
--env TESTHUB_SERVER=$TESTHUB_SERVER \
--env TESTHUB_PORT=$TESTHUB_PORT \
--env TESTHUB_TOKEN=$TESTHUB_TOKEN \
--env TESTHUB_TEAM_SPACE=$TESTHUB_TEAM_SPACE \
--env TESTHUB_PATH_CONTEXT=$TESTHUB_PATH_CONTEXT hcl-devops-test-performance:11.0.9
```

5. Go to **Infrastructure > Agents and Intercepts** and verify whether your agent is connected to Test.
6. Run the following commands to stop and remove the Docker container:

   `docker stop <assigned_name_of_the_container>`

   `docker rm <assigned_name_of_the_container>`
7. Run the following command to view all the help options and available environment variables:

   `docker run --rm hcl-devops-test-performance:11.0.9`

Results

You have connected the Docker performance agent to Test.

Test run considerations for running tests on remote performance agents

Before you configure a test to run on a remote performance agent from Test , you must read the considerations that you must take into account.

Supported tests

You can run the following tests that are supported to be run on a remote performance agent:

- AFT Suite
- Compound Tests that contains performance tests
- Compound Tests that contains Web UI tests
- Compound Tests that contains traditional HTML tests
- Rate Schedule
- VU Schedule

Prerequisite tasks

Before you can run any of the supported tests on a remote performance agent from a project on Test, you must have completed the following tasks:

- Installed the HCL DevOps Test Performance agent on the remote computer. See Management of agents on page 1071.
- Configured the agent with your offline user token so that the agent can connect to Test.
- Added the remote agents to your project on Test. See Adding a performance agent to a project on page 1076.

Note: If you want to run an AFT Suite (that contains Web UI tests) on a performance agent, you must start the performance agent as a non-admin user so that certain browsers that are configured can start correctly during the test run time.

Before you add the tests to the remote repository, you must have completed the following tasks:

- Associated the performance agents with the performance schedule in Test Performance.
- Specified the hostname of the remote workstation in the AFT XML file.

You can continue to configure a run for any of the following supported test types:

- Configuring an AFT Suite run on page 1141
- Configuring a run of a Compound Test that contains performance tests on page 1260
- Configuring a run of a Compound Test that contains Web UI tests on page 1222
- Configuring a run of a Compound Test that contains HTML tests on page 1186
- Configuring a run of a Rate Schedule or VU Schedule on page 1404

Viewing performance agents that are registered with DevOps Test

After you install the remote performance agents and configure them with your offline user token, the performance agents register with Test and you can view the registered performance agents on the **Agents and Intercepts** page.

Before you begin

You must have completed the following tasks:

- Installed the performance agent of the same version as the version of Test.
- Configured the performance agent with your offline user token so that the performance agent can register with Test.

Note: When you configure the performance agent to connect to the server, you must specify the offline user token that you generated on Test. This token defines your ownership over the agent.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test.
3. You can view the agents that you own in any of the following ways:
   - Search for the agent by entering the name of the agent in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case sensitive text that you can enter.

   - Sort the **Type** column to sort the items and display the agents in the rows at the top of the table.
   - Sort the **Agents** column and identify the agents by their names or by their owner.

   You can view the following details about the agents that are registered with Test:
   - The projects to which the agent is added, are displayed in the **Projects** column.
   - The status of the agent is displayed in the **Status** column.

     Note: You can add agents that are in the `Ready` state to your project, and then use them as locations to run tests or virtual services.

Results

You have viewed the registered agents from the **Agents and Intercepts** page.

What to do next

You can perform any of the following tasks:

- You can add the performance agents that you own to your project. See Adding a performance agent to a project on page 1076.
- You can add the API agents that you own to your project. See Adding a performance agent to a project on page 1076.

Adding a performance agent to a project

If you have performance tests that distribute workload across different workstations or Accelerated Functional Testing (AFT) Suites that need to run on different platforms and browsers, you can add HCL DevOps Test Performance Agents to your projects on Test to run tests on remote workstations.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Installed the agent by using your offline user token, which makes you the owner of the agent, or you are assigned the role of a *Team Space Owner*.

About this task

Only you can add or remove a performance agent that you own from the project. However, any member of your project with the permission to run the tests can initiate the run of test assets that are associated with the performance agent.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The **Agents and Intercepts** page is displayed.
3. Click **Add > Add performance agent**.

   The performance agents that you configured with your user token are displayed.

   Note: You can add the performance agents that you own and that are in the *Ready* state. You can add any number of performance agents to your project.

4. Select the performance agents that you want to use in the project, and then click **Add**.

   The performance agents that you added to the project are displayed.
5. Perform the following steps to view details and capabilities of the performance agents:

   a. Expand the performance agent to view the details panel.

      You can find the following details of the performance agent displayed:

Parameter	Description
Version	The version of the installed performance agent.
Address	The IP address of the computer on which the performance agent is installed.
License type	The license type that is enabled for you to use the performance agent.
Load generation service	The status of the performance agent whether it can be used for load generation service.
Last contact	The time of the last contact with the performance agent by Test.

b. Expand the capabilities panel to view the system and application capabilities.

You can find the following capabilities of the performance agent displayed:

Capabilities		Description
System capabilities	Architecture	The architecture of the CPU processor of the computer on which the performance agent is installed.
	MAC Address	The MAC address of the computer on which the performance agent is installed.
	Operating system	The operating system of the computer on which the performance agent is installed.
	RAM	The memory that is allotted to RAM in the computer on which the performance agent is installed.
Application capabilities	Browser	The browsers along with their version that are installed on the computer on which the agent is installed.
User Defined capabilities	User Defined	The capabilities that you add for a performance agent. You can also tag a performance agent so that you can identify the performance agent to select as a location.

c. Check for the status of the performance agent from the **Status** column.

Note: You can add performance agents that are in any state to the project.

Results

You have added remote performance agents to your project and viewed the performance agent capabilities that is displayed for each agent that you own.

What to do next

You can perform any of the following tasks:

- Run the tests on the performance agent that is added to the project from the **Execution** page. See Test run configurations on page 1134.
- Define the capabilities that you want to add, and then view, edit, or delete the capabilities that you defined for the performance agents in your project. See Working with the capabilities of a performance agent on page 1078.

Working with the capabilities of a performance agent

When you installed performance agents V10.1.2 or later, and added them to your project on Test , you can view capabilities of the performance agents from the **Infrastructure** page. When you installed performance agents V10.2.0 or later, you can add, view, edit, or delete properties and capabilities of performance agents from the **User Defined** panel of that performance agent.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Installed the agent by using your offline user token, which makes you the owner of the agent, or you are assigned the role of a *Team Space Owner*.
- Installed a performance agent. See Management of agents on page 1071.
- Added performance agents to your project. See Adding a performance agent to a project on page 1076.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The agents that you added to your project are displayed on the **Agents and Intercepts** page.
3. Expand the performance agent.

   The **Details** and **Capabilities** tabs are displayed.
4. Click **Capabilities** to view the capabilities of the performance agent.
5. Click **User Defined**.

   The **User Defined Capabilities** dialog is displayed.
6. Complete the steps for the task that you want to perform as listed in the following table:

Task	Action
Adding capabilities	Perform the following actions: a. Click **Add new**. b. Enter the name of the capability in the **Capability Name** field.

Task	Action
	c. Perform any of the following actions in the **User Defined Category** field: ▪ Select an existing category from the list. ▪ Enter a name of the category for the capability, if the category does not exist. **Note:** You can also click **Add new** to add a category. The category for the capability is either selected or created and the fields for the property name and value are displayed. **Note:** The property for a capability is a *name-value* pair. d. Enter a name for the property in the **Property Name** field and its corresponding value in the **Property Value** field for the capability. **Note:** You can add multiple properties for the same capability under the same category or under different categories by clicking **Add new property**, and then by entering the name and value for the property. e. Click **Save**. The capabilities that you added are displayed.
Viewing capabilities that you added	The **User Defined Capabilities** panel displays the capabilities that you added to the performance agent.
Editing capabilities that you added	Perform the following actions: a. Click the **Edit** icon in the row of the capability that you want to edit. The user-defined capability is enabled for editing. You can edit the name of the capability, or the property name or property value. b. Edit any of the items that you want for the user-defined capability. c. Click **Update**. The updated capability of the performance agent is displayed.
Deleting capabilities that you added	a. Click the **Delete** icon in the row of the capability that you want to delete. b. Click **Delete**. The capability that you selected is deleted along with all the properties that you added for the capability.

Task	Action
Deleting a property defined for a capability	a. Click the **Edit** icon in the row of the capability that you want to edit and remove a defined property. The user-defined capability is enabled for editing. b. Select and delete the contents in the **Property Name** field and its corresponding **Property Value** field. c. Click **Update**. The property is removed for the capability.

Results

You have added, viewed, edited, or deleted a property or the user-defined capability of a performance agent.

What to do next

You can run the tests on the performance agent from the **Execution** page. See Test run configurations on page 1134.

Management of API agents

You can manage the HCL DevOps Test Integrations and APIs (Test Integrations and APIs) agents that you want to use as locations to run tests from Test . When you install the agents by using your offline user token, the agents are registered with the team space in Test. You can view the registered agents before you add them to your projects. You can then select the agents as locations to run virtual services.

Note: The API agent is referred interchangeably as either the Test Integrations and APIs Agent or API agent in the documentation.

Before you run any of the supported virtual services on a remote Test Integrations and APIs Agent from a project on Test, you must have completed the following tasks:

- Installed the Test Integrations and APIs Agent of the same version as the version of Test. Refer to Installing DevOps Test Integrations and APIs Agent.
- Configured the Test Integrations and APIs agent so that the Test Integrations and APIs agent can register with Test.

  Note: When you configure the Test Integrations and APIs agent by using the offline user token, Test considers you as the owner of the API agent.

- Viewed the API agents that are registered with Test. See Viewing API agents that are registered with DevOps Test on page 1081.
- Added the remote API agents that are registered with Test to your project on Test. See Adding an API agent to a project on page 1083.

If you do not want to retain the API agents in a project or if you want to add the API agents to a different project, you can remove the API agents from a project. When you remove an API agent from a project, you cannot select that API agent to run virtual services in the project. See Removing an API agent from a project on page 1084.

If you want to remove a registered API agent from a team space in Test when the API agent is not available for use, you can unregister a remote API agent from a team space. See Unregistering a remote API agent from DevOps Test on page 1085.

Considerations for running virtual services on remote API agents

Before you configure a run of a virtual service resource on a remote API agent from Test , you must read the considerations that you must take into account.

Supported virtual services

You can run all virtual services that virtualize services on a remote API agent registered with a team space in Test except the following services:

- Virtualized DPL calls in CICS® Transaction Server.
- Virtualized services for IBM® Db2® on IBM® z/OS®.

Prerequisite tasks

Before you run any of the supported virtual services on a remote API agent from a project on Test, you must have completed the following tasks:

- Installed the Test Integrations and APIs Agent on the remote computer. See Management of API agents on page 1080.
- Configured the API agent with your offline user token so that the API agent can connect to Test.
- Added the remote API agents to your project on Test. See Adding an API agent to a project on page 1083.

Licensing

When a virtual service is run on an API agent, the license server configured on the remote agent computer determine the license server that is used by the API agent. This might be different from the license server that is configured for the team space.

Viewing API agents that are registered with DevOps Test

After you install the remote HCL DevOps Test Integrations and APIs (Test Integrations and APIs) agents and configure them with your offline user token, Test Integrations and APIs agents register with Test . You can then view the registered API agents on the **Agents and Intercepts** page.

Before you begin

You must have completed the following tasks:

- Installed the Test Integrations and APIs agent. See Management of API agents on page 1080.
- Configured the Test Integrations and APIs agent so that the Test Integrations and APIs agent can register with Test. See Management of API agents on page 1080.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test.
3. You can view the API agents that you own in any of the following ways:
   - Search for the API agent by entering the name of the API agent in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

   - Sort the **Type** column to sort the items and display the API agents in the rows at the top of the table.
   - Sort the **Agents** column and identify the API agents by their names or by their owners.
4. Perform the following steps to view the details and capabilities of the API agents:
   a. Expand the API agent to view the details panel.

      You can find the following details of the API agent that is displayed:

Parameter	Description
Agent ID	The ID of the installed API agent.
Identifier	The unique identifier of the installed API agent that is configured in the `Agent.config` file for the API agent.
Hostname	The hostname of the computer on which the API agent is installed.
Version	The version of the installed API agent.
Operating system	The operating system of the computer on which the API agent is installed.
Configuration location	The path to the location of the `Agent.config` file on the computer where the API agent is installed.
Tags	The agent attributes or tags that exist in the `Agent.config` file.

   b. Expand the capabilities panel to view the system capabilities.

      You can find the following capabilities of the API agent displayed:

Capabilities	Description
System capabilities	The capabilities of the API agent.

c. Check for the status of the API agent from the **Status** column.

Results

You have viewed the registered API agents from the **Agents and Intercepts** page.

What to do next

You can add the API agents that you own to your project. See Adding an API agent to a project on page 1083.

Adding an API agent to a project

You must add the registered API agents to your projects before you select them as the location to run the virtual service resources that are in your project on Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Installed the agent by using your offline user token, which makes you the owner of the agent, or you are assigned the role of a *Team Space Owner*.

About this task

An owner of an API agent or team space owner can add or remove an API agent from the project. However, any member of the project with the permission to run the virtual services can initiate the run of the virtual service resources on API agents that are added to the project.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The **Agents and Intercepts** page is displayed.
3. Click **Add > Add API agent**.

   The API agents that you configured with your user token are displayed.

   Note: You can add the API agents that you own. You can add any number of API agents to your project.
4. Select the API agents that you want to use in the project, and then click **Add**.

The API agents that you added to the project are displayed.

5. Perform the following steps to view the details and capabilities of the API agents:

   a. Expand the API agent to view the details panel.

      You can find the following details of the API agent that is displayed:

Parameter	Description
Agent ID	The ID of the installed API agent.
Identifier	The unique identifier of the installed API agent that is configured in the `Agent.config` file for the API agent.
Hostname	The hostname of the computer on which the API agent is installed.
Version	The version of the installed API agent.
Operating system	The operating system of the computer on which the API agent is installed.
Configuration location	The path to the location of the `Agent.config` file on the computer where the API agent is installed.
Tags	The agent attributes or tags that exist in the `Agent.config` file.

   b. Expand the capabilities panel to view the system capabilities.

      You can find the following capabilities of the API agent displayed:

Capabilities	Description
System capabilities	The capabilities of the API agent.

   c. Check for the status of the API agent from the **Status** column.

Results

You have added remote API agents to your project and viewed the details and capabilities of the API agent that is displayed for each agent that you own.

What to do next

Configure a run of the virtual service resources that are in your project and select an API agent as the location to run the virtual service. See Configuring a run of a virtual service on page 1462.

Removing an API agent from a project

You can remove an API agent from your project in Test when you no longer need the agent to run virtual services.

Before you begin

You must have added the registered API agent to a project in your team space. See Adding an API agent to a project on page 1083.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The agents that you added to your project are displayed on the **Agents and Intercepts** page.
3. You can view the API agents that you own in any of the following ways:
   - Search for the API agent by entering the name of the API agent in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

   - Sort the **Type** column to sort the items and display the API agents in the rows at the top of the table.
   - Sort the **Agents** column and identify the API agents by their names or by their owners.
4. Identify the API agent that you want to remove from the project, and then click the **Remove agent** icon .

   Note: The icon is displayed in the **Actions** column in the row of the API agent only if you are the owner of the remote API agent.

Results

You have removed the registered API agent from your project. The API agent is no longer available as a location to you while you configure a run of virtual service resources that are in your project.

What to do next

You might have to add API agents to your project to use the remote API agents as a location to run tests, if there are no API agents added to your project.

Unregistering a remote API agent from DevOps Test

You can unregister a remote API agent that is registered with Test in a team space when you no longer require it.

Before you begin

You must have completed the following tasks:

- Installed the agent by using your offline user token, which makes you the owner of the agent, or you are assigned the role of a *Team Space Owner*.
- Configured the Test Integrations and APIs agent so that the Test Integrations and APIs agent can register with Test. See Management of API agents on page 1080.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test.
3. Identify the API agent that you want to unregister.

   Note: The icon is displayed in the **Actions** column in the row of the API agent only if you are the owner of the API agent or you are assigned the role of a *Team Space Owner*. The icon is enabled only if the API agent is in a *Lost Contact* state.

4. Unregister the API agent by completing the following steps:
   a. Click the **Unregister API agent** icon .
   b. Click **Unregister** in the **Unregister API agent** dialog box.

Results

You have unregistered the remote API agent from a team space in Test. You cannot run tests on this remote API agent if it is added to your project.

Note: You might have to register it again with Test, if you want to use the remote API agent in your projects.

Management of DevOps Test Runtime agents

When you want to run the server test assets that require resources not available in the cluster, such as the Safari browser, you can use the DevOps Test Runtime agents. You can install the agent on a machine with the required resources, and then select the agent as the location for test runs from Test . You can also manage the registered agents in Test.

When you install the agents by using your offline user token, the agents are registered with the team space in Test, and they are associated with the project that you specified while registering the agents. You can view the registered agents before you add them to the other projects. You can then select the agents as locations to run the server test assets authored in Test.

Before you run any tests on a DevOps Test Runtime agent from a project on Test, you must have completed the following tasks:

- Installed and registered the DevOps Test Runtime agent. See. Installing and registering DevOps Test Runtime agents on page 1087.

  Note: When you configure the DevOps Test Runtime agent by using your offline user token, Test considers you as the owner of the agent.

  Restriction: You can run only one agent on a system.

- Viewed the agents that are registered with Test. See Viewing agents that are registered with DevOps Test on page 1092.
- Added the agents that are registered with Test to your project on Test. See Adding an agent to a project on page 1093.

If the agent is in the **Ready** state, then you can stop the agent by performing the following actions:

1. Switch to the same command line interface where you started the agent.
2. Navigate to the directory where the runtime script is located.
3. Press `Ctrl+C` keys.

If you do not want to retain the agents in a project or if you want to add the agents to a different project, you can remove the agents from a project. When you remove an agent from a project, you cannot select that agent to run tests in the project. See Removing an agent from a project on page 1094.

If you want to remove a registered agent from a team space in Test when the agent is not available for use or in the **Lost Contact** state, you can unregister an agent from a team space. See Unregistering a remote agent from DevOps Test on page 1095.

Installing and registering DevOps Test Runtime agents

When you want to run Web UI tests authored in Test on a Linux, Mac, or Windows system using an agent, you must first install and register the system as an agent by downloading and running the DevOps Test Runtime agent.

Before you begin

You must have completed the following tasks:

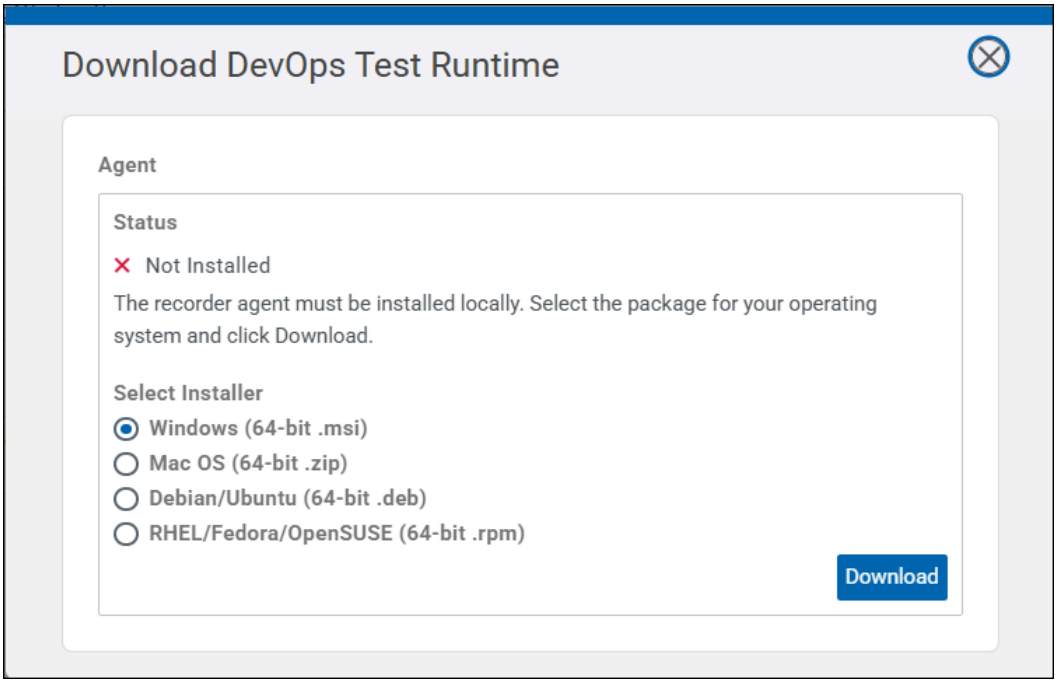
- Ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.
- Generated, copied, and then saved an offline token in a secure location.

1. Log in to Test on the system that you want to register as an agent.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts**.

Alternatively, you can select a project for which the agent should be added and then click **Infrastructure > Agents and Intercepts**.

The **Agents and Intercepts** page is displayed.

3. Click **Download > DevOps Test Runtime**.
   The **Download DevOps Test Runtime** pop-up is displayed.



4. Perform the following steps depending on the operating system:

Operating System	Action
Windows (64-bit)	Perform the following steps to install the agent on Windows: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.msi` file is downloaded. b. Double-click the `.msi` file to install the agent. The installation window with the progress bar is displayed. c. Click **Proceed** to accept the download of the proprietary certificate if prompted. d. Click **Verify** to confirm the agent installation. A confirmation message is displayed after verification is complete. e. Click **Done**. Go to step 5 on page 1090.

Operating System	Action
Mac OS (64-bit)	Perform the following steps to install the agent on Mac: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.zip` file is downloaded. b. Extract the contents of the `.zip` file: unzip devops-test-runtime.zip c. Quarantine the installer: xattr -dr com.apple.quarantine ./* d. Run the installer: ./install.sh e. Click **Verify** to confirm the agent installation. A confirmation message is displayed after verification is complete. f. Click **Done**. Go to step 5 on page 1090.
Debian/Ubuntu (64-bit)	Perform the following steps to install the agent on Ubuntu: a. Click **Download** to download the recording agent installer. The `devops-test-runtime_11.0.9_amd64.deb` file is downloaded. b. Navigate to the directory where the installer is downloaded: cd <download-directory> c. Run the installer: sudo apt install ./devops-test-runtime_11.0.9_amd64.deb d. Click **Verify** to confirm the agent installation. A confirmation message is displayed after verification is complete. e. Click **Done**. Go to step 5 on page 1090.
RHEL/Fedora/OpenSUSE (64-bit)	Perform the following steps to install the agent on Linux: a. Click **Download** to download the recording agent installer. The `devops-test-runtime-11.0.9-1.x86_64.rpm` file is downloaded.

Operating System	Action
	b. Navigate to the directory where the installer is downloaded: cd <download-directory> c. Run the following command: INGRESS_DOMAIN=<domain_name> dnf localinstall ./devops-test-runtime-11.0.9-1.x86_64.rpm d. Click **Verify** to confirm the agent installation. A confirmation message is displayed after verification is complete. e. Click **Done**. Go to step 5 on page 1090.

5. Perform the following steps to register the system as an agent in Test:
   You must provide the following details to register the system as an agent in Test:
   - `<dth_url>`: The URL of Test. For example, https://10.0.2.15.nip.io/test.
   - `<project_id>`: The ID of a project in Test to which the agent must be associated. For example, `2600` is the project ID in https://10.0.2.15.nip.io/test/#/Initial/project/2600.
   - `<offline_token>`: An offline token generated from Test for the logged-in user who is registering the agent to run tests.
   - `<agent_name>`: The name of the agent to be displayed in Test. The name must be unique and must conform to the DNS name format, however, it need not be a real hostname. For example, my-agent.

Operating System	Action

Windows (64-bit .msi)	Perform the following steps:
	a. Navigate to the `C:Users\<user_name>\AppData\HCL\devops-test-runtime` directory where the runtime script is located.
	b. Run the following commands:
	`set DEVOPS_TEST_HUB_URL=<dth_url>`
	`set DEVOPS_TEST_PROJECT_ID=<project_id>`
	`set DEVOPS_TEST_OFFLINE_TOKEN=<offline_token>`
	`set DEVOPS_TEST_AGENT_NAME=<agent_name>`
	`.\devops-test-runtime.exe agent`
	Confirmation messages about the agent starting and registering are displayed. Go to step 6 on page 1091.

Mac OS (64-bit .zip)	Perform the following steps:

Operating System	Action

	a. Navigate to the `~/Applications/devops-test-runtime.app/Contents/Resources` directory where the runtime script is located.
	b. Run the following commands:
	`export DEVOPS_TEST_HUB_URL=<dth_url>`
	`export DEVOPS_TEST_PROJECT_ID=<project_id>`
	`export DEVOPS_TEST_OFFLINE_TOKEN=<offline_token>`
	`export DEVOPS_TEST_AGENT_NAME=<agent_name>`
	`./devops-test-runtime agent`
	Confirmation messages about the agent starting and registering are displayed. Go to step 6 on page 1091.

Debian/Ubuntu (64-bit .deb)	Perform the following steps:
	a. Navigate to the `/opt/hcl/devops-test` directory where the runtime script is located.
	b. Run the following commands:
	`export DEVOPS_TEST_HUB_URL=<dth_url>`
	`export DEVOPS_TEST_PROJECT_ID=<project_id>`
	`export DEVOPS_TEST_OFFLINE_TOKEN=<offline_token>`
	`export DEVOPS_TEST_AGENT_NAME=<agent_name>`
	`./devops-test-runtime agent`
	Confirmation messages about the agent starting and registering are displayed. Go to step 6 on page 1091.

RHEL/Fedora/OpenSUSE (64-bit .rpm)	Perform the following steps:
	a. Navigate to the `/opt/hcl/devops-test` directory where the runtime script is located.
	b. Run the following commands:
	`export DEVOPS_TEST_HUB_URL=<dth_url>`
	`export DEVOPS_TEST_PROJECT_ID=<project_id>`
	`export DEVOPS_TEST_OFFLINE_TOKEN=<offline_token>`
	`export DEVOPS_TEST_AGENT_NAME=<agent_name>`
	`./devops-test-runtime agent`
	Confirmation messages about the agent starting and registering are displayed. Go to step 6 on page 1091.

6. Log in to Test and navigate to **Infrastructure > Agents and Intercepts** to view the agent details that you registered.

Results

You have installed and registered a DevOps Test Runtime agent.

What to do next

You can run the test and view the results. See Running server test assets on an agent on page 1324.

Viewing agents that are registered with DevOps Test

After you install and register the remote DevOps Test Runtime agents with Test , you can view the registered agents on the **Agents and Intercepts** page.

Before you begin

You must have installed and registered the DevOps Test Runtime agents. See Installing and registering DevOps Test Runtime agents on page 1087.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test. The page displays the following columns:
   - **Type**: Type of the agent
   - **Agents**: IP address of the agent with the owner's name
   - **Projects**: Projects that are associated with the agent
   - **Status**: Status of the agent to indicate whether it is **Ready** or **Lost Contact**
   - **Actions**: Actions that are allowed on the agent
3. View the DevOps Test Runtime agents that are registered.
   If the list is long, you can search for the agent by entering the name of the agent in the **Search** field.

   Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

4. Expand the agent to view the details of the agent in four different tabs.
   You can find the following details:

Parameter	Description
DETAILS	
Agent ID	The ID of the installed DevOps Test Runtime agent.
Name	The name that you assigned to the agent during registration.
Hostname	The hostname of the computer on which the DevOps Test Runtime agent is installed.
Address	The IP address of the computer on which the DevOps Test Runtime agent is installed.
Version	The version of the installed DevOps Test Runtime agent.
Operating system	The operating system of the computer on which the agent is installed.
SYSTEM	

Parameter	Description
Architecture	The processor type of the system.
Operating system	The operating system of the computer on which the agent is installed.
RAM	The total RAM size of the system.
APPLICATION	
Browser	Browsers that are installed on the system are listed with the name and version details.

Results

You have viewed the registered DevOps Test Runtime agents from the **Agents and Intercepts** page.

What to do next

You can add the DevOps Test Runtime agents that you own to your project. See Adding an agent to a project on page 1093.

Adding an agent to a project

You must add the registered DevOps Test Runtime agents to your projects before you select them as the location to run the tests.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Installed the agent by using your offline user token, which makes you the owner of the agent, or you are assigned the role of a *Team Space Owner*.

About this task

The owner of a DevOps Test Runtime agent or a team space owner can add or remove an agent from the project. However, any member of the project with the permission to run the tests can initiate the run on agents that are added to the project.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The **Agents and Intercepts** page is displayed.
3. Click **Add > Add DevOps Test Runtime agent**.
   The agents that you configured with your user token are displayed.

Note: You can add the agents that you own. You can add any number of agents to your project.

4. Select the agents that you want to use in the project, and then click **Add**.

   The agents that you added to the project are displayed.

Results

You have added remote agents to your project.

What to do next

You can perform the following tasks:

- View the details and capabilities of the agent that you added. See Viewing agents that are registered with DevOps Test on page 1092.
- Run a Web UI test that is in your project and select an agent as the location to run the test. See Running server test assets on an agent on page 1324.

Removing an agent from a project

You can remove a DevOps Test Runtime agent from your project in Test when you no longer need the agent to run tests.

Before you begin

You must have added the registered DevOps Test Runtime agent to a project in your team space. See Adding an agent to a project on page 1093.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project, and then click **Infrastructure > Agents and Intercepts**.

   The agents that you added to your project are displayed on the **Agents and Intercepts** page.
3. View the DevOps Test Runtime agents that are registered.
   If the list is long, you can search for the agent by entering the name of the agent in the **Search** field.

   Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

4. Identify the agent that you want to remove from the project, and then click the **Remove agent** icon .

   Note: The icon is displayed in the **Actions** column in the row of the agent only if you are the owner of the remote agent.

Results

You have removed the registered agent from your project. The DevOps Test Runtime agent is no longer available as a location to you while you configure a test run in your project.

Unregistering a remote agent from DevOps Test

You can unregister a remote DevOps Test Runtime agent that is registered with Test in a team space when you no longer require it.

Before you begin

You must have installed and registered the DevOps Test Runtime agents, or you are assigned the role of a *Team Space Owner*. See Installing and registering DevOps Test Runtime agents on page 1087.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane.

   The **Agents and Intercepts** page is displayed.

   You can view the API agents, intercepts, Kubernetes clusters, performance agents, or DevOps Test Runtime agents that are registered with Test.
3. Identify the DevOps Test Runtime agent that you want to unregister.

   Note: The icon is displayed in the **Actions** column in the row of the agent only if you are the owner of the agent or you are assigned the role of a *Team Space Owner*. The icon is enabled only if the agent is in a *Lost Contact* state.

4. Unregister the agent by completing the following steps:
   a. Click the **Unregister DevOps Test Runtime agent** icon .
   b. Click **Unregister** in the **Unregister DevOps Test Runtime agent** dialog.

Results

You have unregistered the remote agent from a team space in Test. As a result, you cannot run tests on this remote agent if it is added to your project.

Management of the personal agent

A personal agent is a local agent that provides a dedicated, isolated runtime environment to run and diagnose Web UI tests and suites directly on your local machine.

A personal agent is a localized DevOps test runtime instance that is linked to your user account. The personal agent is designed for your individual use and remains invisible and inaccessible to other users. For clear identification, each agent is named using a unique `personal:username` format based on your profile credentials. There can be only one active personal agent per user across all machines. When the agent is ready, you can select the **Run on personal agent** option from

the test editor to run the tests locally through that agent instead of a remote container. You can also choose the personal agent as a targeted location to run tests through the **Execute test asset** dialog on the **Execution** page.

The personal agent simplifies and improves the local debugging experience for Web UI tests and suites. As the agent allows you to bypass remote test containers and route tests directly to your local machine, you can visually observe browser behavior in real time and identify the exact point of test failure. This visibility helps you quickly resolve playback errors.

You can use the Personal Agent button located on the test editor page to download, start, or stop the agent. Once you stop the agent, the agent's state changes to inactive in the editor. When the agent is in the inactive state, the **Run on personal agent** option is automatically disabled in the editor interface, and it cannot be used for test runs. As the agent automatically associates with every project you belong to, you can switch between different project workspaces without the need to manually re-associate the agent. You can view the agent listed on the **Agents & Intercepts** page both inside a project and in the initial team space. To ensure privacy and prevent shared access, a different user in the same project can neither view the agent on the **Agents & Intercepts** page nor select it as a target location to run tests.

Installing and starting the personal agent

When you want to run server test assets or server suite assets locally on your system and view the live test run, you can install and use the personal agent. To run tests locally, you must first download the DevOps Test Runtime agent, and then install and start the agent in **Test Editor**.

Before you begin

You must have ensured that you are a Team Space Owner, Project Owner, or Member with a Tester role to create or edit a test resource.

1. Log in to Test on the system that you want to register as an agent.
   The **Projects** page of the initial team space is displayed.
2. Click **My projects > project_name** to open the project that contains the test assets.
   The **Overview** page of the project is displayed.
3. Click **Author > Test Editor**.
   The **Test Editor** page and the test navigator panel are displayed.
4. Click the button located in the page title bar next to the branch selector.
   The **Manage DevOps Test Runtime** dialog opens and checks the status of your local installation.
5. Perform one of the following steps depending on the installation status of the agent:

If...	Then...
The agent is not installed, and the screen displays the following options: ◦ Windows (64-bit .msi) ◦ Mac OS (64-bit .zip)	Perform the following steps to install the agent on Windows: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.msi` file is downloaded. b. Double-click the `.msi` file to install the agent.

If...	Then...
◦ Debian/Ubuntu (64-bit .deb) ◦ RHEL/Fedora/OpenSUSE (64-bit .rpm)	The installation window with the progress bar is displayed. c. Click **Proceed** to accept the download of the proprietary certificate if prompted. d. Click **Verify** to confirm the agent installation. A browser notification might get displayed for you to confirm the opening of the agent. You must click **Open Link**. The **Launch** button is enabled. Go to step 6 on page 1099.
	Perform the following steps to install the agent on Mac: a. Click **Download** to download the recording agent installer. The `devops-test-runtime.zip` file is downloaded. b. Extract the `.zip` file: unzip devops-test-runtime.zip c. Quarantine the installer: xattr -dr com.apple.quarantine ./* d. Run the installer: ./install.sh e. Click **Verify** to confirm the agent installation. The **Launch** button is enabled. Go to step 6 on page 1099.
	Perform the following steps to install the agent on Ubuntu: a. Click **Download** to download the recording agent installer. The `devops-test-runtime_11.0.9_amd64.deb` file is downloaded. b. Navigate to the directory where the installer is downloaded: cd <download-directory> c. Run the installer: sudo apt install ./devops-test-runtime_11.0.9_amd64.deb d. Click **Verify** to confirm the agent installation. The **Launch** button is enabled. Go to step 6 on page 1099.
	Perform the following steps to install the agent on Linux:

<table>
<tr><th>If...</th><th>Then...</th></tr>
<tr><td></td><td>a. Click Download to download the recording agent installer.

The <code>devops-test-runtime-11.0.9-1.x86_64.rpm</code> file is downloaded.
b. Navigate to the directory where the installer is downloaded:

cd <download-directory>
c. Run the following command:

INGRESS_DOMAIN=<domain_name> dnf

localinstall ./devops-test-runtime-11.0.9-1.x86_64.rpm
d. Click Verify to confirm the agent installation.

The Launch button is enabled. Go to step 6 on page 1099.</td></tr>
<tr><td rowspan="2">The agent is installed, but not updated, and the screen displays the following options:
◦ Windows (64-bit .msi)
◦ Mac OS (64-bit .zip)
◦ Debian/Ubuntu (64-bit .deb)
◦ RHEL/Fedora/OpenSUSE (64-bit .rpm)</td><td>Perform the following steps to update the agent on Windows:
a. Click Upgrade.

The installation screen with the progress bar is displayed. The latest DevOps Test Runtime is installed and configured.
b. Click Proceed to accept the download of the proprietary certificate if prompted.

The Launch button is enabled. Go to step 6 on page 1099.</td></tr>
<tr><td>Perform the following steps to install the agent on Mac:
a. Click Download to download the recording agent installer.
b. Uninstall the existing agent:

rm -rf ~/Applications/devops-test-runtime.app
c. Extract the downloaded <code>.zip</code> file:

unzip devops-test-runtime.zip
d. Quarantine the installer:

xattr -dr com.apple.quarantine ./*
e. Run the installer:

./install.sh
f. Click Verify to confirm the agent installation.

The Launch button is enabled. Go to step 6 on page 1099.</td></tr>
</table>

If...	Then...
	Perform the following steps to install the agent on Ubuntu: a. Click **Download** to download the recording agent installer. b. Uninstall the existing agent: sudo apt remove devops-test-runtime c. Navigate to the directory where the installer is downloaded: cd <download-directory> d. Run the following command: sudo apt install ./devops-test-runtime_11.0.9_amd64.deb e. Click **Verify** to confirm the agent installation. The **Launch** button is enabled. Go to step 6 on page 1099.
	Perform the following steps to install the agent on Linux: a. Click **Download** to download the recording agent installer. b. Uninstall the existing agent: sudo yum remove devops-test-runtime c. Navigate to the directory where the installer is downloaded: cd <download-directory> d. Run the installer: sudo INGRESS_DOMAIN=<domain_name> dnf localinstall ./devops-test-runtime-11.0.9-1.x86_64.rpm e. Click **Verify** to confirm the agent installation. The **Launch** button is enabled. Go to step 6 on page 1099.
The agent is installed.	The **Launch** button is displayed. Go to step 6 on page 1099.

6. Click **Launch**.

   The personal agent button changes to , and the tooltip displays the following message when hovered over: `Personal Agent Ready - Click to stop`. This message indicates that the agent is active.

Results

You have downloaded and installed a DevOps Test Runtime agent. The personal agent is listed and visible only to you when you navigate to **Infrastructure > Agents and Intercepts**, both in the initial team space and in the projects that you are associated with.

What to do next

You can run the Web UI tests or suites and view the results. See Running server test assets on page 1321 and Running server suite assets on page 1329.

Stopping or unregistering the personal agent

You can stop or unregister the personal agent when you no longer need the agent to run tests.

Before you begin

You must have added the personal agent in your team space, and it must be in the active state. See Installing and starting the personal agent on page 1096.

Perform the steps by using one of the following two methods:

- Stop the agent through the **Test Editor** page.
  a. Log in to Test on the system that you want to register as an agent.

     The **Projects** page of the initial team space is displayed.

  b. Click **My projects > project_name** to open the project that contains the test assets.

     The **Overview** page of the project is displayed.

  c. Click **Author > Test Editor**.

     The **Test Editor** page and the test navigator panel are displayed.

  d. Click the button located in the page title bar next to the branch selector.

     The **Stop DevOps Test Runtime** dialog opens.

  e. Click **Yes** to stop the agent.

     The personal agent button changes to , and the tooltip displays the following message when hovered over:

     `Personal Agent Inactive - Click to launch` . This message indicates that the agent is inactive.

- Unregister the agent through the **Agents and Intercepts** page.
  a. Open the **Initial Team Space** page and then navigate to the **Infrastructure > Agents and Intercepts** page.
  b. View the personal agent that is listed with the personal:username name.

     If the list is long, you can search for the agent by entering the name of the agent in the **Search** field.

Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

c. Identify the agent, and then click the **Remove agent** icon .

The **Unregister DevOps Test Runtime** dialog opens.

d. Click **Unregister** to remove the agent.

Results

You have stopped or unregistered the personal agent. The agent will not be available as a location to run tests till you start it again.

Management of remote Kubernetes clusters

You can find information about the tasks that you can perform on remote Kubernetes clusters. After you set up a remote Kubernetes cluster, you can register the external cluster with a team space on Test . You must then add the remote cluster to a project before you run test assets or resources on the remote Kubernetes cluster.

You can find the following information about managing the external Kubernetes cluster:

- Considerations for using a remote Kubernetes cluster on page 1101
- Registering a remote Kubernetes cluster on page 1104
- Viewing remote Kubernetes clusters on page 1107
- Adding a remote Kubernetes cluster to a project on page 1109
- Editing configurations of a remote Kubernetes cluster on page 1110
- Removing a remote Kubernetes cluster from a project on page 1113
- Unregistering a remote Kubernetes cluster from a team space on page 1114

Considerations for using a remote Kubernetes cluster

When you want to use a remote Kubernetes cluster as a location to run the supported tests or test resources, you must read the considerations first.

Before you want to run any of the supported tests or test resources on Test that are configured to run on a remote Kubernetes cluster, you must have completed the following tasks:

- Verified that the Kubernetes cluster that you want to use is a supported one by referring to the OS, platform, and containers that are specified for Test in System Requirements for DevOps Test 2026.06 (11.0.9).
- Kept a suitable `kubeconfig` file with access to the remote Kubernetes cluster in a folder on the computer that you want to use to access an instance of Test.

You must be familiar with the administration of a Kubernetes cluster. When you as the cluster administrator, set up the remote Kubernetes cluster must consider the following requirements:

- You must have a `kubeconfig` file with access to the remote Kubernetes cluster in a folder on the computer that you want to use to access an instance of Test.

  Note: If the `kubeconfig` file references certificate files by using filepaths then the certificate data must be embedded in the `kubeconfig` file to make it usable by Test. If the `kubeconfig` file contains multiple contexts, then only the current context is required.

  You can use the following kubectl command to create a suitable `kubeconfig` file called `portable-config` in the current folder. The `portable-config` file contains embedded certificate data and the information used by the current context:

  ```
  kubectl config view --flatten --minify > portable-config
  ```

- You must ensure that the remote Kubernetes cluster is able to access the Test image registry which is the same registry that you used to install Test. There is no need to copy the Test image to the remote Kubernetes cluster but the remote cluster must be able to access the image registry at test runtime.

  If the remote cluster that you want to use is a Lightweight Kubernetes (k3s) cluster, it might require a *Secret* to pull the Test image. You must run the following command on the remote k3s cluster:

  ```
  kubectl create secret docker-registry hclcr.io \
  -n {remote-namespace} \
  --docker-server=hclcr.io \
  --docker-username={okta-email-address} \
  --docker-password={harbor-cli-secret} \
  --docker-email={example@abc.com}
  ```

  Notes:
  - You must replace *{remote-namespace}* with the value of the *namespace* that you have used for the remote cluster.
  - You must replace *{okta-email-address}* with the username of the Harbor repository and replace *{harbor-cli-secret}* with the secret key that you copied from the Harbor repository.
  - If the username contains any special characters, such as *$*, you must enclose it within single quotation-marks.
  - You can replace *{example@abc.com}* with the email address of the administrator, if required.

- You need not configure separate licenses for running on the remote cluster because the licenses are consumed from the pool of available licenses that are configured for the team space on Test. The licenses are returned to the pool when the test run is completed on the remote cluster.
- You must ensure that the Test domain is accessible from the remote cluster so that the pod in the cluster is able to communicate with Test.
- You must ensure that the appropriate **PriorityClass** exists on the remote cluster if you want to control the priority given to the remote execution pod by the scheduler. The same **PriorityClass** that is used by the Test execution pod is used by the remote execution pod. If the named **PriorityClass** does not exist in the remote cluster, then no **PriorityClass** is specified by the remote execution pod.

- You must create an HTTP or an HTTPS Emissary listener when you want to run virtual services on the remote cluster. You must create both listeners when you want to run virtual services that use both HTTP and HTTPS transports. For information about creating listeners, refer to https://www.getambassador.io/docs/emissary/latest/topics/running/listener. The Emissary listener associates with the hosts created by Test in the target namespace for executions that require Ingress. For example, when you want to run virtual services on the remote cluster and run tests from the remote cluster that use static agents.
- You can enter the code snippets for *nodeSelectors* and *tolerations* in a `yaml` format, if you want to use *nodeSelectors* and *tolerations* on the remote cluster. You can enter these in the fields provided in the **Advanced** configuration dialog when you register a remote cluster with your team space on Test.

  For more information about *nodeSelector*, see nodeSelector and for *tolerations*, see Tolerations.

Restrictions: The following restrictions apply when you want to run the supported tests on a remote Kubernetes cluster:

- Using the **UserLibs** that are required for running certain API Suites are not supported on the remote cluster.
- Running of Compound Tests that contain performance tests, which require the **NodePort** access to connect to static agents, are not supported on the remote cluster.

When you plan to run any of the test assets or resources on a remote Kubernetes cluster from a project on Test, you must complete the following tasks:

	Tasks	More information...
1	Register a remote Kubernetes cluster with a team space on Test.	Registering a remote Kubernetes cluster on page 1104
2	View remote Kubernetes clusters added to a team space.	Viewing remote Kubernetes clusters on page 1107
3	Add a remote Kubernetes cluster to a project in a team space.	Adding a remote Kubernetes cluster to a project on page 1109
4.1	Configure a run for your test that you want to run on the remote Kubernetes cluster by performing the following actions: 1. Check for the prerequisite tasks that you must perform before you configure a test run for the test. 2. Select the task for the test that you want to configure for a run, and then follow the steps to run the test.	1. Test run configurations on page 1134 2. Prerequisites to running tests on page 1057 3. Test run configurations on page 1134

	Tasks	More information...
4.2	Configure a run of the virtual service resources that you want to run on the remote Kubernetes cluster by performing the following actions: 1. Check for the prerequisite tasks that you must perform before you configure a run of the virtual services. 2. Select the virtual service resources in your project that you want to configure for a run, and then follow the steps to run them.	1. Prerequisites for running HTTP virtual services on page 1455 2. Configuring a run of a virtual service on page 1462

Management of remote Kubernetes clusters on page 1101

Registering a remote Kubernetes cluster

You must register a remote Kubernetes cluster to your team space on Test before you add the remote cluster to your project.

Before you begin

You must have completed the following tasks:

- Verified that the Kubernetes cluster that you want to use is a supported one by referring to the OS, platform, and containers that are specified for Test in System Requirements for DevOps Test 2026.06 (11.0.9).
- Kept a suitable `kubeconfig` file with access to the remote Kubernetes cluster in a folder on the computer that you want to use to access an instance of Test.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane of the team space.

   The **Agents and Intercepts** page is displayed.
3. Click **Add new > Add new cluster**.

   The **New cluster** dialog is displayed.

4. Perform the following steps to add the `kubeconfig` file:

    a. Click **Browse**, and locate the `kubeconfig` file of the Kubernetes cluster that you want to add.

    b. Select the `kubeconfig` file, and then click **Open**.

    The name of the `kubeconfig` file that you selected is displayed along with the address of the Kubernetes cluster that is specified in the file.

    c. Click **Next**.

The address of the Kubernetes cluster that is configured in the `kubeconfig` file is displayed in the **Address** field.

Note: You can change the address of the Kubernetes cluster if it is different from the address in the `kubeconfig` file.

5. Perform the following steps to add a namespace and name for the cluster:

    a. Enter the namespace of the cluster in the **Namespace** field.

    b. Enter a name for the cluster in the **Name** field.

    The name helps you to identify the cluster.

    c. Click **Next**.

6. Perform the following steps to add the ingress details of the cluster:

    a. Select the ingress type of the cluster from the **Ingress type** list.

    You can select the ingress type from the following options that are displayed:

Option	Description	Result
None	When selected specifies that no ingress type is configured for the remote Kubernetes cluster.	You can run any of the supported tests on the remote cluster but not on the remote agents.
NGINX	When selected specifies that NGINX is configured as the ingress type for the remote Kubernetes cluster.	You can run any of the supported tests on the remote cluster or on any of the remote agents.

    b. Enter the ingress host pattern of the cluster in the **Ingress host pattern** field.

    The DNS used by a computer that runs a client application (such as a static agent) or the HTTP proxy that routes traffic to the virtual service needs to resolve such hostnames to the IP address of the ingress domain.

    For example, if the IP of the remote cluster is 12.12.12.123, then you must enter the ingress host pattern as **.12.12.12.123.nip.io*

The *Unique ID* of the virtual service is prefixed to the ingress hostname when virtual services are routed from the Test cluster.

c. Enter the name of the secret in the remote namespace, which contains the certificate information.

You must have created the secret and named it following the naming conventions per the Kubernetes guidelines. The certificate that you create is a wildcard certificate which contains the Ingress host pattern of the Kubernetes cluster. This wildcard certificate ensures that the client applications can trust the virtual services.

Note: If a secret name is not provided then the default certificate that is provided by NGINX is used, which might cause issues to authenticate the virtual service by the client applications.

d. Click **Next**.

7. Optionally, perform the following steps to enter the code snippets for *nodeSelectors* and *tolerations*, if applicable for the remote cluster:

a. Enter the code snippet for *nodeSelectors* in a `yaml` format in the **Node selectors** field.

b. Enter the code snippet for *tolerations* in a `yaml` format in the **Tolerations** field.

c. Select the **Copy pull secret to the cluster** checkbox, if it is not already selected.

Note: The remote Kubernetes cluster pulls the secret to access the Test image registry which is the same registry that you used to install Test. The remote Kubernetes cluster must be able to access the image registry at test runtime.

d. Click **Register**.

The remote cluster is added to the team space and is displayed with the icon in the **Type** column on the **Agents and Intercepts** page. You can identify the cluster with its name in the **Agents** column.

Note: The **Projects** column does not display any projects that are associated with the cluster yet.

Results

You have registered a remote Kubernetes cluster with your team space on Test.

What to do next

You must add the remote cluster to your project in your team space before you use the remote cluster as a location to run test assets or resources in your project. See Adding a remote Kubernetes cluster to a project on page 1109.

Related information

Management of remote Kubernetes clusters on page 1101

Viewing remote Kubernetes clusters

You can view the clusters that you have registered with a team space on Test to view their details or edit their configurations.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Registered a remote Kubernetes cluster with your team space on Test. See Registering a remote Kubernetes cluster on page 1104.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane of the team space.

   The **Agents and Intercepts** page is displayed.

   You can view the agents, intercepts, or clusters that are registered with the team space on Test.
3. You can view the clusters that you own in any of the following ways:
   - Search for the cluster by entering the name of the cluster in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

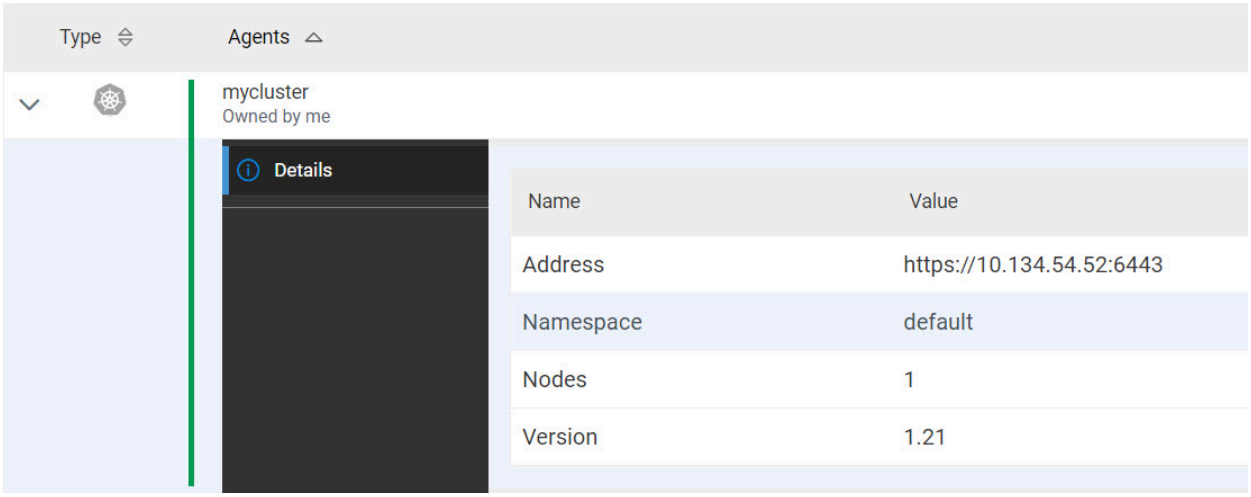
   - Sort the **Type** column to sort the items, and then identify the cluster by the name or owner.
   - Sort the **Agents** column to sort the items, and then identify the cluster by the name or owner.

   You can view the following details about the clusters that are in the team space:

- The projects in the team space to which the cluster is added are displayed in the **Projects** column.
- The status of the cluster is displayed in the **Status** column.

Note: You can add clusters that are in the `Ready` state to your project, and then use them as locations to run tests.

You can view the details of the cluster by clicking the **Expand** icon.



The following table describes the details about the cluster:

Name	Description
Address	Specifies the address of the remote Kubernetes API.
Namespace	Specifies the *namespace* of the remote Kubernetes cluster in which the test runs occur.
Nodes	Specifies the number of nodes in the remote Kubernetes cluster.
Version	Specifies the Kubernetes version of the remote Kubernetes cluster.

Results

You have viewed details of the remote clusters that are registered with a team space on Test.

What to do next

You must add the remote cluster to your project in your team space before you can use the remote cluster as a location to run test assets or resources that are in your project. See Adding a remote Kubernetes cluster to a project on page 1109.

Related information

Management of remote Kubernetes clusters on page 1101

Adding a remote Kubernetes cluster to a project

You must add a remote Kubernetes cluster to your project after you register the cluster with your team space on Test .

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Registered a remote Kubernetes cluster with your team space on Test. See Registering a remote Kubernetes cluster on page 1104.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Been assigned a role as an *Owner* in the project.
- Created a project.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open your project.
   The **Overview** page is displayed.
3. Click **Infrastructure > Agents and Intercepts** in the navigation pane of the team space.

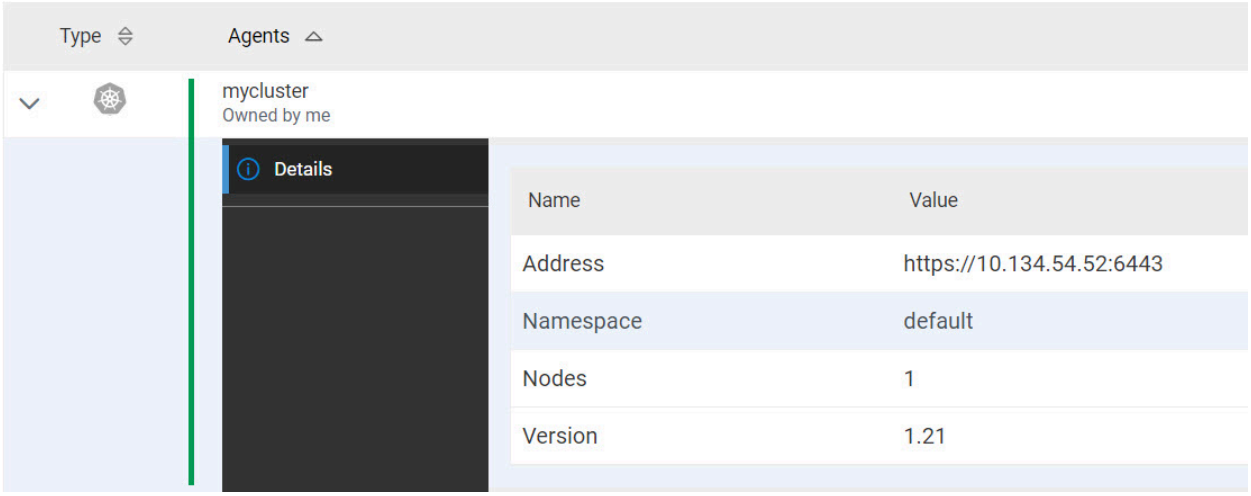
   The **Agents and Intercepts** page is displayed.
4. Click **Add > Add cluster**.

   The **Add cluster** dialog is displayed.
5. Select the cluster that you want to add to the project from the list of clusters that are registered with the team space, and then click **Add**.

   Note: You can add the clusters that are registered with the team space. You can add any number of clusters to your project.

   The clusters that you added to the project are displayed.

   You can view the details of the cluster by clicking the **Expand** icon ›.



The following table describes the details about the cluster:

Name	Description
Address	Specifies the address of the remote Kubernetes API.
Namespace	Specifies the *namespace* of the remote Kubernetes cluster in which the test runs occur.
Nodes	Specifies the number of nodes in the remote Kubernetes cluster.
Version	Specifies the Kubernetes version of the remote Kubernetes cluster.

What to do next

You can select any of the remote clusters as an alternate location to run the test assets or resources that are in your project while you configure a run from the **Execution** page.

Related information

Test run configurations on page 1134

Management of remote Kubernetes clusters on page 1101

Editing configurations of a remote Kubernetes cluster

You can edit the `kubeconfig` file, address, namespace, name, or ingress details of the remote Kubernetes cluster that you added to a team space on Test .

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Registered a remote Kubernetes cluster with your team space on Test. See Registering a remote Kubernetes cluster on page 1104.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane of the team space.

   The **Agents and Intercepts** page is displayed.

   You can view the agents, intercepts, or clusters that are registered with the team space on Test.
3. You can view the clusters that you own in any of the following ways:
   - Search for the cluster by entering the name of the cluster in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

   - Sort the **Type** column to sort the items, and then identify the cluster by the name or owner.
   - Sort the **Agents** column to sort the items, and then identify the cluster by the name or owner.

   You can view the following details about the clusters that are in the team space:
   - The projects in the team space to which the cluster is added, are displayed in the **Projects** column.
   - The status of the cluster is displayed in the **Status** column.

     Note: You can add clusters that are in the `Ready` state to your project, and then use them as locations to run tests.

4. Identify the cluster that you want to modify the configurations, and then click the **Edit** icon .

   Note: The icon is displayed in the **Actions** column in the row of the cluster only if you own the cluster.

   The **Update cluster** dialog is displayed.
5. Perform the following steps to change the `kubeconfig` file:
   a. Click **Browse**, and locate the `kubeconfig` file of the Kubernetes cluster that you want to use.

   b. Select the `kubeconfig` file, and then click **Open**.

The name of the `kubeconfig` file that you selected is displayed along with the address of the Kubernetes cluster that is specified in the file.

c. Click **Next**.

6. Perform the following steps to change the namespace or name of the cluster:
   a. Edit or change the namespace of the cluster that you want to use, in the **Namespace** field.
   b. Edit or change the name of the cluster in the **Name** field.
   c. Click **Next**.
7. Perform the following steps to change the ingress details of the cluster:

   a. Select the ingress type of the cluster from the **Ingress type** list, if you want to use a different cluster.

   b. Enter or change the ingress host pattern of the cluster in the **Ingress host pattern** field, if you did not provide it when setting up the remote cluster or change it to match the cluster you want to use.

   c. Enter the secret if you did not provide it when setting up the remote cluster.
   The secret is used to authenticate the remote cluster to use the licenses from the Team space License Server so that the inbound traffic is allowed into the ingress domain.

   Note: The secret to use must be available with your Test server administrator.

   d. Click **Next**.

8. Optionally, perform the following steps to edit or change the code snippets for *nodeSelectors* and *tolerations*, if applicable for the remote cluster:
   a. Enter the code snippet for *nodeSelectors* in a `yaml` format in the **Node selectors** field.
   b. Enter the code snippet for *tolerations* in a `yaml` format in the **Tolerations** field.
9. Click **Update**.

   The remote cluster is displayed with the updated configurations.

   Note: The projects that are associated with the cluster are displayed in the **Projects** column and you need not add the cluster to the same project again.

Results

You have updated an existing remote cluster with the changed configurations.

What to do next

You can select the updated cluster as an alternate location to run the test assets or resources that are in your project while you configure a run from the **Execution** page.

Related information

Management of remote Kubernetes clusters on page 1101

Removing a remote Kubernetes cluster from a project

You can remove a remote Kubernetes cluster from a project in a team space on Test when you no longer need the cluster to run tests.

Before you begin

You must have completed the following tasks:

1. Registered a remote Kubernetes cluster with your team space on Test. See Registering a remote Kubernetes cluster on page 1104.
2. Added the Kubernetes cluster to a project in your team space. See Adding a remote Kubernetes cluster to a project on page 1109.

   Note: You can remove remote Kubernetes clusters that only you added to the project.

3. Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
4. Been assigned a role as an *Owner* in the project.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project in your team space.

   The **Overview** page is displayed.
3. Click **Infrastructure > Agents and Intercepts** in the navigation pane of your team space.

   The **Agents and Intercepts** page is displayed.

   You can view the agents, intercepts, or clusters that are added to your project.
4. You can view the clusters that you own in any of the following ways:
   - Search for the cluster by entering the name of the cluster in the **Search** field.

     Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

   - Sort the **Type** column to sort the items, and then identify the cluster by the name or owner.
   - Sort the **Agents** column to sort the items, and then identify the cluster by the name or owner.

5. Identify the cluster that you want to remove from the project, and then click the **Remove cluster** icon .

   Note: The icon is displayed in the **Actions** column in the row of the cluster only if you own the remote cluster.

   A message is displayed that the remote cluster is removed from the project successfully.

Results

You have removed the remote cluster from your project. The remote cluster is no longer available as a location when you configure a run of the test assets or resources that are in your project.

What to do next

You might have to add a remote cluster to your project to use the remote cluster as a location to run test assets or resources.

Unregistering a remote Kubernetes cluster from a team space

You can unregister a remote Kubernetes cluster from a team space in Test when you no longer require it.

Before you begin

You must have completed the following tasks:

1. Registered a remote Kubernetes cluster with your team space on Test. See Registering a remote Kubernetes cluster on page 1104.
2. Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
3. Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Agents and Intercepts** in the navigation pane of the team space.

   The **Agents and Intercepts** page is displayed.

   You can view the agents, intercepts, or clusters that are registered with the team space on Test.

3. You can view the clusters that you own in any of the following ways:
    - Search for the cluster by entering the name of the cluster in the **Search** field.

      Note: You can enter either the full name or any text that is in the name. The search is enabled for case-sensitive text that you can enter.

    - Sort the **Type** column to sort the items, and then identify the cluster by the name or owner.
    - Sort the **Agents** column to sort the items, and then identify the cluster by the name or owner.
4. Identify the cluster that you want to remove.

   Note: The and icons are displayed in the **Actions** column in the row of the cluster only if you own the remote cluster.

5. Unregister the cluster by completing the following steps:
    a. Click the **Unregister cluster** icon .
    b. Click **Unregister** in the **Unregister cluster** dialog box.

   A message is displayed that the remote cluster is unregistered successfully.

Results

You have unregistered the remote cluster from a team space on Test. You cannot run test assets or resources on this remote cluster if it is added to your project. You might have to add it again to your team space, if you want to use the remote cluster in your projects.

Management of cloud credentials

You can find information about managing the credentials that are required to connect to cloud-based applications such as mobile device clouds and AI providers from Test .

Contents

- Mobile device clouds on page 1116
- Mobile device clouds and Test on page 1116
- Mobile device clouds that are supported on page 1116

- Details required of mobile device clouds on page 1116
- Prerequisites for using mobile devices on mobile device clouds on page 1117
- Overview of tasks to manage mobile device clouds on page 1118
- AI providers on page 1118
- Details required of AI providers on page 1119

Mobile device clouds

Mobile device clouds are cloud computing services offered by cloud service providers who host real mobile devices in a cloud. You can purchase plans from the service providers to use the mobile devices in the cloud to test your mobile apps. The cloud service providers also offer different browsers in the cloud to test web applications.

To use the cloud services, you must subscribe to their services that suit your testing requirements.

Mobile device clouds and Test

If you already use mobile device clouds to test your mobile apps, testers in your organization must be required to set up the connection to the mobile device clouds individually. They use the same credentials that you subscribed to as an organization. This can be a potential risk of exposure of your subscription details and without proper monitoring can lead to misuse of the credentials.

You can use Test to connect to mobile device clouds. You must first configure a cloud credential by using the details of your cloud subscription account.

You can then add testers from your organization as authorized users who can use the credential to connect to mobile device clouds. Such members need not enter the subscription details to connect to the cloud. Only the authorized users of the credential can run their tests on the devices that are connected to the mobile device cloud. With this mechanism, you can prevent the exposure of the credentials of your subscription to testers and also prevent testers from creating separate connections to the same mobile device cloud.

Mobile device clouds that are supported

Test supports connections to the following mobile device clouds:

- BitBar Cloud
- BrowserStack Cloud
- LambdaTest Cloud
- pCloudy Cloud
- Perfecto Mobile Cloud

Details required of mobile device clouds

You must ensure that you have the details and valid credentials of your subscription to the mobile device cloud that you want to connect and use. See the following table for the details required for the different mobile device clouds:

Attribute	Description	Mobile device cloud				
		BitBar Cloud	**BrowserStack Cloud**	**LambdaTest Cloud**	**pCloudy Cloud**	**Perfecto Mobile Cloud**
Host	The hostname of the mobile device cloud instance.	Required	Required	Required	Required	Required
API key	The API key of your cloud account to authenticate the connection.	Required	Required	Required	Required	Not applicable
Security token	The token used to authenticate the connection.	Not applicable	Not applicable	Not applicable	Not applicable	Required
Project	The project name to use on the mobile device cloud.	Required	Required	Required	Not applicable	Not applicable
Username	The username of your cloud account.	Not applicable	Required	Required	Required	Not applicable

Prerequisites for using mobile devices on mobile device clouds

When you want to use the available mobile devices that are connected to a mobile device cloud, you must ensure that you have completed certain tasks. Refer to the following table for details of the tasks that must be completed before tests can be run on the mobile devices connected to mobile device clouds:

Device cloud	Testing on Android OS	Testing on iOS
BitBar Cloud BrowserStack Cloud Perfecto Mobile Cloud	• Uploaded the `.apk` file of the Android application that you want to test. • Installed the Android application that you want to test on the Android device.	• Installed the `.ipa` or `.app` file of the iOS application that you want to test. • Installed the iOS application that you want to test on the iOS device.
pCloudy Cloud LambdaTest Cloud	• Uploaded the `.apk` file of the Android application that you want to test. • Installed the Android application that you want to test on the Android device. • Verified that the device you want to test is available and in the *Released* state on the cloud platform.	• Uploaded the `.ipa` file of the iOS application that you want to test. • Installed the iOS application that you want to test on the iOS device. • Verified that the device you want to test is available and in the *Released* state on the cloud platform.

Overview of tasks to manage mobile device clouds

You as a *Team Space Owner* can perform the following tasks:

- Configure the connection to mobile device clouds. You must create a *cloud credential* in the team space that represents a connection to a mobile device cloud. You must use the details of your mobile device cloud subscription account to configure the cloud credential to the mobile device cloud. See Adding cloud credentials of mobile device clouds on page 1119.
- Add your team space members to access the mobile device cloud. The added members become the authorized users of the cloud credential, and then can connect to the mobile device cloud from Test. See Adding authorized users to a cloud credential on page 1124.
- View the details of the cloud credential that you added to the team space. See Viewing details of cloud credentials on page 1126.
- Remove the authorized users of the cloud credential, when you want to reduce the number of users accessing the mobile device cloud. See Removing authorized users from a cloud credential on page 1132.
- Edit an existing cloud credential that you configured to modify the name of the credential, project, or username of your cloud subscription account. See Editing details of cloud credentials on page 1129.
- Delete an existing cloud credential that you configured, from the team space. You might want to delete the credential when your cloud subscription to the mobile device cloud has expired and you no longer need the connection. See Deleting an existing cloud credential on page 1133.
- Export details of all existing cloud credentials that are configured in your team space, when you might want to use the details elsewhere. You can export details such as the name of the credentials, the credential type, and the email ID of authorized users of the credentials. See Viewing details of cloud credentials on page 1126.

You as a *Project Owner* or *Tester* can perform the following tasks on cloud credentials or the mobile device clouds:

- Ensure that you are added as an authorized user of a cloud credential in the team space. See Viewing details of cloud credentials on page 1126.
- Configure the following mobile tests to run on the mobile devices that are connected to mobile device clouds:
  - Configuring an AFT Suite to run on a mobile device by using a cloud credential on page 1166.
  - Configuring a run of a Compound Test that contains mobile tests to run by using a cloud credential on page 1212.

AI providers

AI providers are the organizations that build, develop, and offer AI technologies. They offer models and tools that power artificial intelligence in everything from virtual assistants to complex data analysis systems. You can purchase plans from the AI providers to use the services in the cloud or locally to generate Web UI tests. For the cloud-based provider such as OpenAI, you must subscribe to their services. For the locally hosted provider such as Ollama, you must download the software and set up a server.

Test supports the following AI providers:

- OpenAI
- Ollama
- IBM watsonx
- Anthropic

Details required of AI providers

You must ensure that you have the details and valid credentials of the AI account that you want to connect and use. The following table lists the details required for the different accounts:

Attribute	Description	AI Agents			
		OpenAI	**Ollama**	**IBM watsonx**	**Anthropic**
API End Point	The URL of the AI provider.	Optional	Required	Required	Optional
API key	The API key of the AI provider account to authenticate the connection.	Required	Optional	Required	Required
Project Id	A unique identifier assigned to the project that you have created.	Not applicable	Not applicable	Required	Not applicable
Model	The name of the large language model (LLM) that you want to use for test generation.	Not applicable	Optional	Required	Optional

Adding cloud credentials of mobile device clouds

You as a *Team Space Owner* can add a cloud credential in the team space by using the details of your mobile device cloud subscription. This cloud credential represents a connection between Test and a mobile device cloud.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you have the details of your subscription and valid credentials of the mobile device cloud to which you want to connect. See Details required of mobile device clouds on page 1116.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed.
3. Click **Add cloud credential**.

The **Details** tab of the **Add cloud credential** dialog is displayed.

4. Perform the following steps in the **Details** tab:

    a. Enter a name in the **Name** field so that you can identify the mobile device cloud, which is associated with a specific subscription account.

    b. Select the mobile device cloud from the **Cloud Authentication** list.

    c. Click **Next**.

    The **Authentication** tab of the **Add cloud credential** dialog is displayed.

5. Enter the relevant details of your subscription account that you have in the mobile device cloud, in the **Authentication** tab.

    You can find information about the details that are required for each of the supported mobile device clouds and the action you need to perform for the required fields in the following table:

Field	**Mobile device cloud**					**Action**
	BitBar Cloud	**BrowserStack Cloud**	**LambdaTest Cloud**	**pCloudy Cloud**	**Perfecto Mobile Cloud**	
Host	Required	Required	Required	Required	Required	Enter the hostname of the mobile device cloud instance.
API key	Required	Required	Required	Required	Not applicable	Enter the API key of your cloud subscription account to authenticate the connection.
Security token	Not applicable	Not applicable	Not applicable	Not applicable	Required	Enter the token used to authenticate the connection.
Project	Required	Required	Required	Not applicable	Not applicable	Enter or select the project to use that is in the mobile device cloud.
Username	Not applicable	Required	Required	Required	Not applicable	Enter the username of your cloud subscription account.

6. Click **Add**.

    The cloud credential for your specific subscription account with a mobile device cloud is displayed in a table on the **Cloud Credentials** page.

    You can find the following details about the cloud credential on the **Cloud Credentials** page.

<table>
<tr><th>Column header</th><th>Details displayed</th></tr>
<tr><td>Provider</td><td>The name of the mobile device cloud service provider.

You can view the Toggle icon associated with the service providers when you add a cloud credential.

Note: If you are the owner of the cloud credential, you can switch to an On/Off position. However, when you are not the owner and you try to use the Toggle icon an error message is displayed.</td></tr>
<tr><td>Name</td><td>The name you entered for the cloud credential when you created the connection in the team space.</td></tr>
<tr><td>Credential Type</td><td>The type of cloud that is connected to Test. Displays Device Cloud when you create a credential to connect to a mobile device cloud.</td></tr>
<tr><td>Members</td><td>The abbreviated names of the team space members who are authorized users of the cloud credential. The abbreviated name is the combination of the first letters of the first name and last name.</td></tr>
<tr><td>Actions</td><td>The icons for the different actions that you can perform on the credential. Refer to the following table for the icons and the actions:

<table>
<tr><th>Icon</th><th>Action</th><th>Available for</th></tr>
<tr><td></td><td>Click to view details of the credential of the cloud subscription account.</td><td>Team space owner and authorized user</td></tr>
<tr><td></td><td>Click to edit and update the credential for any of your cloud subscription details.</td><td>Team space owner</td></tr>
<tr><td></td><td>Click to remove the configured connection to the mobile device cloud account from the server.</td><td>Team space owner</td></tr>
<tr><td></td><td>Click to add team space members as authorized users of the credential.</td><td>Team space owner</td></tr>
</table>
</td></tr>
</table>

Results

You have added credentials of mobile device cloud accounts so that Test can connect to the mobile device clouds.

What to do next

You can add team space members as authorized users of the credentials. See Adding authorized users to a cloud credential on page 1124.

Related information

Management of cloud credentials on page 1115

Adding cloud credentials of AI providers

You can add a cloud credential in the team space by using the details of your AI provider accounts so that Test can connect to the providers.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you have the details of your subscription and valid credentials of the cloud account to which you want to connect. See Details required of AI providers on page 1119.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed.
3. Click **Add cloud credential**.

   The **Details** tab of the **Add cloud credential** dialog is displayed.
4. Perform the following steps in the **Details** tab:
   a. Enter a name in the **Name** field so that you can identify the mobile device cloud, which is associated with a specific subscription account.
   b. Select an AI provider from the **Cloud Authentication** list.
   c. Click **Next**.

      The **Authentication** tab of the **Add cloud credential** dialog is displayed.
5. Enter the relevant details of your subscription account for AI providers in the **Authentication** tab.

You can find information about the details that are required for each of the supported AI providers in the following table:

Attribute	Description	AI Agents			
		OpenAI	**Ollama**	**IBM watsonx**	**Anthropic**
API End Point	The URL of the AI provider.	Optional	Required	Required	Optional
API key	The API key of the AI provider account to authenticate the connection.	Required	Optional	Required	Required
Project Id	A unique identifier assigned to the project that you have created.	Not applicable	Not applicable	Required	Not applicable
Model	The name of the large language model (LLM) that you want to use for test generation.	Not applicable	Optional	Required	Optional

6. Click **Add**.

The cloud credential for your specific subscription account is displayed in a table on the **Cloud Credentials** page.

You can find the following details about the cloud credentials on the **Cloud Credentials** page.

Column header	Details
Provider	The name of the AI provider. You can view the Toggle icon associated with the service providers when you add a cloud credential. **Note:** If you are the owner of the credential, you can switch to an On/Off position. However, when you are not the owner and you try to use the Toggle icon, an error message is displayed.
Name	The name you entered for the credential when you created the connection in the team space.
Credential Type	The type of account that is connected to Test. Displays *AI Provider* when you create a credential to connect to an AI account.

Column header	Details
Members	The abbreviated names of the team space members who are authorized users of the cloud credential. The abbreviated name is the combination of the first letters of the first name and last name.
Actions	The icons for the different actions that you can perform on the credential. Refer to the following table for the icons and the actions:

Icon	Action	Available for
	Click to view details of the credential.	Team space owner and authorized user
	Click to edit and update the credential.	Team space owner
	Click to remove the configured connection to the AI provider account from the server.	Team space owner
	Click to add team space members as authorized users of the credential.	Team space owner

Results

You have added credentials of AI provider accounts in Test.

What to do next

You can add team space members as authorized users of the credentials. See Adding authorized users to a cloud credential on page 1124.

Related information

Management of cloud credentials on page 1115

Adding authorized users to a cloud credential

After you add the cloud application account details to a cloud credential in your team space inTest , you can add other team space members as authorized users of this cloud credential. The authorized users can then use the connected cloud application account for tests.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Added the cloud credentials of your mobile device cloud or AI provider account to configure the connection between Test and the cloud account. See Adding cloud credentials of mobile device clouds on page 1119 and Adding cloud credentials of AI providers on page 1122.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed with the cloud credentials that are added to the team space.
3. Identify the cloud credential by performing any of the following actions:
   - Scroll through the table of cloud credentials to identify the cloud credential with the name you provided.
   - Search for the cloud credential by entering the name of the credential in the **Search** field.
   - Sort the **Provider** column so that the names of the cloud providers are listed alphabetically in either increasing or decreasing order. Identify your cloud provider and look for the name of your credential.

   You identified the cloud credential that you want to use.
4. Perform the following steps to add team space members as authorized users:
   a. Click the **Add Members** icon in the row of the credential.

      The **Add New Member** dialog is displayed.

   b. Enter any text that is contained in the name or email ID of the team space member that you want to add in the field.

      The team space users are listed whose names or email ID matches the search text.

   c. Select the team space member.

      The selected member is added to the list of authorized users and is displayed under **Members with access**.

   d. Click **Close** to close the dialog.

      The abbreviated name of the team space member is displayed under the **Members** column in the row of the cloud credential.

      Note: The abbreviated name is the combination of the first letters of the first name and last name.

      You can view the first name, last name, username, and the email ID of the added member when you hover over the abbreviated name.

Results

You as a *Team Space Owner* added team space members as authorized users of the cloud credential.

What to do next

You can inform the team space members that they are added as authorized users of the cloud credential. The authorized users can then use the credential to connect to the cloud account from Test and run or generate tests. The authorized users of the credential can manage the following tasks:

- Configuring an AFT Suite to run on a mobile device by using a cloud credential on page 1166.
- Configuring a run of a Compound Test that contains mobile tests to run by using a cloud credential on page 1212.
- Configuring a run of a Compound Test that contains Web UI tests to run by using a cloud credential on page 1249
- Configuring a run of a mobile test to run on a mobile device by using a cloud credential on page 1286
- Configuring a run of a Web UI test to run by using a cloud credential on page 1354
- Running server test assets by using a cloud credential on page 1326
- Running server suite assets by using a cloud credential on page 1331

Viewing details of cloud credentials

If you are a *Team Space Owner* in Test , you can view the details of the cloud credential when you want to decide your action for adding or removing team space members, changing your cloud subscription details, or deleting a credential. If you are a *Project Owner* or *Tester*, you can verify whether you are added as an authorized user to use the cloud credential.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space, a *Project Owner*, or a *Tester* in the project. See Managing members and their roles in a team space on page 1721.
- Added the cloud credentials of your mobile device cloud or AI provider account to configure the connection between Test and the cloud account. See Adding cloud credentials of mobile device clouds on page 1119 and Adding cloud credentials of AI providers on page 1122.
- Added team space members as authorized users of the cloud credential. See Adding authorized users to a cloud credential on page 1124.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed with the cloud credentials that are added to the team space.
3. Identify the cloud credential by performing any of the following actions:

- Scroll through the table of cloud credentials to identify the cloud credential with the name you provided.
- Search for the cloud credential by entering the name of the credential in the **Search** field.
- Sort the **Provider** column so that the names of the cloud providers are listed alphabetically in either increasing or decreasing order. Identify your cloud provider and look for the name of your credential.

You identified the cloud credential that you want to use.

4. Select the action that you want to perform:
   - Verify whether you are added as an authorized user of the cloud credential by the *Team Space Owner*, if you are a *Project Owner* or *Tester*, go to Step 5 on page 1127.
   - View details of the cloud credential, if you are a *Team Space Owner*, *Project Owner*, or *Tester*, go to Step 6 on page 1127.
   - Export the details of all the cloud credentials in your team space, if you are a *Team Space Owner*, go to Step 7 on page 1129.
5. Perform the following steps to verify whether you are added as an authorized user of the cloud credential:
   a. Look for your abbreviated name under the **Members** column in the row of the identified cloud credential.

      Note: The abbreviated name is the combination of the first letters of the first name and last name.

   b. Hover over the abbreviated name to view the first name, last name, username, and the email ID to verify that they are your details.

      You have verified whether you are an authorized user of the cloud credential.

      Note: If you do not find your abbreviated name or details, you need to contact your team space owner to add you as an authorized user.

   c. Go to Results on page 1129.
6. Click the **View** icon in the row of the credential that you want to view.

   The details of the cloud credential are displayed in the **View cloud credential** dialog.

   You can view the following details of the mobile device cloud or AI provider that was configured in the cloud credential:

Attribute	Description	Mobile device cloud or AI provider details								
		BitBar Cloud	BrowserStack Cloud	LambdaTest Cloud	pCloudy Cloud	Perfecto Mobile Cloud	OpenAI	Ollama	IBM watsonx	Anthropic
Owner	The username and email ID of the team space owner who configured the cloud credential.	✔	✔	✔	✔	✔	✔	✔	✔	✔
Credential name	The name provided to the cloud credential by the team space owner when the credential was configured.	✔	✔	✔	✔	✔	✔	✔	✔	✔
Type	The name of the mobile device cloud or AI provider to which the connection was configured in the cloud credential.	✔	✔	✔	✔	✔	✔	✔	✔	✔
Host	The hostname or URL of the mobile device cloud instance.	✔	✔	✔	✔	✔	✘	✘	✘	✘
Project	The name of the project that you created in your cloud subscription account.	✔	✔	✘	✘	✘	✘	✘	✔	✘
Username	The username of your cloud subscription account.	✘	✔	✔	✔	✘	✘	✘	✘	✘
API End Point *	The URL of the AI provider.	✘	✘	✘	✘	✘	✘	✔	✔	✔
Model	The name of large language model (LLM) that you want to use for test generation.	✘	✘	✘	✘	✘	✘	✔	✔	✔
API key	The API key of your cloud subscription account to authenticate the connection.	✔	✔	✔	✔	✘	✔	✔	✔	✔
Security token	The token used to authenticate the connection.	✘	✘	✘	✘	✔	✘	✘	✘	✘

Attribute	Description	Mobile device cloud or AI provider details								
		BitBar Cloud	BrowserStack Cloud	LambdaTest Cloud	pCloudy Cloud	Perfecto Mobile Cloud	OpenAI	Ollama	IBM watsonx	Anthropic
Access to	The team space members that the team space owner added as authorized users of the cloud credential.	✔	✔	✔	✔	✔	✔	✔	✔	✔

You can close the dialog by clicking **Close**.

7. Click the **Download CSV** option to export details of all existing cloud credentials that are configured in your team space when you want to use the details elsewhere, such as the name of the credentials, the credential type, and email ID of authorized users of the credentials members.

   You saved the details of all the credentials in your team space as a CSV file to your computer.

Results

You have completed the following tasks:

- If you are a *Project Owner* or *Tester*, you verified whether you are an authorized user of the cloud credential.
- If you are a *Team Space Owner*, *Project Owner*, or *Tester*, you have viewed the details of the cloud credential that you added.
- If you are a *Team Space Owner*, you saved the details of all cloud credentials that are in your team space to a file on your computer.

Editing details of cloud credentials

If any of the details of your cloud subscription account change, as a *Team Space Owner* in Test you can view the details of the existing cloud credential and edit it to update the credential with the latest details.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Added the cloud credentials of your mobile device cloud or AI provider account to configure the connection between Test and the cloud account. See Adding cloud credentials of mobile device clouds on page 1119 and Adding cloud credentials of AI providers on page 1122.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed with the cloud credentials that are added to the team space.
3. Identify the cloud credential by performing any of the following actions:
   - Scroll through the table of cloud credentials to identify the cloud credential with the name you provided.
   - Search for the cloud credential by entering the name of the credential in the **Search** field.
   - Sort the **Provider** column so that the names of the cloud providers are listed alphabetically in either increasing or decreasing order. Identify your cloud provider and look for the name of your credential.

   You identified the cloud credential that you want to use.
4. Click the **Edit cloud credential** icon in the row of the credential that you want to edit.

   The **Update cloud credential** dialog is displayed.
5. Modify the name of the cloud credential in the **Details** tab, and then click **Next**.

   The **Authentication** tab of the **Update cloud credential** dialog is displayed.
6. Modify relevant fields of your subscription account if they have changed, in the **Authentication** tab.

   You can find information about the details that are required for the following account types:
   - Mobile device clouds: Click here on page 1130 to refer to the table.
   - AI providers: Click here on page 1131 to refer to the table.

   The following table lists details for the relevant and required fields for mobile device clouds.

Field	Mobile device cloud					Action
	BitBar Cloud	BrowserStack Cloud	LambdaTest Cloud	pCloudy Cloud	Perfecto Mobile Cloud	
Host	Required	Required	Required	Required	Required	Enter the hostname of the mobile device cloud instance.
API key	Required	Required	Required	Required	Not applicable	Enter the API key of your cloud subscription account to authenticate the connection.

Field	Mobile device cloud					Action
	BitBar Cloud	**BrowserStack Cloud**	**LambdaTest Cloud**	**pCloudy Cloud**	**Perfecto Mobile Cloud**	
Security token	Not applicable	Not applicable	Not applicable	Not applicable	Required	Enter the token used to authenticate the connection.
Project	Required	Required	Required	Not applicable	Not applicable	Enter or select the project to use that is in the mobile device cloud.
Username	Not applicable	Required	Required	Required	Not applicable	Enter the username of your cloud subscription account.

The following table lists details for the relevant and required fields for AI providers.

Attribute	Description	AI Agents			
		OpenAI	**Ollama**	**IBM watsonx**	**Anthropic**
API End Point	The URL of the AI provider.	Optional	Required	Required	Optional
API key	The API key of the AI provider account to authenticate the connection.	Required	Optional	Required	Required
Project Id	A unique identifier assigned to the project that you have created.	Not applicable	Not applicable	Required	Not applicable
Model	The name of the large language model (LLM) that you want to use for test generation.	Not applicable	Optional	Required	Optional

7. Click **Update**.

   The existing cloud credential is updated with the changed details of your account.

Results

You edited an existing cloud credential in your team space and updated it with the changed details of your cloud subscription account.

Removing authorized users from a cloud credential

When you want to restrict the number of users that are using your cloud credential due to any change in your subscription fee or for other valid reasons, you might want to remove some of the authorized users of the cloud credential in Test .

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Added the cloud credentials of your mobile device cloud or AI provider account to configure the connection between Test and the cloud account. See Adding cloud credentials of mobile device clouds on page 1119 and Adding cloud credentials of AI providers on page 1122.
- Added team space members as authorized users of the cloud credential. See Adding authorized users to a cloud credential on page 1124.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed with the cloud credentials that are added to the team space.
3. Identify the cloud credential by performing any of the following actions:
   - Scroll through the table of cloud credentials to identify the cloud credential with the name you provided.
   - Search for the cloud credential by entering the name of the credential in the **Search** field.
   - Sort the **Provider** column so that the names of the cloud providers are listed alphabetically in either increasing or decreasing order. Identify your cloud provider and look for the name of your credential.

   You identified the cloud credential that you want to use.
4. Perform the following steps to remove authorized users of the cloud credential:
   a. Click the **Add Members** icon in the row of the credential.

      The **Add New Member** dialog is displayed.

   b. Identify the member from the listed members displayed under **Members with access**.

   c. Click in the row of the identified member.

      The selected member is removed from the list displayed under **Members with access**.

   d. Click **Close** to close the dialog.

      The abbreviated name of the authorized user is removed from the display under the **Members** column in the row of the cloud credential.

Results

You as a *Team Space Owner* removed authorized users from the cloud credential.

What to do next

You can inform the team space members that they are removed as authorized users of the cloud credential.

Related information

Management of cloud credentials on page 1115

Deleting an existing cloud credential

When your cloud subscription to the mobile device cloud or AI provider expires and you no longer need the connection from Test , you can delete an existing cloud credential that you configured in your team space.

Before you begin

You must have completed the following tasks:

- Ensured that you are assigned a role as a *Team Space Owner* in the team space. See Managing members and their roles in a team space on page 1721.
- Added the cloud credentials of your mobile device cloud or AI provider account to configure the connection between Test and the cloud account. See Adding cloud credentials of mobile device clouds on page 1119 and Adding cloud credentials of AI providers on page 1122.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Click **Infrastructure > Cloud Credentials** on the navigation pane.

   The **Cloud Credentials** page is displayed with the cloud credentials that are added to the team space.
3. Identify the cloud credential by performing any of the following actions:
   - Scroll through the table of cloud credentials to identify the cloud credential with the name you provided.
   - Search for the cloud credential by entering the name of the credential in the **Search** field.
   - Sort the **Provider** column so that the names of the cloud providers are listed alphabetically in either increasing or decreasing order. Identify your cloud provider and look for the name of your credential.

   You identified the cloud credential that you want to use.
4. Click the **Delete cloud credential** icon in the row of the credential that you want to delete.

   The **Delete cloud credential** dialog is displayed.
5. Click **Delete**.

   The existing cloud credential is deleted and removed from the display on the **Cloud Credentials** page.

Results

You deleted an existing cloud credential that you previously configured, from your team space.

Test run configurations

You can configure and run tests in Test after you add the test resources to your project in your team space.

Before you configure a test run, you must have completed the following tasks:

- Created a project on Test or you must have been granted access to a project with the *Tester* role assigned. See Managing DevOps Test projects on page 1724.
- Created tests in the desktop clients and committed the test assets and test resources to a remote repository. You must have added the remote repository to the project.
- Read the considerations that you must take into account for certain types of tests. See Prerequisites to running tests on page 1057.

You must be a project *Owner* or a member with the *Tester* role assigned to configure and run a test.

You can find information about how to configure and run the following types of test assets:

Type of Suite or test	Suite or test	More information
AFT Suite	Suite	• Configuring an AFT Suite run on page 1141 • Configuring an AFT Suite to run on a mobile device by using a cloud credential on page 1166
API Suite	Suite	• Configuring an API Suite or an API test run on page 1174

Configuring a Suite or test for a quick run

You can configure any type of Suite or test to be run on Test when you want to quickly ensure that the test runs correctly. You might not want to set the different options for the test nor want to schedule the run.

Before you begin

You must have completed the following tasks:

- Read and completed the tasks mentioned in Prerequisites to running tests on page 1057 if they apply to the test you want to configure for a run.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

   The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:

   - Scroll through the list.

   Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

   Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:

- Type
- Test Asset Name
- Test Asset Path
- Last Result
- Next Run
- Components

e. Save the filter query to save and apply the filter query to filter the assets based on the query.

The test assets that match the filter criteria are displayed.

- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run, if you want to run a different version other than the latest version.
8. No action is required if you want to initiate the test run immediately after you click **Execute**.
9. Enter a label for the test run that helps you to identify the test on the **Results** page.

After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page.

10. Click **Execute**.
    The test run is initiated.

Results

You have started a test run.

What to do next

You can perform any of the following tasks::

- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Canceling scheduled test runs on page 1452

Configuring an AFT Suite run

After you added the test resources that you created in the desktop client to the project, you can configure an AFT Suite to be run on Test or a remote Kubernetes cluster.

Before you begin

You must have completed the following tasks:

- Read Test run considerations for AFT Suites or Functional tests on page 1057, if you want to configure a run for an AFT Suite that has the agent location configured in the `AFT XML` file.
- Read and completed the tasks mentioned in Test run considerations for browser-based Web UI tests on page 1061, if you want to run tests that use Chrome or Edge browsers.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.

- Read and completed the tasks mentioned in Considerations for using a remote Kubernetes cluster on page 1101, if you want to use a remote Kubernetes cluster as a location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
SUITES	Lists all suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules that are in the selected branch of the repository.
TESTS	Lists all API tests, functional tests, performance tests, or server test assets that are in the selected branch of the repository.
ADVANCED	Lists all assets that are displayed when custom filters are applied for assets in the selected branch of the repository.

4. Select the tab based on the type of test assets that you want to run as indicated in the following table:

If...	Then...
You want to run AFT Suites, API Suites, Compound Tests, JMeter tests, JUnit tests, Postman tests, Rate Schedules, Selenium tests, or VU Schedules.	Click the **SUITES** tab.
You want to run an individual API test, functional test, or performance test.	Click the **TESTS** tab.
You want to find Suites and tests by using custom filters, and then run Suites and tests.	Click the **ADVANCED** tab.

The test assets in the selected tab are displayed.

5. Identify the test asset that you want to run by performing any of the following actions:
   - Scroll through the list.

Tip: You can hover over the icon in the **Type** column to know the type of the test asset.

Note: You can also identify the type of the asset from the icon that represents the test type as shown in the following table:

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	API test		✓	✓
	Functional test		✓	✓
	Performance test		✓	✓
	AFT Suite	✓		✓
	API Suite	✓		✓
	Compound Test	✓		✓
	HCL® AppScan CodeSweep	✓		✓
	JMeter Test	✓		✓
	JUnit Test	✓		✓
	Postman test	✓		✓
	Rate Schedule	✓		✓
	Selenium test	✓		✓
	Server Suite asset	✓		✓

Icon	Represents	Listed in the SUITES tab	Listed in the TESTS tab	Listed in the ADVANCED tab
	Server Test asset		✓	✓
	VU Schedule	✓		✓

- Search for the test asset by entering any text contained in the test asset name in the **Search** field. When you search by name, the number of rows that are matching with the search keyword are displayed next to the **Search** field.
- Click the **Filter** icon in the **SUITES** or **TESTS** tab to filter the displayed assets based on the asset type.

  For example, select **API Suite** in the **SUITES** tab to display all API Suites or select **Functional Test** in the **TESTS** tab to display all functional tests that are in the selected branch of the repository.
- Click the **Filter** icon in the **ADVANCED** tab, and then create a filter query by using the **New filter** option by performing the following steps:
  a. Click **New filter**.
  b. Enter a name for the filter.
  c. Select an operator, and then add a rule or a group of rules.
  d. Add or enter the relevant parameters and either select or enter the condition and the criteria for the condition.

     You can select a parameter from the following list:
     - Type
     - Test Asset Name
     - Test Asset Path
     - Last Result
     - Next Run
     - Components

  e. Save the filter query to save and apply the filter query to filter the assets based on the query.

     The test assets that match the filter criteria are displayed.
- Retrieve and apply a saved filter query, if you have saved filter queries previously by performing the following steps:

Note: The filter query applied previously is selected and the assets based on that filter query are displayed. To apply a different filter query, you must have created and saved the filter query.

a. Click the **Filter** icon in the **ADVANCED** tab.

The filter queries that you created and saved are displayed.

b. Click the filter that you want to apply.

The test assets that match the filter criteria are displayed.

You have identified the test asset that you want to run.

Clicking the test name displays the **Details** panel. You can view the details of the test such as the description, the branch in the repository that contains the asset, the Git details, and the details of the commits to the repository. You can also view the history of the test runs for the specific test under the **History** tab of the **Details** panel.

6. Click the **Execute** icon in the row of the identified test asset.

The **Execute test asset** dialog is displayed.

Notes:

- If you have configured some or all of the settings for the current test run, and you do not want to continue with those settings, you can reset the settings by clicking **Reset**.
- If you want to repeat a test run and do not want to use the saved settings from a previous run, you can reset all the saved settings to their default values by clicking **Reset**.

7. Select the version of the test resources that you want to run by completing any of the following actions:

Note: The test resources in the version can contain the test assets, datasets, `AFT XML` files, API environment tags, and other resources specific to projects that are created in any of the desktop products.

- Expand the list in the **Version** field, find the version of the test resources, and then select the version.

  Use the following details about the version of the test resources that are displayed to identify the version that you want:
  - Commit message.
  - Tags labeled by the user for the version committed.
  - The user who committed the version to the repository.
  - Relative time of the commit. For example, *2 hours ago* or *3 days ago*.

The list displays the versions of the test resources committed by all users to the branch in the repository. The versions are arranged with the latest version that is committed, and then followed by the versions committed previously.

- Expand the list in the **Version** field, and then search for the version that you want to select by entering a partial or the complete commit message of that version.

  The version that matches the search criteria is displayed and it is selected for the test run.

The default value for the version selected for the run is the latest version in the selected branch of the repository. If you do not select any version, then the latest version is selected for the test run.

Notes:

- If you selected a version but you do not want to use that version in the test run, you can remove the selected version by clicking the ✖ icon. As a result, the default version is selected for the test run.
- If you repeated a test or ran the test again from the **Results** page, then the version of the test resources that you chose for the earlier run is shown as selected. You can either retain this version or select any other version from the list. You can also remove the previous version by clicking the ✖ icon.

8. Select the time for scheduling the test run from the following options:

   - No action is required if you want to initiate the test run immediately after you click **Execute**.

     Important: Click **Execute** only after you have configured the other settings in this dialog.

     Note: The default time for scheduling a run is **Now**.

   - Select **Schedule** and perform the following actions if you want to schedule a single test run or configure recurring test runs:

Schedule	Actions
A single test run	Perform the following steps: a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Select the **Never** option in the **Repeat every** field. e. Click **Save**. The test run is scheduled to run at the selected time on the scheduled date.
Recurring test runs	Perform the following steps:

Schedule	Actions
	a. Click the **Calendar** icon in the row of the **Start** field. b. Select the date. c. Select the time at which the test run must start. d. Set the frequency at which the test runs must run by entering the number in the **Repeat every** field, and then select the period from the list. You can select from the following options: ▪ Minute ▪ Hour ▪ Day ▪ Week ▪ Month For example, if you want the test run to be run every day at the set time, enter `1` and, then select the **Day(s)** option. You can also schedule the test to run at the set time on specific weekdays by selecting the **Week(s)** option. For example, the following image displays the days selected for the test runs as *Monday*, *Wednesday*, and *Friday*:  e. Set the option to end the recurring test runs from the following options: ▪ Select the **Never** option, if you do not want the recurring test runs to end. ▪ Select the **On** option, and then click the **Calendar** icon. You can select the date and time after which the scheduled test runs do not run. f. Click **Save**. The recurring test runs are scheduled to start the first run at the selected time on the scheduled date, and to repeat the run at the frequency that you set.

9. Enter a label for the test run that helps you to identify the test on the **Results** page.

   After the test run completes, the label that you entered is displayed for the test under the **Labels** column on the **Results** page. After you have created a label, any member of the project can use that label.

   The default value for the **Label** field is null or an empty field.

Important: The configuration that you set for the test run in the **Execute test asset** dialog is preserved when you run the same test again. Those changes are not visible when another user logs in to Test. For example, if you created new variables on the server, those variables are available only for you when the same test is run again.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

If you are running an AFT Suite and the following conditions are true, then you must perform the next step:

- You do not want to run the test on the agent configured in the `AFT XML` file.
- You have not selected the agent from the **Override** column in the **Location** tab.

10. Click **Advanced** to make the following advanced configurations:

    a. Add the following setting in the **Program Arguments** field:

    ```
    -swaplocation <configured_agent_location>:<overriding_agent_location>
    ```

    For example, if the configured agent location is *91.2.352.24* and the remote agent where you want to run the test is *100.35.117.164*, then the entry in the **Program Arguments** field is as follows:

    ```
    -swaplocation 91.2.352.24:100.35.117.164
    ```

    If you want the test log for the test, you must enter `-history testlog` in the **Program Arguments** field.

Note: You must separate the arguments or variables with a white space when you enter them in the same line or start each argument or variable on a new line.

The default value for each of the fields for the advanced settings is null or an empty field.

If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

11. Follow the instructions if you are running a test asset that contains datasets:

    a. Click the **DATA SOURCES** tab, if it is not already open.

    b. Consider the following information about datasets before you select a dataset:

    The default value for the datasets in the **DATA SOURCES** tab is null if the test asset did not have an associated dataset. If the asset had an associated dataset, the default value is the associated dataset.

    You can utilize the dataset stored as an Excel or CSV file to override the original dataset associated with the Suite, test, or schedule. For example, when you have associated a dataset in `.xlsx`, `.xls`, or `.csv` format with the test or schedule in desktop clients and if you have another set of data stored in an Excel or CSV file, then you can select that dataset from the **Override** list.

Remember: You must have uploaded the dataset as an Excel or CSV file into the Git repository, and ensured that both the original dataset (from the test asset) and new datasets (added to the project) have the same column names.

c. Select the dataset that you want to use in the test run from any of the following options:

- Select the dataset that is displayed as the default dataset when the test asset contains a single dataset.

  Note: If there is only one dataset in the test asset, then that dataset is displayed as the default dataset.

- Select the dataset from the list.

  Note: If there are multiple datasets in the test asset, the datasets are listed in their increasing alphabetical order.

- Select the dataset from the **Override** list to override the dataset that was associated with the test in the desktop client.

  Important: If the test contains an encrypted dataset, the Project Owner must classify it in the **DATA SECURITY** tab on the Project page before you can select it. You must have added datasets to your project from the **Dataset** page for the datasets to be displayed in the **Override** list.

- Select a data definition from the **Override** list.
- Select one of the following options from the **Generation Type** list:

Option	Description
Standard	Select this option to generate standard test data. Specify the **Number of rows** to generate test data, and optionally, specify the **Seed value**.
Negative	Select this option to generate negative test data to test how the application handles error conditions.

Option	Description
	Select the **One per row** check box to generate one negative data per row, and optionally specify the **Seed value**.

- Click **Set** to apply the selected data generation settings.
- Click **Execute** if you want to run the test immediately or at the scheduled time. Otherwise, continue with the next step.

12. Follow the instructions if the test requires a variable that must be passed to the test at the test run time.

    a. Click the **VARIABLES** tab, if it is not already open.

    b. Choose one of the following methods to add the variables:

    - To add new variables manually, click the **Add Variable** icon, enter the name, and value of the variable.
    - To add new variables from your local computer or from the Git repository that is associated with your server project, click the **Upload** icon and select the **Upload from local system** or **Browse from server** to select the variable file.

    Note: You must have created a file with the variables before you can select the file.

    The default value for the variables is null or an empty field.

    If you want to run the test immediately or at the scheduled time, click **Execute**, or continue with the next step.

13. Follow the instructions if you want to export the test results to a Jira issue in your Xray project in Jira:

    a. Click the **RESULTS** tab.

    b. Perform the actions listed in the following table to select an option to export the test results:

Export options	Results in...	Actions
Jira Xray	The test results of the test that you configure for a run are exported to the selected issue after the test run is completed. The results are exported to the selected issue that exists in your Xray project in Jira.	Perform the following steps: i. Select the **Jira Xray** option. The **Select issue** field is displayed. ii. Click the field to view the list of issues in the Xray project in Jira. Alternatively, you can enter the issue key in the Jira Xray project.

Export options	Results in...	Actions
		iii. Select the issue to which you want to export the test results. iv. Continue with the next step.
New Jira item	The test results of the test that you configure for a run are exported to a new Jira issue. The issue is created in your project in Jira after the test run is completed.	Perform the following steps: i. Select the **New Jira item** option. ii. Continue with the next step.
None	The test results are not exported. **Note:** This export option is the default option.	Perform the following steps when: ▪ You do not want to export the test results. ▪ You selected a Jira issue in a previous run of the same test, and you do not want to export the results of the current run. i. Select the **None** option. ii. Continue with the next step.

14. Select any of the following steps that depends on the location to run the test:
    - If you want to run the tests on the remote agents, go to Step 15 on page 1151.
    - If you want to run the tests on a Kubernetes cluster, go to Step 16 on page 1152.
15. Follow the instructions if you want to run a test on the remote performance agent that is connected either to the default Kubernetes cluster or the remote Kubernetes cluster:

    a. Click the **LOCATION** tab, if it is not already open.

    The performance agents that are configured in the test asset are listed under the **Host** column. The information about the availability of the performance agent is displayed.

    Note: You must have added performance agents to your project from the **Agents and Intercepts** page for the performance agents to be displayed under the **Override** column.

    The default value for the performance agents is null or an empty field if no performance agents were configured in the test asset. If the test asset contains performance agents that are configured, then the default performance agent is the first item to be displayed on the list of performance agents listed in increasing alphabetical order.

    b. Select the performance agent where you want to run the test asset in the following scenarios:

If...	Then...	Action
The performance agent that is specified in the test assets is available and no other performance agents are added to the project.	The performance agent that is specified in the test assets is displayed in the **Override** column.	Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test.
The performance agent that is specified in the test assets is not available and no other performance agents are added to the project.	There is no performance agent displayed for override in the **Override** column.	You cannot run the test on the performance agent. You must wait until the performance agent is available to run the test on the agent.
The agent that is specified in the test assets is available and other agents added to the project.	Performance agents that have capabilities that match with the agent capabilities specified in the test assets are listed in the **Override** column as follows: ▪ Performance agents with capabilities that best match the capabilities of the agent in the asset are at the top of the list. ▪ Performance agents with capabilities that do not match with the capabilities of the agent in the asset are listed subsequently. You can find details of both performance agents for the matching capabilities when you hover over the performance agent in the **Override** column.	Perform any of the following actions: ▪ Select the performance agent in the **Host** that is also displayed in the **Override** column as the location to run the test. ▪ Select a performance agent in the **Override** column as the location to run the test.

c. Click **Execute**.

The test run is initiated.

16. Follow the instructions if you want to change the location of a Kubernetes cluster for running the test:

a. Click the **LOCATION** tab, if it is not already open.

The **Default Cluster** is the default location where the test runs, and it is listed under the **Host** column. The information about the availability of the default location is displayed.

Important: You must have added the following remote host to your project that are then displayed under the **Override** column:

Kubernetes clusters that are registered with a team space.

Notes:

- If the remote clusters are not added to your project, the option **No override options** is displayed as the default value and the test runs in the Kubernetes cluster of Test.
- If remote clusters are added to your project, the added clusters are displayed along with their availability status and ownership information.

b. Select the location where you want to run the test asset from the following options:

- Select the **Default Cluster** when no remote clusters are available in your project.
- Select the remote cluster from the list when a remote cluster is available in your project.
- Select **No override options**, if you selected any remote cluster and want to revert to the **Default Cluster** to run the test asset.

c. Click **Execute**.

The test run is initiated.

Results

You have started or scheduled a test run of an AFT Suite.

What to do next

You can perform any of the following tasks:

- Stop the test run at any point after the test run is initiated from the **Execution** page. See Stopping test runs on page 1449.
- Cancel a scheduled test run from the **Execution** page. See Canceling scheduled test runs on page 1452.
- View all the states of the test asset by clicking the **Show in the Progress page** icon for the test asset for which you started or scheduled the run. See Viewing the state of test assets on page 1440.
- View the progress of the test from the **Progress** page. See Viewing the progress of running test assets on page 1444.
- View the results, reports, and logs of the test from the **Results** page after the test completes the run. See Test results on page 1499.

Unable to run AFT Suites on page 1791

Configuring an AFT Suite to run on a mobile device by using variables

After you added the test resources that you created in the desktop client to the project, you can configure an AFT Suite to run on a mobile device from Test . You must specify the variables for the mobile tests to run on mobile devices that are connected to an agent or a device cloud.

Before you begin

You must have completed the following tasks:

- Read Test run considerations for AFT Suites or Functional tests on page 1057, if you want to configure a run for an AFT Suite that has the agent location configured in the `AFT XML` file.
- Read Test run considerations for using mobile device clouds on page 1069, if you want to configure a run on a mobile device cloud.
- Created a variable file if you want to import the variables file. The file must contain the details of the UI Test agent or the device cloud to which the mobile device is connected.
- Read and completed the tasks mentioned in Test run considerations for running tests on remote performance agents on page 1073, if you want to use a remote agent as the location to run the test.
- Completed the Xray integration, if you want to export the test results to a Jira issue in your Xray project in Jira. See Integration with Xray test management for Jira on page 1703.
- Ensured that you are assigned a role as a *Member* or *Project Creator* in the team space. See Managing members and their roles in a team space on page 1721.
- Ensured that you are assigned a role as a *Project Owner* or *Tester* in the project. See Managing access to the server projects on page 1735.
- Created a project in your team space in Test. See Creating a project on page 1728.
- Added the remote Git repository that contains the test resources to the project. See Adding repositories to a server project on page 1729.
- Ensured that you are a member of the cloud credential that is configured to connect to the mobile device cloud. See Viewing details of cloud credentials on page 1126.

About this task

You can run an AFT Suite, which contains Web UI or mobile tests to run on a mobile device, emulator, or simulator that is connected to an agent or a device cloud. You must create the tests in Test UI, and then add the test asset to your project on Test UI. You can then run the tests on the mobile device, emulator, or simulator that is connected to any of the following agents or clouds:

- Remote UI Test agents. Requires the variables at test run time as specified in Variables for the UI Test agent on page 1155.
- The BitBar Cloud. Requires the variables at test run time as specified in Table 592: Variables for the BitBar Cloud on page 1155.
- The BrowserStack Cloud. Requires the variables at test run time as specified in Table 593: Variables for the BrowserStack Cloud on page 1156.
- The pCloudy Cloud. Requires the variables at test run time as specified in Table 594: Variables for the pCloudy Cloud on page 1156.
- The Perfecto Mobile Cloud. Requires the variables at test run time as specified in Table 595: Variables for the Perfecto Mobile Cloud on page 1157.

You must provide the details of the UI Test agent or the mobile cloud to which the mobile devices are connected as variables in Step 10 on page 1163. You can either enter the variables or use the file in which you entered the variables.

You must refer to the following tables for the variables that are required for a successful run:

Table 591. Variables for the UI Test agent

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the UI Test agent. For example, *Emulator:Pixel_3a_API_33*.
appium.server.host	Specify the hostname or IP address of the UI Test agent.
appium.server.port	Specify the port on the UI Test agent that is configured to communicate with Test.

Table 592. Variables for the BitBar Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BitBar Cloud. For example, *BitBar Cloud:Google Pixel 7 Pro*.
bitbar.apikey	Specify the user token generated for your BitBar Cloud account to authenticate your connection with the BitBar Cloud.
bitbar.host	Specify the hostname of the BitBar Cloud instance.

Table 592. Variables for the BitBar Cloud (continued)

Name of the Variable	Action for the Value field
bitbar.project	Specify the name of the project that contains the recorded test.
bitbar.testrun	Specify a name for the test run that must be displayed in the BitBar Cloud dashboard for the test run.

Table 593. Variables for the BrowserStack Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the BrowserStack Cloud. For example, *BrowserStack Cloud:Google Pixel 7 Pro*.
browserstack.host	Specify the URL of the BrowserStack Cloud instance.
browserstack.username	Specify the user name of your BrowserStack Cloud account.
browserstack.apikey	Specify the API key of your BrowserStack Cloud account to authenticate your connection with the BrowserStack Cloud.
browserstack.project	Specify the name of the project that contains the recorded test. **Note:** This variable is optional.

Table 594. Variables for the pCloudy Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the pCloudy Cloud. For example, *pCloudy Cloud:Google Pixel 7 Pro*.
pcloudy.apikey	Specify the API key that is generated for your pCloudy Cloud account to authenticate your connection with the pCloudy Cloud.

Table 594. Variables for the pCloudy Cloud (continued)

Name of the Variable	Action for the Value field
pcloudy.username	Specify the username with which you can access the pCloudy Cloud instance.
pcloudy.host	Specify the hostname of the pCloudy Cloud instance.

Table 595. Variables for the Perfecto Mobile Cloud

Name of the Variable	Action for the Value field
Mobile_Device_Selection	Specify the name of the mobile device that is connected to the Perfecto Mobile Cloud. For example, *Perfecto Mobile Cloud:Google Pixel 7 Pro*.
perfecto.securitytoken	Specify the user token generated for your Perfecto Mobile Cloud account to authenticate your connection with the Perfecto Mobile Cloud.
perfecto.host	Specify the hostname of the Perfecto Mobile Cloud instance.

1. Log in to Test.
   The **Projects** page of the initial team space is displayed.
2. Open the project that contains the test assets, and then click **Execution**.
3. Select the branch of the repository that contains the test assets.

   The test assets that are contained in the selected branch of the repository are displayed in the following tabs on the **Execution** page:

Tab	Description
